  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
```

```
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

72.1.7.4.15 TForm.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver: TDockOverEvent;
```

C++

```
__property TDockOverEvent OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
```

```
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
```

```
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

72.1.7.4.16 TForm.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}
```

```
/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
```

```
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;

72.1.7.4.17 TForm.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;
```

```
procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin

72.1.7.4.18 TForm.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

72.1.7.4.19 TForm.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
property OnGetSiteInfo: TGetSiteInfoEvent;
```

C++

```
__property TGetSiteInfoEvent OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver event.

OnGetSiteInfo occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
```

```
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
```

```
    Accept := Source.Control is TDockableForm;
    if Accept then
    begin
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;
```

72.1.7.4.20 TForm.OnHelp Event

Occurs when the form receives a request for help.

Pascal

```
property OnHelp: THelpEvent;
```

C++

```
__property THelpEvent OnHelp;
```

Description

Write an OnHelp event handler to perform special processing when the user requests help. The HelpContext and the HelpJump methods automatically trigger the OnHelp event.

Set the CallHelp parameter to true if the application should still invoke the help system after the event. Set CallHelp to false to prevent the default response by the help system. The form calls the help system only if OnHelp's CallHelp parameter returns true or if no OnHelp event handler is assigned.

To find the possible values of the Command and Data parameters, search for WinHelp in the Win32 Developer's Reference Help (Win32.HLP) file, which explains the WinHelp API (application programming interface). The possible values for the Data parameter depend upon the value of the Command parameter.

The event handler returns true if it succeeds, false if it fails.

HelpJump (see page 13679)

HelpFile (see page 13711)

OnHelp (see page 13730)

72.1.7.4.21 TForm.OnHide Event

Occurs when the form is hidden (that is, when its Visible property is set to false).

Pascal

```
property OnHide: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnHide;
```

Description

Use OnHide to perform special processing when the form is hidden (that is, when the form's Visible property is set to false).

C++ Examples:

```
/*
This example uses two forms, each with a label and a button.
When the user clicks a button, the other form appears and
the current form disappears. Also, a message appears in the
label of the form that is showing, indicating that the other
form is hidden. Set the OnHide event handle for each form to

72.1.7.4.22 TForm.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
```

```
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(

72.1.7.4.23 TForm.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

72.1.7.4.24 TForm.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
```

```
  event to FormKeyUp.  Set the KeyPreview on the form to True.
  }
  var
    FormColor: TColor;
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    KeyPreview := True;
    FormColor := Form1.Color;
  end;

  procedure TForm1.FormKeyDown(
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := clAqua;
      if (ComboBox1.Text = 'KeyDown') then
        ComboBox1.Text := 'KeyDown2'
      else
        ComboBox1.Text := 'KeyDown';
      WriteLn(ComboBox1.Text);
    end;
  end;

  procedure TForm1.FormKeyUp(
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := FormColor;
      if (ComboBox1.Text = 'KeyUp') then
        ComboBox1.Text := 'KeyUp2'
      else
        ComboBox1.Text := 'KeyUp';
      WriteLn(ComboBox1.Text);
    end;
  end;

72.1.7.4.25 TForm.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

72.1.7.4.26 TForm.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
```

```
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,

72.1.7.4.27 TForm.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

72.1.7.4.28 TForm.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

72.1.7.4.29 TForm.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```

    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
      end;
  end;
end;
```

OnMouseDown (see page 5862)

OnMouseUp (see page 5867)

MouseCapture (see page 5831)

72.1.7.4.30 TForm.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form’s unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
```

```
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then

Responding to a Mouse-up Action

72.1.7.4.31 TForm.OnMouseWheel Event

Occurs when the mouse wheel is rotated.

Pascal

```
property OnMouseWheel: TMouseWheelEvent;
```

C++

```
__property TMouseWheelEvent OnMouseWheel;
```

Description

Write code in the OnMouseWheel event handler to respond to mouse wheel messages. If there is no OnMouseWheel event handler, or if the mouse wheel message is not handled in the OnMouseWheel event handler, then an OnMouseWheelUp or OnMouseWheelDown event occurs, depending on the direction the mouse wheel was rotated.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheelUp (see page 5870)

72.1.7.4.32 TForm.OnMouseWheelDown Event

Occurs when the mouse wheel is rotated downward.

Pascal

```
property OnMouseWheelDown: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelDown;
```

Description

Write code in the OnMouseWheelDown event handler to perform actions when the mouse wheel is rotated downward. OnMouseWheelDown occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheel (see page 5869)

OnMouseWheelUp (see page 5870)

72.1.7.4.33 TForm.OnMouseWheelUp Event

Occurs when the mouse wheel is rotated upward.

Pascal

```
property OnMouseWheelUp: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelUp;
```

Description

Write code in the OnMouseWheelUp event handler to perform actions when the mouse wheel is rotated upward. OnMouseWheelUp occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheel (see page 5869)

72.1.7.4.34 TForm.OnPaint Event

Occurs when the form is redrawn.

Pascal

```
property OnPaint: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnPaint;
```

Description

Use OnPaint to perform special processing when the form is redrawn. Any special painting on the form should be done in this event. OnPaint occurs before any controls on the form are painted.

To determine which portions of the form's canvas need to be repainted, use the ClipRect property of the canvas.

If you use the form's Canvas property outside the OnPaint event, it will be erased and drawn-over by the next OnPaint event.

C++ Examples:

```
/*
The following code loads a background bitmap onto the Canvas
of the main form in the OnPaint event handler.
*/
Graphics::TBitmap *TheGraphic;

void __fastcall TForm1::FormPaint(TObject *Sender)// OnPaint event handler
{
  Form1->Canvas->Draw(0, 0, TheGraphic); // Draw the graphic on the Canvas
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TheGraphic = new Graphics::TBitmap(); // Create the bitmap object
  TheGraphic->LoadFromFile("..\\bigf.bmp"); // Load the bitmap from a file
}
//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  delete TheGraphic;
}
```

Delphi Examples:

```
{
The following code loads a background bitmap onto the Canvas
of the main form in the OnPaint event handler.
}
procedure TForm1.FormPaint(Sender: TObject); { OnPaint event handler}
begin
  Form1.Canvas.Draw(0, 0, TheGraphic); { Draw the graphic on the Canvas }
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  TheGraphic := TBitmap.Create; { Create the bitmap object }
  TheGraphic.LoadFromFile('bigf.bmp'); { Load the bitmap from a file}
```

```
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  (TheGraphic as TObject).Free;
end;
```

Canvas (see page 13900)

ClipRect (see page 14486)

72.1.7.4.35 TForm.OnResize Event

Occurs immediately after the control is resized.

Pascal

```
property OnResize: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnResize;
```

Description

Use OnResize to make any final adjustments after a control is resized.

To modify the way a control responds when an attempt is made to resize it, use OnCanResize or OnConstrainedResize.

Note: Some controls call this event handler when the control is first created.

Delphi Examples:

```
{
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
}
procedure TForm1.FormResize(Sender: TObject);
begin
  Button1.Left := Form1.ClientWidth-Button1.Width;
end;
```

See Also

OnCanResize (see page 5851)

SetBounds (see page 5783)

AutoSize (see page 5803)

OnConstrainedResize (see page 5853)

72.1.7.4.36 TForm.OnShortCut Event

Occurs when the user presses a key (before the OnKeyDown event).

Pascal

```
property OnShortCut: TShortCutEvent;
```

C++

```
__property TShortCutEvent OnShortCut;
```

Description

Use OnShortCut to dispatch shortcut keystrokes before the form handles them. When the user presses a key, the form can dispatch it as a shortcut key instead of allowing the standard keystroke processing (OnKeyDown, OnKeyPress, and OnKeyUp). Built-in shortcut processing is provided for menu shortcuts and actions associated with the form. OnShortCut allows the form to implement additional shortcuts.

If the OnShortCut implements a response to the keystroke, set the Handled parameter of the event handler to true. This prevents the keystroke from being passed on to menus or actions associated with the form. It also prevents the standard keystroke processing in the same way that a menu or action shortcut does.

See Also

OnKeyDown (see page 6225)

IsShortCut (see page 13880)

IsShortCut (see page 322)

IsShortCut (see page 16078)

72.1.7.4.37 TForm.OnShow Event

Occurs when the form is shown (that is, when its Visible property is set to true).

Pascal

```
property OnShow: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnShow;
```

Description

Use OnShow to perform special processing when the form is shown (that is, when the form's Visible property is set to true).

C++ Examples:

```
/*
This project requires a Page Control.  You will need to
populate the Page Control by right clicking and selecting
New Page from the context menu. As the tabs are selected by
the user, the Page Control OnChange event fires, which
causes the form caption to display the captions of each of
the TTabSheets attached to the Page Control.
Note the use of the Form’s OnShow event handler to set the
caption when the form first appears.  This occurs before
any changes trigger the OnChange event of the Page Control.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  Caption = AnsiString("Now working on tab: " + PageControl1->ActivePage->Caption);
}

void __fastcall TForm1::FormShow(TObject *Sender)
{
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This project requires a Page Control.  You will need to
populate the Page Control by right clicking and selecting
New Page from the context menu. As the tabs are selected by
```

```
the user, the Page Control OnChange event fires, which
causes the form caption to display the captions of each of
the TTabSheets attached to the Page Control.
Note the use of the Form's OnShow event handler to set the
caption when the form first appears.  This occurs before
any changes trigger the OnChange event of the Page Control.
}
procedure TForm1.PageControl1Change(Sender: TObject);
begin
  Caption := ' Now working on tab:  ' + PageControl1.ActivePage.Caption;
end;

procedure TForm1.FormShow(Sender: TObject);
begin
  PageControl1Change(Sender);
end;
```

See Also

OnHide (see page 13960)

72.1.7.4.38 TForm.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

See Also

OnEndDock (see page 5859)

TDragDockObjectEx (see page 6018)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

72.1.7.4.39 TForm.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock: TUnDockEvent;
```

C++

```
__property TUnDockEvent OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
```

```
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
```

```
    var Accept: Boolean);
  var
    ARect: TRect;
  begin
    Accept := Source.Control is TDockableForm;
    if Accept then
    begin
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

72.1.8 TFrame Class

TFrame is a container for components; it can be nested within forms or other frames.

Class Hierarchy

Pascal

```
TFrame = class(TCustomFrame);
```

C++

```
class TFrame : public TCustomFrame;
```

File

Forms

Description

When you create frames, they are implemented as descendants of TFrame.

A frame, like a form, is a container for other components. It uses the same ownership mechanism as forms for automatic instantiation and destruction of the components on it, and the same parent-child relationships for synchronization of component properties. But frames can be nested within forms or other frames, and they can be saved on the Component palette for easy reuse. After a frame is created and saved, it continues to function as a unit and to inherit changes from the components (including other frames) it contains. Moreover, an embedded frame continues to inherit changes made to the frame from which it is derived.

There is a nonstandard A-footnote (Frames_Object) in the main topic for TFrame. Please do not remove it, since it is necessary for making the Component palette Help work.

See Also

TForm (see page 13992)

72.1.8.1 TFrame Members

The following tables list the members exposed by TFrame.

Protected Events

	Name	Description
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.

	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
	Click (see page 5743)	Respond to user click.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 13990)	Initializes frame creation parameters for efficient redrawing.
	CreateParams (see page 14326)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.

	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoFlipChildren (see page 14327)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetChildren (see page 13990)	Calls a specified method for each child of the frame.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.

	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
V	PaintWindow (see page 13991)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
V	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.

	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParent (see page 13991)	Sets the Parent property.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 5731)	Creates an instance of TControl (see page 5724).
	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
	Create (see page 13989)	Creates and initializes a TCustomFrame (see page 13978) object.

	Create (see page 14323)	Creates and initializes a new TScrollingWinControl (see page 14312) object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
	Destroy (see page 14323)	Removes the TScrollingWinControl (see page 14312) object from memory.
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.

	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.

V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.

R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 14150)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14151)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 14152)	Occurs when an attempt is made to resize the control.
	OnClick (see page 14152)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 14154)	Adjust resize constraints.
	OnContextPopup (see page 14155)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 14155)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 14156)	Occurs when another control is docked to the control.
	OnDockOver (see page 14158)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 14160)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14162)	Occurs when the user drags an object over a control.
	OnEndDock (see page 14164)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 14165)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 14166)	Occurs when a control receives the input focus.
	OnExit (see page 14168)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 14170)	Returns the control's docking information.
	OnMouseActivate (see page 14172)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14173)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14175)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14175)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14175)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14178)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 14180)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 14180)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14181)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 14181)	Occurs immediately after the control is resized.
	OnStartDock (see page 14182)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 14182)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 14183)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Align (see page 14126)	Determines how the control aligns within its container (parent control).

	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 14130)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 14130)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 14131)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BiDiMode (see page 14131)	Specifies the bi-directional mode for the control.
	Color (see page 14132)	Specifies the background color of the control.
	Constraints (see page 14132)	Specifies the size constraints for the control.
	Ctl3D (see page 14133)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DockSite (see page 14133)	Specifies whether the control can be the target of drag-and-dock operations.
	DragCursor (see page 14134)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 14135)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14135)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14137)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 14137)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 14329)	Represents the horizontal scroll bar for the scrolling windowed control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Padding (see page 14138)	Specifies the padding of a control.
	ParentBackground (see page 14139)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 14139)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 14139)	Determines where a control looks for its color information.
	ParentCtl3D (see page 14140)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 14140)	Determines where a control looks for its font information.
	ParentShowHint (see page 14141)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 14141)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 14146)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 14147)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 14148)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	VertScrollBar (see page 14330)	Represents the vertical scroll bar for the scrolling windowed control.
	Visible (see page 14148)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

72.1.8.2 TFrame Properties

The properties of the TFrame class are listed here.

Published Properties

	Name	Description
	Align (see page 14126)	Determines how the control aligns within its container (parent control).
	Anchors (see page 14130)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 14130)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 14131)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BiDiMode (see page 14131)	Specifies the bi-directional mode for the control.
	Color (see page 14132)	Specifies the background color of the control.
	Constraints (see page 14132)	Specifies the size constraints for the control.
	Ctl3D (see page 14133)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 14133)	Specifies whether the control can be the target of drag-and-dock operations.
	DragCursor (see page 14134)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 14135)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14135)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14137)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 14137)	Controls the attributes of text written on or in the control.
	Padding (see page 14138)	Specifies the padding of a control.
	ParentBackground (see page 14139)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 14139)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 14139)	Determines where a control looks for its color information.
	ParentCtl3D (see page 14140)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 14140)	Determines where a control looks for its font information.
	ParentShowHint (see page 14141)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 14141)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 14146)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 14147)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 14148)	Determines if the user can tab to a control.
	Visible (see page 14148)	Determines whether the component appears onscreen.

72.1.8.2.1 TFrame.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on

it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
```

```
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{

    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i].Free;
```

```
    end;
    PageControl1.Free;
  end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

72.1.8.2.2 TFrame.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

72.1.8.2.3 TFrame.AutoScroll Property

Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.

Pascal

```
property AutoScroll: Boolean;
```

C++

```
__property Boolean AutoScroll;
```

Description

If AutoScroll is true, the scroll bars appear automatically when necessary. For example, if the user resizes the control so that some of its controls are partially obscured, scroll bars appear.

If AutoScroll is false, scroll bars don't appear automatically. In this case, use the HorzScrollBar and VertScrollBar properties to make scroll bars appear.

See Also

AutoScrollInView (see page 14325)

HorzScrollBar (see page 14329)

VertScrollBar (see page 14330)

72.1.8.2.4 TFrame.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints (see page 5812)

CanAutoSize (see page 5741)

72.1.8.2.5 TFrame.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

72.1.8.2.6 TFrame.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

72.1.8.2.7 TFrame.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

72.1.8.2.8 TFrame.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

72.1.8.2.9 TFrame.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite: Boolean;
```

C++

```
__property Boolean DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

72.1.8.2.10 TFrame.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

72.1.8.2.11 TFrame.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

72.1.8.2.12 TFrame.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
```

```
  OnDragOver event handler must be implemented to accept the
  drop.
  */
  void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
        int X, int Y)
  {
    if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
      return;
    THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
    TNodeAttachMode AttachMode;
    TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
    if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
      AttachMode = naAddChild;
    else if (HT.Contains(htNowhere))
      AttachMode = naAdd;
    else if (HT.Contains(htOnIndent))
      AttachMode = naInsert;
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == (TObject *)TreeView1);
  }
```

Delphi Examples:

```
  {
  The following code uses GetNodeAt to add a dragged node as a
  child of the node under the mouse when it is dropped.  This
  example requires a populated TreeView.  Also, the TTreeView
  DragMode property set to dmAutomatic, and the TTreeView
  OnDragOver event handler must be implemented to accept the
  drop.
  }
  procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
  var
    AnItem: TTreeNode;
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TTreeView;
  end;
```

Arranging the Order of Persistent Columns

72.1.8.2.13 TFrame.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

72.1.8.2.14 TFrame.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
```

```
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

See Also

DesktopFont (see page 5818)

ParentFont (see page 5834)

Displaying and Editing Text in a Memo Control

72.1.8.2.15 TFrame.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding: TPadding;
```

C++

```
__property TPadding Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding.

See Also

TPadding (see page 6103)

72.1.8.2.16 TFrame.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground: Boolean;
```

C++

```
__property Boolean ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

72.1.8.2.17 TFrame.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

72.1.8.2.18 TFrame.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

72.1.8.2.19 TFrame.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

72.1.8.2.20 TFrame.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

72.1.8.2.21 TFrame.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

72.1.8.2.22 TFrame.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
```

```
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
```

```
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
```

```
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

type
  TForm1 = class(TForm)
    AddButton: TButton;
    EditButton: TButton;
    DestroyButton: TButton;
    PopupMenu1: TPopupMenu;
```

```
    procedure AddButtonClick(Sender: TObject);
    procedure EditButtonClick(Sender: TObject);
    procedure DestroyButtonClick(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
  private
    { Private declarations }
  public
    procedure PopupMenuItemsClick(Sender: TObject);

  end;

72.1.8.2.23 TFrame.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
```

```
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

72.1.8.2.24 TFrame.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

72.1.8.2.25 TFrame.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

72.1.8.2.26 TFrame.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
```

```
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

72.1.8.3 TFrame Events

The events of the TFrame class are listed here.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 14150)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14151)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 14152)	Occurs when an attempt is made to resize the control.
	OnClick (see page 14152)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 14154)	Adjust resize constraints.
	OnContextPopup (see page 14155)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 14155)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 14156)	Occurs when another control is docked to the control.
	OnDockOver (see page 14158)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 14160)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14162)	Occurs when the user drags an object over a control.
	OnEndDock (see page 14164)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 14165)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 14166)	Occurs when a control receives the input focus.
	OnExit (see page 14168)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 14170)	Returns the control's docking information.
	OnMouseActivate (see page 14172)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14173)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14175)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14175)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14175)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14178)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 14180)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 14180)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14181)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 14181)	Occurs immediately after the control is resized.
	OnStartDock (see page 14182)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 14182)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 14183)	Occurs when the application tries to undock a control that is docked to the windowed control.

72.1.8.3.1 TFrame.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore: TAlignInsertBeforeEvent;
```

C++

```
__property TAlignInsertBeforeEvent OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

See Also

CustomAlignInsertBefore (see page 6137)

Align (see page 5798)

TAlignInsertBeforeEvent (see page 6293)

72.1.8.3.2 TFrame.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition: TAlignPositionEvent;
```

C++

```
__property TAlignPositionEvent OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.	

See Also

CustomAlignPosition (see page 6138)

Align (see page 5798)

Anchors (see page 5802)

TAlignInfo (see page 6269)

TAlignPositionEvent (see page 6293)

72.1.8.3.3 TFrame.OnCanResize Event

Occurs when an attempt is made to resize the control.

Pascal

```
property OnCanResize: TCanResizeEvent;
```

C++

```
__property TCanResizeEvent OnCanResize;
```

Description

Use OnCanResize to adjust the way a control is resized. If necessary, change the new width and height of the control in the OnCanResize event handler. The OnCanResize event handler also allows applications to indicate that the entire resize should be aborted.

If there is no OnCanResize event handler, or if the OnCanResize event handler indicates that the resize attempt can proceed, the OnCanResize event is followed immediately by an OnConstrainedResize event.

See Also

OnConstrainedResize (see page 5853)

SetBounds (see page 5783)

OnResize (see page 5870)

72.1.8.3.4 TFrame.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B.

However, focus does not move to the control in these instances.

- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
```

```
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

72.1.8.3.5 TFrame.OnConstrainedResize Event

Adjust resize constraints.

Pascal

```
property OnConstrainedResize: TConstrainedResizeEvent;
```

C++

```
__property TConstrainedResizeEvent OnConstrainedResize;
```

Description

Use OnConstrainedResize to adjust a control's constraints when an attempt is made to resize it. Upon entry to the OnConstrainedResize event handler, the parameters of the event handler are set to the corresponding properties of the control's Constraints object. The event handler can adjust those values before they are applied to the new height and width that is being applied to the control. (The CanAutoSize method or an OnCanResize event handler may already have adjusted this new height and width).

On exit from the OnConstrainedResize event handler, the constraints are applied to the attempted new height and width. Once the constraints are applied, the control's height and width are changed. After the control's height and width change, an OnResize event occurs to allow any final adjustments or responses.

Note: The OnConstrainedResize handler is called immediately after the OnCanResize handler.

See Also

OnCanResize (see page 5851)

CanAutoSize (see page 5741)

72.1.8.3.6 TFrame.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

PopupMenu (see page 5835)

AutoPopup (see page 16178)

72.1.8.3.7 TFrame.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

72.1.8.3.8 TFrame.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop: TDockDropEvent;
```

C++

```
__property TDockDropEvent OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
```

```
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock = DockClient->ClassNameIs("TDockableForm");
    if (!CanDock)
    {
       ShowMessage("GetSiteInfo CanDock went bad!");
    }
  }
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

72.1.8.3.9 TFrame.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver: TDockOverEvent;
```

C++

```
__property TDockOverEvent OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
```

```
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

72.1.8.3.10 TFrame.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
```

```
end;

72.1.8.3.11 TFrame.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
```

```
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
```

```
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

72.1.8.3.12 TFrame.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

72.1.8.3.13 TFrame.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

72.1.8.3.14 TFrame.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
```

```
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
```

```
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

72.1.8.3.15 TFrame.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK

button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

72.1.8.3.16 TFrame.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
property OnGetSiteInfo: TGetSiteInfoEvent;
```

C++

```
__property TGetSiteInfoEvent OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver event.

OnGetSiteInfo occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
```

```
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

72.1.8.3.17 TFrame.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

72.1.8.3.18 TFrame.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
```

```
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

72.1.8.3.19 TFrame.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

72.1.8.3.20 TFrame.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

72.1.8.3.21 TFrame.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
```

```
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

Responding to a Mouse-up Action

72.1.8.3.23 TFrame.OnMouseWheel Event

Occurs when the mouse wheel is rotated.

Pascal

```
property OnMouseWheel: TMouseWheelEvent;
```

C++

```
__property TMouseWheelEvent OnMouseWheel;
```

Description

Write code in the OnMouseWheel event handler to respond to mouse wheel messages. If there is no OnMouseWheel event handler, or if the mouse wheel message is not handled in the OnMouseWheel event handler, then an OnMouseWheelUp or OnMouseWheelDown event occurs, depending on the direction the mouse wheel was rotated.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheelUp (see page 5870)

72.1.8.3.24 TFrame.OnMouseWheelDown Event

Occurs when the mouse wheel is rotated downward.

Pascal

```
property OnMouseWheelDown: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelDown;
```

Description

Write code in the OnMouseWheelDown event handler to perform actions when the mouse wheel is rotated downward.

OnMouseWheelDown occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheel (see page 5869)

OnMouseWheelUp (see page 5870)

72.1.8.3.25 TFrame.OnMouseWheelUp Event

Occurs when the mouse wheel is rotated upward.

Pascal

```
property OnMouseWheelUp: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelUp;
```

Description

Write code in the OnMouseWheelUp event handler to perform actions when the mouse wheel is rotated upward. OnMouseWheelUp occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheel (see page 5869)

72.1.8.3.26 TFrame.OnResize Event

Occurs immediately after the control is resized.

Pascal

```
property OnResize: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnResize;
```

Description

Use OnResize to make any final adjustments after a control is resized.

To modify the way a control responds when an attempt is made to resize it, use OnCanResize or OnConstrainedResize.

Note: Some controls call this event handler when the control is first created.

Delphi Examples:

```
{
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
}
procedure TForm1.FormResize(Sender: TObject);
begin
  Button1.Left := Form1.ClientWidth-Button1.Width;
end;
```

See Also

OnCanResize (see page 5851)

SetBounds (see page 5783)

AutoSize (see page 5803)

OnConstrainedResize (see page 5853)

72.1.8.3.27 TFrame.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

See Also

OnEndDock (see page 5859)

TDragDockObjectEx (see page 6018)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

72.1.8.3.28 TFrame.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

See Also

OnEndDrag (see page 5860)

TDragControlObjectEx (see page 6007)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDragDrop (see page 5855)

72.1.8.3.29 TFrame.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock: TUnDockEvent;
```

C++

```
__property TUnDockEvent OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
/*
```

```
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
```

```
    // Only 2 dock clients means the host must be destroyed and
    // the remaining window undocked to its old position and size.
    // Recall that OnUnDock gets called before the undocking
    // actually occurs.
    if Client is TDockableForm then
      TDockableForm(Client).DockSite := True;
    if (DockClientCount = 2) and (NewTarget <> Self) then
      PostMessage(Self.Handle, WM_CLOSE, 0, 0);
    UpdateCaption(Client);
  end;
  {
  The following example is taken from the docking demo. It
  shows how set permissions to dock dockable objects onto a
  docking site.
  }

  procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
    Source: TDragDockObject; X, Y: Integer);
  begin
    //OnDockDrop gets called AFTER the client has actually docked,
    //so we check for DockClientCount = 1 before making the dock panel visible.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, True, nil);
    (Sender as TPanel).DockManager.ResetBounds(True);
    //Make DockManager repaints it's clients.
  end;

  procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
    Source: TDragDockObject; X, Y: Integer; State: TDragState;
    var Accept: Boolean);
  var
    ARect: TRect;
  begin
    Accept := Source.Control is TDockableForm;
    if Accept then
    begin
      //Modify the DockRect to preview dock area.
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;
```

72.1.9 TGlassFrame Class

TGlassFrame controls Windows Vista Aero glass effects.

Class Hierarchy

Pascal

```
TGlassFrame = class(TPersistent);
```

C++

```
class TGlassFrame : public TPersistent;
```

File

Forms

Description

TGlassFrame uses the DwmExtendFrameIntoClientArea API to extend glass effects into the client area. Use the Top (see page 14190), Left (see page 14190), Bottom (see page 14190), and Right (see page 14190) properties to specify the amount to extend the glass effect into the client area, or use SheetOfGlass (see page 14190) to render the entire client area as a glass surface. This is only available on Windows Vista with Aero.

See Also

TForm (see page 13992)

TCustomForm (see page 13849)

72.1.9.1 TGlassFrame Members

The following tables list the members exposed by TGlassFrame.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Change (see page 14189)	This is Change, a member of class TGlassFrame.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.

Public Events

	Name	Description
	OnChange (see page 14191)	Occurs when the dimensions for glass effects change, or when they are enabled/disabled.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 14188)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.

	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 14187)	This is Create, a member of class TGlassFrame.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FrameExtended (see page 14189)	Returns True if glass effects are extended into the client area.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IntersectsControl (see page 14189)	Returns True if a control intersects the glass area.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Published Properties

	Name	Description
	Bottom (see page 14190)	Specifies the amount (in pixels) glass effects are extended into the client area.
	Enabled (see page 14190)	This property controls whether glass effects are extended into the client area or not.
	Left (see page 14190)	Specifies the amount (in pixels) glass effects are extended into the client area.
	Right (see page 14190)	Specifies the amount (in pixels) glass effects are extended into the client area.
	SheetOfGlass (see page 14190)	Extends glass effects into the entire client area.
	Top (see page 14190)	Specifies the amount (in pixels) glass effects are extended into the client area.

72.1.9.2 TGlassFrame.Create Constructor

Pascal

```
constructor Create(Client: TCustomForm);
```

C++

```
__fastcall TGlassFrame(TCustomForm Client);
```

Description

This is Create, a member of class TGlassFrame.

72.1.9.3 TGlassFrame Methods

The methods of the TGlassFrame class are listed here.

Protected Methods

	Name	Description
	Change (see page 14189)	This is Change, a member of class TGlassFrame.

Public Methods

	Name	Description
	Assign (see page 14188)	Copies the contents of another, similar object.
	FrameExtended (see page 14189)	Returns True if glass effects are extended into the client area.
	IntersectsControl (see page 14189)	Returns True if a control intersects the glass area.

72.1.9.3.1 TGlassFrame.Assign Method

Copies the contents of another, similar object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Call Assign to copy the properties or other attributes of one object from another. The standard form of a call to Assign is

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

which tells the Destination object to copy the contents of the Source object to itself.

Most objects override Assign to handle the assignment of properties from similar objects. When overriding Assign, call the inherited method if the destination object can't handle the assignment of properties from the class of the Source parameter.

If no overridden Assign method can handle the assignment of properties from Source, the method implemented in TPersistent calls the source object's AssignTo method. This allows the source object to handle the assignment. If the Source object is nil (Delphi) or NULL (C++), Assign raises an EConvertError exception.

In general, the statement

```
Destination := Source; {Delphi}
Destination = Source; // C++
```

is not the same as the statement

```
Destination.Assign(Source); {Delphi}
Destination->Assign(Source); // C++
```

The assignment operator makes Destination reference the same object as Source, whereas the Assign method copies the contents of the object referenced by Source into the object referenced by Destination.

Note: The types of some properties are also objects. If these properties have write methods that use Assign to set the value of the property, then in these cases the assignment operator does the same thing as the Assign method.

See Also

AssignTo (see page 2931)

EConvertError (see page 22724)

72.1.9.3.2 TGlassFrame.Change Method

Pascal

```
procedure Change; virtual;
```

C++

```
virtual __fastcall Change();
```

Description

This is Change, a member of class TGlassFrame.

72.1.9.3.3 TGlassFrame.FrameExtended Method

Returns True if glass effects are extended into the client area.

Pascal

```
function FrameExtended: Boolean;
```

C++

```
__fastcall Boolean FrameExtended();
```

Description

Use FrameExtended to determine if glass effects are supported and enabled. The return value is True if Desktop Window Manager (DWM) composition is enabled, Enabled (see page 14190) is True and either SheetOfGlass (see page 14190) is True or any of the properties Top (see page 14190), Left (see page 14190), Bottom (see page 14190) or Right (see page 14190) have a value other than zero.

72.1.9.3.4 TGlassFrame.IntersectsControl Method

Returns True if a control intersects the glass area.

Pascal

```
function IntersectsControl(Control: TControl): Boolean;
```

C++

```
__fastcall Boolean IntersectsControl(TControl * Control);
```

72.1.9.4 TGlassFrame Properties

The properties of the TGlassFrame class are listed here.

Published Properties

	Name	Description
	Bottom (see page 14190)	Specifies the amount (in pixels) glass effects are extended into the client area.
	Enabled (see page 14190)	This property controls whether glass effects are extended into the client area or not.
	Left (see page 14190)	Specifies the amount (in pixels) glass effects are extended into the client area.
	Right (see page 14190)	Specifies the amount (in pixels) glass effects are extended into the client area.
	SheetOfGlass (see page 14190)	Extends glass effects into the entire client area.
	Top (see page 14190)	Specifies the amount (in pixels) glass effects are extended into the client area.

72.1.9.4.1 TGlassFrame.Bottom Property

Specifies the amount (in pixels) glass effects are extended into the client area.

Pascal

```
property Bottom: Integer;
```

C++

```
__property int Bottom;
```

72.1.9.4.2 TGlassFrame.Enabled Property

This property controls whether glass effects are extended into the client area or not.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

72.1.9.4.3 TGlassFrame.Left Property

Specifies the amount (in pixels) glass effects are extended into the client area.

Pascal

```
property Left: Integer;
```

C++

```
__property int Left;
```

72.1.9.4.4 TGlassFrame.Right Property

Specifies the amount (in pixels) glass effects are extended into the client area.

Pascal

```
property Right: Integer;
```

C++

```
__property int Right;
```

72.1.9.4.5 TGlassFrame.SheetOfGlass Property

Extends glass effects into the entire client area.

Pascal

```
property SheetOfGlass: Boolean;
```

C++

```
__property Boolean SheetOfGlass;
```

72.1.9.4.6 TGlassFrame.Top Property

Specifies the amount (in pixels) glass effects are extended into the client area.

Pascal

```
property Top: Integer;
```

C++

```
__property int Top;
```

72.1.9.5 TGlassFrame Events

The events of the TGlassFrame class are listed here.

Public Events

	Name	Description
	OnChange (see page 14191)	Occurs when the dimensions for glass effects change, or when they are enabled/disabled.

72.1.9.5.1 TGlassFrame.OnChange Event

Occurs when the dimensions for glass effects change, or when they are enabled/disabled.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

72.1.10 TMonitor Class

TMonitor represents a monitor on which an application runs.

Class Hierarchy

Pascal

```
TMonitor = class(TObject);
```

C++

```
class TMonitor : public TObject;
```

File

Forms

Description

TMonitor represents a monitor that displays the user interface of an application. It introduces properties to describe the dimensions of a single monitor. In addition, the Primary (see page 14195) property distinguishes the primary property from other monitors on the system.

When writing multi-monitor applications, use TMonitor to help lay out forms and dialogs so that they are not split over several monitors.

Applications do not create instances of TMonitor. Instead, monitor components for all available monitors are listed by the Monitors property of the global Screen (see page 14385) variable. The global Screen (see page 14385) variable also provides global information about the monitors on which the application runs, such as screen resolution, available fonts, and so

on.

72.1.10.1 TMonitor Members

The following tables list the members exposed by TMonitor.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	BoundsRect (see page 14193)	Indicates the dimensions of the monitor in pixels.
R	Handle (see page 14194)	Indicates the Windows handle for the monitor.
R	Height (see page 14194)	Indicates the vertical size of the monitor in pixels.

R	Left (see page 14194)	Indicates the logical position of the left edge of the monitor.
R	MonitorNum (see page 14195)	Specifies the index of the monitor in the global screen object's Monitors list.
R	Primary (see page 14195)	Indicates whether this is the primary monitor.
R	Top (see page 14196)	Indicates the logical position of the top edge of the monitor.
R	Width (see page 14196)	Indicates the horizontal size of the monitor in pixels.
R	WorkareaRect (see page 14197)	Gives the application useable area of the monitor.

72.1.10.2 TMonitor Properties

The properties of the TMonitor class are listed here.

Public Properties

	Name	Description
R	BoundsRect (see page 14193)	Indicates the dimensions of the monitor in pixels.
R	Handle (see page 14194)	Indicates the Windows handle for the monitor.
R	Height (see page 14194)	Indicates the vertical size of the monitor in pixels.
R	Left (see page 14194)	Indicates the logical position of the left edge of the monitor.
R	MonitorNum (see page 14195)	Specifies the index of the monitor in the global screen object's Monitors list.
R	Primary (see page 14195)	Indicates whether this is the primary monitor.
R	Top (see page 14196)	Indicates the logical position of the top edge of the monitor.
R	Width (see page 14196)	Indicates the horizontal size of the monitor in pixels.
R	WorkareaRect (see page 14197)	Gives the application useable area of the monitor.

72.1.10.2.1 TMonitor.BoundsRect Property

Indicates the dimensions of the monitor in pixels.

Pascal

```
property BoundsRect: TRect;
```

C++

```
__property TRect BoundsRect;
```

Description

Read BoundsRect to learn the dimensions of the monitor. BoundsRect gives the dimensions of the monitor in pixels, where (0,0) represents the top-left corner of the primary monitor.

The top of BoundsRect is given by the Top (see page 14196) property, the left edge by the Left (see page 14194) property, and the height and width by the Height (see page 14194) and Width (see page 14196) properties respectively.

Note: The BoundsRect property does not take into account any task bars or tool bars docked on the monitor. To determine the area on the monitor that is free of such docked windows, use the WorkAreaRect property.

See Also

Width (see page 14196)

Top (see page 14196)

Left (see page 14194)

Height (see page 14194)

WorkAreaRect (see page 14197)

DesktopRect (see page 14218)

Primary (see page 14195)

72.1.10.2.2 TMonitor.Handle Property

Indicates the Windows handle for the monitor.

Pascal

```
property Handle: HMONITOR;
```

C++

```
__property HMONITOR Handle;
```

Description

Read Monitor to obtain a Windows handle for the monitor represented by this TMonitor (see page 14191) component. Use this handle for Windows API calls such as GetMonitorInfo.

See Also

MonitorNum (see page 14195)

72.1.10.2.3 TMonitor.Height Property

Indicates the vertical size of the monitor in pixels.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Read Height to learn the size of the monitor in pixels. Use this value along with the Top (see page 14196) property to calculate how to position objects vertically in multi-monitor applications.

Note: The Height property does not take into account any task bars or tool bars docked on the monitor. To determine the area on the monitor that is free of such docked windows, use the WorkAreaRect property.

See Also

Height (see page 14225)

DesktopHeight (see page 14217)

Width (see page 14196)

Top (see page 14196)

BoundsRect (see page 14193)

WorkAreaRect (see page 14197)

72.1.10.2.4 TMonitor.Left Property

Indicates the logical position of the left edge of the monitor.

Pascal

```
property Left: Integer;
```

C++

```
__property int Left;
```

Description

In multi-monitor applications, the available screen space can span multiple monitors from left to right. Read Left to determine where, in the entire available screen space, this monitor appears. The value of Left is in pixels relative to the left edge of the primary monitor.

See Also

Width (see page 14196)

Top (see page 14196)

BoundsRect (see page 14193)

WorkAreaRect (see page 14197)

Primary (see page 14195)

DesktopLeft (see page 14218)

72.1.10.2.5 TMonitor.MonitorNum Property

Specifies the index of the monitor in the global screen object's Monitors list.

Pascal

```
property MonitorNum: Integer;
```

C++

```
__property int MonitorNum;
```

Description

The global screen variable maintains a list of all monitors in a multi-monitor application. MonitorNum is the index of this monitor in the list object that is the screen's Monitors property.

Use MonitorNum to identify a specific monitor when working with multiple monitors.

See Also

Monitors (see page 14228)

Screen (see page 14385)

72.1.10.2.6 TMonitor.Primary Property

Indicates whether this is the primary monitor.

Pascal

```
property Primary: Boolean;
```

C++

```
__property Boolean Primary;
```

Description

Read Primary to determine whether a monitor is the primary monitor in a multi-monitor application. When Primary is true, the monitor is the primary monitor. The coordinates of other monitors are given in terms of the primary monitor.

See Also

Monitors (see page 14228)

BoundsRect (see page 14193)

DesktopRect (see page 14218)

72.1.10.2.7 TMonitor.Top Property

Indicates the logical position of the top edge of the monitor.

Pascal

```
property Top: Integer;
```

C++

```
__property int Top;
```

Description

In multi-monitor applications, the available screen space can span multiple monitors from top to bottom. Read Top to determine where, in the entire available screen space, this monitor appears. The value of Top is in pixels relative to the top edge of the primary monitor.

See Also

Height (see page 14194)

Left (see page 14194)

BoundsRect (see page 14193)

WorkAreaRect (see page 14197)

Primary (see page 14195)

DesktopTop (see page 14219)

72.1.10.2.8 TMonitor.Width Property

Indicates the horizontal size of the monitor in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Read Width to learn the size of the monitor in pixels. Use this value along with the Left (see page 14194) property to calculate vertical positions for objects in multi-monitor applications.

Note: The Width property does not take into account any task bars or tool bars docked on the monitor. To determine the area on the monitor that is free of such docked windows, use the WorkAreaRect property.

See Also

Height (see page 14194)

Left (see page 14194)

Width (see page 14229)

DesktopWidth (see page 14219)

BoundsRect (see page 14193)

WorkAreaRect (see page 14197)

72.1.10.2.9 TMonitor.WorkareaRect Property

Gives the application useable area of the monitor.

Pascal

```
property WorkareaRect: TRect;
```

C++

```
__property TRect WorkareaRect;
```

Description

WorkareaRect returns a TRect value furnished with the coordinates and dimensions of the work area of the Monitor. On Windows, for example, the application tabs at the screen mean that the Workarea is smaller than the monitor size.

Note: The TRect Right and Bottom values are one pixel beyond Workarea boundary. They are given these values to allow for easy calculation of Workarea width and height as (Right-Left (see page 14194)) and (Bottom-Top (see page 14196)) respectively.

See Also

TRect (see page 23302)

72.1.11 TScreen Class

TScreen represents the state of the screen in which an application runs.

Class Hierarchy

Pascal

```
TScreen = class(TComponent);
```

C++

```
class TScreen : public TComponent;
```

File

Forms

Description

TScreen introduces properties that keep track of

What forms and data modules have been instantiated by the application.

The active form, and the active control within that form.

The size and resolution of the screen.

The cursors and fonts available for the application to use.

The monitors on which the application's forms can appear, including their dimensions.

There is a global variable, Screen (see page 14385), of type TScreen, which is already instantiated for use by GUI applications. Use Screen (see page 14385) to obtain information about the current state of the screen in an application.

See Also

TApplication (see page 13660)

TDataModule (see page 2824)

TForm (see page 13992)

TFont (see page 14497)

Screen (see page 14385)

72.1.11.1 TScreen Members

The following tables list the members exposed by TScreen.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).

	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Events

	Name	Description
	OnActiveControlChange (see page 14234)	Occurs immediately after input focus changes to a new windowed control.
	OnActiveFormChange (see page 14236)	Occurs immediately after a new form becomes active in a multi-form application.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 14202)	Creates an instance of TScreen (see page 14197).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 14202)	Destroys an instance of TScreen (see page 14197).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 14203)	Prevents forms from being aligned in the screen.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.

	EnableAlign (see page 14203)	Allows forms to be aligned in the screen.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MonitorFromPoint (see page 14203)	Returns the monitor where a specified point is located.
	MonitorFromRect (see page 14204)	Returns the monitor where a specified rectangle is located.
	MonitorFromWindow (see page 14204)	Returns the monitor where a specified window is located.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 14205)	Realigns the screen's forms according to their Align properties.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	ResetFonts (see page 14205)	Reinitializes the fonts listed in the Fonts (see page 14220) property.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ActiveControl (see page 14206)	Indicates which control currently has input focus on the screen.
R	ActiveCustomForm (see page 14207)	Indicates the descendant of TCustomForm (see page 13849) that currently has focus.
R	ActiveForm (see page 14207)	Indicates which form currently has focus.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.

R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Cursor (see page 14209)	Controls (see page 5711) the mouse cursor image on a global level.
R	CursorCount (see page 14212)	This is CursorCount, a member of class TScreen.
	Cursors (see page 14212)	Lists the cursors available to the application.
R	CustomFormCount (see page 14214)	Indicates the number of forms or property pages displayed on the screen.
R	CustomForms (see page 14215)	Lists all the forms and property pages that are currently displayed in the application.
R	DataModuleCount (see page 14216)	Indicates the number of data modules that are currently instantiated in the application.
R	DataModules (see page 14216)	Lists all the data modules that are currently instantiated in the application.
R	DefaultIme (see page 14216)	Indicates which input method editor (IME) is active when the TScreen (see page 14197) object is created.
R	DefaultKbLayout (see page 14217)	Indicates the Windows handle to the keyboard layout that was active when the application started running.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DesktopHeight (see page 14217)	Specifies the height of the entire virtual desktop.
R	DesktopLeft (see page 14218)	Specifies the x-coordinate of the desktop's left edge relative to the upper-left corner of the primary monitor.
R	DesktopRect (see page 14218)	Specifies the boundaries of the virtual desktop relative to the upper-left corner of the primary monitor.
R	DesktopTop (see page 14219)	Specifies the y-coordinate of the entire desktop's top edge relative to the upper-left corner of the primary monitor.
R	DesktopWidth (see page 14219)	Specifies the width of the entire virtual desktop.
	FocusedForm (see page 14220)	Provides a reference to the form that has focus.
R	Fonts (see page 14220)	Lists the face names for all fonts supported by the screen.
R	FormCount (see page 14221)	Indicates the number of forms displayed on the screen.
R	Forms (see page 14223)	Lists all the forms currently displayed in the application.
R	Height (see page 14225)	Indicates the vertical size of the screen in pixels.
	HintFont (see page 14226)	Specifies the font used to display help hints.
	IconFont (see page 14226)	Specifies the font used to display the labels on the icons in file selection dialogs.
R	Imes (see page 14227)	Lists all input method editors (IMEs) installed on the system.
	MenuFont (see page 14227)	Specifies the font used for menu commands.
R	MonitorCount (see page 14228)	Specifies the number of monitors used to comprise the desktop.
R	Monitors (see page 14228)	Provides access to an individual monitor used to comprise the desktop.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	PixelsPerInch (see page 14228)	Indicates the number of screen pixels that make up a logical inch in the vertical direction.
R	PrimaryMonitor (see page 14229)	Provides a reference to the primary monitor.
R	SaveFocusedList (see page 14229)	This is SaveFocusedList, a member of class TScreen.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	Width (see page 14229)	Indicates the horizontal size of the screen in pixels.
R	WorkAreaHeight (see page 14231)	Specifies the height of the work area on the primary monitor.
R	WorkAreaLeft (see page 14231)	Specifies the left edge of the work area on the primary monitor.
R	WorkAreaRect (see page 14232)	Specifies the boundaries of the usable work area on the primary monitor.
R	WorkAreaTop (see page 14232)	Specifies the top edge of the work area on the primary monitor.
R	WorkAreaWidth (see page 14233)	Specifies the width of the work area on the primary monitor.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

72.1.11.2 TScreen.Create Constructor

Creates an instance of TScreen (see page 14197).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TScreen(TComponent * AOwner);
```

Description

Do not create separate instances of TScreen (see page 14197). There is a global variable, Screen (see page 14385), of type TScreen (see page 14197), which is already instantiated for use by GUI applications. The properties of Screen (see page 14385) are global to the entire application.

AOwner specifies the Owner of the screen, which is responsible for freeing it. For the global TScreen (see page 14197) object, this is the application.

See Also

Screen (see page 14385)

Owner (see page 2807)

TApplication (see page 13660)

72.1.11.3 TScreen.Destroy Destructor

Destroys an instance of TScreen (see page 14197).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TScreen();
```

Description

Do not destroy the global object Screen (see page 14385) that is automatically instantiated in GUI applications.

See Also

Screen (see page 14385)

Free (see page 22300)

72.1.11.4 TScreen Methods

The methods of the TScreen class are listed here.

Public Methods

	Name	Description
	DisableAlign (see page 14203)	Prevents forms from being aligned in the screen.
	EnableAlign (see page 14203)	Allows forms to be aligned in the screen.
	MonitorFromPoint (see page 14203)	Returns the monitor where a specified point is located.

	MonitorFromRect (see page 14204)	Returns the monitor where a specified rectangle is located.
	MonitorFromWindow (see page 14204)	Returns the monitor where a specified window is located.
	Realign (see page 14205)	Realigns the screen's forms according to their Align properties.
	ResetFonts (see page 14205)	Reinitializes the fonts listed in the Fonts (see page 14220) property.

72.1.11.4.1 TScreen.DisableAlign Method

Prevents forms from being aligned in the screen.

Pascal

```
procedure DisableAlign;
```

C++

```
__fastcall DisableAlign();
```

Description

Call DisableAlign to prevent forms from being aligned in the screen. After calling DisableAlign, the Align properties of the screen's forms are ignored until the call is matched by a call to EnableAlign (see page 14203).

See Also

EnableAlign (see page 14203)

Realign (see page 14205)

Constraints (see page 5812)

72.1.11.4.2 TScreen.EnableAlign Method

Allows forms to be aligned in the screen.

Pascal

```
procedure EnableAlign;
```

C++

```
__fastcall EnableAlign();
```

Description

Call EnableAlign to allow forms to be aligned in the screen. After calling DisableAlign (see page 14203), the Align properties of the screen's forms are ignored until that call is matched by a call to EnableAlign.

See Also

DisableAlign (see page 14203)

Realign (see page 14205)

Constraints (see page 5812)

72.1.11.4.3 TScreen.MonitorFromPoint Method

Returns the monitor where a specified point is located.

Pascal

```
function MonitorFromPoint(const Point: TPoint; MonitorDefault: TMonitorDefaultTo = mdNearest):
TMonitor;
```

C++

```
__fastcall TMonitor MonitorFromPoint(const TPoint Point, TMonitorDefaultTo MonitorDefault =
mdNearest);
```

Description

Call MonitorFromPoint determine the monitor where a specified point is located.

Point is the coordinates of the point to locate. It is in pixels relative to the upper-left corner of the primary monitor.

MonitorDefault indicates how to select a monitor when the point does not fall clearly on a single monitor.

See Also

Monitors (see page 14228)

DesktopRect (see page 14218)

BoundsRect (see page 14193)

72.1.11.4.4 TScreen.MonitorFromRect Method

Returns the monitor where a specified rectangle is located.

Pascal

```
function MonitorFromRect(const Rect: TRect; MonitorDefault: TMonitorDefaultTo = mdNearest):
TMonitor;
```

C++

```
__fastcall TMonitor MonitorFromRect(const TRect Rect, TMonitorDefaultTo MonitorDefault =
mdNearest);
```

Description

Call MonitorFromRect determine the monitor where a specified boundary rectangle falls.

Rect is the coordinates of the rectangle to locate. It is in pixels relative to the upper-left corner of the primary monitor.

MonitorDefault indicates how to select a monitor when the rectangle does not fall entirely on a single monitor.

See Also

Monitors (see page 14228)

DesktopRect (see page 14218)

BoundsRect (see page 14193)

72.1.11.4.5 TScreen.MonitorFromWindow Method

Returns the monitor where a specified window is located.

Pascal

```
function MonitorFromWindow(const Handle: THandle; MonitorDefault: TMonitorDefaultTo =
mdNearest): TMonitor;
```

C++

```
__fastcall TMonitor MonitorFromWindow(const THandle Handle, TMonitorDefaultTo MonitorDefault =
mdNearest);
```

Description

Call MonitorFromWindow determine the monitor that displays a specified window.

Handle is the window handle for the window to be located.

MonitorDefault indicates how to select a monitor when the window does not fall entirely on a single monitor.

See Also

Monitors (see page 14228)

DesktopRect (see page 14218)

BoundsRect (see page 14193)

72.1.11.4.6 TScreen.Realign Method

Realigns the screen's forms according to their Align properties.

Pascal

```
procedure Realign;
```

C++

```
__fastcall Realign();
```

Description

Call Realign to realign the screen's forms according to their Align properties.

See Also

EnableAlign (see page 14203)

DisableAlign (see page 14203)

Constraints (see page 5812)

72.1.11.4.7 TScreen.ResetFonts Method

Reinitializes the fonts listed in the Fonts (see page 14220) property.

Pascal

```
procedure ResetFonts;
```

C++

```
__fastcall ResetFonts();
```

Description

Call ResetFonts to ensure that the fonts listed in the Fonts (see page 14220) property are up to date. ResetFonts reinitializes the Fonts (see page 14220) property so that its value is reread from the operating system the next time it is needed.

TScreen (see page 14197) calls ResetFonts internally in response to messages from Windows that the available fonts have changed.

See Also

Fonts (see page 14220)

72.1.11.5 TScreen Properties

The properties of the TScreen class are listed here.

Public Properties

	Name	Description
R	ActiveControl (see page 14206)	Indicates which control currently has input focus on the screen.
R	ActiveCustomForm (see page 14207)	Indicates the descendant of TCustomForm (see page 13849) that currently has focus.
R	ActiveForm (see page 14207)	Indicates which form currently has focus.
	Cursor (see page 14209)	Controls (see page 5711) the mouse cursor image on a global level.
R	CursorCount (see page 14212)	This is CursorCount, a member of class TScreen.
	Cursors (see page 14212)	Lists the cursors available to the application.
R	CustomFormCount (see page 14214)	Indicates the number of forms or property pages displayed on the screen.
R	CustomForms (see page 14215)	Lists all the forms and property pages that are currently displayed in the application.
R	DataModuleCount (see page 14216)	Indicates the number of data modules that are currently instantiated in the application.
R	DataModules (see page 14216)	Lists all the data modules that are currently instantiated in the application.
R	DefaultIme (see page 14216)	Indicates which input method editor (IME) is active when the TScreen (see page 14197) object is created.
R	DefaultKbLayout (see page 14217)	Indicates the Windows handle to the keyboard layout that was active when the application started running.
R	DesktopHeight (see page 14217)	Specifies the height of the entire virtual desktop.
R	DesktopLeft (see page 14218)	Specifies the x-coordinate of the desktop's left edge relative to the upper-left corner of the primary monitor.
R	DesktopRect (see page 14218)	Specifies the boundaries of the virtual desktop relative to the upper-left corner of the primary monitor.
R	DesktopTop (see page 14219)	Specifies the y-coordinate of the entire desktop's top edge relative to the upper-left corner of the primary monitor.
R	DesktopWidth (see page 14219)	Specifies the width of the entire virtual desktop.
	FocusedForm (see page 14220)	Provides a reference to the form that has focus.
R	Fonts (see page 14220)	Lists the face names for all fonts supported by the screen.
R	FormCount (see page 14221)	Indicates the number of forms displayed on the screen.
R	Forms (see page 14223)	Lists all the forms currently displayed in the application.
R	Height (see page 14225)	Indicates the vertical size of the screen in pixels.
	HintFont (see page 14226)	Specifies the font used to display help hints.
	IconFont (see page 14226)	Specifies the font used to display the labels on the icons in file selection dialogs.
R	Imes (see page 14227)	Lists all input method editors (IMEs) installed on the system.
	MenuFont (see page 14227)	Specifies the font used for menu commands.
R	MonitorCount (see page 14228)	Specifies the number of monitors used to comprise the desktop.
R	Monitors (see page 14228)	Provides access to an individual monitor used to comprise the desktop.
R	PixelsPerInch (see page 14228)	Indicates the number of screen pixels that make up a logical inch in the vertical direction.
R	PrimaryMonitor (see page 14229)	Provides a reference to the primary monitor.
R	SaveFocusedList (see page 14229)	This is SaveFocusedList, a member of class TScreen.
R	Width (see page 14229)	Indicates the horizontal size of the screen in pixels.
R	WorkAreaHeight (see page 14231)	Specifies the height of the work area on the primary monitor.
R	WorkAreaLeft (see page 14231)	Specifies the left edge of the work area on the primary monitor.
R	WorkAreaRect (see page 14232)	Specifies the boundaries of the usable work area on the primary monitor.
R	WorkAreaTop (see page 14232)	Specifies the top edge of the work area on the primary monitor.
R	WorkAreaWidth (see page 14233)	Specifies the width of the work area on the primary monitor.

72.1.11.5.1 TScreen.ActiveControl Property

Indicates which control currently has input focus on the screen.

Pascal

```
property ActiveControl: TWinControl;
```

C++

```
__property TWinControl * ActiveControl;
```

Description

Read ActiveControl to learn which windowed control object in the active form currently receives the input from the keyboard.

ActiveControl is a read-only property. To change the ActiveControl, use the SetFocusedControl method of the form that contains the control that should receive focus.

After focus shifts from one control to another, the screen receives an OnActiveControlChange (see page 14234) event.

See Also

OnActiveControlChange (see page 14234)

ActiveControl (see page 13896)

SetFocusedControl (see page 13887)

72.1.11.5.2 TScreen.ActiveCustomForm Property

Indicates the descendant of TCustomForm (see page 13849) that currently has focus.

Pascal

```
property ActiveCustomForm: TCustomForm;
```

C++

```
__property TCustomForm ActiveCustomForm;
```

Description

Read ActiveCustomForm to learn which form or property page has input focus. If the active custom form is a TForm (see page 13992) object, ActiveCustomForm is the same as ActiveForm (see page 14207).

See Also

ActiveForm (see page 14207)

OnActiveFormChange (see page 14236)

TForm (see page 13992)

TPropertyPage (see page 1603)

72.1.11.5.3 TScreen.ActiveForm Property

Indicates which form currently has focus.

Pascal

```
property ActiveForm: TForm;
```

C++

```
__property TForm * ActiveForm;
```

Description

Read ActiveForm to learn which form in the application has input focus. If the application is not currently active, ActiveForm is the form that will have focus when the application becomes active again.

ActiveForm is a read-only property. To change the ActiveForm, use the SetFocus method of the form that should receive focus. ActiveForm also changes if the SetFocusedControl method of an inactive form is called to set focus to a control on that inactive

form.

After focus shifts from one form to another, the screen receives an OnActiveFormChange (see page 14236) event.

Note: If the application window with focus is not a TForm (see page 13992) descendant (for example, if it is a property page), it will not appear as ActiveForm. To handle such cases, use the ActiveCustomForm (see page 14207) property instead.

C++ Examples:

```
/*
This example uses a two forms with a button on the first
form. When the user clicks the button, the second form
appears. As the user switches between forms, the form that
is active is colored aqua.
Note:   You must include the unit header for form 2 to the
unit file for form 1, and add the public ColorForm method
to the definition of the TForm1 class.
*/
#include "Unit2.h"

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::ColorForm(TObject *Sender)
{
  Color = clWhite;
  Form2->Color = clWhite;
  Screen->ActiveForm->Color = clAqua;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Screen->OnActiveFormChange = ColorForm;
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  // This stops ColorForm from being called during termination.
  Screen->OnActiveFormChange = NULL;
}
```

Delphi Examples:

```
{
This example uses a two forms with a button on the first
form. When the user clicks the button, the second form
appears. As the user switches between forms, the form that
is active is colored aqua.
Note:   You must include the unit header for form 2 to the
unit file for form 1, and add the public ColorForm method
to the header for form 1's unit.
}
type
  TForm1 = class(TForm)
    Button1: TButton;
    procedure Button1Click(Sender: TObject);
    procedure FormCreate(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
  private
    { Private declarations }
  public
    procedure ColorForm(Sender: TObject);
  end;
```

```
var
  Form1: TForm1;

implementation

{$R *.dfm}

uses Unit2;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;

procedure TForm1.ColorForm(Sender: TObject);
begin
  Color := clWhite;
  Form2.Color := clWhite;
  Screen.ActiveForm.Color := clAqua;
end;
procedure TForm1.FormCreate(Sender: TObject);
begin
  Screen.OnActiveFormChange := ColorForm;
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  // This stops ColorForm from being called during termination.
  Screen.OnActiveFormChange := nil;
end;
```

SetFocusedControl (see page 13887)

How Actions Find Their Targets

72.1.11.5.4 TScreen.Cursor Property

Controls (see page 5711) the mouse cursor image on a global level.

Pascal

```
property Cursor: TCursor;
```

C++

```
__property TCursor Cursor;
```

Description

Set Cursor to override the cursor image associated with individual control objects. When Cursor is crDefault, the individual objects determine the cursor image. Assigning any other value sets the mouse cursor image for all windows belonging to the application. The global mouse cursor image remains in effect until the screen's Cursor property is changed back to crDefault.

Cursor can be set to any of the cursor values available in the Cursors (see page 14212) property. This can be one of the built-in cursor values, or a custom cursor that has been added to the Cursors (see page 14212) property.

Note: Changes to the value of the Cursor property may not show up immediately. Call the ProcessMessages method of the global Application (see page 14383) object to allow the application to respond to a notification that the value has changed.

C++ Examples:

```
/*
This example shows how to add custom cursors to an
application.  The following code makes this cursor available
to the application via the constant crMyCursor, and sets it
as the global cursor to the application.
*/
Graphics::TBitmap *bmpMask, *bmpColor;
TIconInfo *iconInfo;

const crMyCursor = 5;

  void __fastcall TForm1::Button2Click(TObject *Sender)
{
  bmpMask = new Graphics::TBitmap();
  bmpColor = new Graphics::TBitmap();
  iconInfo = new TIconInfo();

  bmpMask->LoadFromFile("../SquareMask.bmp");
  bmpColor->LoadFromFile("../Square.bmp");

  iconInfo->fIcon = false;
  iconInfo->xHotspot = 15;
  iconInfo->yHotspot = 15;
  iconInfo->hbmMask = bmpMask->Handle;
  iconInfo->hbmColor = bmpColor->Handle;

  Screen->Cursors[crMyCursor] = CreateIconIndirect(iconInfo);

  Screen->Cursor = crMyCursor;

  delete bmpMask;
  delete bmpColor;
  delete iconInfo;
}
/*
Assignments to the Screen object's cursor property are
typically guarded by a try...finally statement to ensure
that normal cursor behavior is restored. Note that the
original cursor is saved and restored.  This allows cursor
changes to be nested without accidentally restoring the
cursor to a hard-coded value prematurely.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
TCursor Save_Cursor = Screen->Cursor;
Screen->Cursor = crHourGlass;    // Show hourglass cursor
try
{
  // Do some lengthy operation
  int I = 0;
  int J = 0;
  int X, Y;
  const magicnumber = 150000000;
  while (I < magicnumber)
  {
    Randomize;
    while (J < magicnumber)
    {
      Y = Random(J);
```

```
      J++;
    }
    X = Random(I);
    I++;
  }
}
__finally
{
  Screen->Cursor = Save_Cursor; // always restore the cursor
}
}
```

Delphi Examples:

```
{
This example shows how to add custom cursors to an
application.  The following code makes this cursor available
to the application via the constant crMyCursor, and sets it
as the global cursor to the application.
}
var
  bmpMask : TBitmap;
  bmpColor : TBitmap;
  iconInfo : TIconInfo;
const
  crMyCursor = 5;

procedure TForm1.Button2Click(Sender: TObject);
begin
  bmpMask := TBitmap.Create;
  bmpColor := TBitmap.Create;

  bmpMask.LoadFromFile('SquareMask.bmp');
  bmpColor.LoadFromFile('Square.bmp');

  with iconInfo do
  begin
    fIcon := false;
    xHotspot := 15;
    yHotspot := 15;
    hbmMask := bmpMask.Handle;
    hbmColor := bmpColor.Handle;
  end;

  Screen.Cursors[crMyCursor] := CreateIconIndirect(iconInfo);

  Screen.Cursor := crMyCursor;

  bmpMask.Free;
  bmpColor.Free;
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  DestroyIcon(Screen.Cursors[crMyCursor]);
end;
{
Assignments to the Screen object's cursor property are
typically guarded by a try...finally statement to ensure
that normal cursor behavior is restored. Note that the
original cursor is saved and restored.  This allows cursor
changes to be nested without accidentally restoring the
cursor to a hard-coded value prematurely.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Save_Cursor : TCursor;
```

```
    I, J: Integer;
    X, Y: Word;
  const
    magicnumber = 3000000;
  begin
    Save_Cursor := Screen.Cursor;
    Screen.Cursor := crHourGlass;    { Show hourglass cursor }
    try
      { Do some lengthy operation }
    I := 0;
    J := 0;
    while I < magicnumber do
    begin
      Randomize;
      while J < magicnumber do
      begin
        Y := Random(J);
        Inc(J);
      end;
      X := Random(I);
      Inc(I);
    end;
    finally
      Screen.Cursor := Save_Cursor;  { Always restore to normal }
    end;
  end;
```

Cursors (see page 14212)

Cursor (see page 5815)

ProcessMessages (see page 13691)

72.1.11.5.5 TScreen.CursorCount Property

Pascal

```
property CursorCount: Integer;
```

C++

```
__property int CursorCount;
```

Description

This is CursorCount, a member of class TScreen.

72.1.11.5.6 TScreen.Cursors Property

Lists the cursors available to the application.

Pascal

```
property Cursors [Index: Integer]: HCURSOR;
```

C++

```
__property HCURSOR Cursors[int Index];
```

Description

Use Cursor (see page 14209) to access a particular cursor for use by the application or by a control within the application. TScreen (see page 14197) includes several built-in cursors that are indexed by symbolic cursor constants. The image associated with the built-in cursors constants can be changed by setting the Cursors property.

Custom cursors can be added to the Cursors property for use by the application or any of its controls. To add a custom cursor to an application:

1Create (see page 14202) the cursor resource using a resource editor.

2Declare a cursor constant with a value that does not conflict with an existing cursor constant.

3Use the Windows API function LoadCursor to obtain a handle to the new cursor.

4Set the Cursors property, indexed by the newly declared cursor constant, to the handle obtained from LoadCursor.

Note: Don't call the Windows API function DestroyCursor when finished with a custom cursor; it is handled automatically.

C++ Examples:

```
/*
This example shows how to add custom cursors to an
application.  The following code makes this cursor available
to the application via the constant crMyCursor, and sets it
as the global cursor to the application.
*/
Graphics::TBitmap *bmpMask, *bmpColor;
TIconInfo *iconInfo;

const crMyCursor = 5;

  void __fastcall TForm1::Button2Click(TObject *Sender)
{
  bmpMask = new Graphics::TBitmap();
  bmpColor = new Graphics::TBitmap();
  iconInfo = new TIconInfo();

  bmpMask->LoadFromFile("../SquareMask.bmp");
  bmpColor->LoadFromFile("../Square.bmp");

  iconInfo->fIcon = false;
  iconInfo->xHotspot = 15;
  iconInfo->yHotspot = 15;
  iconInfo->hbmMask = bmpMask->Handle;
  iconInfo->hbmColor = bmpColor->Handle;

  Screen->Cursors[crMyCursor] = CreateIconIndirect(iconInfo);

  Screen->Cursor = crMyCursor;

  delete bmpMask;
  delete bmpColor;
  delete iconInfo;
}
```

Delphi Examples:

```
{
This example shows how to add custom cursors to an
application.  The following code makes this cursor available
to the application via the constant crMyCursor, and sets it
as the global cursor to the application.
}
var
  bmpMask : TBitmap;
  bmpColor : TBitmap;
  iconInfo : TIconInfo;
const
  crMyCursor = 5;
```

```
procedure TForm1.Button2Click(Sender: TObject);
begin
  bmpMask := TBitmap.Create;
  bmpColor := TBitmap.Create;

  bmpMask.LoadFromFile('SquareMask.bmp');
  bmpColor.LoadFromFile('Square.bmp');

  with iconInfo do
  begin
    fIcon := false;
    xHotspot := 15;
    yHotspot := 15;
    hbmMask := bmpMask.Handle;
    hbmColor := bmpColor.Handle;
  end;

  Screen.Cursors[crMyCursor] := CreateIconIndirect(iconInfo);

  Screen.Cursor := crMyCursor;

  bmpMask.Free;
  bmpColor.Free;
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  DestroyIcon(Screen.Cursors[crMyCursor]);
end;
```

See Also

Cursor (see page 14209)

Cursor (see page 5815)

72.1.11.5.7 TScreen.CustomFormCount Property

Indicates the number of forms or property pages displayed on the screen.

Pascal

```
property CustomFormCount: Integer;
```

C++

```
__property int CustomFormCount;
```

Description

Read CustomFormCount to learn the number of forms or property pages currently displayed on the screen. These forms can be accessed by the CustomForms (see page 14215) property. CustomFormCount can be used with CustomForms (see page 14215) to iterate over all the forms and property pages in an application.

C++ Examples:

```
/*
The following code adds the name of all forms and dialogs on
the screen to ListBox1 when Button1 is clicked.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < Screen->CustomFormCount; i++)
    ListBox1->Items->Add(Screen->CustomForms[i]->Name);
}
```

Delphi Examples:

```
{
The following code adds the name of all forms and dialogs on
the screen to ListBox1 when Button1 is clicked.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to Screen.CustomFormCount-1 do
    ListBox1.Items.Add(Screen.CustomForms[I].Name);
end;
```

See Also

CustomForms (see page 14215)

FormCount (see page 14221)

72.1.11.5.8 TScreen.CustomForms Property

Lists all the forms and property pages that are currently displayed in the application.

Pascal

```
property CustomForms [Index: Integer]: TCustomForm;
```

C++

```
__property TCustomForm CustomForms[int Index];
```

Description

Use CustomForms to access a form or property page by index. The value of Index is a number between zero (the first custom form) and CustomFormCount (see page 14214) - 1. CustomForms can be used with CustomFormCount (see page 14214) when an application needs to iterate over all its forms and property pages.

Unlike the Forms (see page 14223) property, CustomForms lists TCustomForm (see page 13849) descendants that do not derive from TForm (see page 13992) (such as property pages).

Warning: The order in which CustomForms lists its forms is affected by the Z order of the forms. Do not change the Z order of forms when using CustomForms to iterate over the forms in an application.

C++ Examples:

```
/*
The following code adds the name of all forms and dialogs on
the screen to ListBox1 when Button1 is clicked.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < Screen->CustomFormCount; i++)
    ListBox1->Items->Add(Screen->CustomForms[i]->Name);
}
```

Delphi Examples:

```
{
The following code adds the name of all forms and dialogs on
the screen to ListBox1 when Button1 is clicked.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  for I := 0 to Screen.CustomFormCount-1 do
```

```
    ListBox1.Items.Add(Screen.CustomForms[I].Name);
end;
```

See Also

CustomFormCount (see page 14214)

Forms (see page 14223)

72.1.11.5.9 TScreen.DataModuleCount Property

Indicates the number of data modules that are currently instantiated in the application.

Pascal

```
property DataModuleCount: Integer;
```

C++

```
__property int DataModuleCount;
```

Description

Read DataModuleCount to learn the number of data modules in the DataModules (see page 14216) property. DataModuleCount can be used with DataModules (see page 14216) when an application needs to iterate over all its data modules.

See Also

DataModules (see page 14216)

TDataModule (see page 2824)

72.1.11.5.10 TScreen.DataModules Property

Lists all the data modules that are currently instantiated in the application.

Pascal

```
property DataModules [Index: Integer]: TDataModule;
```

C++

```
__property TDataModule DataModules[int Index];
```

Description

Use DataModules to access an instantiated data module by index. The value of Index is a number between zero (the first data module) and DataModuleCount (see page 14216) - 1. DataModules can be used with DataModuleCount (see page 14216) when an application needs to iterate over all its data modules.

See Also

DataModuleCount (see page 14216)

72.1.11.5.11 TScreen.DefaultIme Property

Indicates which input method editor (IME) is active when the TScreen (see page 14197) object is created.

Pascal

```
property DefaultIme: string;
```

C++

```
__property AnsiString DefaultIme;
```

Description

In applications that support Asian language characters, read DefaultIme to determine the IME that is active when the application starts.

An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application. There can be multiple IMEs installed on a single system. They vary in user interface, conversion dictionaries, and input method.

Individual controls can override the default IME. When a control specifies a different IME should be used to enter information into the control, the IME that processes keyboard input changes when the control has focus. When the control loses focus, DefaultIme is restored as the system IME.

See Also

DefaultKbLayout (see page 14217)

Imes (see page 14227)

ImeName (see page 6208)

ResetIme (see page 6174)

72.1.11.5.12 TScreen.DefaultKbLayout Property

Indicates the Windows handle to the keyboard layout that was active when the application started running.

Pascal

```
property DefaultKbLayout: HKL;
```

C++

```
__property HKL DefaultKbLayout;
```

Description

Use DefaultKbLayout for making Windows API calls that require a handle to a keyboard layout. For example, if an application changes the keyboard layout to match the settings for another country, the value of DefaultKbLayout can be used as a parameter to the Windows ActivateKeyboardLayout function in order to restore the original layout.

For asian keyboards, the keyboard layout identifies the input method editor (IME) as well as the default language. Use DefaultKbLayout in Windows API calls that work with the IME. DefaultKbLayout is the keyboard layout handle associated with the IME named by the DefaultIme (see page 14216) property.

See Also

DefaultIme (see page 14216)

Imes (see page 14227)

72.1.11.5.13 TScreen.DesktopHeight Property

Specifies the height of the entire virtual desktop.

Pascal

```
property DesktopHeight: Integer;
```

C++

```
__property int DesktopHeight;
```

Description

Use DesktopHeight to determine the height of the entire desktop. The desktop is defined as the entire virtual desktop, which includes all monitors in the system.

On a single-monitor system, DesktopHeight corresponds to Height (see page 14225).

See Also

DesktopLeft (see page 14218)

DesktopRect (see page 14218)

DesktopTop (see page 14219)

DesktopWidth (see page 14219)

WorkAreaHeight (see page 14231)

Height (see page 14225)

72.1.11.5.14 TScreen.DesktopLeft Property

Specifies the x-coordinate of the desktop's left edge relative to the upper-left corner of the primary monitor.

Pascal

```
property DesktopLeft: Integer;
```

C++

```
__property int DesktopLeft;
```

Description

Use DesktopLeft to determine the x-coordinate of the entire desktop's left edge relative to the upper-left corner of the primary monitor. The primary monitor is the monitor with its Primary property set to true. The desktop is defined as the entire virtual desktop, which includes all monitors in the system.

On a single-monitor system, DesktopLeft is 0.

See Also

DesktopHeight (see page 14217)

DesktopRect (see page 14218)

DesktopTop (see page 14219)

DesktopWidth (see page 14219)

WorkAreaLeft (see page 14231)

Primary (see page 14195)

Monitors (see page 14228)

72.1.11.5.15 TScreen.DesktopRect Property

Specifies the boundaries of the virtual desktop relative to the upper-left corner of the primary monitor.

Pascal

```
property DesktopRect: TRect;
```

C++

```
__property TRect DesktopRect;
```

Description

Use DesktopRect to determine the coordinates of the entire virtual desktop, which includes all monitors in the system. DesktopRect is expressed in coordinates where (0,0) is the upper-left corner of the primary monitor. The primary monitor is the monitor with its Primary property set to true.

See Also

DesktopHeight (see page 14217)

DesktopLeft (see page 14218)

DesktopTop (see page 14219)

DesktopWidth (see page 14219)

WorkAreaRect (see page 14232)

Primary (see page 14195)

Monitors (see page 14228)

72.1.11.5.16 TScreen.DesktopTop Property

Specifies the y-coordinate of the entire desktop's top edge relative to the upper-left corner of the primary monitor.

Pascal

```
property DesktopTop: Integer;
```

C++

```
__property int DesktopTop;
```

Description

Use DesktopTop to determine the y-coordinate of the desktop's top edge relative to the upper-left corner of the primary monitor. The primary monitor is the monitor with its Primary property set to true. The desktop is defined as the entire virtual desktop, which includes all monitors in the system.

On a single-monitor system, DesktopTop is 0.

See Also

DesktopHeight (see page 14217)

DesktopRect (see page 14218)

DesktopLeft (see page 14218)

DesktopWidth (see page 14219)

WorkAreaTop (see page 14232)

Primary (see page 14195)

Monitors (see page 14228)

72.1.11.5.17 TScreen.DesktopWidth Property

Specifies the width of the entire virtual desktop.

Pascal

```
property DesktopWidth: Integer;
```

C++

```
__property int DesktopWidth;
```

Description

Use DesktopWidth to determine the width of the desktop. The desktop is defined as the entire virtual desktop, which includes all monitors in the system.

On a single-monitor system, DesktopWidth corresponds to Width (see page 14229).

See Also

DesktopHeight (see page 14217)

DesktopRect (see page 14218)

DesktopLeft (see page 14218)

DesktopTop (see page 14219)

WorkAreaWidth (see page 14233)

Width (see page 14229)

72.1.11.5.18 TScreen.FocusedForm Property

Provides a reference to the form that has focus.

Pascal

```
property FocusedForm: TCustomForm;
```

C++

```
__property TCustomForm FocusedForm;
```

Description

FocusedForm returns a reference to the form that currently has focus.

See Also

TCustomForm (see page 13849)

72.1.11.5.19 TScreen.Fonts Property

Lists the face names for all fonts supported by the screen.

Pascal

```
property Fonts: TStrings;
```

C++

```
__property TStrings Fonts;
```

Description

Read Fonts to learn what screen fonts are currently installed. Applications can use Fonts to ensure that they do not request a font that is not installed on the user's system. When an application uses a TFont object to request a font that is not installed, the system substitutes another font, which may not be a font appropriate to the application's needs.

Note: Fonts is a list of screen fonts. It does not give any indication of the printer fonts available to the application.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

See Also

TFont (see page 14497)

ResetFonts (see page 14205)

72.1.11.5.20 TScreen.FormCount Property

Indicates the number of forms displayed on the screen.

Pascal

```
property FormCount: Integer;
```

C++

```
__property int FormCount;
```

Description

Read FormCount to learn the number of forms currently displayed on the screen. These forms can be accessed by the Forms (see page 14223) property. FormCount can be used with Forms (see page 14223) to iterate over all the forms in an application.

C++ Examples:

```
/*
This example assumes that the main form of the application
has a main menu with a menu item. The following code adds a
separator, and the name of all forms to the menu. Do not
access FormCount in the mainform's FormCreate.  The other
forms do not exist yet!
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMenuItem *NewItem;
  // first create the separator
  NewItem = new TMenuItem(this); // If you change the AOwner (this) to MainMenu1->Items[1] and
then you add the new menu you will get "Menu inserted twice"?  Doesn't happen in Delphi.
  NewItem->Name = "Separator";
  NewItem->Caption = "-";
  // add the new item to the Windows menu
  MainMenu1->Items[1].Add(NewItem);
  // now create and add a menu item for each form
  for  (int I = 0; I < Screen->FormCount; I++)
  {
    NewItem = new TMenuItem(this);
    NewItem->Caption = Screen->Forms[I]->Name + "Item";
    NewItem->Name = Screen->Forms[I]->Name;
    MainMenu1->Items[1].Add(NewItem);
  }
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  // Count down, not up!
  for  (int I = MainMenu1->Items[1].Count - 1; I >= 0; I--)
  {
    delete MainMenu1->Items[1].Items[I];
  }
}
```

Delphi Examples:

```
{
This example assumes that the main form of the application
has a main menu with a menu item. The following code adds a
separator, and the name of all forms to the menu. Do not
access FormCount in the mainform's FormCreate.  The other
forms do not exist yet!
}
procedure TForm1.Button1Click(Sender: TObject);
var
  NewItem: TMenuItem;
  I : integer;
begin
  { first create the separator }
  NewItem := TMenuItem.Create(MainMenu1.Items[1]);
  NewItem.Name:= 'Separator';
  NewItem.Caption := '-';
  { add the new item to the Windows menu }
  MainMenu1.Items[1].Add(NewItem);
  { now create and add a menu item for each form }
  for  I := 0 to Screen.FormCount-1 do
  begin
```

```
      NewItem := TMenuItem.Create(MainMenu1.Items[1]);
      NewItem.Caption := Screen.Forms[I].Name + 'Item';
      NewItem.Name := Screen.Forms[I].Name;
      MainMenu1.Items[1].Add(NewItem);
     end;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    I : Integer;
  begin
    // Count down, not up!
    for  I := MainMenu1.Items[1].Count - 1 downto 0 do
    begin
      MainMenu1.Items[1].Items[I].Free;
    end;
  end;
```

See Also

Forms (see page 14223)

TForm (see page 13992)

72.1.11.5.21 TScreen.Forms Property

Lists all the forms currently displayed in the application.

Pascal

```
property Forms [Index: Integer]: TForm;
```

C++

```
__property TForm * Forms[int Index];
```

Description

Use Forms to access a form by index. The value of Index is a number between zero (the first form) and FormCount (see page 14221) - 1. Forms can be used with FormCount (see page 14221) when an application needs to iterate over all its forms, including all dialogs.

Forms only lists the TForm (see page 13992) descendants in the application. This does not include, for example, property pages. To get a list that includes TCustomForm (see page 13849) descendants that do not descend from TForm (see page 13992), use CustomForms (see page 14215) instead.

Warning: The order in which Forms lists its forms is affected by the Z order of the forms. Do not change the Z order of forms when using Forms to iterate over the forms in an application.

C++ Examples:

```
/*
This example assumes that the main form of the application
has a main menu with a menu item. The following code adds a
separator, and the name of all forms to the menu. Do not
access FormCount in the mainform's FormCreate.  The other
forms do not exist yet!
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMenuItem *NewItem;
  // first create the separator
  NewItem = new TMenuItem(this); // If you change the AOwner (this) to MainMenu1->Items[1] and
then you add the new menu you will get "Menu inserted twice"?  Doesn't happen in Delphi.
```

```
    NewItem->Name = "Separator";
    NewItem->Caption = "-";
    // add the new item to the Windows menu
    MainMenu1->Items[1].Add(NewItem);
    // now create and add a menu item for each form
    for  (int I = 0; I < Screen->FormCount; I++)
    {
      NewItem = new TMenuItem(this);
      NewItem->Caption = Screen->Forms[I]->Name + "Item";
      NewItem->Name = Screen->Forms[I]->Name;
      MainMenu1->Items[1].Add(NewItem);
    }
  }

  void __fastcall TForm1::FormDestroy(TObject *Sender)
  {
    // Count down, not up!
    for  (int I = MainMenu1->Items[1].Count - 1; I >= 0; I--)
    {
      delete MainMenu1->Items[1].Items[I];
    }
  }
```

Delphi Examples:

```
{
This example assumes that the main form of the application
has a main menu with a menu item. The following code adds a
separator, and the name of all forms to the menu. Do not
access FormCount in the mainform's FormCreate.  The other
forms do not exist yet!
}
procedure TForm1.Button1Click(Sender: TObject);
var
  NewItem: TMenuItem;
  I : integer;
begin
  { first create the separator }
  NewItem := TMenuItem.Create(MainMenu1.Items[1]);
  NewItem.Name:= 'Separator';
  NewItem.Caption := '-';
  { add the new item to the Windows menu }
  MainMenu1.Items[1].Add(NewItem);
  { now create and add a menu item for each form }
  for  I := 0 to Screen.FormCount-1 do
  begin
    NewItem := TMenuItem.Create(MainMenu1.Items[1]);
    NewItem.Caption := Screen.Forms[I].Name + 'Item';
    NewItem.Name := Screen.Forms[I].Name;
    MainMenu1.Items[1].Add(NewItem);
   end;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I : Integer;
begin
  // Count down, not up!
  for  I := MainMenu1.Items[1].Count - 1 downto 0 do
  begin
    MainMenu1.Items[1].Items[I].Free;
  end;
end;
```

See Also

FormCount (see page 14221)

CustomForms (see page 14215)

72.1.11.5.22 TScreen.Height Property

Indicates the vertical size of the screen in pixels.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Read Height to learn the size of the user's screen in pixels. The size or position of objects placed on the screen, can then be set to ensure that the objects fit on screen and don't look crowded.

C++ Examples:

```
/*
The following code determines the height of all forms on the
screen and resizes any that are taller than the screen height.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < Screen->FormCount; i++)
  {
    if (Screen->Forms[i]->Top < 0)
    {
      Screen->Forms[i]->Height += Screen->Forms[i]->Top;
      Screen->Forms[i]->Top = 0;
    }
    if (Screen->Forms[i]->Left < 0)
    {
      Screen->Forms[i]->Width += Screen->Forms[i]->Left;
      Screen->Forms[i]->Left = 0;
    }
    if (Screen->Forms[i]->Height > Screen->Height)
      Screen->Forms[i]->Height = Screen->Height;
    if (Screen->Forms[i]->Width > Screen->Width)
      Screen->Forms[i]->Width = Screen->Width;
  }
}
```

Delphi Examples:

```
{
The following code determines the height of all forms on the
screen and resizes any that are taller than the screen height.
}
procedure TForm1.Button1Click(Sender: TObject);
var I: Integer;
begin
with Screen do
  for I := 0 to FormCount-1 do
    begin
    if Forms[I].Top < 0 then
    begin
      Forms[I].Height := Forms[I].Height + Forms[I].Top;
      Forms[I].Top := 0;
    end;
    if Forms[I].Left < 0 then
    begin
      Forms[I].Width := Forms[I].Width + Forms[I].Left;
      Forms[I].Left := 0;
```

```
    end;
    if Forms[I].Width > Width then
      Forms[I].Width := Width;
    if Forms[I].Height > Height then
      Forms[I].Height := Height;
    if Forms[I].Width > Width then
      Forms[I].Width := Width;
    end;
end;
```

Considerations When Dynamically Resizing Forms and Controls

72.1.11.5.23 TScreen.HintFont Property

Specifies the font used to display help hints.

Pascal

```
property HintFont: TFont;
```

C++

```
__property TFont HintFont;
```

Description

HintFont stores the Windows status font setting. This font is used by default for the help hints that appear when the user pauses the mouse over a control or menu item.

See Also

Fonts (see page 14220)

IconFont (see page 14226)

MenuFont (see page 14227)

Font (see page 5823)

Hint (see page 5827)

Hint (see page 13712)

72.1.11.5.24 TScreen.IconFont Property

Specifies the font used to display the labels on the icons in file selection dialogs.

Pascal

```
property IconFont: TFont;
```

C++

```
__property TFont IconFont;
```

Description

IconFont stores the Windows icon font setting. This font is used to label the icons on the desktop, and icons in the file selection dialogs.

See Also

Fonts (see page 14220)

HintFont (see page 14226)

MenuFont (see page 14227)

72.1.11.5.25 TScreen.Imes Property

Lists all input method editors (IMEs) installed on the system.

Pascal

```
property Imes: TStrings;
```

C++

```
__property TStrings Imes;
```

Description

Read Imes to obtain a list of all IMEs that are listed in the Windows registry. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application. IMEs vary in user interface, conversion dictionaries, and input method.

Individual controls can require a specific IME to process the keyboard input when they have focus. To specify an IME, the control sets its ImeName property to one of the strings in Imes.

Each IME name in Imes has an associated keyboard layout handle. A keyboard layout handle is a Windows handle that identifies the primary language and IME used to process keyboard input. Use the keyboard layout handle in Windows API calls for programming the IME. To get the keyboard layout handle for a particular IME, a control can use code such as the following:

```
HKeyboard := Screen.Imes.Objects(Screen.Imes.IndexOf(ImeName));
HKeyboard = Screen->Imes->Objects(Screen->Imes->IndexOf(ImeName));
```

See Also

DefaultIme (see page 14216)

DefaultKbLayout (see page 14217)

TStrings (see page 3029)

ImeName (see page 6208)

72.1.11.5.26 TScreen.MenuFont Property

Specifies the font used for menu commands.

Pascal

```
property MenuFont: TFont;
```

C++

```
__property TFont MenuFont;
```

Description

MenuFont stores the Windows menu font setting. This font is used for menu items in main menus or popup menus that do not

draw their own menu items in an OnDrawItem event handler.

See Also

Fonts (see page 14220)

IconFont (see page 14226)

HintFont (see page 14226)

OnDrawItem (see page 16159)

72.1.11.5.27 TScreen.MonitorCount Property

Specifies the number of monitors used to comprise the desktop.

Pascal

```
property MonitorCount: Integer;
```

C++

```
__property int MonitorCount;
```

Description

Use MonitorCount to determine the number of monitors used to comprise the desktop.

See Also

Monitors (see page 14228)

DesktopRect (see page 14218)

72.1.11.5.28 TScreen.Monitors Property

Provides access to an individual monitor used to comprise the desktop.

Pascal

```
property Monitors [Index: Integer]: TMonitor;
```

C++

```
__property TMonitor Monitors[int Index];
```

Description

Use Monitors to access an individual monitor used to comprise the desktop.

The Monitor with its Primary property set to true is the primary monitor.

See Also

MonitorCount (see page 14228)

DesktopRect (see page 14218)

Primary (see page 14195)

72.1.11.5.29 TScreen.PixelsPerInch Property

Indicates the number of screen pixels that make up a logical inch in the vertical direction.

Pascal

```
property PixelsPerInch: Integer;
```

C++

```
__property int PixelsPerInch;
```

Description

Read PixelsPerInch to convert between measurements in pixels and measurements in logical inches. PixelsPerInch is only accurate for vertical measurements. Most screens have a different scaling factor for horizontal measurements. The value in PixelsPerInch is set from system when the application loads.

See Also

Height (see page 14225)

PixelsPerInch (see page 13928)

72.1.11.5.30 TScreen.PrimaryMonitor Property

Provides a reference to the primary monitor.

Pascal

```
property PrimaryMonitor: TMonitor;
```

C++

```
__property TMonitor PrimaryMonitor;
```

Description

The coordinates of Monitors (see page 14228) in a multi-monitor configuration are related to the primary monitor. PrimaryMonitor returns a reference to the primary monitor. Use the Primary property to determine whether a specific monitor is the primary one.

See Also

TMonitor (see page 14191)

72.1.11.5.31 TScreen.SaveFocusedList Property

Pascal

```
property SaveFocusedList: TList;
```

C++

```
__property TList SaveFocusedList;
```

Description

This is SaveFocusedList, a member of class TScreen.

72.1.11.5.32 TScreen.Width Property

Indicates the horizontal size of the screen in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Read Width to learn the size of the user's screen in pixels. The size or position of objects placed on the screen, can then be set to ensure that the objects fit on screen and don't look crowded.

C++ Examples:

```
/*
The following code determines the height of all forms on the
screen and resizes any that are taller than the screen height.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < Screen->FormCount; i++)
  {
    if (Screen->Forms[i]->Top < 0)
    {
      Screen->Forms[i]->Height += Screen->Forms[i]->Top;
      Screen->Forms[i]->Top = 0;
    }
    if (Screen->Forms[i]->Left < 0)
    {
      Screen->Forms[i]->Width += Screen->Forms[i]->Left;
      Screen->Forms[i]->Left = 0;
    }
    if (Screen->Forms[i]->Height > Screen->Height)
      Screen->Forms[i]->Height = Screen->Height;
    if (Screen->Forms[i]->Width > Screen->Width)
      Screen->Forms[i]->Width = Screen->Width;
  }
}
```

Delphi Examples:

```
{
The following code determines the height of all forms on the
screen and resizes any that are taller than the screen height.
}
procedure TForm1.Button1Click(Sender: TObject);
var I: Integer;
begin
with Screen do
  for I := 0 to FormCount-1 do
    begin
    if Forms[I].Top < 0 then
    begin
      Forms[I].Height := Forms[I].Height + Forms[I].Top;
      Forms[I].Top := 0;
    end;
    if Forms[I].Left < 0 then
    begin
      Forms[I].Width := Forms[I].Width + Forms[I].Left;
      Forms[I].Left := 0;
    end;
    if Forms[I].Width > Width then
      Forms[I].Width := Width;
    if Forms[I].Height > Height then
      Forms[I].Height := Height;
    if Forms[I].Width > Width then
      Forms[I].Width := Width;
    end;
end;
```

See Also

Height (see page 14225)

DesktopWidth (see page 14219)

WorkAreaWidth (see page 14233)

Considerations When Dynamically Resizing Forms and Controls

72.1.11.5.33 TScreen.WorkAreaHeight Property

Specifies the height of the work area on the primary monitor.

Pascal

```
property WorkAreaHeight: Integer;
```

C++

```
__property int WorkAreaHeight;
```

Description

Use WorkAreaHeight to determine the height of the usable space on the primary monitor. WorkAreaHeight differs from the Height (see page 14225) property in that it adjusts the work area to subtract any space occupied by the task bar and any tool bars that sit on the desktop.

The primary monitor is the monitor whose Primary property is true.

See Also

WorkAreaLeft (see page 14231)

WorkAreaRect (see page 14232)

WorkAreaTop (see page 14232)

WorkAreaWidth (see page 14233)

DesktopHeight (see page 14217)

Height (see page 14225)

Monitors (see page 14228)

Primary (see page 14195)

72.1.11.5.34 TScreen.WorkAreaLeft Property

Specifies the left edge of the work area on the primary monitor.

Pascal

```
property WorkAreaLeft: Integer;
```

C++

```
__property int WorkAreaLeft;
```

Description

Use WorkAreaLeft to determine the left edge of the usable space on the primary monitor. This value indicates the number of pixels between the left edge of the primary monitor, and the space left after accounting for the task bar and any tool bars that sit

on the desktop.

The primary monitor is the monitor whose Primary property is true.

See Also

WorkAreaHeight (see page 14231)

WorkAreaRect (see page 14232)

WorkAreaTop (see page 14232)

WorkAreaWidth (see page 14233)

DesktopLeft (see page 14218)

Primary (see page 14195)

Monitors (see page 14228)

72.1.11.5.35 TScreen.WorkAreaRect Property

Specifies the boundaries of the usable work area on the primary monitor.

Pascal

```
property WorkAreaRect: TRect;
```

C++

```
__property TRect WorkAreaRect;
```

Description

Use WorkAreaRect to determine the coordinates of the usable space on the primary monitor. The usable work space is the surface of the primary monitor with the space occupied by the task bar and any tool bars subtracted off.

The primary monitor is the monitor with its Primary property set to true.

See Also

WorkAreaHeight (see page 14231)

WorkAreaLeft (see page 14231)

WorkAreaTop (see page 14232)

WorkAreaWidth (see page 14233)

Primary (see page 14195)

Monitors (see page 14228)

WorkAreaRect (see page 14197)

72.1.11.5.36 TScreen.WorkAreaTop Property

Specifies the top edge of the work area on the primary monitor.

Pascal

```
property WorkAreaTop: Integer;
```

C++

```
__property int WorkAreaTop;
```

Description

Use WorkAreaTop to determine the top edge of the usable space on the primary monitor. This value indicates the number of pixels between the top edge of the primary monitor, and the space left after accounting for the task bar and any tool bars that sit on the desktop.

The primary monitor is the monitor whose Primary property is true.

Primary (see page 14195)

Monitors (see page 14228)

72.1.11.5.37 TScreen.WorkAreaWidth Property

Specifies the width of the work area on the primary monitor.

Pascal

```
property WorkAreaWidth: Integer;
```

C++

```
__property int WorkAreaWidth;
```

Description

Use WorkAreaWidth to determine the width of the usable space on the primary monitor. WorkAreaWidth differs from the Width (see page 14229) property in that it adjusts the work area to subtract any space occupied by the task bar and any tool bars that sit on the desktop.

The primary monitor is the monitor whose Primary property is true.

Width (see page 14229)

72.1.11.6 TScreen Events

The events of the TScreen class are listed here.

Public Events

	Name	Description
	OnActiveControlChange (see page 14234)	Occurs immediately after input focus changes to a new windowed control.
	OnActiveFormChange (see page 14236)	Occurs immediately after a new form becomes active in a multi-form application.

72.1.11.6.1 TScreen.OnActiveControlChange Event

Occurs immediately after input focus changes to a new windowed control.

Pascal

```
property OnActiveControlChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnActiveControlChange;
```

Description

Write an OnActiveControlChange event handler to take specific action when input focus changes to a new control. The change in focus may be within the active form, or across forms to a new form that then becomes the active form.

When focus moves from one control to another, the following events occur.

1If the new focused control is in a different form, focus moves to the new form.

2Focus moves to the new active control.

3If the active form changed, an OnActiveFormChange (see page 14236) event occurs.

4An OnActiveControlChange event occurs.

C++ Examples:

```
/*
This example uses the OnActiveControlChange event to detect
when focus changes on the form. When focus changes, the hint
for the active control is displayed on the status bar. To use
this example, you must add a status bar to the form and set
its SimplePanel property to true.  Add a new public procedure,
ActiveControlChanged, to the TForm1 class declaration.
*/
void _fastcall TForm1::ActiveControlChanged(System::TObject *Sender)
{
  TWinControl *Active = NULL;
  for (int I = 0; I < Form1->ControlCount; I++)
  {
    TWinControl *Temp = dynamic_cast<TWinControl *>(Form1->Controls[I]);
    if (Temp && Temp->Focused())
      Active = Temp;
  }
  if ((Active != NULL) && (Active->Hint != ""))
    StatusBar2->SimpleText = GetLongHint(Active->Hint) + " focus";
}

void __fastcall TForm1::MouseOverChanged(TObject *Sender)
{
  TWinControl *Active = dynamic_cast<TWinControl *>(Sender);
  if (Active != NULL)
```

```
    StatusBar1->SimpleText = GetLongHint(Active->Hint) + " mouse over";
}

/*
Assign this method as the OnActiveControlChange event
handler by setting it from the form's OnCreate event handler:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Screen->OnActiveControlChange = ActiveControlChanged;
}

/*
Make sure you clean up the screen object when the form is
freed by adding this OnDestroy event handler to the form:
*/
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  Screen->OnActiveControlChange = 0;
}
```

Delphi Examples:

```
{
This example uses the OnActiveControlChange event to detect
when focus changes on the form. When focus changes, the hint
for the active control is displayed on the status bar. To use
this example, you must add a status bar to the form and set
its SimplePanel property to true.  Add a new public procedure,
ActiveControlChanged, to the TForm1 class declaration.
}

type
  TForm1 = class(TForm)
    StatusBar1, StatusBar2: TStatusBar;
    Button1: TButton;
    RadioButton1: TRadioButton;
    procedure FormCreate(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
    procedure MouseOverChanged(Sender: TObject);
  private
    { Private declarations }
  public
    procedure ActiveControlChanged(Sender: TObject);
  end;

var
  Active : TWinControl;
  I: Integer;
  Form1: TForm1;

implementation

{$R *.dfm}

procedure TForm1.ActiveControlChanged(Sender: TObject);
var
  Active : TWinControl;
  I: Integer;
begin
  Active := nil;
  for I:= 0 to ControlCount -1 do
  begin
    if (Controls[I] is TWinControl) then
      if (Controls[I] as TWinControl).Focused then
        Active := TWinControl(Controls[I]);
  end;
```

```
    if ((Active <> nil) and (Active.Hint <> '')) then
    begin
      StatusBar2.SimpleText := GetLongHint(Active.Hint) + ' focus';
    end
  end;

  procedure TForm1.MouseOverChanged(Sender: TObject);
  var

72.1.11.6.2 TScreen.OnActiveFormChange Event

Occurs immediately after a new form becomes active in a multi-form application.

Pascal

```
property OnActiveFormChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnActiveFormChange;
```

Description

Write an OnActiveFormChange event handler to take specific action when a new form becomes active. OnActiveFormChange occurs when the active form for the application changes, not when a form becomes active because the application becomes active.

C++ Examples:

```
/*
This example uses a two forms with a button on the first
form. When the user clicks the button, the second form
```

```
appears. As the user switches between forms, the form that
is active is colored aqua.
Note:   You must include the unit header for form 2 to the
unit file for form 1, and add the public ColorForm method
to the definition of the TForm1 class.
*/
#include "Unit2.h"

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Form2->Show();
}

void __fastcall TForm1::ColorForm(TObject *Sender)
{
  Color = clWhite;
  Form2->Color = clWhite;
  Screen->ActiveForm->Color = clAqua;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Screen->OnActiveFormChange = ColorForm;
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  // This stops ColorForm from being called during termination.
  Screen->OnActiveFormChange = NULL;
}
```

Delphi Examples:

```
{
This example uses a two forms with a button on the first
form. When the user clicks the button, the second form
appears. As the user switches between forms, the form that
is active is colored aqua.
Note:   You must include the unit header for form 2 to the
unit file for form 1, and add the public ColorForm method
to the header for form 1's unit.
}
type
  TForm1 = class(TForm)
    Button1: TButton;
    procedure Button1Click(Sender: TObject);
    procedure FormCreate(Sender: TObject);
    procedure FormDestroy(Sender: TObject);
  private
    { Private declarations }
  public
    procedure ColorForm(Sender: TObject);
  end;

var
  Form1: TForm1;

implementation

{$R *.dfm}

uses Unit2;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Form2.Show;
end;
```

```
procedure TForm1.ColorForm(Sender: TObject);
begin
  Color := clWhite;
  Form2.Color := clWhite;

72.1.12 TScrollBox Class

TScrollBox represents a scrolling area (a scroll box) in a window.

Class Hierarchy

Pascal

```
TScrollBox = class(TScrollingWinControl);
```

C++

```
class TScrollBox : public TScrollingWinControl;
```

File

Forms

Description

Use TScrollBox to create a scroll box in a window.

One use of a scroll box is to prevent areas of a window, such as a toolbar or status bar built with TPanel components, from scrolling. To prevent a toolbar and status bar from scrolling, hide the window's scroll bars, and then position a scroll box in the client area of the window between the toolbar and status bar. The scroll bars associated with the scroll box will appear to belong to the window, but will scroll only the area inside the scroll box.

Another use of scroll boxes is to create multiple scrolling areas (views) in a window. Views are common in commercial word-processor, spreadsheet, and project management applications.

A scroll box can contain objects, such as TButton and TCheckBox objects.

Scroll Boxes

72.1.12.1 TScrollBox Members

The following tables list the members exposed by TScrollBox.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
V	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.

	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
	Click (see page 5743)	Respond to user click.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 14250)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.

	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
V	DoFlipChildren (see page 14327)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.

	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 14250)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
V	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.

	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).

	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 14249)	Creates and initializes a new TScrollBox (see page 14238) object.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 14323)	Removes the TScrollingWinControl (see page 14312) object from memory.
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.

	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.

	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.

R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 14278)	Occurs when an attempt is made to resize the control.
	OnClick (see page 14278)	Occurs when the user clicks the control.

	OnConstrainedResize (see page 14280)	Adjust resize constraints.
	OnContextPopup (see page 14281)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 14282)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 14282)	Occurs when another control is docked to the control.
	OnDockOver (see page 14284)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 14286)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14288)	Occurs when the user drags an object over a control.
	OnEndDock (see page 14291)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 14291)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 14292)	Occurs when a control receives the input focus.
	OnExit (see page 14294)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 14296)	Returns the control's docking information.
	OnMouseActivate (see page 14298)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14299)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14301)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14302)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14302)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14304)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 14306)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 14307)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14307)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 14307)	Occurs immediately after the control is resized.
	OnStartDock (see page 14308)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 14309)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 14309)	Occurs when the application tries to undock a control that is docked to the windowed control.

Published Properties

	Name	Description
	Align (see page 14251)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 14255)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 14255)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 14256)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 14256)	Specifies which edges of the control are beveled.
	BevelInner (see page 14257)	Specifies the cut of the inner bevel.
	BevelKind (see page 14257)	Specifies the control's bevel style.
	BevelOuter (see page 14258)	Specifies the cut of the outer bevel.
	BevelWidth (see page 14258)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 14258)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 14259)	Specifies whether the scroll box has a border.
	Color (see page 14259)	Specifies the background color of the control.
	Constraints (see page 14260)	Specifies the size constraints for the control.
	Ctl3D (see page 14261)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DockSite (see page 14261)	Specifies whether the control can be the target of drag-and-dock operations.

	DragCursor (see page 14262)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 14262)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14263)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14264)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 14265)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 14329)	Represents the horizontal scroll bar for the scrolling windowed control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Padding (see page 14266)	Specifies the padding of a control.
	ParentBackground (see page 14266)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 14266)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 14267)	Determines where a control looks for its color information.
	ParentCtl3D (see page 14267)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 14268)	Determines where a control looks for its font information.
	ParentShowHint (see page 14268)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 14269)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 14273)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 14275)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 14275)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	VertScrollBar (see page 14330)	Represents the vertical scroll bar for the scrolling windowed control.
	Visible (see page 14276)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

72.1.12.2 TScrollBox.Create Constructor

Creates and initializes a new TScrollBox (see page 14238) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TScrollBox(TComponent * AOwner);
```

Description

Use Create to create and initialize a new TScrollBox (see page 14238) object.

AOwner is a component, typically the form, that is responsible for freeing the scroll box.

See Also

Owner (see page 2807)

72.1.12.3 TScrollBox Methods

The methods of the TScrollBox class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 14250)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	PaintWindow (see page 14250)	Renders the image of a windowed control.

72.1.12.3.1 TScrollBox.CreateParams Method

Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. CreateParams calls the inherited method and uses that Window class style, removing the CS_HREDRAW and CS_VREDRAW styles from it.

By removing these styles the scrolling windowed control will only redraw the invalidated regions, not the entire window.

See Also

CreateWnd (see page 14327)

CreateWindowHandle (see page 6137)

72.1.12.3.2 TScrollBox.PaintWindow Method

Renders the image of a windowed control.

Pascal

```
procedure PaintWindow(DC: HDC); override;
```

C++

```
virtual __fastcall PaintWindow(HDC DC);
```

Description

Call PaintWindow to repaint the control. PaintWindow sends a WM_PAINT message to the windowed control's DefaultHandler method, setting the message record's WParam field to the value passed in DC and the other parameter and result fields to zeros.

See Also

DefaultHandler (see page 6139)

PaintTo (see page 6167)

DoubleBuffered (see page 6205)

72.1.12.4 TScrollBox Properties

The properties of the TScrollBox class are listed here.

Published Properties

	Name	Description
	Align (see page 14251)	Determines how the control aligns within its container (parent control).
	Anchors (see page 14255)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 14255)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 14256)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 14256)	Specifies which edges of the control are beveled.
	BevelInner (see page 14257)	Specifies the cut of the inner bevel.
	BevelKind (see page 14257)	Specifies the control's bevel style.
	BevelOuter (see page 14258)	Specifies the cut of the outer bevel.
	BevelWidth (see page 14258)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 14258)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 14259)	Specifies whether the scroll box has a border.
	Color (see page 14259)	Specifies the background color of the control.
	Constraints (see page 14260)	Specifies the size constraints for the control.
	Ctl3D (see page 14261)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DockSite (see page 14261)	Specifies whether the control can be the target of drag-and-dock operations.
	DragCursor (see page 14262)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 14262)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14263)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14264)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 14265)	Controls the attributes of text written on or in the control.
	Padding (see page 14266)	Specifies the padding of a control.
	ParentBackground (see page 14266)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 14266)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 14267)	Determines where a control looks for its color information.
	ParentCtl3D (see page 14267)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 14268)	Determines where a control looks for its font information.
	ParentShowHint (see page 14268)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 14269)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 14273)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 14275)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 14275)	Determines if the user can tab to a control.
	Visible (see page 14276)	Determines whether the component appears onscreen.

72.1.12.4.1 TScrollBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
```

```
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
```

```
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

var

        Brush.Color := colorPalette[i];
    end;
  end;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  i: Integer;
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

72.1.12.4.2 TScrollBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

72.1.12.4.3 TScrollBox.AutoScroll Property

Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.

Pascal

```
property AutoScroll: Boolean;
```

C++

```
__property Boolean AutoScroll;
```

Description

If AutoScroll is true, the scroll bars appear automatically when necessary. For example, if the user resizes the control so that some of its controls are partially obscured, scroll bars appear.

If AutoScroll is false, scroll bars don't appear automatically. In this case, use the HorzScrollBar and VertScrollBar properties to make scroll bars appear.

See Also

AutoScrollInView (see page 14325)

HorzScrollBar (see page 14329)

VertScrollBar (see page 14330)

72.1.12.4.4 TScrollBox.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints (see page 5812)

CanAutoSize (see page 5741)

72.1.12.4.5 TScrollBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

72.1.12.4.6 TScrollBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

72.1.12.4.7 TScrollBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

72.1.12.4.8 TScrollBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelWidth (see page 6194)

72.1.12.4.9 TScrollBox.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth: TBevelWidth;
```

C++

```
__property TBevelWidth BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelOuter (see page 6194)

72.1.12.4.10 TScrollBox.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

72.1.12.4.11 TScrollBox.BorderStyle Property

Specifies whether the scroll box has a border.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to get or set whether the scroll box has a border.

72.1.12.4.12 TScrollBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
```

```
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

72.1.12.4.13 TScrollBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

72.1.12.4.14 TScrollBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

72.1.12.4.15 TScrollBox.DockSite Property

Specifies whether the control can be the target of drag-and-dock operations.

Pascal

```
property DockSite: Boolean;
```

C++

```
__property Boolean DockSite;
```

Description

Set DockSite to true to allow other controls to be docked to this windowed control.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
```

```
    if ((DockClientCount == 2) && (NewTarget != this))        // Self?
      PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
    UpdateCaption(Client);
  }
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
```

72.1.12.4.16 TScrollBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

72.1.12.4.17 TScrollBox.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

72.1.12.4.18 TScrollBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
```

```
  example requires a populated TreeView.  Also, the TTreeView
  DragMode property set to dmAutomatic, and the TTreeView
  OnDragOver event handler must be implemented to accept the
  drop.
  }
  procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
  var
    AnItem: TTreeNode;
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TTreeView;
  end;
```

Arranging the Order of Persistent Columns

72.1.12.4.19 TScrollBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

72.1.12.4.20 TScrollBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
```

```
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

See Also

DesktopFont (see page 5818)

ParentFont (see page 5834)

Displaying and Editing Text in a Memo Control

72.1.12.4.21 TScrollBox.Padding Property

Specifies the padding of a control.

Pascal

```
property Padding: TPadding;
```

C++

```
__property TPadding Padding;
```

Description

Use Padding to specify the padding of a control. This value is an instance of the class TPadding.

See Also

TPadding (see page 6103)

72.1.12.4.22 TScrollBox.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground: Boolean;
```

C++

```
__property Boolean ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

72.1.12.4.23 TScrollBox.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's

BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

72.1.12.4.24 TScrollBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

72.1.12.4.25 TScrollBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

72.1.12.4.26 TScrollBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

72.1.12.4.27 TScrollBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

72.1.12.4.28 TScrollBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
```

```
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
```

```
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
```

```
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

72.1.12.4.29 TScrollBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

72.1.12.4.30 TScrollBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

72.1.12.4.31 TScrollBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

72.1.12.4.32 TScrollBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
```

```
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

72.1.12.5 TScrollBox Events

The events of the TScrollBox class are listed here.

Published Events

	Name	Description
	OnCanResize (see page 14278)	Occurs when an attempt is made to resize the control.
	OnClick (see page 14278)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 14280)	Adjust resize constraints.
	OnContextPopup (see page 14281)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 14282)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 14282)	Occurs when another control is docked to the control.
	OnDockOver (see page 14284)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 14286)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14288)	Occurs when the user drags an object over a control.
	OnEndDock (see page 14291)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 14291)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 14292)	Occurs when a control receives the input focus.
	OnExit (see page 14294)	Occurs when the input focus shifts away from one control to another.

	OnGetSiteInfo (see page 14296)	Returns the control's docking information.
	OnMouseActivate (see page 14298)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14299)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14301)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14302)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14302)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14304)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 14306)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 14307)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14307)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 14307)	Occurs immediately after the control is resized.
	OnStartDock (see page 14308)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 14309)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 14309)	Occurs when the application tries to undock a control that is docked to the windowed control.

72.1.12.5.1 TScrollBox.OnCanResize Event

Occurs when an attempt is made to resize the control.

Pascal

```
property OnCanResize: TCanResizeEvent;
```

C++

```
__property TCanResizeEvent OnCanResize;
```

Description

Use OnCanResize to adjust the way a control is resized. If necessary, change the new width and height of the control in the OnCanResize event handler. The OnCanResize event handler also allows applications to indicate that the entire resize should be aborted.

If there is no OnCanResize event handler, or if the OnCanResize event handler indicates that the resize attempt can proceed, the OnCanResize event is followed immediately by an OnConstrainedResize event.

See Also

OnConstrainedResize (see page 5853)

SetBounds (see page 5783)

OnResize (see page 5870)

72.1.12.5.2 TScrollBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
```

```
  edit control placed somewhere on the client area of the
  sheet.  Unchecking the checkbox will cause the client area
  (not the tab area) of the Tab Control to become invisible.
  }
  procedure TForm1.CheckBox1Click(Sender: TObject);
  begin
    PageControl1.ActivePage.Visible := CheckBox1.Checked;
  end;

  procedure TForm1.PageControl1Change(Sender: TObject);
  begin
    CheckBox1.Checked := PageControl1.ActivePage.Visible;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  begin
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

Adding Silent Video Clips to an Application

72.1.12.5.3 TScrollBox.OnConstrainedResize Event

Adjust resize constraints.

Pascal

```
property OnConstrainedResize: TConstrainedResizeEvent;
```

C++

```
__property TConstrainedResizeEvent OnConstrainedResize;
```

Description

Use OnConstrainedResize to adjust a control's constraints when an attempt is made to resize it. Upon entry to the OnConstrainedResize event handler, the parameters of the event handler are set to the corresponding properties of the control's Constraints object. The event handler can adjust those values before they are applied to the new height and width that is being

applied to the control. (The CanAutoSize method or an OnCanResize event handler may already have adjusted this new height and width).

On exit from the OnConstrainedResize event handler, the constraints are applied to the attempted new height and width. Once the constraints are applied, the control's height and width are changed. After the control's height and width change, an OnResize event occurs to allow any final adjustments or responses.

Note: The OnConstrainedResize handler is called immediately after the OnCanResize handler.

See Also

OnCanResize (see page 5851)

SetBounds (see page 5783)

Constraints (see page 5812)

OnResize (see page 5870)

CanAutoSize (see page 5741)

72.1.12.5.4 TScrollBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

AutoPopup (see page 16178)

72.1.12.5.5 TScrollBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

72.1.12.5.6 TScrollBox.OnDockDrop Event

Occurs when another control is docked to the control.

Pascal

```
property OnDockDrop: TDockDropEvent;
```

C++

```
__property TDockDropEvent OnDockDrop;
```

Description

Write code in the OnDockDrop event to perform actions when another control is docked on the control.

OnDockDrop can only occur if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
```

```
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
```

```
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

See Also

DockSite (see page 6204)

OnDockOver (see page 6216)

72.1.12.5.7 TScrollBox.OnDockOver Event

Occurs when another control is dragged over the control.

Pascal

```
property OnDockOver: TDockOverEvent;
```

C++

```
__property TDockOverEvent OnDockOver;
```

Description

Write code in the OnDockOver event to indicate whether a dockable control that is dragged over the windowed control can be accepted as a dock client. OnDockOver occurs after the TDragDockObject has been initialized by an OnGetSiteInfo event.

OnDockOver occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
```

```
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;

procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
```

```
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
  DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
  var CanDock: Boolean);
begin
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock := DockClient is TDockableForm;
end;
```

72.1.12.5.8 TScrollBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
```

```
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:
```

```
procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;

72.1.12.5.9 TScrollBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler

is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;
```

```
procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

72.1.12.5.10 TScrollBox.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

72.1.12.5.11 TScrollBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

72.1.12.5.12 TScrollBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
```

```
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
```

```
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

72.1.12.5.13 TScrollBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
```

```
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

72.1.12.5.14 TScrollBox.OnGetSiteInfo Event

Returns the control's docking information.

Pascal

```
property OnGetSiteInfo: TGetSiteInfoEvent;
```

C++

```
__property TGetSiteInfoEvent OnGetSiteInfo;
```

Description

Write code in the OnGetSiteInfo event handler to initialize a TDragDockObject with information about where a dragged object can be docked, if at all. OnGetSiteInfo occurs before the OnDockOver event.

OnGetSiteInfo occurs only if DockSite is true.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
```

```
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
```

```
      ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
      ARect.BottomRight := LeftDockPanel.ClientToScreen(
        Point(Self.ClientWidth div 3, LeftDockPanel.Height));
      Source.DockRect := ARect;
    end;
  end;

  procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
    NewTarget: TWinControl; var Allow: Boolean);
  begin
    //OnUnDock gets called BEFORE the client is undocked, in order to optionally
    //disallow the undock. DockClientCount is never 0 when called from this event.
    if (Sender as TPanel).DockClientCount = 1 then
      ShowDockPanel(Sender as TPanel, False, nil);
  end;

  procedure TMainForm.LeftDockPanelGetSiteInfo(Sender: TObject;
    DockClient: TControl; var InfluenceRect: TRect; MousePos: TPoint;
    var CanDock: Boolean);
  begin
    //if CanDock is true, the panel will not automatically draw the preview rect.
    CanDock := DockClient is TDockableForm;
  end;

72.1.12.5.15 TScrollBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of

whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

72.1.12.5.16 TScrollBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form’s unit
```

```
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
```

```
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
      end;
  end;
end;
```

72.1.12.5.17 TScrollBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

72.1.12.5.18 TScrollBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

72.1.12.5.19 TScrollBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/

72.1.12.5.20 TScrollBox.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

Responding to a Mouse-up Action

72.1.12.5.21 TScrollBox.OnMouseWheel Event

Occurs when the mouse wheel is rotated.

Pascal

```
property OnMouseWheel: TMouseWheelEvent;
```

C++

```
__property TMouseWheelEvent OnMouseWheel;
```

Description

Write code in the OnMouseWheel event handler to respond to mouse wheel messages. If there is no OnMouseWheel event handler, or if the mouse wheel message is not handled in the OnMouseWheel event handler, then an OnMouseWheelUp or

OnMouseWheelDown event occurs, depending on the direction the mouse wheel was rotated.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheelUp (see page 5870)

72.1.12.5.22 TScrollBox.OnMouseWheelDown Event

Occurs when the mouse wheel is rotated downward.

Pascal

```
property OnMouseWheelDown: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelDown;
```

Description

Write code in the OnMouseWheelDown event handler to perform actions when the mouse wheel is rotated downward. OnMouseWheelDown occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheel (see page 5869)

OnMouseWheelUp (see page 5870)

72.1.12.5.23 TScrollBox.OnMouseWheelUp Event

Occurs when the mouse wheel is rotated upward.

Pascal

```
property OnMouseWheelUp: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelUp;
```

Description

Write code in the OnMouseWheelUp event handler to perform actions when the mouse wheel is rotated upward. OnMouseWheelUp occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheel (see page 5869)

72.1.12.5.24 TScrollBox.OnResize Event

Occurs immediately after the control is resized.

Pascal

```
property OnResize: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnResize;
```

Description

Use OnResize to make any final adjustments after a control is resized.

To modify the way a control responds when an attempt is made to resize it, use OnCanResize or OnConstrainedResize.

Note: Some controls call this event handler when the control is first created.

Delphi Examples:

```
{
The following code keeps the right edge on Button1 against
the right edge of Form1 when Form1 is resized.
}
procedure TForm1.FormResize(Sender: TObject);
begin
  Button1.Left := Form1.ClientWidth-Button1.Width;
end;
```

See Also

OnCanResize (see page 5851)

SetBounds (see page 5783)

AutoSize (see page 5803)

OnConstrainedResize (see page 5853)

72.1.12.5.25 TScrollBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

See Also

OnEndDock (see page 5859)

TDragDockObjectEx (see page 6018)

DragKind (see page 5819)

OnDragOver (see page 5857)

72.1.12.5.26 TScrollBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

72.1.12.5.27 TScrollBox.OnUnDock Event

Occurs when the application tries to undock a control that is docked to the windowed control.

Pascal

```
property OnUnDock: TUnDockEvent;
```

C++

```
__property TUnDockEvent OnUnDock;
```

Description

Write an OnUnDock event handler to adjust the windowed control when a dock client is undocked. The OnUnDock event handler can make any necessary adjustments, or it can block the undock attempt by setting the Allow parameter to false.

C++ Examples:

```
/*
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
*/
void __fastcall TConjoinDockHost::FormUnDock(TObject *Sender, TControl *Client,
      TWinControl *NewTarget, bool &Allow)
{
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if (Client->ClassNameIs("TDockableForm"))
    dynamic_cast<TDockableForm *>(Client)->DockSite = True;
  if ((DockClientCount == 2) && (NewTarget != this))        // Self?
    PostMessage(dynamic_cast<TConjoinDockHost *>(this)->Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
}
/*
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
*/

void __fastcall TMainForm::LeftDockPanelDockDrop(TObject *Sender,
      TDragDockObject *Source, int X, int Y)
{
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, True, NULL);
  panel->DockManager->ResetBounds(True);
  //Make DockManager repaints it's clients.
}

void __fastcall TMainForm::LeftDockPanelDockOver(TObject *Sender,
      TDragDockObject *Source, int X, int Y, TDragState State, bool &Accept)
{
  Accept = (dynamic_cast<TDockableForm*>(Source->Control) != NULL);
  if (Accept)
  {
    // Modify the DockRect to preview dock area.
    Types::TPoint TopLeft = LeftDockPanel->ClientToScreen(Point(0, 0));
    Types::TPoint BottomRight = LeftDockPanel->ClientToScreen(
      Point(this->ClientWidth/3, LeftDockPanel->Height));
    Source->DockRect = Types::TRect(TopLeft, BottomRight);
  }
}

void __fastcall TMainForm::LeftDockPanelUnDock(TObject *Sender,
      TControl *Client, TWinControl *NewTarget, bool &Allow)
{
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  TPanel *panel = dynamic_cast<TPanel *>(Sender);
  if (panel->DockClientCount == 1)
    ShowDockPanel(panel, False, NULL);
}

void __fastcall TMainForm::LeftDockPanelGetSiteInfo(TObject *Sender,
      TControl *DockClient, TRect &InfluenceRect, TPoint &MousePos,
```

```
      bool &CanDock)
{
  //if CanDock is true, the panel will not automatically draw the preview rect.
  CanDock = DockClient->ClassNameIs("TDockableForm");
  if (!CanDock)
  {
     ShowMessage("GetSiteInfo CanDock went bad!");
  }
}
```

Delphi Examples:

```
{
The following example is taken from the docking demo. It
shows how the OnUnDock event handler of the conjoinment
docking site re-enables docking in the control that is
undocked (if it is a dockable form). In addition, when the
next to last docked control is undocked, the conjoinment
docking site sends itself a close message so that the last
docked control is undocked to its old position and size.
}
procedure TConjoinDockHost.FormUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  // Only 2 dock clients means the host must be destroyed and
  // the remaining window undocked to its old position and size.
  // Recall that OnUnDock gets called before the undocking
  // actually occurs.
  if Client is TDockableForm then
    TDockableForm(Client).DockSite := True;
  if (DockClientCount = 2) and (NewTarget <> Self) then
    PostMessage(Self.Handle, WM_CLOSE, 0, 0);
  UpdateCaption(Client);
end;
{
The following example is taken from the docking demo. It
shows how set permissions to dock dockable objects onto a
docking site.
}

procedure TMainForm.LeftDockPanelDockDrop(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer);
begin
  //OnDockDrop gets called AFTER the client has actually docked,
  //so we check for DockClientCount = 1 before making the dock panel visible.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, True, nil);
  (Sender as TPanel).DockManager.ResetBounds(True);
  //Make DockManager repaints it's clients.
end;

procedure TMainForm.LeftDockPanelDockOver(Sender: TObject;
  Source: TDragDockObject; X, Y: Integer; State: TDragState;
  var Accept: Boolean);
var
  ARect: TRect;
begin
  Accept := Source.Control is TDockableForm;
  if Accept then
  begin
    //Modify the DockRect to preview dock area.
    ARect.TopLeft := LeftDockPanel.ClientToScreen(Point(0, 0));
    ARect.BottomRight := LeftDockPanel.ClientToScreen(
      Point(Self.ClientWidth div 3, LeftDockPanel.Height));
    Source.DockRect := ARect;
  end;
end;
```

```
procedure TMainForm.LeftDockPanelUnDock(Sender: TObject; Client: TControl;
  NewTarget: TWinControl; var Allow: Boolean);
begin
  //OnUnDock gets called BEFORE the client is undocked, in order to optionally
  //disallow the undock. DockClientCount is never 0 when called from this event.
  if (Sender as TPanel).DockClientCount = 1 then
    ShowDockPanel(Sender as TPanel, False, nil);
end;

72.1.13 TScrollingWinControl Class

TScrollingWinControl is the base class for controls that support scrolling.

Class Hierarchy

Pascal

```
TScrollingWinControl = class(TWinControl);
```

C++

```
class TScrollingWinControl : public TWinControl;
```

File

Forms

Description

Use TScrollingWinControl as a base class when defining a custom windowed control that supports scrolling.

Typically, a scrolling windowed control has horizontal and vertical scroll bars and scrolls a child control into view when the child control receives focus.

Examples of scrolling windowed controls include TForm (see page 13992) and TScrollBox (see page 14238) objects.

The scrolling window's BiDiMode determines whether the left or right side of the window's contents are displayed by default. The BiDiMode does not affect the window's coordinate system. The scroll bars must be adjusted programmatically according to the system locale.

TForm (see page 13992)

TScrollBox (see page 14238)

72.1.13.1 TScrollingWinControl Members

The following tables list the members exposed by TScrollingWinControl.

Protected Events

	Name	Description
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.

	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
V	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
V	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 14326)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.

	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
V	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
V	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
V	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
V	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
V	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
V	DoFlipChildren (see page 14327)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.

	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.

	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.

	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoScroll (see page 14329)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 14323)	Creates and initializes a new TScrollingWinControl (see page 14312) object.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 14323)	Removes the TScrollingWinControl (see page 14312) object from memory.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.

	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.

	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.

R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 14329)	Represents the horizontal scroll bar for the scrolling windowed control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	VertScrollBar (see page 14330)	Represents the vertical scroll bar for the scrolling windowed control.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

72.1.13.2 TScrollingWinControl.Create Constructor

Creates and initializes a new TScrollingWinControl (see page 14312) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TScrollingWinControl(TComponent * AOwner);
```

Description

Use Create to create and initialize a new TScrollingWinControl (see page 14312) object.

AOwner is a TComponent object that owns the scrolling windowed control.

See Also

AutoScroll (see page 14329)

HorzScrollBar (see page 14329)

Create (see page 6123)

VertScrollBar (see page 14330)

72.1.13.3 TScrollingWinControl.Destroy Destructor

Removes the TScrollingWinControl (see page 14312) object from memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TScrollingWinControl();
```

Description

Do not call Destroy.TScrollingWinControl (see page 14312) Instead, call Free, which calls DestroyWinControl if the TScrollingWinControl (see page 14312) object is not nil.

See Also

Destroy (see page 6124)

Free (see page 22300)

72.1.13.4 TScrollingWinControl Methods

The methods of the TScrollingWinControl class are listed here.

Protected Methods

	Name	Description
	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.
	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
	CreateParams (see page 14326)	Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.
	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
	DoFlipChildren (see page 14327)	Flips the control's children.
	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.

Public Methods

	Name	Description
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.

72.1.13.4.1 TScrollingWinControl.AdjustClientRect Method

Adjusts the ClientRect property to exclude the scroll bars.

Pascal

```
procedure AdjustClientRect(var Rect: TRect); override;
```

C++

```
virtual __fastcall AdjustClientRect(TRect Rect);
```

Description

AdjustClientRect is called internally when the control needs accurate information on where to place child controls within the client area. It indents Rect to exclude the area taken by the scroll bars, then calls the inherited AdjustClientRect method.

See Also

ClientRect

72.1.13.4.2 TScrollingWinControl.AlignControls Method

Aligns the controls in the scrolling windowed control.

Pascal

```
procedure AlignControls(AControl: TControl; var ARect: TRect); override;
```

C++

```
virtual __fastcall AlignControls(TControl * AControl, TRect ARect);
```

Description

Use AlignControls to align the controls in the scrolling control according to the values of their Align properties.

AControl specifies the control that takes precedence in alignment when other controls have the same Align value. AControl can be nil (Delphi) or NULL (C++).

ARect indicates the area in the scrolling control that contains the controls to align. ARect is automatically set to the entire area of the scrolling control.

If AutoScroll (see page 14329) is true and the scrolling control is not being resized, the ranges of the scroll bars on the scrolling control are automatically recalculated.

After recalculating the ranges of the scroll bars and setting the value of ARect, AlignControls calls the inherited AlignControls method, passing the AControl and ARect objects.

See Also

Align (see page 5798)

AutoScroll (see page 14329)

AlignControls (see page 6129)

72.1.13.4.3 TScrollingWinControl.AutoScrollEnabled Method

Indicates whether automatic scrolling is enabled.

Pascal

```
function AutoScrollEnabled: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean AutoScrollEnabled();
```

Description

Call AutoScrollEnabled to determine whether automatic scrolling is enabled.

AutoScrollEnabled returns true if the control is not a dock site using the dock manager and the AutoSize property is false.

See Also

AutoScroll

AutoSize (see page 5803)

UseDockManager (see page 6212)

72.1.13.4.4 TScrollingWinControl.AutoScrollInView Method

Scrolls a control into the visible area of the scrolling windowed control.

Pascal

```
procedure AutoScrollInView(AControl: TControl); virtual;
```

C++

```
virtual __fastcall AutoScrollInView(TControl * AControl);
```

Description

Use AutoScrollInView to scroll the control specified by the AControl parameter into the visible area of the scrolling windowed control.

Unlike ScrollInView (see page 14328), AutoScrollInView does not perform scrolling when the scrolling windowed control or the specified control are being loaded from a stream.

AutoScrollInView calls ScrollInView (see page 14328) to perform any needed scrolling.

See Also

ScrollInView (see page 14328)

72.1.13.4.5 TScrollingWinControl.ChangeScale Method

Resizes the scrolling windowed control by a specific ratio.

Pascal

```
procedure ChangeScale(M: Integer; D: Integer); override;
```

C++

```
virtual __fastcall ChangeScale(int M, int D);
```

Description

Use ChangeScale to resize the scrolling windowed control by a specific ratio.

M is the multiplier of the ratio; D is the divisor of the ratio. For example, to resize the scrolling windowed control to four-fifths of its current size, set M to four and D to five.

See Also

ChangeScale (see page 5743)

72.1.13.4.6 TScrollingWinControl.CreateParams Method

Initializes the window creation parameters so that the entire window is not redrawn when the width or height of the client area changes.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd (see page 14327) method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. CreateParams calls the inherited method and uses that Window class style, removing the CS_HREDRAW and CS_VREDRAW styles from it.

By removing these styles the scrolling windowed control will only redraw the invalidated regions, not the entire window.

See Also

CreateWnd (see page 14327)

CreateWindowHandle (see page 6137)

72.1.13.4.7 TScrollingWinControl.CreateWnd Method

Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the window must be destroyed and recreated to reflect property changes.

See Also

CreateWnd (see page 6137)

DestroyWnd (see page 6141)

72.1.13.4.8 TScrollingWinControl.DisableAutoRange Method

Disables automatic scrolling.

Pascal

```
procedure DisableAutoRange;
```

C++

```
__fastcall DisableAutoRange();
```

Description

Use DisableAutoRange to temporarily disable scrolling when rearranging controls in a scrolling windowed control. Use the EnableAutoRange (see page 14328) method to turn scrolling on again when finished rearranging the controls.

See Also

EnableAutoRange (see page 14328)

AutoScroll (see page 14329)

72.1.13.4.9 TScrollingWinControl.DoFlipChildren Method

Flips the control's children.

Pascal

```
procedure DoFlipChildren; override;
```

C++

```
virtual __fastcall DoFlipChildren();
```

Description

The FlipChildren method calls DoFlipChildren to reverse the positions of child controls. DoFlipChildren moves the control's children to opposite positions on the control; that is, children on the left side of the control are moved to the right side of the control and vice versa. In addition, DoFlipChildren moves the vertical scroll bars to the other side of the control.

Note: DoFlipChildren is a protected helper method for the public FlipChildren method. Unlike FlipChildren, DoFlipChildren does not adjust the alignment of controls that are aligned to one of the edges of the windowed control.

See Also

FlipChildren (see page 6150)

BiDiMode (see page 5803)

72.1.13.4.10 TScrollingWinControl.EnableAutoRange Method

Reenables automatic scrolling.

Pascal

```
procedure EnableAutoRange;
```

C++

```
__fastcall EnableAutoRange();
```

Description

Use EnableAutoRange to reenable scrolling after turning it off. This method can be used with the DisableAutoRange (see page 14327) method to turn scrolling on and off.

See Also

DisableAutoRange (see page 14327)

AutoScroll (see page 14329)

72.1.13.4.11 TScrollingWinControl.Resizing Method

Pascal

```
procedure Resizing(State: TWindowState); virtual;
```

C++

```
virtual __fastcall Resizing(TWindowState State);
```

Description

This is Resizing, a member of class TScrollingWinControl.

72.1.13.4.12 TScrollingWinControl.ScrollInView Method

Scrolls a control into the visible area of the scrolling windowed control.

Pascal

```
procedure ScrollInView(AControl: TControl);
```

C++

```
__fastcall ScrollInView(TControl * AControl);
```

Description

Use ScrollInView to ensure that a specified control is in the visible area of the scrolling windowed control. AControl specifies the TControl object to scroll into view.

Note: If the ComponentState property for AControl or the scrolling windowed control might be csLoading, use AutoScrollInView (see page 14325) instead.

See Also

AutoScrollInView (see page 14325)

ComponentState (see page 2804)

72.1.13.5 TScrollingWinControl Properties

The properties of the TScrollingWinControl class are listed here.

Protected Properties

	Name	Description
	AutoScroll (see page 14329)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.

Published Properties

	Name	Description
	HorzScrollBar (see page 14329)	Represents the horizontal scroll bar for the scrolling windowed control.
	VertScrollBar (see page 14330)	Represents the vertical scroll bar for the scrolling windowed control.

72.1.13.5.1 TScrollingWinControl.AutoScroll Property

Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.

Pascal

```
property AutoScroll: Boolean;
```

C++

```
__property Boolean AutoScroll;
```

Description

If AutoScroll is true, the scroll bars appear automatically when necessary. For example, if the user resizes the control so that some of its controls are partially obscured, scroll bars appear.

If AutoScroll is false, scroll bars don't appear automatically. In this case, use the HorzScrollBar (see page 14329) and VertScrollBar (see page 14330) properties to make scroll bars appear.

See Also

AutoScrollInView (see page 14325)

HorzScrollBar (see page 14329)

VertScrollBar (see page 14330)

72.1.13.5.2 TScrollingWinControl.HorzScrollBar Property

Represents the horizontal scroll bar for the scrolling windowed control.

Pascal

```
property HorzScrollBar: TControlScrollBar;
```

C++

```
__property TControlScrollBar HorzScrollBar;
```

Description

Use HorzScrollBar to hide, show, or manipulate the horizontal scroll bar for the scrolling windowed control.

C++ Examples:

```
/*
This example starts the form in a position scrolled so that
the right hand edge shows:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  /* set the width of the form window to display 300 pixels in the client area */
  ClientWidth = 300;
  /* now set the range to twice the client width.
   This means that the form has a logical size
   that is twice as big as the physical window.
   Note that Range must always be at least as big as ClientWidth! */
  HorzScrollBar->Range = 600;
  /* start the form fully scrolled */
  HorzScrollBar->Position = HorzScrollBar->Range - ClientWidth;
  /* clicking the scroll arrows moves the form 10 pixels */
  HorzScrollBar->Increment = 10;
  HorzScrollBar->Visible = true;  // Show the scrollbar
}
```

Delphi Examples:

```
{
This example starts the form in a position scrolled so that
the right hand edge shows:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  ClientWidth := 300;
  with HorzScrollBar do
  begin
    { Set the range to twice the ClientWidth of the form }
    { This means that the form's logical size is twice as big }
    { as the physical window. }
    { Note that Range must always be larger than the ClientWidth }
    Range := 600;
    Position := Range - ClientWidth; { start form out fully scrolled }
    Increment := 10;  { clicking the scroll arrows moves the form 10 pixels }
    Visible := True;  { Show the scrollbar }
  end;
end;
```

See Also

AutoScroll (see page 14329)

VertScrollBar (see page 14330)

TControlScrollBar (see page 13744)

72.1.13.5.3 TScrollingWinControl.VertScrollBar Property

Represents the vertical scroll bar for the scrolling windowed control.

Pascal

```
property VertScrollBar: TControlScrollBar;
```

C++

```
__property TControlScrollBar VertScrollBar;
```

Description

Use VertScrollBar to hide, show, or manipulate the vertical scroll bar for the scrolling windowed control.

C++ Examples:

```
/*
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  const int iPageDelta = 10;

  if (Key == VK_NEXT)
    VertScrollBar->Position += iPageDelta;
  else if (Key == VK_PRIOR)
    VertScrollBar->Position -= iPageDelta;
}
```

Delphi Examples:

```
{
The following example demonstrates form scrolling with the
PgUp and PgDn keys.
}
procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word;
Shift: TShiftState);
const
  PageDelta = 10;
begin
  With VertScrollbar do
    if Key = VK_NEXT then
      Position := Position + PageDelta
    else if Key = VK_PRIOR then
      Position := Position - PageDelta;
end;
```

See Also

AutoScroll (see page 14329)

HorzScrollBar (see page 14329)

TControlScrollBar (see page 13744)

72.1.13.6 TScrollingWinControl Events

The events of the TScrollingWinControl class are listed here.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.

72.1.13.6.1 TScrollingWinControl.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore: TAlignInsertBeforeEvent;
```

C++

```
__property TAlignInsertBeforeEvent OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

See Also

CustomAlignInsertBefore (see page 6137)

Align (see page 5798)

TAlignInsertBeforeEvent (see page 6293)

72.1.13.6.2 TScrollingWinControl.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition: TAlignPositionEvent;
```

C++

```
__property TAlignPositionEvent OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.	

See Also

CustomAlignPosition (see page 6138)

Align (see page 5798)

Anchors (see page 5802)

TAlignInfo (see page 6269)

TAlignPositionEvent (see page 6293)

72.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IDesignerHook (see page 14334)	IDesignerHook is an interface that allows component writers to interact with the form designer in the IDE.
	IOleForm (see page 14340)	IOleForm is designed to communicate with OLE containers. To embed a VCL form in an OLE container, CodeGear recommends using ActiveForms and TOleControl instead of IOleForm.

72.2.1 IDesignerHook Interface

IDesignerHook is an interface that allows component writers to interact with the form designer in the IDE.

Class Hierarchy

Pascal

```
IDesignerHook = interface(IDesignerNotify);
```

C++

```
__interface IDesignerHook : public IDesignerNotify;
```

File

Forms

Description

IDesignerHook provides access to the form currently under construction in the form designer, and influences the behavior of the designer by specifying whether the object under construction is a form (as opposed to a composite component), drawing the grid that assists in layout, and so on.

Component writers can access the current IDesignerHook interface using the Designer property of a form.

Note: C++ method declarations that use IDesignerHook use the _di_IDesignerHook type instead. This is a DelphiInterface wrapper around the IDesignerHook interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IDesignerHook > _di_IDesignerHook;
```

See Also

TCustomForm (see page 13849)

TComponentEditor (see page 10927)

TPropertyEditor (see page 11019)

IFormDesigner

72.2.1.1 IDesignerHook Members

The following tables list the members exposed by IDesignerHook.

Public Methods

	Name	Description
	GetCustomForm (see page 14335)	Specifies the value returned when the Form (see page 14339) property is read.
	GetIsControl (see page 14336)	Specifies the value returned when the IsControl (see page 14339) property is read.
	GetRoot (see page 14336)	Returns the current entity being edited by the form designer.
	IsDesignMsg (see page 14336)	Determines when the designer should handle a Windows message.
	Modified (see page 3196)	Notifies property and component editors when a change is made to a component.
	Notification (see page 3196)	Allows the designer to respond when a notification is sent to the form.
	PaintGrid (see page 14337)	Paints the alignment grid on the form's canvas.
	PaintMenu (see page 14337)	This is PaintMenu, a member of class IDesignerHook.
	SetCustomForm (see page 14337)	Specifies what happens when the Form (see page 14339) property is set.
	SetIsControl (see page 14338)	Specifies what happens when the IsControl (see page 14339) property is set.
	UniqueName (see page 14338)	Generates a unique name from a specified base string.
	ValidateRename (see page 14338)	Restricts the names that can be given to components on the form that is being designed.

Public Properties

	Name	Description
	Form (see page 14339)	Provides a reference to the form currently being designed.
	IsControl (see page 14339)	Specifies whether the form is in its form state or its control state.

72.2.1.2 IDesignerHook Methods

The methods of the IDesignerHook class are listed here.

Public Methods

	Name	Description
	GetCustomForm (see page 14335)	Specifies the value returned when the Form (see page 14339) property is read.
	GetIsControl (see page 14336)	Specifies the value returned when the IsControl (see page 14339) property is read.
	GetRoot (see page 14336)	Returns the current entity being edited by the form designer.
	IsDesignMsg (see page 14336)	Determines when the designer should handle a Windows message.
	PaintGrid (see page 14337)	Paints the alignment grid on the form's canvas.
	PaintMenu (see page 14337)	This is PaintMenu, a member of class IDesignerHook.
	SetCustomForm (see page 14337)	Specifies what happens when the Form (see page 14339) property is set.
	SetIsControl (see page 14338)	Specifies what happens when the IsControl (see page 14339) property is set.
	UniqueName (see page 14338)	Generates a unique name from a specified base string.
	ValidateRename (see page 14338)	Restricts the names that can be given to components on the form that is being designed.

72.2.1.2.1 IDesignerHook.GetCustomForm Method

Specifies the value returned when the Form (see page 14339) property is read.

Pascal

```
function GetCustomForm: TCustomForm;
```

C++

```
__fastcall TCustomForm GetCustomForm();
```

Description

Implement GetCustomForm to specify the value returned when the Form (see page 14339) property is read.

See Also

Form (see page 14339)

SetCustomForm (see page 14337)

72.2.1.2.2 IDesignerHook.GetIsControl Method

Specifies the value returned when the IsControl (see page 14339) property is read.

Pascal

```
function GetIsControl: Boolean;
```

C++

```
__fastcall Boolean GetIsControl();
```

Description

Implement GetIsControl to specify the value returned when the IsControl (see page 14339) property is read.

See Also

IsControl (see page 14339)

SetIsControl (see page 14338)

72.2.1.2.3 IDesignerHook.GetRoot Method

Returns the current entity being edited by the form designer.

Pascal

```
function GetRoot: TComponent;
```

C++

```
__fastcall TComponent * GetRoot();
```

Description

Call GetRoot to obtain the object the form designer is working on. If this object is a descendant of TCustomForm (see page 13849), GetRoot returns the value of the Form (see page 14339) property.

Use GetRoot rather than the Form (see page 14339) property, to ensure that code works even when editing a data module, remote data module, active form, or other entity that is not a descendant of TCustomForm (see page 13849).

See Also

Form (see page 14339)

ContainerWindow

72.2.1.2.4 IDesignerHook.IsDesignMsg Method

Determines when the designer should handle a Windows message.

Pascal

```
function IsDesignMsg(Sender: TControl; var Message: TMessage): Boolean;
```

C++

```
__fastcall Boolean IsDesignMsg(TControl * Sender, TMessage Message);
```

Description

IsDesignMsg is called for each message sent to a component in the designer. This method returns true if the message is a design message, meaning one the designer should handle for the component.

See Also

WindowProc (see page 5872)

WndProc (see page 6187)

72.2.1.2.5 IDesignerHook.PaintGrid Method

Paints the alignment grid on the form's canvas.

Pascal

```
procedure PaintGrid;
```

C++

```
__fastcall PaintGrid();
```

Description

Forms (see page 13657) that are associated with a designer call the PaintGrid method in response to Windows paint messages. If there is no designer associated with the form, the form's Paint method is called instead.

See Also

Paint (see page 13882)

72.2.1.2.6 IDesignerHook.PaintMenu Method

Pascal

```
procedure PaintMenu;
```

C++

```
__fastcall PaintMenu();
```

Description

This is PaintMenu, a member of class IDesignerHook.

72.2.1.2.7 IDesignerHook.SetCustomForm Method

Specifies what happens when the Form (see page 14339) property is set.

Pascal

```
procedure SetCustomForm(Value: TCustomForm);
```

C++

```
__fastcall SetCustomForm(TCustomForm Value);
```

Description

Implement SetCustomForm to specify what happens when the Form (see page 14339) property is set.

See Also

Form (see page 14339)

GetCustomForm (see page 14335)

72.2.1.2.8 IDesignerHook.SetIsControl Method

Specifies what happens when the IsControl (see page 14339) property is set.

Pascal

```
procedure SetIsControl(Value: Boolean);
```

C++

```
__fastcall SetIsControl(Boolean Value);
```

Description

Implement SetIsControl specify what happens when the IsControl (see page 14339) property is set.

See Also

IsControl (see page 14339)

GetIsControl (see page 14336)

72.2.1.2.9 IDesignerHook.UniqueName Method

Generates a unique name from a specified base string.

Pascal

```
function UniqueName(const BaseName: string): string;
```

C++

```
__fastcall AnsiString UniqueName(const AnsiString BaseName);
```

Description

Call UniqueName to automatically generate a unique name for a component. Specify the base string for the name by the BaseName parameter. UniqueName appends a number to BaseName to ensure that there are no name-space conflicts.

See Also

GetComponentName

72.2.1.2.10 IDesignerHook.ValidateRename Method

Restricts the names that can be given to components on the form that is being designed.

Pascal

```
procedure ValidateRename(AComponent: TComponent; const CurName: string; const NewName: string);
```

C++

```
__fastcall ValidateRename(TComponent * AComponent, const AnsiString CurName, const AnsiString
NewName);
```

Description

Call ValidateRename to determine if the component specified by AComponent, which currently has the name specified by CurName, can be renamed to the string specified by NewName. This method is usually called by the form's ValidateRename method to provide tighter restrictions on renaming, such as prohibiting reserved words.

See Also

ValidateRename (see page 13892)

72.2.1.3 IDesignerHook Properties

The properties of the IDesignerHook class are listed here.

Public Properties

	Name	Description
	Form (see page 14339)	Provides a reference to the form currently being designed.
	IsControl (see page 14339)	Specifies whether the form is in its form state or its control state.

72.2.1.3.1 IDesignerHook.Form Property

Provides a reference to the form currently being designed.

Pascal

```
property Form: TCustomForm;
```

C++

```
__property TCustomForm Form;
```

Description

Use Form to access the form, if any, that is being designed. When the user specifies changes in the form designer, the changes can be made to the form specified by the Form property.

Note: Not every designer has a form. For example, when the designer is used for a data module, remote data module, or active form, the Form property should not be used. Instead, use the object that the GetRoot (see page 14336) method returns.

See Also

Designer (see page 13910)

IsControl (see page 14339)

GetRoot (see page 14336)

72.2.1.3.2 IDesignerHook.IsControl Property

Specifies whether the form is in its form state or its control state.

Pascal

```
property IsControl: Boolean;
```

C++

```
__property Boolean IsControl;
```

Description

If the designer is used to create a control, rather than a form, set IsControl to true when the user finishes designing the control.

See Also

IsControl (see page 5829)

Form (see page 14339)

72.2.2 IOleForm Interface

IOleForm is designed to communicate with OLE containers. To embed a VCL form in an OLE container, CodeGear recommends using ActiveForms and TOleControl instead of IOleForm.

Class Hierarchy

Forms.IOleForm

Pascal

```
IOleForm = interface;
```

C++

```
__interface IOleForm;
```

File

Forms

See Also

TOleControl (see page 18030)

72.2.2.1 IOleForm Members

The following tables list the members exposed by IOleForm.

Public Methods

	Name	Description
	OnDestroy (see page 14340)	This is OnDestroy, a member of class IOleForm.
	OnResize (see page 14341)	This is OnResize, a member of class IOleForm.

72.2.2.2 IOleForm Methods

The methods of the IOleForm class are listed here.

Public Methods

	Name	Description
	OnDestroy (see page 14340)	This is OnDestroy, a member of class IOleForm.
	OnResize (see page 14341)	This is OnResize, a member of class IOleForm.

72.2.2.2.1 IOleForm.OnDestroy Method

Pascal

```
procedure OnDestroy;
```

C++

```
__fastcall OnDestroy();
```

Description

This is OnDestroy, a member of class IOleForm.

72.2.2.2.2 IOleForm.OnResize Method

Pascal

```
procedure OnResize;
```

C++

```
__fastcall OnResize();
```

Description

This is OnResize, a member of class IOleForm.

72.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AllocateHWnd (see page 14342)	Creates a window that implements a specified window procedure.
	DeallocateHWnd (see page 14343)	Frees a window that was created using AllocateHWnd (see page 14342).
	DisableTaskWindows (see page 14343)	This is function Forms.DisableTaskWindows.
	DoneCtl3D (see page 14344)	This is function Forms.DoneCtl3D.
	EnableTaskWindows (see page 14344)	This is function Forms.EnableTaskWindows.
	ForegroundTask (see page 14344)	Indicates whether the current thread is running in the foreground.
	FreeObjectInstance (see page 14345)	This is function Forms.FreeObjectInstance.
	GetApplicationMainFormOnTaskBar (see page 14345)	This is function Forms.GetApplicationMainFormOnTaskBar.
	GetCustomFormGlassFrame (see page 14345)	This is function Forms.GetCustomFormGlassFrame.
	GetParentForm (see page 14346)	Returns the form or property page that contains a specified control.
	InitCtl3D (see page 14346)	This is function Forms.InitCtl3D.
	IsAccel (see page 14346)	Indicates whether a particular character is an accelerator character (or hot key) within a given menu caption or other text string.
	KeyboardStateToShiftState (see page 14347)	Convert array of virtual keys to TShiftState.
	KeyboardStateToShiftState (see page 14347)	Convert array of virtual keys to TShiftState.
	KeyDataToShiftState (see page 14348)	Convert keyboard message data to TShiftState.
	KeysToShiftState (see page 14348)	Convert mouse event parameter to TShiftState.
	MakeObjectInstance (see page 14349)	This is function Forms.MakeObjectInstance.
	RestoreFocusState (see page 14349)	This is function Forms.RestoreFocusState.
	SaveFocusState (see page 14349)	This is function Forms.SaveFocusState.
	SetApplicationMainFormOnTaskBar (see page 14350)	This is function Forms.SetApplicationMainFormOnTaskBar.
	SetAutoSubClass (see page 14350)	This is function Forms.SetAutoSubClass.
	SetCustomFormGlassFrame (see page 14350)	This is function Forms.SetCustomFormGlassFrame.
	Subclass3DDlg (see page 14351)	This is function Forms.Subclass3DDlg.
	Subclass3DWnd (see page 14351)	This is function Forms.Subclass3DWnd.
	ValidParentForm (see page 14351)	Returns the form or property page that contains a specified control.

72.3.1 Forms.AllocateHWnd Function

Creates a window that implements a specified window procedure.

Pascal

```
function AllocateHWnd(Method: TWndMethod): HWND; deprecated;
```

C++

```
HWND AllocateHWnd(TWndMethod Method);
```

File

Forms

Description

Call AllocateHWnd to create a window that is not associated with a windowed control. Typically, this method is used to create non-visual windows that respond to messages but that do not appear in the user interface. For example, the TTimer component

uses this method to create a window that responds to timer messages from Windows.

The **Method** parameter specifies the window procedure that the generated window uses to respond to messages.

AllocateHWnd returns the handle of the newly created window.

Note: Use the DeallocateHWnd (see page 14343) procedure to free windows that are created using AllocateHWnd.

See Also

DeallocateHWnd (see page 14343)

TTimer

72.3.2 Forms.DeallocateHWnd Function

Frees a window that was created using AllocateHWnd (see page 14342).

Pascal

```
procedure DeallocateHWnd(Wnd: HWND); deprecated;
```

C++

```
DeallocateHWnd(HWND Wnd);
```

File

Forms

Description

Call DeallocateHWnd to free a window that was created using the AllocateHWnd (see page 14342) function. Windows must be freed to release the system resources that they consume.

The **Wnd** parameter is the window handle of the window to be freed. This value is the same as the handle returned by the call to AllocateHWnd (see page 14342).

Warning: Do not use DeallocateHWnd on the handle of a windowed control. Windowed controls free their handles using the protected DestroyHandle method, which ensures that the control is left in a consistent state.

See Also

AllocateHWnd (see page 14342)

72.3.3 Forms.DisableTaskWindows Function

Pascal

```
function DisableTaskWindows(ActiveWindow: HWnd): Pointer;
```

C++

```
void * DisableTaskWindows(HWnd ActiveWindow);
```

File

Forms

Description

This is function Forms.DisableTaskWindows.

72.3.4 Forms.DoneCtl3D Function

Pascal

```
procedure DoneCtl3D; deprecated;
```

C++

```
DoneCtl3D();
```

File

Forms

Description

This is function Forms.DoneCtl3D.

72.3.5 Forms.EnableTaskWindows Function

Pascal

```
procedure EnableTaskWindows(WindowList: Pointer);
```

C++

```
EnableTaskWindows(void * WindowList);
```

File

Forms

Description

This is function Forms.EnableTaskWindows.

72.3.6 Forms.ForegroundTask Function

Indicates whether the current thread is running in the foreground.

Pascal

```
function ForegroundTask: Boolean;
```

C++

```
Boolean ForegroundTask();
```

File

Forms

Description

Call ForegroundTask to determine whether the current thread is executing in the Foreground. This is useful if you want to provide feedback to users only if they are currently interacting with a window on the same thread, but do not want to interrupt other processes.

ForegroundTask checks whether the window that currently has focus belongs to the thread that executes the function. It returns

true if the focused window belongs to the current thread, false otherwise.

72.3.7 Forms.FreeObjectInstance Function

Pascal

```
procedure FreeObjectInstance(ObjectInstance: Pointer); deprecated;
```

C++

```
FreeObjectInstance(void * ObjectInstance);
```

File

Forms

Description

This is function Forms.FreeObjectInstance.

72.3.8 Forms.GetApplicationMainFormOnTaskBar Function

Pascal

```
function GetApplicationMainFormOnTaskBar(const Application: TApplication): Boolean; deprecated;
```

C++

```
Boolean GetApplicationMainFormOnTaskBar(const TApplication Application);
```

File

Forms

Description

This is function Forms.GetApplicationMainFormOnTaskBar.

72.3.9 Forms.GetCustomFormGlassFrame Function

Pascal

```
function GetCustomFormGlassFrame(const CustomForm: TCustomForm): TGlassFrame; deprecated;
```

C++

```
TGlassFrame GetCustomFormGlassFrame(const TCustomForm CustomForm);
```

File

Forms

Description

This is function Forms.GetCustomFormGlassFrame.

72.3.10 Forms.GetParentForm Function

Returns the form or property page that contains a specified control.

Pascal

```
function GetParentForm(Control: TControl; TopForm: Boolean = True): TCustomForm;
```

C++

```
TCustomForm GetParentForm(TControl * Control, Boolean TopForm = True);
```

File

Forms

Description

Call GetParentForm to obtain the descendant of TCustomForm (see page 13849) that contains the control specified by the **Control** parameter. If the **TopForm** parameter if true, this function goes all the way up the parent chain for **Control** until it finds a Form with no parent. If **TopForm** if false, this function goes up the parent chain until it finds a Form that is a TCustomForm (see page 13849).

If the control is not contained in a form (for example, an ActiveX control embedded in another type of window), GetParentForm returns **nil** (Delphi) or **NULL** (C++).

See Also

TControl (see page 5724)

TCustomForm (see page 13849)

ValidParentForm (see page 14351)

72.3.11 Forms.InitCtl3D Function

Pascal

```
procedure InitCtl3D; deprecated;
```

C++

```
InitCtl3D();
```

File

Forms

Description

This is function Forms.InitCtl3D.

72.3.12 Forms.IsAccel Function

Indicates whether a particular character is an accelerator character (or hot key) within a given menu caption or other text string.

Pascal

```
function IsAccel(VK: Word; const Str: string): Boolean;
```

C++

```
Boolean IsAccel(Word VK, const AnsiString Str);
```

File

Forms

Description

Call IsAccel to determine whether the character represented by the VK (virtual key) parameter appears as an accelerator in the string specified by the Str parameter. IsAccel only looks for accelerators that are identified by a preceding ampersand (&). Such accelerators appear underlined in the string when displayed as a control's caption.

Use IsAccel when processing key events to determine whether a key matches an accelerator character in a control's caption.

Note: IsAccel does not recognize hot key combinations in menu items that are identified by the HotKey property.

See Also

TCustomLabel

TCustomStaticText

TMenuItem

72.3.13 Forms.KeyboardStateToShiftState Function

Convert array of virtual keys to TShiftState.

Pascal

```
function KeyboardStateToShiftState(const KeyboardState: TKeyboardState): TShiftState; overload;
function KeyboardStateToShiftState: TShiftState; overload;
```

C++

```
TShiftState KeyboardStateToShiftState(const TKeyboardState KeyboardState);
TShiftState KeyboardStateToShiftState();
```

File

Forms

Description

Convert the given array of virtual keys **KeyboardState** to a TShiftState type. This array can be provided by the Windows function GetKeyboardState.

See Also

KeyDataToShiftState (see page 14348)

KeysToShiftState (see page 14348)

TShiftState (see page 3302)

72.3.14 Forms.KeyDataToShiftState Function

Convert keyboard message data to TShiftState.

Pascal

```
function KeyDataToShiftState(KeyData: Longint): TShiftState;
```

C++

```
TShiftState KeyDataToShiftState(Longint KeyData);
```

File

Forms

Description

Convert the current keyboard state and given **KeyData** to a TShiftState type.

See Also

KeyboardStateToShiftState (see page 14347)

KeysToShiftState (see page 14348)

TShiftState (see page 3302)

72.3.15 Forms.KeysToShiftState Function

Convert mouse event parameter to TShiftState.

Pascal

```
function KeysToShiftState(Keys: Word): TShiftState;
```

C++

```
TShiftState KeysToShiftState(Word Keys);
```

File

Forms

Description

Convert the parameter **Keys** to a TShiftState type. **Keys** contains flags that indicate the status of the mouse buttons and the CTRL and SHIFT keys at the time of the mouse event

See Also

KeyDataToShiftState (see page 14348)

KeyboardStateToShiftState (see page 14347)

TShiftState (see page 3302)

72.3.16 Forms.MakeObjectInstance Function

Pascal

```
function MakeObjectInstance(Method: TWndMethod): Pointer; deprecated;
```

C++

```
void * MakeObjectInstance(TWndMethod Method);
```

File

Forms

Description

This is function Forms.MakeObjectInstance.

72.3.17 Forms.RestoreFocusState Function

Pascal

```
procedure RestoreFocusState(FocusState: TFocusState);
```

C++

```
RestoreFocusState(TFocusState FocusState);
```

File

Forms

Description

This is function Forms.RestoreFocusState.

72.3.18 Forms.SaveFocusState Function

Pascal

```
function SaveFocusState: TFocusState;
```

C++

```
TFocusState SaveFocusState();
```

File

Forms

Description

This is function Forms.SaveFocusState.

72.3.19 Forms.SetApplicationMainFormOnTaskBar Function

Pascal

```
procedure SetApplicationMainFormOnTaskBar(const Application: TApplication; Value: Boolean);
deprecated;
```

C++

```
SetApplicationMainFormOnTaskBar(const TApplication Application, Boolean Value);
```

File

Forms

Description

This is function Forms.SetApplicationMainFormOnTaskBar.

72.3.20 Forms.SetAutoSubClass Function

Pascal

```
procedure SetAutoSubClass(Enable: Boolean); deprecated;
```

C++

```
SetAutoSubClass(Boolean Enable);
```

File

Forms

Description

This is function Forms.SetAutoSubClass.

72.3.21 Forms.SetCustomFormGlassFrame Function

Pascal

```
procedure SetCustomFormGlassFrame(const CustomForm: TCustomForm; const GlassFrame:
TGlassFrame); deprecated;
```

C++

```
SetCustomFormGlassFrame(const TCustomForm CustomForm, const TGlassFrame GlassFrame);
```

File

Forms

Description

This is function Forms.SetCustomFormGlassFrame.

72.3.22 Forms.Subclass3DDlg Function

Pascal

```
procedure Subclass3DDlg(Wnd: HWnd; Flags: Word); deprecated;
```

C++

```
Subclass3DDlg(HWnd Wnd, Word Flags);
```

File

Forms

Description

This is function Forms.Subclass3DDlg.

72.3.23 Forms.Subclass3DWnd Function

Pascal

```
function Subclass3DWnd(Wnd: HWnd): Boolean; deprecated;
```

C++

```
Boolean Subclass3DWnd(HWnd Wnd);
```

File

Forms

Description

This is function Forms.Subclass3DWnd.

72.3.24 Forms.ValidParentForm Function

Returns the form or property page that contains a specified control.

Pascal

```
function ValidParentForm(Control: TControl; TopForm: Boolean = True): TCustomForm;
```

C++

```
TCustomForm ValidParentForm(TControl * Control, Boolean TopForm = True);
```

File

Forms

Description

Call ValidParentForm to obtain the descendant of TCustomForm (see page 13849) that contains the control specified by the **Control** parameter. If the **TopForm** parameter if true, this function goes all the way up the parent chain for **Control** until it finds a Form with no parent. If **TopForm** if false, this function goes up the parent chain until it finds a Form that is a TCustomForm (see page 13849).

If the control is not contained in a form (for example, an ActiveX control embedded in another type of window), ValidParentForm raises an EInvalidOperation exception.

See Also

GetParentForm (see page 14346)

TControl (see page 5724)

TCustomForm (see page 13849)

72.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TActiveFormBorderStyle (see page 14353)	Specifies the style of an active form's border.
	TBorderIcon (see page 14354)	TBorderIcons (see page 14370) and TBorderIcons (see page 14370) specify the buttons that appear on the title bar of a form window.
	TCloseAction (see page 14355)	TCloseAction describes how a form should respond when it is closed.
	TDefaultMonitor (see page 14357)	Specifies the monitor on which the form appears.
	TFormBorderStyle (see page 14357)	TFormBorderStyle is the type of the BorderStyle property for windows-only forms and TBorderStyle (see page 14371) is the type of the BorderStyle property for other controls in windows-only applications.
	TFormStyle (see page 14358)	TFormStyle describes form style.
	TMonitorDefaultTo (see page 14361)	TMonitorDefautlTo specifies which monitor to select when there is no match to the specified criteria.
	TPopupMode (see page 14362)	TPopupMode enumerates the possible values of a Form's PopupMode property.
	TPosition (see page 14363)	TPosition describes the positioning of a form.
	TPrintScale (see page 14364)	Represents the proportions of a printed form.
	TScrollBarKind (see page 14365)	TScrollBarKind indicates the orientation of a scrollbar.
	TScrollBarStyle (see page 14366)	TScrollBarStyle specifies a scroll bar style.
	TShowAction (see page 14366)	This is record Forms.TShowAction.
	TTileMode (see page 14367)	Represents how MDI child forms are arranged when the Tile method is called.
	TTimerMode (see page 14367)	This is record Forms.TTimerMode.
	TWindowState (see page 14368)	TWindowState indicates whether a form is maximized, minimized, or normally sized.

Records

	Name	Description
	TCMHintShow (see page 14355)	This is record Forms.TCMHintShow.
	TCMHintShowPause (see page 14356)	This is record Forms.TCMHintShowPause.
	TCursorRec (see page 14356)	This is record Forms.TCursorRec.
	THintInfo (see page 14359)	THintInfo is used to define the appearance and behavior of the Help window.
	TPopupForm (see page 14362)	This is record Forms.TPopupForm.
	TPopupWnd (see page 14363)	This is record Forms.TPopupWnd.

72.4.1 Forms.TActiveFormBorderStyle Enumeration

Specifies the style of an active form's border.

Pascal

```
TActiveFormBorderStyle = (
  afbNone,
  afbSingle,
  afbSunken,
  afbRaised
);
```

C++

```
enum TActiveFormBorderStyle {
```

```
  afbNone,
  afbSingle,
  afbSunken,
  afbRaised
};
```

File

Forms

Description

TActiveFormBorderStyle is an enumeration of possible active form border styles, and may have on of the following are possible values :

Value	Meaning
afbNone	The form has no border.
afbSingle	The form has a regular single-line border.
afbSunken	The form has a 3D look—that is, a border with a sunken edge.
afbRaised	The form has a border with a raised edge.

72.4.2 Forms.TBorderIcon Enumeration

TBorderIcons (see page 14370) and TBorderIcons (see page 14370) specify the buttons that appear on the title bar of a form window.

Pascal

```
TBorderIcon = (
  biSystemMenu,
  biMinimize,
  biMaximize,
  biHelp
);
```

C++

```
enum TBorderIcon {
  biSystemMenu,
  biMinimize,
  biMaximize,
  biHelp
};
```

File

Forms

Description

TBorderIcons (see page 14370) can include any of the following TBorderIcon values:

Value	Meaning
biSystemMenu	The form has a Control menu (also known as a System (see page 22079) menu).
biMinimize	The form has a Minimize button
biMinimize	The form has a Maximize button

biHelp	If BorderStyle is bsDialog or biMinimize and biMaximize are excluded, a question mark appears in the form's title bar and when clicked, the cursor changes to crHelp; otherwise, no question mark appears.

72.4.3 Forms.TCloseAction Enumeration

TCloseAction describes how a form should respond when it is closed.

Pascal

```
TCloseAction = (
  caNone,
  caHide,
  caFree,
  caMinimize
);
```

C++

```
enum TCloseAction {
  caNone,
  caHide,
  caFree,
  caMinimize
};
```

File

Forms

Description

TCloseAction consists of the following values:

Value	Meaning
caNone	The form is not allowed to close, so nothing happens.
caHide	The form is not closed, but just hidden. Your application can still access a hidden form.
caFree	The form is closed and all allocated memory for the form is freed.
caMinimize	The form is minimized, rather than closed.

72.4.4 Forms.TCMHintShow Record

Pascal

```
TCMHintShow = record
  Msg: Cardinal;
  Reserved: Integer;
  HintInfo: PHintInfo;
  Result: Integer;
end;
```

C++

```
struct TCMHintShow {
  unsigned Msg;
  int Reserved;
```

```
    PHintInfo HintInfo;
    int Result;
  };
```

File

Forms

Description

This is record Forms.TCMHintShow.

72.4.5 Forms.TCMHintShowPause Record

Pascal

```
  TCMHintShowPause = record
    Msg: Cardinal;
    WasActive: Integer;
    Pause: PInteger;
    Result: Integer;
  end;
```

C++

```
  struct TCMHintShowPause {
    unsigned Msg;
    int WasActive;
    PInteger Pause;
    int Result;
  };
```

File

Forms

Description

This is record Forms.TCMHintShowPause.

72.4.6 Forms.TCursorRec Record

Pascal

```
  TCursorRec = record
    Next: PCursorRec;
    Index: Integer;
    Handle: HCURSOR;
  end;
```

C++

```
  struct TCursorRec {
    PCursorRec Next;
    int Index;
    HCURSOR Handle;
  };
```

File

Forms

Description

This is record Forms.TCursorRec.

72.4.7 Forms.TDefaultMonitor Enumeration

Specifies the monitor on which the form appears.

Pascal

```
TDefaultMonitor = (
  dmDesktop,
  dmPrimary,
  dmMainForm,
  dmActiveForm
);
```

C++

```
enum TDefaultMonitor {
  dmDesktop,
  dmPrimary,
  dmMainForm,
  dmActiveForm
};
```

File

Forms

Description

Use TDefaultMonitor to associate a form with a particular monitor in a multi-monitor application. The following table lists the possible values:

Value	Meaning
dmDesktop	No attempt is made to position the form on a specific monitor.
dmPrimary	The form is positioned on the first monitor listed in the global screen object's Monitors property.
dmMainForm	The form appears on the same monitor as the application's main form.
dmActiveForm	The form appears on the same monitor as the currently active form.

72.4.8 Forms.TFormBorderStyle Enumeration

TFormBorderStyle is the type of the BorderStyle property for windows-only forms and TBorderStyle (see page 14371) is the type of the BorderStyle property for other controls in windows-only applications.

Pascal

```
TFormBorderStyle = (
  bsNone,
  bsSingle,
  bsSizeable,
  bsDialog,
  bsToolWindow,
  bsSizeToolWin
```

```
);
```

C++

```
enum TFormBorderStyle {
  bsNone,
  bsSingle,
  bsSizeable,
  bsDialog,
  bsToolWindow,
  bsSizeToolWin
};
```

File

Forms

Description

These are the possible values of the TFormBorderStyle type:

Value	Meaning
bsNone	No visible border. (not resizable)
bsSingle	Single-line border. (not resizable)
bsDialog	Standard dialog box border. (not resizable)
bsSizeable	Standard resizable border.
bsToolWindow	Like bsSingle but with a smaller caption.
bsSizeToolWin	Like bsSizeable but with a smaller caption.

Only the bsNone and bsSingle values are possible values of TBorderStyle (see page 14371).

72.4.9 Forms.TFormStyle Enumeration

TFormStyle describes form style.

Pascal

```
TFormStyle = (
  fsNormal,
  fsMDIChild,
  fsMDIForm,
  fsStayOnTop
);
```

C++

```
enum TFormStyle {
  fsNormal,
  fsMDIChild,
  fsMDIForm,
  fsStayOnTop
};
```

File

Forms

Description

TFormStyle consists of the following values.

Value	Meaning
fsNormal	The form is neither an MDI parent window nor an MDI child window.
fsMDIChild	The form is an MDI child window.
fsMDIForm	The form is an MDI parent window.
fsStayOnTop	This form remains on top of the desktop and of other forms in the project, except any others that also have FormStyle set to fsStayOnTop. If one fsStayOnTop form launches another, neither form will consistently remain on top.

See Also

TCustomForm (see page 13849)

72.4.10 Forms.THintInfo Record

THintInfo is used to define the appearance and behavior of the Help window.

Pascal

```
THintInfo = record
  HintControl: TControl;
  HintWindowClass: THintWindowClass;
  HintPos: TPoint;
  HintMaxWidth: Integer;
  HintColor: TColor;
  CursorRect: TRect;
  CursorPos: TPoint;
  ReshowTimeout: Integer;
  HideTimeout: Integer;
  HintStr: string;
  HintData: Pointer;
end;
```

C++

```
struct THintInfo {
  TControl * HintControl;
  THintWindowClass HintWindowClass;
  TPoint HintPos;
  int HintMaxWidth;
  TColor HintColor;
  TRect CursorRect;
  TPoint CursorPos;
  int ReshowTimeout;
  int HideTimeout;
  AnsiString HintStr;
  void * HintData;
};
```

File

Forms

Description

The THintInfo type is used to define the appearance and behavior of the Help window in a TShowHintEvent (see page 14381) type OnShowHint event handler. The following table describes the meaning of its fields:

Field	Meaning
HintControl	The name of the control for which hint processing is occurring.
HintWindowClass	The class of the hint-window control. The default is THintWindow, but you can specify any class derived from THintWindow. Use this field if you want to substitute a custom hint window for THintWindow.
HintPos	The default position in screen coordinates of the top-left corner of the hint window. Change where the window appears by changing this value.
HintMaxWidth	The maximum width of the hint window before word wrapping begins. By default, the value is the width of the screen (the Width property of the global Screen (see page 14385) variable).
HintColor	The background color of the Hint window.
CursorRect	The rectangle the user's mouse pointer must be in for the hint window to appear. The default value for CursorRect is the client rectangle of the control. Change this value so that a single control can be divided into several hint regions. When the user moves the mouse pointer outside the rectangle, the hint window disappears.
CursorPos	The location of the mouse pointer within the control.
ReshowTimeout	How long the hint system should wait before asking about the hint status again. By default, this field is zero, indicating that the hint status will not change. Setting it to a non-zero value will cause the hint to act, after the requested milliseconds have elapsed, as if the user moved the mouse outside the hint rectangle and back in. This can be used to either put off hint processing for a period of time, or to allow the hint to be updated periodically.
HideTimeout	The number of milliseconds to show the hint. By default, it is set to the value of the Application (see page 14383) variable's HintHidePause property.
HintStr	The string to be displayed in the hint window. This allows an OnHint event handler to modify the contents of a hint before it is displayed. By default, it contains the value returned by the GetShortHint function when passed the value of the Application (see page 14383) variable's Hint property.
HintData	Additional data to be passed to the hint-window control. Use this field in conjunction with HintWindowClass.

C++ Examples:

```
/*
This example uses three speed buttons on a panel. The code
changes the color, width, and position of the text in the
Help Hint for the third speed button. Set the ShowHint
property of each speed button to true and give a value to
the Hint property of each.  You must declare the DoShow
method in the type declaration of the form. Once it is
declared, write the code for the DoShow method in the
implementation part of the unit. Finally, in the OnCreate
event handler for the form, assign the method to the
OnShowHint event of the application.
*/
void __fastcall TForm1::DoShowHint(AnsiString &HintStr, bool &CanShow, THintInfo &HintInfo)
{
  if (HintInfo.HintControl == SpeedButton3)
  {
    HintInfo.HintColor = clAqua;// Changes only for this hint
    HintInfo.HintMaxWidth = 120; // Hint text word wraps if width is greater than 120
    HintInfo.HintPos.x += SpeedButton3->Width; // Move hint to right edge
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->ShowHint = true;
  Application->OnShowHint = DoShowHint;
}
```

Delphi Examples:

```
{
This example uses three speed buttons on a panel. The code
changes the color, width, and position of the text in the
Help Hint for the third speed button. Set the ShowHint
property of each speed button to true and give a value to
the Hint property of each.  You must declare the DoShow
method in the type declaration of the form. Once it is
declared, write the code for the DoShow method in the
implementation part of the unit. Finally, in the OnCreate
event handler for the form, assign the method to the
OnShowHint event of the application.
}

procedure TForm1.DoShowHint(var HintStr: String; var CanShow: Boolean; var HintInfo:
THintInfo);
begin
  if HintInfo.HintControl = SpeedButton3 then
  begin
    with HintInfo do
    begin
      HintColor := clAqua;{ Changes only for this hint }
      HintMaxWidth := 120;{Hint text word wraps if width is greater than 120 }
      Inc(HintPos.X, SpeedButton3.Width); { Move hint to right edge }
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Application.ShowHint := True;
  Application.OnShowHint := DoShowHint;
end;

72.4.11 Forms.TMonitorDefaultTo Enumeration

TMonitorDefautlTo specifies which monitor to select when there is no match to the specified criteria.

Pascal

```
TMonitorDefaultTo = (
  mdNearest,
  mdNull,
  mdPrimary
);
```

C++

```
enum TMonitorDefaultTo {
  mdNearest,
  mdNull,
  mdPrimary
};
```

File

Forms

Description

TMonitorDefaultTo indicates which monitor should be used when the selection criteria do not match any of the monitors in the system. It can have any of the following values:

Value	Meaning
mdNearest	Choose the monitor that comes closest to matching the criteria (the monitor closest to a point, on which most of a rectangle lies, etc).
mdNull	Do not select any monitor if the criteria can't be met. Use nil (Delphi) or NULL (C++) to indicate that no monitor could be found.
mdPrimary	Choose the primary monitor if no monitor matches the criteria.

72.4.12 Forms.TPopupForm Record

Pascal

```
TPopupForm = record
  FormID: Integer;
  Form: TCustomForm;
  WasPopup: Boolean;
end;
```

C++

```
struct TPopupForm {
  int FormID;
  TCustomForm Form;
  Boolean WasPopup;
};
```

File

Forms

Description

This is record Forms.TPopupForm.

72.4.13 Forms.TPopupMode Enumeration

TPopupMode enumerates the possible values of a Form's PopupMode property.

Pascal

```
TPopupMode = (
  pmNone,
  pmAuto,
  pmExplicit
);
```

C++

```
enum TPopupMode {
  pmNone,
  pmAuto,
  pmExplicit
};
```

File

Forms

Description

The PopupMode property controls how the top-level form behaves with respect to Window's WS_POPUP style. The TPopupMode can have one of these values :

Value	Meaning
pmNone	Set the PopupMode property to pmNone if you want the popup window to have the pre-Delphi 8 behavior.
pmAuto	Popup handling is automatic.
pmExplicit	Set the PopupMode property to pmExplicit for non-modal design windows such as tool palettes and other floating tool windows. This causes the windows to always remain on top of the main form.

See Also

PopupMode (see page 14054)

72.4.14 Forms.TPopupWnd Record

Pascal

```
TPopupWnd = record
  ID: Integer;
  ControlWnd: HWND;
end;
```

C++

```
struct TPopupWnd {
  int ID;
  HWND ControlWnd;
};
```

File

Forms

Description

This is record Forms.TPopupWnd.

72.4.15 Forms.TPosition Enumeration

TPosition describes the positioning of a form.

Pascal

```
TPosition = (
  poDesigned,
  poDefault,
  poDefaultPosOnly,
  poDefaultSizeOnly,
  poScreenCenter,
  poDesktopCenter,
  poMainFormCenter,
```

```
  poOwnerFormCenter
);
```

C++

```
enum TPosition {
  poDesigned,
  poDefault,
  poDefaultPosOnly,
  poDefaultSizeOnly,
  poScreenCenter,
  poDesktopCenter,
  poMainFormCenter,
  poOwnerFormCenter
};
```

File

Forms

Description

TPosition consists of the following values:

Value	Meaning
poDesigned	The form appears positioned on the screen and with the same height and width as it had at design time.
poDefault	The form appears in a position on the screen and with a height and width determined by the operating system.
poDefaultPosOnly	The form displays with the size you created it at design time, but the operating system chooses its position on the screen.
poDefaultSizeOnly	The form appears in the position you left it at design time, but the operating system chooses its size.
poScreenCenter	The form remains the size you left it at design time, but is positioned in the center of the screen. Note that in multi-monitor applications, this may result in a form that does not fall entirely on one monitor, because CLX does not include multi-monitor support.
poDesktopCenter	The form remains the size you left it at design time, but is positioned in the center of the screen.
poMainFormCenter	The form remains the size you left it at design time, but is positioned in the center of the application's main form. This position should only be used with secondary forms. If set for a main form, it acts like poScreenCenter.
poOwnerFormCenter	The form remains the size you left it at design time, but is positioned in the center of the form specified by the Owner property. If the Owner property does not specify a form, this position acts like poMainFormCenter.

See Also

TCustomForm (see page 13849)

72.4.16 Forms.TPrintScale Enumeration

Represents the proportions of a printed form.

Pascal

```
TPrintScale = (
  poNone,
  poProportional,
  poPrintToFit
);
```

C++

```
enum TPrintScale {
  poNone,
  poProportional,
  poPrintToFit
};
```

File

Forms

Description

Use TPrintScale to get or set the proportions of the printed form. TPrintScale can have one of the following values:

Value	Meaning
poNone	No special scaling occurs; therefore, the printed form and how the form appears onscreen may appear squished or stretched.
poProportional	The form is printed so that the printed image is approximately the same visible size as on the screen (WYSIWYG). The form image is scaled so that the printed image is approximately the same visible size as on the screen.
poPrintToFit	The form is printed using the same screen proportions, but in a size that just fits the printed page.

72.4.17 Forms.TScrollBarKind Enumeration

TScrollBarKind indicates the orientation of a scrollbar.

Pascal

```
TScrollBarKind = (
  sbHorizontal,
  sbVertical
);
```

C++

```
enum TScrollBarKind {
  sbHorizontal,
  sbVertical
};
```

File

Forms

Description

TScrollBarKind indicates whether a scrollbar is horizontal or vertical. It includes the following values:

Value	Meaning
sbHorizontal	Horizontal scrollbar.
sbVertical	Vertical scrollbar.

72.4.18 Forms.TScrollBarStyle Enumeration

TScrollBarStyle specifies a scroll bar style.

Pascal

```
TScrollBarStyle = (
  ssRegular,
  ssFlat,
  ssHotTrack
);
```

C++

```
enum TScrollBarStyle {
  ssRegular,
  ssFlat,
  ssHotTrack
};
```

File

Forms

Description

TScrollBarStyle can have one of the following values:

Value	Meaning
ssRegular	The scroll bar is normal.
ssFlat	The scroll bar is flat.
ssHotTrack	The scroll bar uses hot tracking.

72.4.19 Forms.TShowAction Enumeration

Pascal

```
TShowAction = (
  saIgnore,
  saRestore,
  saMinimize,
  saMaximize
);
```

C++

```
enum TShowAction {
  saIgnore,
  saRestore,
  saMinimize,
  saMaximize
};
```

File

Forms

Description

This is record Forms.TShowAction.

72.4.20 Forms.TTileMode Enumeration

Represents how MDI child forms are arranged when the Tile method is called.

Pascal

```
TTileMode = (
  tbHorizontal,
  tbVertical
);
```

C++

```
enum TTileMode {
  tbHorizontal,
  tbVertical
};
```

File

Forms

Description

TTileMode can have one of the following values:

Value	Meaning
tbHorizontal	Each form stretches across the width of the parent form.
tbVertical	Each form stretches along the height of the parent form.

Note: TTileMode is meaningful only if the form is an MDI child (that is, if the form's FormStyle property is set to fsMDIChild).

72.4.21 Forms.TTimerMode Enumeration

Pascal

```
TTimerMode = (
  tmShow,
  tmHide
);
```

C++

```
enum TTimerMode {
  tmShow,
  tmHide
};
```

File

Forms

Description

This is record Forms.TTimerMode.

72.4.22 Forms.TWindowState Enumeration

TWindowState indicates whether a form is maximized, minimized, or normally sized.

Pascal

```
TWindowState = (
  wsNormal,
  wsMinimized,
  wsMaximized
);
```

C++

```
enum TWindowState {
  wsNormal,
  wsMinimized,
  wsMaximized
};
```

File

Forms

Description

TWindowState describes the state of a form window. The following table lists the possible values:

Value	Meaning
wsNormal	The form is in its normal state (that is, neither minimized nor maximized).
wsMinimized	The form is minimized.
wsMaximized	The form is maximized.

See Also

TCustomForm (see page 13849)

72.5 Types

The following table lists types in this documentation.

Types

Name	Description
PCursorRec (see page 14369)	This is type Forms.PCursorRec.
PHintInfo (see page 14370)	PHintInfo declares a pointer to a Help Window appearance record.
TBorderIcons (see page 14370)	TBorderIcons specifies the buttons that appear on the title bar of a form window.
TBorderStyle (see page 14371)	TBorderStyle is the type of the BorderStyle property for framed controls.
TCloseEvent (see page 14371)	TCloseEvent is the type of a form's OnClose event handle.
TCloseQueryEvent (see page 14372)	TCloseQueryEvent is used for event handlers that are called when a window is about to close.
TCustomFormClass (see page 14372)	TCustomFormClass defines the metaclass for TCustomForm (see page 13849).
TCustomFrameClass (see page 14373)	TCustomFrameClass defines the metaclass for TCustomFrame (see page 13978).
TExceptionEvent (see page 14373)	TExceptionEvent is the type of event handlers that respond when the application traps an unhandled exception.
TFocusState (see page 14374)	This is type Forms.TFocusState.
TFormClass (see page 14374)	TFormClass defines the metaclass for TForm (see page 13992).
TFormState (see page 14374)	TFormState describes the possible state of a form.
TGetHandleEvent (see page 14375)	This is type Forms.TGetHandleEvent.
THelpEvent (see page 14375)	THelpEvent is the type of an OnHelp event handler.
TIdleEvent (see page 14376)	TIdleEvent is the type of event handler that perform actions when the application is idle.
TMessageEvent (see page 14376)	TMessageEvent is the type of an OnMessage event handler.
TPopupFormArray (see page 14377)	This is type Forms.TPopupFormArray.
TPopupWndArray (see page 14377)	This is type Forms.TPopupWndArray.
TScrollBarInc (see page 14377)	TScrollBarInc represents a number of logical units on a TControlScrollBar (see page 13744).
TSetLayeredWindowAttributes (see page 14378)	This is type Forms.TSetLayeredWindowAttributes.
TSettingChangeEvent (see page 14378)	TSettingChangeEvent is the type of an OnSettingChange event handler.
TShortCutEvent (see page 14381)	TShortCutEvent is the type of an OnShortCut event handler.
TShowHintEvent (see page 14381)	TShowHintEvent is the type of the OnShowHint event handler.
TWindowHook (see page 14382)	TWindowHook is the type for a dialog procedure.

72.5.1 Forms.PCursorRec Type

Pascal

```
PCursorRec = ^TCursorRec;
```

C++

```
^TCursorRec PCursorRec;
```

File

Forms

Description

This is type Forms.PCursorRec.

72.5.2 Forms.PHintInfo Type

PHintInfo declares a pointer to a Help Window appearance record.

Pascal

```
PHintInfo = ^THintInfo;
```

C++

```
^THintInfo PHintInfo;
```

File

Forms

Description

The PHintInfo type declares a pointer to a THintInfo (see page 14359) variable. The THintInfo (see page 14359) type is used to define the appearance and behavior of the Help window in a TShowHintEvent (see page 14381) type OnShowHint event handler.

See Also

OnShowHint (see page 13742)

TShowHintEvent (see page 14381)

THintInfo (see page 14359)

72.5.3 Forms.TBorderIcons Type

TBorderIcons specifies the buttons that appear on the title bar of a form window.

Pascal

```
TBorderIcons = set of TBorderIcon;
```

C++

```
TBorderIcon TBorderIcons;
```

File

Forms

Description

TBorderIcons type declares a pointer to a TBorderIcon (see page 14354) variable. TBorderIcons can include any of the following TBorderIcon (see page 14354) values:

Value	Meaning
biSystemMenu	The form has a Control menu (also known as a System (see page 22079) menu).
biMinimize	The form has a Minimize button
biMinimize	The form has a Maximize button
biHelp	If BorderStyle is bsDialog or biMinimize and biMaximize are excluded, a question mark appears in the form's title bar and when clicked, the cursor changes to crHelp; otherwise, no question mark appears.

See Also

TBorderIcon (see page 14354)

72.5.4 Forms.TBorderStyle Type

TBorderStyle is the type of the BorderStyle property for framed controls.

Pascal

```
TBorderStyle = bsNone..bsSingle;
```

C++

```
bsNone..bsSingle TBorderStyle;
```

File

Forms

Description

These are the possible values of the TBorderStyle type:

Value	Meaning
bsNone	No visible border.
bsSingle	Single-line border.

72.5.5 Forms.TCloseEvent Type

TCloseEvent is the type of a form's OnClose event handle.

Pascal

```
TCloseEvent = procedure (Sender: TObject; var Action: TCloseAction) of object;
```

C++

```
(Sender: TObject; var Action: TCloseAction) ( TCloseEvent)();
```

File

Forms

Description

The TCloseEvent type points to a method that handles the closing of a form. The **Sender** parameter is the form that the user tried to close. The **Action** parameter returns the action you want the form to take when it closes.

Setting **Action** controls how the form responds to the attempt to close it as shown below :

Value	Meaning
caNone	The form is not allowed to close, so nothing happens.
caHide	The form is not closed, but just hidden. Your application can still access a hidden form.
caFree	The form is closed and all allocated memory for the form is freed.

caMinimize	The form is minimized, rather than closed. This is the default action for MDI child forms.

See Also

OnClose (see page 14072)

72.5.6 Forms.TCloseQueryEvent Type

TCloseQueryEvent is used for event handlers that are called when a window is about to close.

Pascal

```
TCloseQueryEvent = procedure (Sender: TObject; var CanClose: Boolean) of object;
```

C++

```
(Sender: TObject; var CanClose: Boolean) ( TCloseQueryEvent)();
```

File

Forms

Description

The TCloseQueryEvent type is the type for event handlers that allow an application to block the closing of a window (form or dialog).

Sender is the object whose event handler is called. This is the form that is about to close or the dialog whose window is about to close.

CanClose is set by the event handler to indicate whether the form or dialog can close (true) or whether the user should be blocked from closing it (false).

See Also

OnClose (see page 14072)

TCloseQueryEvent

72.5.7 Forms.TCustomFormClass Type

TCustomFormClass defines the metaclass for TCustomForm (see page 13849).

Pascal

```
TCustomFormClass = class of TCustomForm;
```

C++

```
TCustomForm TCustomFormClass;
```

File

Forms

Description

TCustomFormClass is the metaclass for TCustomForm (see page 13849). Its value is the class reference for TCustomForm (see page 13849) or for one of its descendants.

See Also

TCustomForm (see page 13849)

72.5.8 Forms.TCustomFrameClass Type

TCustomFrameClass defines the metaclass for TCustomFrame (see page 13978).

Pascal

```
TCustomFrameClass = class of TCustomFrame;
```

C++

```
TCustomFrame TCustomFrameClass;
```

File

Forms

Description

TCustomFrameClass is the metaclass for TCustomFrame (see page 13978). Its value is the class reference for TCustomFrame (see page 13978) or for one of its descendants.

See Also

TCustomFrame (see page 13978)

72.5.9 Forms.TExceptionEvent Type

TExceptionEvent is the type of event handlers that respond when the application traps an unhandled exception.

Pascal

```
TExceptionEvent = procedure (Sender: TObject; E: Exception) of object;
```

C++

```
(Sender: TObject; E: Exception) ( TExceptionEvent)();
```

File

Forms

Description

The TExceptionEvent type is the type of the OnException event handler.

Sender is the object that receives the event notification. Typically, this is the application object.

E is the exception object that represents the exception.

See Also

OnException (see page 13728)

72.5.10 Forms.TFocusState Type

Pascal

```
TFocusState = type Pointer;
```

C++

```
type Pointer TFocusState;
```

File

Forms

Description

This is type Forms.TFocusState.

72.5.11 Forms.TFormClass Type

TFormClass defines the metaclass for TForm (see page 13992).

Pascal

```
TFormClass = class of TForm;
```

C++

```
TForm * TFormClass;
```

File

Forms

Description

TFormClass is the metaclass for TForm (see page 13992). Its value is the class reference for TForm (see page 13992) or for one of its descendants.

See Also

TForm (see page 13992)

72.5.12 Forms.TFormState Type

TFormState describes the possible state of a form.

Pascal

```
TFormState = set of (fsCreating, fsVisible, fsShowing, fsModal, fsCreatedMDIChild,
fsActivated);
```

C++

```
(fsCreating, fsVisible, fsShowing, fsModal, fsCreatedMDIChild, fsActivated) TFormState;
```

File

Forms

Description

The following table lists the values that can be included in a form's state:

Value	Meaning
fsCreating	The form's constructor is currently executing.
fsVisible	The form's window is visible. This state is used to update the Visible property.
fsShowing	The form's WindowState property is changing. This state is used to prevent WindowState changes from interfering with a transition that is in progress.
fsModal	The form was created as a modal window.
fsActivated	The form has received focus or the application became active but has not yet called the Activate method to generate an OnActivate event.

72.5.13 Forms.TGetHandleEvent Type

Pascal

```
TGetHandleEvent = procedure (var Handle: HWND) of object;
```

C++

```
(var Handle: HWND) ( TGetHandleEvent)();
```

File

Forms

Description

This is type Forms.TGetHandleEvent.

72.5.14 Forms.THelpEvent Type

THelpEvent is the type of an OnHelp event handler.

Pascal

```
THelpEvent = function (Command: Word; Data: Longint; var CallHelp: Boolean): Boolean of object;
```

C++

```
(Command: Word; Data: Longint; var CallHelp: Boolean): Boolean ( THelpEvent)();
```

File

Forms

Description

THelpEvent includes the following parameters:

Command indicates the type of help command that was issued. It's meaning depends on the current help system. For example, when using WinHelp, Command is the command used by the WinHelp API. For details on possible commands, see the documentation provided by the developer of the application's help system. For example, if the application uses WinHelp, the possible commands are listed in the WinHelp section of the Win32 Developer's Reference.

Data provides additional data to describe the desired action by the help system. Its value depends on the value of the Command property. Typically, Data specifies a keyword or context ID. For details, see the documentation provided by the application's help system.

CallHelp is set by the event handler. If CallHelp is true when the event handler exits, the application should forward the help command to the help system. If the event handler handles the command, it sets CallHelp to false so that the application does not forward the help command to the help system.

72.5.15 Forms.TIdleEvent Type

TIdleEvent is the type of event handler that perform actions when the application is idle.

Pascal

```
TIdleEvent = procedure (Sender: TObject; var Done: Boolean) of object;
```

C++

```
(Sender: TObject; var Done: Boolean) ( TIdleEvent)();
```

File

Forms

Description

The TIdleEvent type is the type of the OnIdle event.

Sender is the object that receives the event notification. Typically, this is the application object.

Done indicates whether the event handler has finished its background processing.

If the event handler exits when **Done** is true, all action components are then given a chance to update themselves and, on Windows, the application yields control to Windows until a new message appears in the application's message queue. When **Done** is false, any action components in the application are not allowed to update themselves when the event handler exits and, on Windows, the application does not explicitly yield control to the operating system.

See Also

OnIdle (see page 13733)

72.5.16 Forms.TMessageEvent Type

TMessageEvent is the type of an OnMessage event handler.

Pascal

```
TMessageEvent = procedure (var Msg: TMsg; var Handled: Boolean) of object;
```

C++

```
(var Msg: TMsg; var Handled: Boolean) ( TMessageEvent)();
```

File

Forms

Description

TMessageEvent includes the following parameters:

Msg identifies the Windows message that triggered the event.

Handled indicates whether the event handler responded to the message. If the event handler sets Handled to true, the application assumes that the message has been completely handled and halts any subsequent processing of the message.

72.5.17 Forms.TPopupFormArray Type

Pascal

```
TPopupFormArray = array of TPopupForm;
```

C++

```
array of TPopupForm TPopupFormArray;
```

File

Forms

Description

This is type Forms.TPopupFormArray.

72.5.18 Forms.TPopupWndArray Type

Pascal

```
TPopupWndArray = array of TPopupWnd;
```

C++

```
array of TPopupWnd TPopupWndArray;
```

File

Forms

Description

This is type Forms.TPopupWndArray.

72.5.19 Forms.TScrollBarInc Type

TScrollBarInc represents a number of logical units on a TControlScrollBar (see page 13744).

Pascal

```
TScrollBarInc = 1..32767;
```

C++

```
1..32767 TScrollBarInc;
```

File

Forms

Description

TScrollBarInc has a value between 1 and 32767 (inclusive). It indicates the number of positions to scroll.

See Also

TControlScrollBar

72.5.20 Forms.TSetLayeredWindowAttributes Type

Pascal

```
TSetLayeredWindowAttributes = function (Hwnd: THandle; crKey: COLORREF; bAlpha: Byte; dwFlags:
DWORD): Boolean;
```

C++

```
(Hwnd: THandle; crKey: COLORREF; bAlpha: Byte; dwFlags: DWORD): Boolean (
TSetLayeredWindowAttributes)();
```

File

Forms

Description

This is type Forms.TSetLayeredWindowAttributes.

72.5.21 Forms.TSettingChangeEvent Type

TSettingChangeEvent is the type of an OnSettingChange event handler.

Pascal

```
TSettingChangeEvent = procedure (Sender: TObject; Flag: Integer; const Section: string; var
Result: Longint) of object;
```

C++

```
(Sender: TObject; Flag: Integer; const Section: string; var Result: Longint) (
TSettingChangeEvent)();
```

File

Forms

Description

TSettingChangeEvent has the following parameters:

Sender is the application object.

Section indicates the area that contains the system parameter that changed. Typically, this is a registry key or the name of a section in Win.ini. If the notification indicates a policy change, Section is the string 'Policy'. If the notification indicates a change in locale settings, Section is the string 'intl'.

Result is the value returned to Windows. It should be 0 if the event handler responded to the setting change, nonzero otherwise.

Flag indicates what setting changed. The following table lists the possible values:

Value	Meaning
0	A user policy was applied or a user locale setting changed.
1	A computer policy was applied.
SPI_SETDESKWALLPAPER	The bitmap for the desktop wallpaper changed.
SPI_SETCURSORS	The system cursors changed.
SPI_SETDESKPATTERN	The desktop pattern was reloaded from Win.ini.
SPI_SETFONTSMOOTING	The font smoothing feature was enabled or disabled.
SPI_SETWORKAREA	The size of the work area (the portion of the screen not obscured by the system taskbar or desktop toolbars) changed.
SPI_ICONHORIZONTALSPACING	The width, in pixels, of an icon cell changed. This affects the arrangement of icons in large icon view.
SPI_ICONVERTICALSPACING	The height, in pixels, of an icon cell changed. This affects the arrangement of icons in large icon view.
SPI_SETICONMETRICS	The metrics associated with system icons changed.
SPI_SETICONS	The system icons were reloaded.
SPI_SETICONTITLELOGFONT	The font for icon titles changed.
SPI_SETICONTITLEWRAP	Icon title-wrapping was turned on or off.
SPI_SETBEEP	The warning beeper was turned on or off.
SPI_SETDEFAULTINPUTLANG	The default input language for the system shell changed
SPI_SETDOUBLECLICKTIME	The double-click time for the mouse changed.
SPI_SETDOUBLECLICKHEIGHT	The height of the double-click rectangle changed.
SPI_SETDOUBLECLICKWIDTH	The width of the double-click rectangle changed.
SPI_SETKEYBOARDCUES	The setting for whether Menu access key letters appear always or only when the menu is activated from the keyboard changed.
SPI_SETKEYBOARDDELAY	The keyboard repeat-delay setting changed.
SPI_SETKEYBOARDPREF	The keyboard preference changed. This indicates whether the user wants applications to display hidden keyboard interfaces.
SPI_SETKEYBOARDSPEED	The keyboard repeat-speed setting changed.
SPI_SETLANGTOGGLE	The hotkey for switching input languages changed.
SPI_SETMOUSE	The mouse threshold values or acceleration changed.
SPI_SETMOUSEBUTTONSWRAP	The meaning of left and right mouse buttons changed.
SPI_SETMOUSEHOVERHEIGHT	The height of the rectangle in which the mouse must stay for mouse hover messages changed.
SPI_SETMOUSEHOVERTIME	The time the mouse must stay in the hover rectangle to generate mouse hover messages changed.
SPI_SETMOUSEHOVERWIDTH	The width of the rectangle in which the mouse must stay for mouse hover messages changed.
SPI_SETMOUSESPEED	The mouse speed changed.
SPI_SETMOUSETRAILS	Mouse trails were turned on or off.
SPI_SETSNAPTODEFBUTTON	The automatic snapping of the mouse to the default button was turned on or off.
SPI_SETWHEELSCROLLLINES	The number of lines to scroll when the mouse wheel rotates changed.

SPI_SETMENUDROPALIGNMENT	Popup menus changed between left- and right-alignment.
SPI_SETMENUFADE	Menu fade animation was turned on or off (Windows 2K)
SPI_SETMENUSHOWDELAY	The delay before displaying a shortcut menu when the mouse is over a submenu item changed.
SPI_SETLOWPOWERACTIVE	The low-power phase of screen saving was activated or deactivated.
SPI_SETLOWPOWERTIMEOUT	The time period before the low-power phase of screen saving is activated changed.
SPI_SETPOWEROFFACTIVE	The power-off phase of screen saving came on or off.
SPI_SETPOWEROFFTIMEOUT	The delay before activating the power-off phase of screen saving changed.
SPI_SETSCREENSAVEACTIVE	The screen saver was activated or deactivated.
SPI_SETSCREENSAVETIMEOUT	The delay before the screen saver appears changed.
SPI_SETCOMBOBOXANIMATION	The slide-open effect for combo boxes was turned on or off.
SPI_SETCURSORSHADOW	The cursor shadow was turned on or off (Windows 2K).
SPI_SETGRADIENTCAPTIONS	The gradient effect on window title bars was turned on or off.
SPI_SETHOTTRACKING	Hot-tracking was enabled or disabled.
SPI_SETLISTBOXSMOOTHSCROLLING	Smooth scrolling of list boxes was enabled or disabled.
SPI_SETMENUANIMATION	Menu animation was enabled or disabled.
SPI_SETMENUUNDERLINES	Same as SPI_SETKEYBOARDCUES.
SPI_SETSELECTIONFADE	The menu selection fade feature was enabled or disabled. (Windows 2K)
SPI_SETTOOLTIPANIMATION	ToolTip animation was enabled or disabled. (Windows 2K)
SPI_SETTOOLTIPFADE	ToolTip animation changed between a fade and a slide effect. (Windows 2K)
SPI_SETUIEFFECTS	UI effects were enabled or disabled. (Windows 2K)
SPI_SETACTIVEWINDOWTRACKING	Active window tracking (where the active window follows the mouse) was enabled or disabled.
SPI_SETACTIVEWNDTRKZORDER	Active window tracking changed whether the active window was brought to the top.
SPI_SETANIMATION	Parameters to the animation effects for user actions changed.
SPI_SETBORDER	The width of a window's sizing border changed.
SPI_SETCARETWIDTH	The width of the caret in edit controls changed (Windows 2K)
SPI_SETDRAGFULLWINDOWS	Dragging of full windows was turned on or off.
SPI_SETDRAGHEIGHT	The height of the rectangle used to detect drag operations changed.
SPI_SETDRAGWIDTH	The width of the rectangle used to detect drag operations changed.
SPI_SETFOREGROUNDFLASHCOUNT	The number of times a taskbar button flashes when rejecting a foreground switch request changed.
SPI_SETFOREGROUNDLOCKTIMEOUT	The time after user input during which applications can't force themselves into the foreground changed.
SPI_SETMINIMIZEDMETRICS	The metrics for minimized windows changed.
SPI_SETNONCLIENTMETRICS	The metrics for the nonclient area of nonminimized windows changed.
SPI_SETSHOWIMEUI	The ability of the IME window to be visible on a per-user basis changed.
SPI_SETPENWINDOWS	Pen windows was loaded or unloaded. (Windows 9x)
SPI_SETACCESSTIMEOUT	The time-out period for accessibility features changed.
SPI_SETFILTERKEYS	The parameters to the FilterKeys accessibility feature changed.

SPI_SETHIGHCONTRAST	The parameters to the HighContrast accessibility feature changed.
SPI_SETMOUSECLICKLOCK	The mouse ClickLock state was turned on or off. (Windows Me)
SPI_SETMOUSECLICKLOCKTIME	The time delay for locking the primary mouse button changed. (Windows Me)
SPI_SETMOUSEKEYS	The parameters for the MouseKeys accessibility feature changed.
SPI_SETMOUSESONAR	The mouse Sonar feature was turned on or off. (Windows Me)
SPI_SETMOUSEVANISH	The mouse Vanish feature was turned on or off. (Windows Me)
SPI_SETSCREENREADER	A screen reviewer utility (such as a speech synthesizer or Braille display utility) started or stopped running.
SPI_SETSERIALKEYS	The parameters to the SerialKeys accessibility feature changed. (Windows 9x)
SPI_SETSHOWSOUNDS	The Show Sounds accessibility feature toggled.
SPI_SETSOUNDSENTRY	The parameters to the SoundSentry accessibility feature changed.
SPI_SETSTICKYKEYS	The parameters to the StickyKeys feature changed.
SPI_SETTOGGLEKEYS	The parameters to the ToggleKeys feature changed.

72.5.22 Forms.TShortCutEvent Type

TShortCutEvent is the type of an OnShortCut event handler.

Pascal

```
TShortCutEvent = procedure (var Msg: TWMKey; var Handled: Boolean) of object;
```

C++

```
(var Msg: TWMKey; var Handled: Boolean) ( TShortCutEvent)();
```

File

Forms

Description

The TShortCutEvent type represents event handlers that respond to keystrokes before they enter the standard keystroke processing. These event handlers allow an application to bypass the standard keystroke processing for special shortcut keys.

The Msg parameter represents the Windows keystroke message. The virtual key code is given by the CharCode field, and the KeyData field contains a set of flags that indicate the repeat count, scan code, extended-key flag, context code, previous key-state flag and transition-state flag. See the Windows documentation for details on these fields.

The Handled parameter indicates whether the event handler processed the key. If Handled is set to true, then the application stops processing the keystroke. Otherwise (if Handled remains false) the application proceeds with normal keystroke processing.

72.5.23 Forms.TShowHintEvent Type

TShowHintEvent is the type of the OnShowHint event handler.

Pascal

```
TShowHintEvent = procedure (var HintStr: string; var CanShow: Boolean; var HintInfo:
THintInfo) of object;
```

C++

```
(var HintStr: string; var CanShow: Boolean; var HintInfo: THintInfo) ( TShowHintEvent)();
```

File

Forms

Description

TShowHintEvent has the following parameters:

HintStr sets the text of the Help Hint. You can change this string in the event handler to change the hint text that appears to the user.

CanShow indicates whether the Help Hint should display. If the event handler sets CanShow to true, the Help Hint displays. If it sets CanShow to false, the Help Hint does not appear.

HintInfo contains information about the appearance and behavior of the Help window. Change its fields to customize the way the Help Hint is displayed.

72.5.24 Forms.TWindowHook Type

TWindowHook is the type for a dialog procedure.

Pascal

```
TWindowHook = function (var Message: TMessage): Boolean of object;
```

C++

```
(var Message: TMessage): Boolean ( TWindowHook)();
```

File

Forms

Description

TWindowHook is the type for the window procedure of a non-VCL dialog box. Like most window procedures, TWindowHook takes a TMessage value as an argument.

Except in response to the WM_INITDIALOG message, the window hook should return true if it processes the message, and false if it does not. When the Msg field of the Message parameter is WM_INITDIALOG, the window hook should return false if it explicitly sets the focus to one of the controls in the dialog box. Otherwise, it should return true, in which case the system sets the focus to the first control in the dialog box that can be given the focus.

TApplication (see page 13660)

72.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
Application (see page 14383)	Represents application-level information.
Ctl3DBtnWndProc (see page 14383)	This is variable Forms.Ctl3DBtnWndProc.
Ctl3DCtlColorEx (see page 14384)	This is variable Forms.Ctl3DCtlColorEx.
Ctl3DDlgFramePaint (see page 14384)	This is variable Forms.Ctl3DDlgFramePaint.
HintWindowClass (see page 14384)	Specifies the class for the window used to display help hints.
Screen (see page 14385)	Represents a screen device.
SetLayeredWindowAttributes (see page 14385)	This is variable Forms.SetLayeredWindowAttributes.

72.6.1 Forms.Application Variable

Represents application-level information.

Pascal

```
Application: TApplication;
```

C++

```
TApplication Application;
```

File

Forms

Description

By default, when a new project is created, the IDE constructs an application object and assigns it to the Application variable in the Forms (see page 13657) or QForms unit. Application has several properties that can be used to get information about an application while it runs.

See Also

TApplication (see page 13660)

TApplication (see page 13660)

TApplication (see page 13660)

72.6.2 Forms.Ctl3DBtnWndProc Variable

Pascal

```
Ctl3DBtnWndProc: Pointer = nil;
```

C++

```
void * Ctl3DBtnWndProc = nil;
```

File

Forms

Description

This is variable Forms.Ctl3DBtnWndProc.

72.6.3 Forms.Ctl3DCtlColorEx Variable

Pascal

```
Ctl3DCtlColorEx: function(Window: HWnd; Msg, wParam, lParam: Longint): Longint stdcall = nil;
```

C++

```
function(Window: HWnd; Msg, wParam, lParam: Longint): Longint stdcall Ctl3DCtlColorEx = nil;
```

File

Forms

Description

This is variable Forms.Ctl3DCtlColorEx.

72.6.4 Forms.Ctl3DDlgFramePaint Variable

Pascal

```
Ctl3DDlgFramePaint: function(Window: HWnd; Msg, wParam, lParam: Longint): Longint stdcall =
nil;
```

C++

```
function(Window: HWnd; Msg, wParam, lParam: Longint): Longint stdcall Ctl3DDlgFramePaint = nil;
```

File

Forms

Description

This is variable Forms.Ctl3DDlgFramePaint.

72.6.5 Forms.HintWindowClass Variable

Specifies the class for the window used to display help hints.

Pascal

```
HintWindowClass: THintWindowClass = THintWindow;
```

C++

```
THintWindowClass HintWindowClass = THintWindow;
```

File

Forms

Description

When the application displays a Help Hint, it creates an instance of HintWindowClass to represent the window used for displaying the hint. Applications can customize this window by creating a descendant of THintWindow and assigning it to the HintWindowClass variable at application startup.

See Also

THintWindow

TApplication (see page 13660)

72.6.6 Forms.Screen Variable

Represents a screen device.

Pascal

```
Screen: TScreen;
```

C++

```
TScreen Screen;
```

File

Forms

Description

The Screen variable is a TScreen (see page 14197) component that represents the screen of the system on which the application runs. By default, applications create a screen component based on information about the current screen device and assign it to Screen.

See Also

TApplication (see page 13660)

72.6.7 Forms.SetLayeredWindowAttributes Variable

Pascal

```
SetLayeredWindowAttributes: TSetLayeredWindowAttributes = nil;
```

C++

```
TSetLayeredWindowAttributes SetLayeredWindowAttributes = nil;
```

File

Forms

Description

This is variable Forms.SetLayeredWindowAttributes.

73 Graphics Namespace

This is namespace Graphics.

Topics

Name	Description
Classes (see page 14395)	The following table lists classes in this documentation.
Interfaces (see page 14606)	The following table lists interfaces in this documentation.
Functions (see page 14608)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 14630)	The following table lists structs, records, enums in this documentation.
Types (see page 14645)	The following table lists types in this documentation.
Variables (see page 14657)	The following table lists variables in this documentation.
Constants (see page 14659)	The following table lists constants in this documentation.

Classes

	Name	Description
	EInvalidGraphic (see page 14395)	EInvalidGraphic is the exception class for unrecognized graphic files.
	EInvalidGraphicOperation (see page 14396)	EInvalidGraphicOperation is the exception class for illegal operations on graphics.
	TBitmap (see page 14396)	TBitmap is an encapsulation of a Windows bitmap (HBITMAP), including its palette (HPALETTE).
	TBitmapImage (see page 14429)	TBitmapImage is the internal representation of the bitmap image for a TBitmap (see page 14396) object.
	TBrush (see page 14430)	TBrush represents the color and pattern used to fill solid shapes.
	TBrushRecall (see page 14439)	TBrushRecall saves and restores a TBrush (see page 14430) object.
	TCanvas (see page 14441)	TCanvas provides an abstract drawing space for objects that must render their own images.
	TFont (see page 14497)	TFont encapsulates a system font.
	TFontRecall (see page 14514)	TFontRecall saves and restores the properties of a TFont (see page 14497) object.
	TGraphic (see page 14516)	TGraphic is the abstract base class type for objects such as icons, bitmaps, and metafiles that can store and display visual images.
	TGraphicsObject (see page 14532)	TGraphicsObject is the abstract base class for objects which encapsulate a system graphics object: TBrush (see page 14430), TFont (see page 14497), and TPen (see page 14571).
	TIcon (see page 14537)	TIcon is an encapsulation of a Windows icon.
	TIconImage (see page 14547)	TIconImage is the internal representation of the bitmap image for a TIcon (see page 14537) object.
	TMetafile (see page 14549)	TMetafile is an encapsulation of the Win32 Enhanced (see page 14562) metafile.

	TMetafileCanvas (see page 14564)	TMetafileCanvas allows applications to create metafile images from scratch.
	TMetafileImage (see page 14569)	TMetafileImage is the internal representation of the metafile image for a TMetafile (see page 14549) object.
	TPen (see page 14571)	TPen is used to draw lines or outline shapes on a canvas.
	TPenRecall (see page 14582)	TPenRecall saves and restores the properties of a TPen (see page 14571) object.
	TPicture (see page 14584)	TPicture contains a bitmap, icon, metafile graphic, or user-defined graphic.
	TSharedImage (see page 14603)	TSharedImage is the base class for classes that contain images used for graphics objects.

Constants

Name	Description
cl3DDkShadow (see page 14663)	Represents the dark shadow of 3D components.
cl3DLight (see page 14663)	Represents the light part of 3D components.
clActiveBorder (see page 14664)	Represents the default border color of an active window.
clActiveCaption (see page 14664)	Represents the default color of the title bar of an active window.
clAppWorkSpace (see page 14665)	Represents the default Application WorkSpace color.
clAqua (see page 14665)	Represents the color Aqua.
clBackground (see page 14666)	Represents the default Windows background color.
clBlack (see page 14666)	Represents the color black.
clBlue (see page 14666)	Represents the color blue.
clBtnFace (see page 14667)	Represents the color of the face of a button.
clBtnHighlight (see page 14667)	Represents the color of the highlighting on a button.
clBtnShadow (see page 14668)	Represents the color of the shadow cast by of a button.
clBtnText (see page 14668)	Represents the default color of the text on a button.
clCaptionText (see page 14669)	Represents the default color of the text on the title bar of an active window.
clCream (see page 14669)	Represents the color cream.
clDefault (see page 14670)	Specifies the default color of a component.
clDkGray (see page 14670)	Represents the color dark gray.
clFuchsia (see page 14670)	Represents the color fuchsia.
clGradientActiveCaption (see page 14671)	Right side color in the color gradient of an active window's title bar.
clGradientInactiveCaption (see page 14671)	Right side color in the color gradient of an inactive window's title bar.
clGray (see page 14672)	Represents the color gray.
clGrayText (see page 14672)	Represents the color of text that is grayed out.
clGreen (see page 14673)	Represents the color green.
clHighlight (see page 14673)	Represents the color of the background of a block of selected text.
clHighlightText (see page 14674)	Represents the color of selected text.
clHotLight (see page 14674)	This is constant Graphics.clHotLight.
clInactiveBorder (see page 14675)	Represents the default border color of an inactive window.
clInactiveCaption (see page 14675)	Represents the default color of the title bar of an inactive window.
clInactiveCaptionText (see page 14675)	Represents the default color of the title text in an inactive window.
clInfoBk (see page 14676)	Represents the color of the background of a tool tip.
clInfoText (see page 14676)	Represents the color of tool tip text.
clLime (see page 14677)	Represents the color lime.
clLtGray (see page 14677)	Represents the color light gray.
clMaroon (see page 14678)	Represents the color maroon.
clMedGray (see page 14678)	Represents the color medium gray.
clMenu (see page 14679)	Represents the color of the background of an unselected menu sub item.
clMenuBar (see page 14679)	Represents the color of the background of an unselected main menu item.
clMenuHighlight (see page 14679)	Represents the color of the background of a selected menu item.
clMenuText (see page 14680)	Represents the default menu text color.
clMoneyGreen (see page 14680)	Represents the color money green.
clNavy (see page 14681)	Represents the color navy.
clNone (see page 14681)	Represents no selected color.
clOlive (see page 14682)	Represents the color olive.

clPurple (see page 14682)	Represents the color purple.
clRed (see page 14683)	Represents the color red.
clScrollBar (see page 14683)	This is constant Graphics.clScrollBar.
clSilver (see page 14683)	Represents the color silver.
clSkyBlue (see page 14684)	Represents the color sky blue.
clSystemColor (see page 14684)	Is a mask used to identify the set of system colors.
clTeal (see page 14685)	Represents the color teal.
clWebAliceBlue (see page 14685)	This is constant Graphics.clWebAliceBlue.
clWebAntiqueWhite (see page 14686)	This is constant Graphics.clWebAntiqueWhite.
clWebAqua (see page 14686)	This is constant Graphics.clWebAqua.
clWebAquamarine (see page 14686)	This is constant Graphics.clWebAquamarine.
clWebAzure (see page 14687)	This is constant Graphics.clWebAzure.
clWebBeige (see page 14687)	This is constant Graphics.clWebBeige.
clWebBisque (see page 14687)	This is constant Graphics.clWebBisque.
clWebBlack (see page 14688)	This is constant Graphics.clWebBlack.
clWebBlanchedAlmond (see page 14688)	This is constant Graphics.clWebBlanchedAlmond.
clWebBlue (see page 14688)	This is constant Graphics.clWebBlue.
clWebBlueViolet (see page 14689)	This is constant Graphics.clWebBlueViolet.
clWebBrown (see page 14689)	This is constant Graphics.clWebBrown.
clWebBurlywood (see page 14689)	This is constant Graphics.clWebBurlywood.
clWebCadetBlue (see page 14690)	This is constant Graphics.clWebCadetBlue.
clWebChartreuse (see page 14690)	This is constant Graphics.clWebChartreuse.
clWebChocolate (see page 14690)	This is constant Graphics.clWebChocolate.
clWebCoral (see page 14691)	This is constant Graphics.clWebCoral.
clWebCornFlowerBlue (see page 14691)	This is constant Graphics.clWebCornFlowerBlue.
clWebCornSilk (see page 14691)	This is constant Graphics.clWebCornSilk.
clWebCrimson (see page 14692)	This is constant Graphics.clWebCrimson.
clWebCyan (see page 14692)	This is constant Graphics.clWebCyan.
clWebDarkBlue (see page 14692)	This is constant Graphics.clWebDarkBlue.
clWebDarkCyan (see page 14693)	This is constant Graphics.clWebDarkCyan.
clWebDarkGoldenRod (see page 14693)	This is constant Graphics.clWebDarkGoldenRod.
clWebDarkGray (see page 14693)	This is constant Graphics.clWebDarkGray.
clWebDarkgreen (see page 14694)	This is constant Graphics.clWebDarkgreen.
clWebDarkKhaki (see page 14694)	This is constant Graphics.clWebDarkKhaki.
clWebDarkMagenta (see page 14694)	This is constant Graphics.clWebDarkMagenta.
clWebDarkOliveGreen (see page 14695)	This is constant Graphics.clWebDarkOliveGreen.
clWebDarkOrange (see page 14695)	This is constant Graphics.clWebDarkOrange.
clWebDarkOrchid (see page 14695)	This is constant Graphics.clWebDarkOrchid.
clWebDarkRed (see page 14696)	This is constant Graphics.clWebDarkRed.
clWebDarkSalmon (see page 14696)	This is constant Graphics.clWebDarkSalmon.
clWebDarkSeaGreen (see page 14696)	This is constant Graphics.clWebDarkSeaGreen.
clWebDarkSlateBlue (see page 14697)	This is constant Graphics.clWebDarkSlateBlue.
clWebDarkSlategray (see page 14697)	This is constant Graphics.clWebDarkSlategray.
clWebDarkTurquoise (see page 14697)	This is constant Graphics.clWebDarkTurquoise.
clWebDarkViolet (see page 14698)	This is constant Graphics.clWebDarkViolet.
clWebDeepPink (see page 14698)	This is constant Graphics.clWebDeepPink.
clWebDeepskyBlue (see page 14698)	This is constant Graphics.clWebDeepskyBlue.
clWebDimGray (see page 14699)	This is constant Graphics.clWebDimGray.
clWebDodgerBlue (see page 14699)	This is constant Graphics.clWebDodgerBlue.
clWebFirebrick (see page 14699)	This is constant Graphics.clWebFirebrick.
clWebFloralWhite (see page 14700)	This is constant Graphics.clWebFloralWhite.
clWebForestGreen (see page 14700)	This is constant Graphics.clWebForestGreen.
clWebFuchsia (see page 14700)	This is constant Graphics.clWebFuchsia.
clWebGainsboro (see page 14701)	This is constant Graphics.clWebGainsboro.

clWebGhostWhite (see page 14701)	This is constant Graphics.clWebGhostWhite.
clWebGold (see page 14701)	This is constant Graphics.clWebGold.
clWebGoldenRod (see page 14702)	This is constant Graphics.clWebGoldenRod.
clWebGray (see page 14702)	This is constant Graphics.clWebGray.
clWebGreen (see page 14702)	This is constant Graphics.clWebGreen.
clWebGreenYellow (see page 14703)	This is constant Graphics.clWebGreenYellow.
clWebHoneydew (see page 14703)	This is constant Graphics.clWebHoneydew.
clWebHotPink (see page 14703)	This is constant Graphics.clWebHotPink.
clWebIndianRed (see page 14704)	This is constant Graphics.clWebIndianRed.
clWebIndigo (see page 14704)	This is constant Graphics.clWebIndigo.
clWebIvory (see page 14704)	This is constant Graphics.clWebIvory.
clWebKhaki (see page 14705)	This is constant Graphics.clWebKhaki.
clWebLavender (see page 14705)	This is constant Graphics.clWebLavender.
clWebLavenderBlush (see page 14705)	This is constant Graphics.clWebLavenderBlush.
clWebLawnGreen (see page 14706)	This is constant Graphics.clWebLawnGreen.
clWebLemonChiffon (see page 14706)	This is constant Graphics.clWebLemonChiffon.
clWebLightBlue (see page 14706)	This is constant Graphics.clWebLightBlue.
clWebLightCoral (see page 14707)	This is constant Graphics.clWebLightCoral.
clWebLightCyan (see page 14707)	This is constant Graphics.clWebLightCyan.
clWebLightGoldenrodYellow (see page 14707)	This is constant Graphics.clWebLightGoldenrodYellow.
clWebLightGreen (see page 14708)	This is constant Graphics.clWebLightGreen.
clWebLightgrey (see page 14708)	This is constant Graphics.clWebLightgrey.
clWebLightPink (see page 14708)	This is constant Graphics.clWebLightPink.
clWebLightSalmon (see page 14709)	This is constant Graphics.clWebLightSalmon.
clWebLightSeaGreen (see page 14709)	This is constant Graphics.clWebLightSeaGreen.
clWebLightSkyBlue (see page 14709)	This is constant Graphics.clWebLightSkyBlue.
clWebLightSlateGray (see page 14710)	This is constant Graphics.clWebLightSlateGray.
clWebLightSteelBlue (see page 14710)	This is constant Graphics.clWebLightSteelBlue.
clWebLightYellow (see page 14710)	This is constant Graphics.clWebLightYellow.
clWebLime (see page 14711)	This is constant Graphics.clWebLime.
clWebLimeGreen (see page 14711)	This is constant Graphics.clWebLimeGreen.
clWebLinen (see page 14711)	This is constant Graphics.clWebLinen.
clWebMagenta (see page 14712)	This is constant Graphics.clWebMagenta.
clWebMaroon (see page 14712)	This is constant Graphics.clWebMaroon.
clWebMediumAquamarine (see page 14712)	This is constant Graphics.clWebMediumAquamarine.
clWebMediumBlue (see page 14713)	This is constant Graphics.clWebMediumBlue.
clWebMediumOrchid (see page 14713)	This is constant Graphics.clWebMediumOrchid.
clWebMediumPurple (see page 14713)	This is constant Graphics.clWebMediumPurple.
clWebMediumSeaGreen (see page 14714)	This is constant Graphics.clWebMediumSeaGreen.
clWebMediumSlateBlue (see page 14714)	This is constant Graphics.clWebMediumSlateBlue.
clWebMediumSpringGreen (see page 14714)	This is constant Graphics.clWebMediumSpringGreen.
clWebMediumTurquoise (see page 14715)	This is constant Graphics.clWebMediumTurquoise.
clWebMediumVioletRed (see page 14715)	This is constant Graphics.clWebMediumVioletRed.
clWebMidnightBlue (see page 14715)	This is constant Graphics.clWebMidnightBlue.
clWebMintcream (see page 14716)	This is constant Graphics.clWebMintcream.
clWebMistyRose (see page 14716)	This is constant Graphics.clWebMistyRose.
clWebMoccasin (see page 14716)	This is constant Graphics.clWebMoccasin.
clWebNavajoWhite (see page 14717)	This is constant Graphics.clWebNavajoWhite.
clWebNavy (see page 14717)	This is constant Graphics.clWebNavy.
clWebOldLace (see page 14717)	This is constant Graphics.clWebOldLace.
clWebOlive (see page 14718)	This is constant Graphics.clWebOlive.
clWebOliveDrab (see page 14718)	This is constant Graphics.clWebOliveDrab.
clWebOrange (see page 14718)	This is constant Graphics.clWebOrange.
clWebOrangeRed (see page 14719)	This is constant Graphics.clWebOrangeRed.

clWebOrchid (see page 14719)	This is constant Graphics.clWebOrchid.
clWebPaleGoldenrod (see page 14719)	This is constant Graphics.clWebPaleGoldenrod.
clWebPaleGreen (see page 14720)	This is constant Graphics.clWebPaleGreen.
clWebPaleTurquoise (see page 14720)	This is constant Graphics.clWebPaleTurquoise.
clWebPaleVioletRed (see page 14720)	This is constant Graphics.clWebPaleVioletRed.
clWebPapayaWhip (see page 14721)	This is constant Graphics.clWebPapayaWhip.
clWebPeachPuff (see page 14721)	This is constant Graphics.clWebPeachPuff.
clWebPeru (see page 14721)	This is constant Graphics.clWebPeru.
clWebPink (see page 14722)	This is constant Graphics.clWebPink.
clWebPlum (see page 14722)	This is constant Graphics.clWebPlum.
clWebPowderBlue (see page 14722)	This is constant Graphics.clWebPowderBlue.
clWebPurple (see page 14723)	This is constant Graphics.clWebPurple.
clWebRed (see page 14723)	This is constant Graphics.clWebRed.
clWebRosyBrown (see page 14723)	This is constant Graphics.clWebRosyBrown.
clWebRoyalBlue (see page 14724)	This is constant Graphics.clWebRoyalBlue.
clWebSaddleBrown (see page 14724)	This is constant Graphics.clWebSaddleBrown.
clWebSalmon (see page 14724)	This is constant Graphics.clWebSalmon.
clWebSandyBrown (see page 14725)	This is constant Graphics.clWebSandyBrown.
clWebSeaGreen (see page 14725)	This is constant Graphics.clWebSeaGreen.
clWebSeashell (see page 14725)	This is constant Graphics.clWebSeashell.
clWebSienna (see page 14726)	This is constant Graphics.clWebSienna.
clWebSilver (see page 14726)	This is constant Graphics.clWebSilver.
clWebSkyBlue (see page 14726)	This is constant Graphics.clWebSkyBlue.
clWebSlateBlue (see page 14727)	This is constant Graphics.clWebSlateBlue.
clWebSlateGray (see page 14727)	This is constant Graphics.clWebSlateGray.
clWebSnow (see page 14727)	This is constant Graphics.clWebSnow.
clWebSpringGreen (see page 14728)	This is constant Graphics.clWebSpringGreen.
clWebSteelBlue (see page 14728)	This is constant Graphics.clWebSteelBlue.
clWebTan (see page 14728)	This is constant Graphics.clWebTan.
clWebTeal (see page 14729)	This is constant Graphics.clWebTeal.
clWebThistle (see page 14729)	This is constant Graphics.clWebThistle.
clWebTomato (see page 14729)	This is constant Graphics.clWebTomato.
clWebTurquoise (see page 14730)	This is constant Graphics.clWebTurquoise.
clWebViolet (see page 14730)	This is constant Graphics.clWebViolet.
clWebWheat (see page 14730)	This is constant Graphics.clWebWheat.
clWebWhite (see page 14731)	This is constant Graphics.clWebWhite.
clWebWhiteSmoke (see page 14731)	This is constant Graphics.clWebWhiteSmoke.
clWebYellow (see page 14731)	This is constant Graphics.clWebYellow.
clWebYellowGreen (see page 14732)	This is constant Graphics.clWebYellowGreen.
clWhite (see page 14732)	Represents the color white.
clWindow (see page 14732)	Represents the default Window background color.
clWindowFrame (see page 14733)	Represents the default Window frame background color.
clWindowText (see page 14733)	Represents the default Window text color.
clYellow (see page 14734)	Represents the color yellow.
cmBlackness (see page 14734)	TCopyMode (see page 14650) value : fills the destination rectangle on the canvas with black.
cmDstInvert (see page 14735)	TCopyMode (see page 14650) value : inverts the image on the canvas and ignores the source.
cmMergeCopy (see page 14735)	TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean AND operator.
cmMergePaint (see page 14736)	TCopyMode (see page 14650) value : combines the inverted source bitmap with the image on the canvas by using the Boolean OR operator.
cmNotSrcCopy (see page 14736)	TCopyMode (see page 14650) value : copies the inverted source bitmap to the canvas.
cmNotSrcErase (see page 14737)	TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean OR operator, and inverts the result.

cmPatCopy (see page 14737)	TCopyMode (see page 14650) value : copies the source pattern to the canvas.
cmPatInvert (see page 14738)	TCopyMode (see page 14650) value : combines the source pattern with the image on the canvas using the Boolean XOR operator.
cmPatPaint (see page 14738)	TCopyMode (see page 14650) value : combines the inverted source bitmap with the source pattern by using the Boolean OR operator. Combines the result of this operation with the image on the canvas by using the Boolean OR operator.
cmSrcAnd (see page 14739)	TCopyMode (see page 14650) value : combines the image on the canvas and source bitmap by using the Boolean AND operator.
cmSrcCopy (see page 14739)	TCopyMode (see page 14650) value : copies the source bitmap to the canvas.
cmSrcErase (see page 14740)	TCopyMode (see page 14650) value : inverts the image on the canvas and combines the result with the source bitmap by using the Boolean AND operator.
cmSrcInvert (see page 14740)	TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean XOR operator.
cmSrcPaint (see page 14741)	TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean OR operator.
cmWhiteness (see page 14741)	TCopyMode (see page 14650) value : fills the destination rectangle on the canvas with white.
ExtendedColorsCount (see page 14742)	The total number of extended colors available
rc3_Cursor (see page 14743)	This is constant Graphics.rc3_Cursor.
rc3_Icon (see page 14743)	This is constant Graphics.rc3_Icon.
rc3_StockIcon (see page 14743)	This is constant Graphics.rc3_StockIcon.
StandardColorsCount (see page 14744)	The total number of standard colors available
WebColorsCount (see page 14745)	The total number of web colors available

Functions

	Name	Description
	AllocPatternBitmap (see page 14608)	Creates a TBitmap (see page 14396) filled with a pattern.
	BytesPerScanline (see page 14609)	This is function Graphics.BytesPerScanline.
	CharsetToIdent (see page 14609)	Obtains the name of a character set.
	ColorToIdent (see page 14610)	Provides the symbolic name of a TColor (see page 14648) value.
	ColorToRGB (see page 14610)	Converts a TColor (see page 14648) value into an RGB representation of the color.
	ColorToString (see page 14611)	Returns a string that represents the name of a TColor (see page 14648) value.
	CopyPalette (see page 14612)	Creates a new palette object that matches an existing palette.
	CreateGrayMappedBmp (see page 14612)	Remaps the standard gray colors in a bitmap with the system grays.
	CreateGrayMappedRes (see page 14613)	Remaps the standard gray colors in a bitmap resource with the system grays.
	CreateMappedBmp (see page 14614)	Changes the color table in a bitmap.
	CreateMappedRes (see page 14614)	Changes the color table in a bitmap resource.
	FreeMemoryContexts (see page 14615)	This is function Graphics.FreeMemoryContexts.
	GetCharsetValues (see page 14615)	Passes the name of every predefined character set string to a callback function.
	GetColorValues (see page 14619)	Passes the name of every predefined color constant to a callback function.
	GetDefFontCharSet (see page 14619)	Returns the character set of the default system font.
	GetDIB (see page 14620)	Returns the info header and image for a device independent bitmap.
	GetDIBSizes (see page 14620)	Returns the size of the info header and of the image for a device independent bitmap.
	GraphicExtension (see page 14621)	Returns the default file-name extension of a graphics object.
	GraphicFileMask (see page 14624)	Returns a file mask that specifies the valid extensions for a graphic class.
	GraphicFilter (see page 14624)	Returns a file filter compatible with the Filter property of an Open or Save dialog.
	IdentToCharset (see page 14627)	Translates the name of a character set constant to the corresponding character set.
	IdentToColor (see page 14627)	Translates the name of a color constant to the corresponding TColor (see page 14648) value.
	PaletteChanged (see page 14628)	This is function Graphics.PaletteChanged.
	StringToColor (see page 14628)	Translates a string representation of a color to the corresponding TColor (see page 14648) value.
	TransparentStretchBlt (see page 14629)	This is function Graphics.TransparentStretchBlt.

Interfaces

	Name	Description
	IChangeNotifier (see page 14606)	IChangeNotifier is the interface used for responding to status changes.

Structs, Records, Enums

	Name	Description
	TBitmapHandleType (see page 14630)	TBitmapHandleType indicates the format used to store the in-memory image of a bitmap.
	TBrushData (see page 14631)	This is record Graphics.TBrushData.
	TBrushStyle (see page 14631)	TBrushStyle specifies the pattern on a brush.
	TCanvasOrientation (see page 14632)	TCanvasOrientation specifies the pixel coordinate system that a canvas uses.
	TCanvasStates (see page 14633)	This is record Graphics.TCanvasStates.
	TCursorOrIcon (see page 14633)	This is record Graphics.TCursorOrIcon.
	TFillMode (see page 14634)	This is record Graphics.TFillMode.
	TFillStyle (see page 14634)	TFillStyle indicates the type of color change defines the boundary of a possibly non-rectangular region n a canvas.
	TFontData (see page 14635)	This is record Graphics.TFontData.
	TFontPitch (see page 14635)	TFontPitch indicates whether the characters in a font have the same width.
	TFontStyle (see page 14636)	TFontStyle and TFontStyles (see page 14653) specify style characteristics of a font.
	TIconRec (see page 14636)	This is record Graphics.TIconRec.
	TPenData (see page 14637)	This is record Graphics.TPenData.
	TPenMode (see page 14637)	TPenMode indicates how the color of a pen interacts with the color of a canvas.
	TPenStyle (see page 14639)	TPenStyle indicates the type of line a pen draws.
	TPixelFormat (see page 14640)	TPixelFormat specifies the format of a bitmap.
	TProgressStage (see page 14641)	TProgressStage indicates the stage of a lengthy operation.
	TResData (see page 14641)	This is record Graphics.TResData.
	TResource (see page 14642)	This is record Graphics.TResource.
	TTextFormats (see page 14642)	This is record Graphics.TTextFormats.
	TTransparentMode (see page 14643)	TTransparentMode indicates how the transparent color of a bitmap is determined.

Types

Name	Description
HENHMETAFILE (see page 14645)	Meta file handle type.
HMETAFILE (see page 14646)	This is type Graphics.HMETAFILE.
PColor (see page 14646)	PColor is a pointer to a TColor (see page 14648) type.
PCursorOrIcon (see page 14646)	This is type Graphics.PCursorOrIcon.
PIconRec (see page 14647)	This is type Graphics.PIconRec.
PResource (see page 14647)	This is type Graphics.PResource.
TCanvasState (see page 14647)	This is type Graphics.TCanvasState.
TColor (see page 14648)	TColor is used to specify the color of a Windows-only control.
TCopyMode (see page 14650)	TCopyMode specifies how a graphical image is copied onto a canvas.
TFontCharset (see page 14651)	TFontCharset represents the character set of a font.
TFontDataName (see page 14652)	This is type Graphics.TFontDataName.
TFontName (see page 14653)	TFontName is a string that holds the typeface name of a font.
TFontStyles (see page 14653)	TFontStyle (see page 14636) and TFontStyles specify style characteristics of a font.
TFontStylesBase (see page 14653)	This is type Graphics.TFontStylesBase.
TGraphicClass (see page 14654)	TGraphicClass defines the metaclass for TGraphic (see page 14516).
TProgressEvent (see page 14655)	TProgressEvent is the type of event handlers that provide feedback during lengthy operations.
TTextFormat (see page 14656)	TTextFormat indicates how a text viewer control displays its contents.

Variables

Name	Description
DDBsOnly (see page 14657)	Determines whether bitmap handles are created as device-dependent bitmaps (DDB).
DefFontData (see page 14658)	This is variable Graphics.DefFontData.
SystemPalette16 (see page 14658)	Contains the 16 VGA system colors.

73.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EInvalidGraphic (see page 14395)	EInvalidGraphic is the exception class for unrecognized graphic files.
	EInvalidGraphicOperation (see page 14396)	EInvalidGraphicOperation is the exception class for illegal operations on graphics.
	TBitmap (see page 14396)	TBitmap is an encapsulation of a Windows bitmap (HBITMAP), including its palette (HPALETTE).
	TBitmapImage (see page 14429)	TBitmapImage is the internal representation of the bitmap image for a TBitmap (see page 14396) object.
	TBrush (see page 14430)	TBrush represents the color and pattern used to fill solid shapes.
	TBrushRecall (see page 14439)	TBrushRecall saves and restores a TBrush (see page 14430) object.
	TCanvas (see page 14441)	TCanvas provides an abstract drawing space for objects that must render their own images.
	TFont (see page 14497)	TFont encapsulates a system font.
	TFontRecall (see page 14514)	TFontRecall saves and restores the properties of a TFont (see page 14497) object.
	TGraphic (see page 14516)	TGraphic is the abstract base class type for objects such as icons, bitmaps, and metafiles that can store and display visual images.
	TGraphicsObject (see page 14532)	TGraphicsObject is the abstract base class for objects which encapsulate a system graphics object: TBrush (see page 14430), TFont (see page 14497), and TPen (see page 14571).
	TIcon (see page 14537)	TIcon is an encapsulation of a Windows icon.
	TIconImage (see page 14547)	TIconImage is the internal representation of the bitmap image for a TIcon (see page 14537) object.
	TMetafile (see page 14549)	TMetafile is an encapsulation of the Win32 Enhanced (see page 14562) metafile.
	TMetafileCanvas (see page 14564)	TMetafileCanvas allows applications to create metafile images from scratch.
	TMetafileImage (see page 14569)	TMetafileImage is the internal representation of the metafile image for a TMetafile (see page 14549) object.
	TPen (see page 14571)	TPen is used to draw lines or outline shapes on a canvas.
	TPenRecall (see page 14582)	TPenRecall saves and restores the properties of a TPen (see page 14571) object.
	TPicture (see page 14584)	TPicture contains a bitmap, icon, metafile graphic, or user-defined graphic.
	TSharedImage (see page 14603)	TSharedImage is the base class for classes that contain images used for graphics objects.

73.1.1 EInvalidGraphic Class

EInvalidGraphic is the exception class for unrecognized graphic files.

Class Hierarchy

Pascal

```
EInvalidGraphic = class(Exception);
```

C++

```
class EInvalidGraphic : public Exception;
```

File

Graphics

Description

EInvalidGraphic is raised when

An application attempts to load a file that is not a valid bitmap, icon, metafile, or user-defined graphic type into a picture.

An application attempts to load a file with an unrecognized extension.

An image does not match the format specified in a call to LoadFromClipboardFormat or SaveToClipboardFormat.

An application attempts to set a bitmap's PixelFormat property to an unsupported value.

73.1.2 EInvalidGraphicOperation Class

EInvalidGraphicOperation is the exception class for illegal operations on graphics.

Class Hierarchy

Pascal

```
EInvalidGraphicOperation = class(Exception);
```

C++

```
class EInvalidGraphicOperation : public Exception;
```

File

Graphics

Description

EInvalidGraphicOperation is raised when an illegal operation is attempted on a graphic. For example, an EInvalidGraphicOperation exception is raised when an application attempts to resize an icon or copy an icon to the Clipboard.

See Also

TCanvas (see page 14441)

TIcon (see page 14537)

LoadFromClipboardFormat

SaveToClipboardFormat

TGraphic (see page 14516)

TGraphic (see page 14516)

73.1.3 TBitmap Class

TBitmap is an encapsulation of a Windows bitmap (HBITMAP), including its palette (HPALETTE).

Class Hierarchy

Pascal

```
TBitmap = class(TGraphic);
```

C++

```
class TBitmap : public TGraphic;
```

File

Graphics

Description

A bitmap is a powerful graphics object used to create, manipulate (scale, scroll, rotate, and paint), and store images in memory and as files on a disk.

TBitmap contains an internal image of the bitmap graphic and automatically manages realization of the palette when drawn.

To draw a bitmap on a canvas, call the Draw (see page 14405) or StretchDraw methods of a TCanvas (see page 14441) object, passing a TBitmap as a parameter.

Creating copies of a TBitmap is very fast since the handle is copied rather than the image. If the image is modified and the handle is shared by more than one TBitmap object, the image is copied before the modification is performed (that is, copy on write).

See Also

TCanvas (see page 14441)

TClipboard (see page 3328)

TGraphic (see page 14516)

TPicture (see page 14584)

Using the Main VCL

73.1.3.1 TBitmap Members

The following tables list the members exposed by TBitmap.

Protected Methods

	Name	Description
	_AddRef (see page 2853)	Increments the reference count for the interfaced object's interface.
	_Release (see page 2854)	Decrements the reference count for the interfaced object's interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Changed (see page 14403)	This is Changed, a member of class TBitmap.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 14520)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	Draw (see page 14405)	This is Draw, a member of class TBitmap.
V	Equals (see page 14521)	This is Equals, a member of class TGraphic.

	GetEmpty (see page 14407)	This is GetEmpty, a member of class TBitmap.
	GetHeight (see page 14407)	This is GetHeight, a member of class TBitmap.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 14407)	This is GetPalette, a member of class TBitmap.
	GetTransparent (see page 14522)	This is GetTransparent, a member of class TGraphic.
	GetWidth (see page 14407)	This is GetWidth, a member of class TBitmap.
	HandleNeeded (see page 14408)	This is HandleNeeded, a member of class TBitmap.
	MaskHandleNeeded (see page 14412)	This is MaskHandleNeeded, a member of class TBitmap.
	PaletteNeeded (see page 14413)	This is PaletteNeeded, a member of class TBitmap.
	Progress (see page 14524)	This is Progress, a member of class TGraphic.
	ReadData (see page 14413)	This is ReadData, a member of class TBitmap.
	SetHeight (see page 14417)	This is SetHeight, a member of class TBitmap.
	SetPalette (see page 14418)	This is SetPalette, a member of class TBitmap.
	SetTransparent (see page 14527)	This is SetTransparent, a member of class TGraphic.
	SetWidth (see page 14418)	This is SetWidth, a member of class TBitmap.
	WriteData (see page 14418)	This is WriteData, a member of class TBitmap.

Public Events

	Name	Description
	OnChange (see page 14531)	Occurs whenever a graphical image changes.
	OnProgress (see page 14531)	Occurs when a graphical image is in the process of changing.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 2854)	Obtains a reference to the Owner's interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 14402)	Copies a new bitmap image to the bitmap object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 14400)	Instantiates a bitmap object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 14401)	Disposes of the instance of the bitmap object.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dormant (see page 14404)	Creates a memory bitmap image in order to release the bitmap handle, forcing the image into DIB format to save resources.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeImage (see page 14405)	Frees the cached file image stored in memory by the bitmap.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	HandleAllocated (see page 14407)	Indicates whether the TBitmap (see page 14396) object has acquired a handle to the underlying GDI object.

	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	LoadFromClipboardFormat (see page 14408)	Loads a bitmap from the Clipboard into the bitmap object.
V	LoadFromFile (see page 14523)	Loads a graphic image stored in a file.
	LoadFromResourceID (see page 14410)	Loads a bitmap from a resource into the bitmap object.
	LoadFromResourceName (see page 14410)	Loads a bitmap resource into the bitmap object.
V	LoadFromStream (see page 14412)	Loads the bitmap from a stream into the bitmap object.
	Mask (see page 14412)	Converts the current bitmap image into a monochrome mask, replacing TransparentColor (see page 14427) with white and every other color with black.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	QueryInterface (see page 2854)	Returns a reference to a specified interface if the object supports that interface.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReleaseHandle (see page 14413)	Returns the handle to the bitmap so that the TBitmap (see page 14396) object no longer knows about the handle.
	ReleaseMaskHandle (see page 14414)	Returns the handle to the bitmap's mask so that the TBitmap (see page 14396) object no longer knows about the mask handle.
	ReleasePalette (see page 14415)	Returns the handle to the bitmap's palette and disassociates the palette from the TBitmap (see page 14396) object.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	SaveToClipboardFormat (see page 14415)	Creates a local copy of the bitmap in Clipboard format.
V	SaveToFile (see page 14525)	Saves a graphics image to a file.
V	SaveToStream (see page 14417)	Saves the bitmap to a stream.
V	SetSize (see page 14418)	Specifies the size of the bitmap.

Public Properties

	Name	Description
R	Canvas (see page 14419)	Provides access to a drawing surface that represents the bitmap.
R	Empty (see page 14528)	Indicates whether the graphics object contains a graphic.
	Handle (see page 14420)	Provides access to the Windows GDI bitmap handle for accessing the GDI bitmap object.
	HandleType (see page 14420)	Indicates whether the bitmap is a device-dependent bitmap, or a device-independent bitmap.
	Height (see page 14528)	Specifies the vertical size of the graphic in pixels.
	IgnorePalette (see page 14421)	Determines whether the bitmap realizes its palette when drawing its image.
	MaskHandle (see page 14421)	Provides access to the Windows GDI bitmap handle for accessing the GDI bitmap object.
	Modified (see page 14528)	Indicates whether the graphics object has been changed or edited.
	Monochrome (see page 14421)	Determines whether the bitmap displays its image in monochrome.
	Palette (see page 14529)	Indicates the color palette of the graphical image.
	PaletteModified (see page 14529)	Indicates whether the palette has changed.
	PixelFormat (see page 14423)	Indicates the bit format of the bitmap image, specifying how the image is displayed and how the pixels of the bitmap image are stored in memory.
R	ScanLine (see page 14425)	Provides indexed access to each line of pixels.
	Transparent (see page 14529)	Indicates whether the image covers its rectangular area.
	TransparentColor (see page 14427)	Determines which color of the bitmap is to be transparent when the bitmap is drawn.
	TransparentMode (see page 14428)	Determines whether the TransparentColor (see page 14427) property's value is automatically calculated or stored with the bitmap object.
	Width (see page 14530)	Determines the maximum width of the graphics object in pixels.

73.1.3.2 TBitmap.Create Constructor

Instantiates a bitmap object.

Pascal

```
constructor Create; override;
```

C++

```
virtual __fastcall TBitmap();
```

Description

Call Create to instantiate a bitmap object at runtime. Create is also called automatically when a bitmap image is loaded into a TImage.

Create allocates memory for a bitmap object, and calls the inherited Create. Then it creates a TBitmapImage (see page 14429) as the internal image that represents the bitmap.

C++ Examples:

```
/*
This example requires a resource file in the sources directory.
*/

#pragma resource "extrares.res"

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *Bitmap1 = new Graphics::TBitmap();
  try
  {
    Bitmap1->LoadFromResourceName((int)HInstance, "Live");
    Canvas->Draw(12,12,Bitmap1);
  }
  catch (...)
  {
    MessageBeep(0);
  }
  delete Bitmap1;
}
```

Delphi Examples:

```
{
LoadFromResourceName example
}

{$R extrares.res}

procedure TForm1.Button1Click(Sender: TObject);
var
 BitMap1 : TBitMap;
begin
  BitMap1 := TBitMap.Create;
  try
    BitMap1.LoadFromResourceName(HInstance,'Live');
    Canvas.Draw(12,12,BitMap1);
  finally
    BitMap1.Free;
  end;
end;
```

See Also

TBitmapImage (see page 14429)

73.1.3.3 TBitmap.Destroy Destructor

Disposes of the instance of the bitmap object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBitmap();
```

Description

Destroy is the destructor for a TBitmap (see page 14396) object.

Do not call the destructor directly in an application. Instead, call Free. Free verifies that the bitmap object is not nil before it calls Destroy.

Destroy releases the internal bitmap image (TBitmapImage (see page 14429) object) and frees the canvas before calling the inherited destructor.

See Also

Free (see page 22300)

delete

TBitmapImage (see page 14429)

73.1.3.4 TBitmap Methods

The methods of the TBitmap class are listed here.

Protected Methods

	Name	Description
	Changed (see page 14403)	This is Changed, a member of class TBitmap.
	Draw (see page 14405)	This is Draw, a member of class TBitmap.
	GetEmpty (see page 14407)	This is GetEmpty, a member of class TBitmap.
	GetHeight (see page 14407)	This is GetHeight, a member of class TBitmap.
	GetPalette (see page 14407)	This is GetPalette, a member of class TBitmap.
	GetWidth (see page 14407)	This is GetWidth, a member of class TBitmap.
	HandleNeeded (see page 14408)	This is HandleNeeded, a member of class TBitmap.
	MaskHandleNeeded (see page 14412)	This is MaskHandleNeeded, a member of class TBitmap.
	PaletteNeeded (see page 14413)	This is PaletteNeeded, a member of class TBitmap.
	ReadData (see page 14413)	This is ReadData, a member of class TBitmap.
	SetHeight (see page 14417)	This is SetHeight, a member of class TBitmap.
	SetPalette (see page 14418)	This is SetPalette, a member of class TBitmap.
	SetWidth (see page 14418)	This is SetWidth, a member of class TBitmap.
	WriteData (see page 14418)	This is WriteData, a member of class TBitmap.

Public Methods

	Name	Description
	Assign (see page 14402)	Copies a new bitmap image to the bitmap object.

	Dormant (see page 14404)	Creates a memory bitmap image in order to release the bitmap handle, forcing the image into DIB format to save resources.
	FreeImage (see page 14405)	Frees the cached file image stored in memory by the bitmap.
	HandleAllocated (see page 14407)	Indicates whether the TBitmap (see page 14396) object has acquired a handle to the underlying GDI object.
V	LoadFromClipboardFormat (see page 14408)	Loads a bitmap from the Clipboard into the bitmap object.
	LoadFromResourceID (see page 14410)	Loads a bitmap from a resource into the bitmap object.
	LoadFromResourceName (see page 14410)	Loads a bitmap resource into the bitmap object.
V	LoadFromStream (see page 14412)	Loads the bitmap from a stream into the bitmap object.
	Mask (see page 14412)	Converts the current bitmap image into a monochrome mask, replacing TransparentColor (see page 14427) with white and every other color with black.
	ReleaseHandle (see page 14413)	Returns the handle to the bitmap so that the TBitmap (see page 14396) object no longer knows about the handle.
	ReleaseMaskHandle (see page 14414)	Returns the handle to the bitmap's mask so that the TBitmap (see page 14396) object no longer knows about the mask handle.
	ReleasePalette (see page 14415)	Returns the handle to the bitmap's palette and disassociates the palette from the TBitmap (see page 14396) object.
V	SaveToClipboardFormat (see page 14415)	Creates a local copy of the bitmap in Clipboard format.
V	SaveToStream (see page 14417)	Saves the bitmap to a stream.
V	SetSize (see page 14418)	Specifies the size of the bitmap.

73.1.3.4.1 TBitmap.Assign Method

Copies a new bitmap image to the bitmap object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Assign copies the bitmap image contained in Source to the bitmap object. If Source is not a bitmap, Assign calls the inherited Assign method, which can copy an image from any class that knows how to copy to a TBitmap (see page 14396) object. If the bitmap needs to be changed, the actual bitmap image is copied before the changes are made (copy on write).

Note: An object of one type can always be assigned to another object of the same type. Also, the Source can be of type TPicture (see page 14584) if the Graphic property of the picture is a bitmap.

C++ Examples:

```
/*
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
Note: For the C++ Builder, capitalization matters for the file
name and path.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *Bitmap1 = new Graphics::TBitmap();
  Graphics::TBitmap *Bitmap2 = new Graphics::TBitmap();
  try
  {
    Bitmap1->LoadFromFile("..\\FACTORY.BMP");
    Bitmap2->Assign(Bitmap1);     // Copy Bitmap1 into Bitmap2
    Bitmap2->Dormant();           // Free up GDI resources
```

```
    Bitmap2->FreeImage();          // Free up Memory.
    Canvas->Draw(20,20,Bitmap2);  // Note that previous calls don't lose the image
    Bitmap2->Monochrome = true;
    Canvas->Draw(80,80,Bitmap2);
    Bitmap2->ReleaseHandle();       // This will actually lose the bitmap;
  }
  catch (...)
  {
    MessageBeep(0);
  }
  delete Bitmap1;
  delete Bitmap2;
}
```

Delphi Examples:

```
{
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
}
procedure TForm1.Button1Click(Sender: TObject);
var
 BitMap1,BitMap2 : TBitMap;
 MyFormat : Word;
begin
   BitMap2 := TBitMap.Create;
   BitMap1 := TBitMap.Create;
try
   BitMap1.LoadFromFile('factory.bmp');
   BitMap2.Assign(BitMap1);     // Copy BitMap1 into BitMap2
   BitMap2.Dormant;             // Free up GDI resources
   BitMap2.FreeImage;           // Free up Memory.
   Canvas.Draw(20,20,BitMap2);  // Note that previous calls don't lose the image
   BitMap2.Monochrome := true;
   Canvas.Draw(80,80,BitMap2);
   BitMap2.ReleaseHandle;       // This will actually lose the bitmap;
 finally
   BitMap1.Free;
   BitMap2.Free;
 end;
end;
```

See Also

Assign (see page 2930)

TPicture (see page 14584)

Graphic (see page 14600)

73.1.3.4.2 TBitmap.Changed Method

Pascal

```
procedure Changed(Sender: TObject); override;
```

C++

```
virtual __fastcall Changed(TObject * Sender);
```

Description

This is Changed, a member of class TBitmap.

73.1.3.4.3 TBitmap.Dormant Method

Creates a memory bitmap image in order to release the bitmap handle, forcing the image into DIB format to save resources.

Pascal

```
procedure Dormant;
```

C++

```
__fastcall Dormant();
```

Description

Use Dormant to change the format of the bitmap in memory thereby reducing the amount of GDI resources used by the application.

Dormant creates a bitmap image in memory using a memory stream object. This preserves the image so that the bitmap can then free the HBITMAP (accessed through the Handle (see page 14420) property) that was assigned to it.

DIB handles may use fewer Win95 GDI resources than DDB, but DIBs may also use more memory than DDBs, depending on the current video driver and mode.

C++ Examples:

```
/*
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
Note: For the C++ Builder, capitalization matters for the file
name and path.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *Bitmap1 = new Graphics::TBitmap();
  Graphics::TBitmap *Bitmap2 = new Graphics::TBitmap();
  try
  {
    Bitmap1->LoadFromFile("..\\FACTORY.BMP");
    Bitmap2->Assign(Bitmap1);     // Copy Bitmap1 into Bitmap2
    Bitmap2->Dormant();           // Free up GDI resources
    Bitmap2->FreeImage();         // Free up Memory.
    Canvas->Draw(20,20,Bitmap2);  // Note that previous calls don't lose the image
    Bitmap2->Monochrome = true;
    Canvas->Draw(80,80,Bitmap2);
    Bitmap2->ReleaseHandle();       // This will actually lose the bitmap;
  }
  catch (...)
  {
    MessageBeep(0);
  }
  delete Bitmap1;
  delete Bitmap2;
}
```

Delphi Examples:

```
{
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
}
procedure TForm1.Button1Click(Sender: TObject);
var
```

```
 BitMap1,BitMap2 : TBitMap;
 MyFormat : Word;
begin
   BitMap2 := TBitMap.Create;
   BitMap1 := TBitMap.Create;
try
   BitMap1.LoadFromFile('factory.bmp');
   BitMap2.Assign(BitMap1);     // Copy BitMap1 into BitMap2
   BitMap2.Dormant;             // Free up GDI resources
   BitMap2.FreeImage;           // Free up Memory.
   Canvas.Draw(20,20,BitMap2);  // Note that previous calls don't lose the image
   BitMap2.Monochrome := true;
   Canvas.Draw(80,80,BitMap2);
   BitMap2.ReleaseHandle;       // This will actually lose the bitmap;
 finally
   BitMap1.Free;
   BitMap2.Free;
 end;
end;
```

See Also

Handle (see page 14420)

TBitmapImage (see page 14429)

TMemoryStream (see page 2902)

73.1.3.4.4 TBitmap.Draw Method

Pascal

```
procedure Draw(ACanvas: TCanvas; const Rect: TRect); override;
```

C++

```
virtual __fastcall Draw(TCanvas ACanvas, const TRect Rect);
```

Description

This is Draw, a member of class TBitmap.

73.1.3.4.5 TBitmap.FreeImage Method

Frees the cached file image stored in memory by the bitmap.

Pascal

```
procedure FreeImage;
```

C++

```
__fastcall FreeImage();
```

Description

Use FreeImage to reduce the memory requirements of an application when color depth and pixel format are not an issue. Freeing the image releases the memory allocated for the bitmap image when it was originally loaded to disk. Consequently, some of the original pixel format of the bitmap is lost (for example, if you changed its format to a DIB) as well as the color depth of the bitmap.

When a bitmap is loaded into a bitmap object, the bitmap object creates an image of the loaded bitmap in memory. If the bitmap isn't changed, the memory image is used when saving the bitmap, to verify that the bitmap has not lost color depth or changed the pixel format.

C++ Examples:

```
/*
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
Note: For the C++ Builder, capitalization matters for the file
name and path.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *Bitmap1 = new Graphics::TBitmap();
  Graphics::TBitmap *Bitmap2 = new Graphics::TBitmap();
  try
  {
    Bitmap1->LoadFromFile("..\\FACTORY.BMP");
    Bitmap2->Assign(Bitmap1);     // Copy Bitmap1 into Bitmap2
    Bitmap2->Dormant();           // Free up GDI resources
    Bitmap2->FreeImage();         // Free up Memory.
    Canvas->Draw(20,20,Bitmap2);  // Note that previous calls don't lose the image
    Bitmap2->Monochrome = true;
    Canvas->Draw(80,80,Bitmap2);
    Bitmap2->ReleaseHandle();       // This will actually lose the bitmap;
  }
  catch (...)
  {
    MessageBeep(0);
  }
  delete Bitmap1;
  delete Bitmap2;
}
```

Delphi Examples:

```
{
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
}
procedure TForm1.Button1Click(Sender: TObject);
var
 BitMap1,BitMap2 : TBitMap;
 MyFormat : Word;
begin
   BitMap2 := TBitMap.Create;
   BitMap1 := TBitMap.Create;
try
   BitMap1.LoadFromFile('factory.bmp');
   BitMap2.Assign(BitMap1);     // Copy BitMap1 into BitMap2
   BitMap2.Dormant;             // Free up GDI resources
   BitMap2.FreeImage;           // Free up Memory.
   Canvas.Draw(20,20,BitMap2);  // Note that previous calls don't lose the image
   BitMap2.Monochrome := true;
   Canvas.Draw(80,80,BitMap2);
   BitMap2.ReleaseHandle;       // This will actually lose the bitmap;
 finally
   BitMap1.Free;
   BitMap2.Free;
 end;
end;
```

73.1.3.4.6 TBitmap.GetEmpty Method

Pascal

```
function GetEmpty: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetEmpty();
```

Description

This is GetEmpty, a member of class TBitmap.

73.1.3.4.7 TBitmap.GetHeight Method

Pascal

```
function GetHeight: Integer; override;
```

C++

```
virtual __fastcall int GetHeight();
```

Description

This is GetHeight, a member of class TBitmap.

73.1.3.4.8 TBitmap.GetPalette Method

Pascal

```
function GetPalette: HPALETTE; override;
```

C++

```
virtual __fastcall HPALETTE GetPalette();
```

Description

This is GetPalette, a member of class TBitmap.

73.1.3.4.9 TBitmap.GetWidth Method

Pascal

```
function GetWidth: Integer; override;
```

C++

```
virtual __fastcall int GetWidth();
```

Description

This is GetWidth, a member of class TBitmap.

73.1.3.4.10 TBitmap.HandleAllocated Method

Indicates whether the TBitmap (see page 14396) object has acquired a handle to the underlying GDI object.

Pascal

```
function HandleAllocated: Boolean;
```

C++

```
__fastcall Boolean HandleAllocated();
```

Description

Use HandleAllocated to determine whether the Handle (see page 14420) property is set to an HBITMAP value. HandleAllocated indicates whether the underlying GDI object has already been created. Use HandleAllocated rather than reading the Handle (see page 14420) property. When an application reads the Handle (see page 14420) property, it automatically creates a bitmap and returns its handle if the underlying GDI object does not already exist.

See Also

Handle (see page 14420)

73.1.3.4.11 TBitmap.HandleNeeded Method

Pascal

```
procedure HandleNeeded;
```

C++

```
__fastcall HandleNeeded();
```

Description

This is HandleNeeded, a member of class TBitmap.

73.1.3.4.12 TBitmap.LoadFromClipboardFormat Method

Loads a bitmap from the Clipboard into the bitmap object.

Pascal

```
procedure LoadFromClipboardFormat(AFormat: Word; AData: THandle; APalette: HPALETTE); override;
```

C++

```
virtual __fastcall LoadFromClipboardFormat(Word AFormat, THandle AData, HPALETTE APalette);
```

Description

LoadFromClipboardFormat is called if the bitmap is registered with the TPicture (see page 14584) object using the RegisterClipboardFormat method.

LoadFromClipboardFormat replaces the current image with the data pointed to by the AData parameter. The palette for the bitmap is specified by the APalette parameter.

C++ Examples:

```
/*
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
*/
#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClipboard *cb = Clipboard();
  if (cb->HasFormat(CF_BITMAP))
  {
    Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
```

```
    try
    {
      Bitmap->LoadFromClipboardFormat(CF_BITMAP, cb->GetAsHandle(CF_BITMAP), 0);
      Canvas->Draw(5,5,Bitmap);
    }
    catch (...)
    {
      MessageBeep(0);
      ShowMessage("Error reading image from clipboard!");
    }
    delete Bitmap;
    cb->Clear();
  }
  else
  {
    MessageBeep(0);
    ShowMessage("Cannot find image in clipboard!");
  }
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  unsigned int DataHandle;
  HPALETTE APalette;
  unsigned short MyFormat;
  Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
  try
  {
    Bitmap->LoadFromFile("C:\\Program Files\\Common Files\\CodeGear
Shared\\Images\\Splash\\256Color\\FACTORY.BMP");
    // generate a clipboard format, with data and palette
    Bitmap->SaveToClipboardFormat(
      MyFormat,
      DataHandle,
      APalette);
    // save the data to the clipboard using that format and
    // the generated data
    Clipboard()->SetAsHandle(MyFormat,DataHandle);
  }
  catch (...)
  {
     ShowMessage("Failed to copy image to clipboard!");
  }
  delete Bitmap;
}
```

Delphi Examples:

```
{
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitmap;
  s : string;
  Icon: TIcon;
begin
 Bitmap := TBitMap.Create;
 try
   Image1.Picture.RegisterClipboardFormat(cf_BitMap,TIcon);
   Bitmap.LoadFromClipBoardFormat(
     cf_BitMap,ClipBoard.GetAsHandle(cf_Bitmap),0);
   Canvas.draw(0,0,Bitmap);
```

```
  finally
    Bitmap.free;
    Clipboard.Clear;
  end;
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  MyFormat : Word;
  Bitmap : TBitMap;
  AData : THandle;
  APalette : HPALETTE;
begin
  Bitmap := TBitmap.Create;
  try
    Bitmap.LoadFromFile('c:\Program Files\Common Files\CodeGear
Shared\Images\Splash\256color\factory.bmp');
    Bitmap.SaveToClipBoardFormat(
      MyFormat,
      AData,
      APalette);
    ClipBoard.SetAsHandle(MyFormat,AData);
  finally
    Bitmap.Free;
  end;
end;
```

See Also

TClipboard (see page 3328)

TPicture (see page 14584)

RegisterClipboardFormat (see page 14592)

73.1.3.4.13 TBitmap.LoadFromResourceID Method

Loads a bitmap from a resource into the bitmap object.

Pascal

```
procedure LoadFromResourceID(Instance: THandle; ResID: Integer);
```

C++

```
__fastcall LoadFromResourceID(THandle Instance, int ResID);
```

Description

Use LoadFromResourceID to load a specified bitmap resource along with palette information from a module's executable file.

Instance is the handle of the module that contains the resource.

ResID is the resource ID for the bitmap.

See Also

LoadFromResourceName (see page 14410)

73.1.3.4.14 TBitmap.LoadFromResourceName Method

Loads a bitmap resource into the bitmap object.

Pascal

```
procedure LoadFromResourceName(Instance: THandle; const ResName: String);
```

C++

```
__fastcall LoadFromResourceName(THandle Instance, const AnsiString ResName);
```

Description

LoadFromResourceName loads the specified bitmap resource along with palette information from a module's executable file.

Instance is the handle of the module that contains the resource.

ResName is the name of the resource to load.

Note: Use this routine to load bitmaps from RES files instead of the LoadBitmap API. LoadBitmap does not support 256-color images.

C++ Examples:

```
/*
This example requires a resource file in the sources directory.
*/

#pragma resource "extrares.res"

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *Bitmap1 = new Graphics::TBitmap();
  try
  {
    Bitmap1->LoadFromResourceName((int)HInstance, "Live");
    Canvas->Draw(12,12,Bitmap1);
  }
  catch (...)
  {
    MessageBeep(0);
  }
  delete Bitmap1;
}
```

Delphi Examples:

```
{
LoadFromResourceName example
}

{$R extrares.res}

procedure TForm1.Button1Click(Sender: TObject);
var
 BitMap1 : TBitMap;
begin
  BitMap1 := TBitMap.Create;
  try
    BitMap1.LoadFromResourceName(HInstance,'Live');
    Canvas.Draw(12,12,BitMap1);
  finally
    BitMap1.Free;
  end;
end;
```

See Also

LoadFromResourceID (see page 14410)

HInstance

73.1.3.4.15 TBitmap.LoadFromStream Method

Loads the bitmap from a stream into the bitmap object.

Pascal

```
procedure LoadFromStream(Stream: TStream); override;
```

C++

```
virtual __fastcall LoadFromStream(TStream Stream);
```

Description

Use LoadFromStream to load the bitmap image from a stream. The Stream parameter specifies the stream from which to read the bitmap image. For example, use LoadFromStream to load a bitmap image from a BLOB stream that reads from a graphic field in a dataset.

See Also

LoadFromClipboardFormat (see page 14408)

LoadFromResourceName (see page 14410)

LoadFromResourceID (see page 14410)

LoadFromFile (see page 14523)

SaveToStream (see page 14417)

73.1.3.4.16 TBitmap.Mask Method

Converts the current bitmap image into a monochrome mask, replacing TransparentColor (see page 14427) with white and every other color with black.

Pascal

```
procedure Mask(TransparentColor: TColor);
```

C++

```
__fastcall Mask(TColor TransparentColor);
```

Description

Use Mask to produce a monochrome mask bitmap based on a given transparent color. Mask produces the same image that MaskHandle (see page 14421) does, except that the resulting mask image replaces the image in the TBitmap (see page 14396) object, so it only makes sense to call Mask once. Use MaskHandle (see page 14421) when only a bitmap handle of the mask image is needed.

See Also

ReleaseMaskHandle (see page 14414)

73.1.3.4.17 TBitmap.MaskHandleNeeded Method

Pascal

```
procedure MaskHandleNeeded;
```

C++

```
__fastcall MaskHandleNeeded();
```

Description

This is MaskHandleNeeded, a member of class TBitmap.

73.1.3.4.18 TBitmap.PaletteNeeded Method

Pascal

```
procedure PaletteNeeded;
```

C++

```
__fastcall PaletteNeeded();
```

Description

This is PaletteNeeded, a member of class TBitmap.

73.1.3.4.19 TBitmap.ReadData Method

Pascal

```
procedure ReadData(Stream: TStream); override;
```

C++

```
virtual __fastcall ReadData(TStream Stream);
```

Description

This is ReadData, a member of class TBitmap.

73.1.3.4.20 TBitmap.ReleaseHandle Method

Returns the handle to the bitmap so that the TBitmap (see page 14396) object no longer knows about the handle.

Pascal

```
function ReleaseHandle: HBITMAP;
```

C++

```
__fastcall HBITMAP ReleaseHandle();
```

Description

Use ReleaseHandle to disassociate the bitmap from the bitmap handle. Use it when you need to give a bitmap handle to a routine or object that will assume ownership (or destroy) the bitmap handle.

C++ Examples:

```
/*
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
Note: For the C++ Builder, capitalization matters for the file
name and path.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *Bitmap1 = new Graphics::TBitmap();
  Graphics::TBitmap *Bitmap2 = new Graphics::TBitmap();
  try
  {
```

```
      Bitmap1->LoadFromFile("..\\FACTORY.BMP");
      Bitmap2->Assign(Bitmap1);     // Copy Bitmap1 into Bitmap2
      Bitmap2->Dormant();           // Free up GDI resources
      Bitmap2->FreeImage();         // Free up Memory.
      Canvas->Draw(20,20,Bitmap2);  // Note that previous calls don't lose the image
      Bitmap2->Monochrome = true;
      Canvas->Draw(80,80,Bitmap2);
      Bitmap2->ReleaseHandle();       // This will actually lose the bitmap;
    }
    catch (...)
    {
      MessageBeep(0);
    }
    delete Bitmap1;
    delete Bitmap2;
  }
```

Delphi Examples:

```
{
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
}
procedure TForm1.Button1Click(Sender: TObject);
var
 BitMap1,BitMap2 : TBitMap;
 MyFormat : Word;
begin
   BitMap2 := TBitMap.Create;
   BitMap1 := TBitMap.Create;
try
   BitMap1.LoadFromFile('factory.bmp');
   BitMap2.Assign(BitMap1);     // Copy BitMap1 into BitMap2
   BitMap2.Dormant;             // Free up GDI resources
   BitMap2.FreeImage;           // Free up Memory.
   Canvas.Draw(20,20,BitMap2);  // Note that previous calls don't lose the image
   BitMap2.Monochrome := true;
   Canvas.Draw(80,80,BitMap2);
   BitMap2.ReleaseHandle;       // This will actually lose the bitmap;
 finally
   BitMap1.Free;
   BitMap2.Free;
 end;
end;
```

See Also

ReleaseMaskHandle (see page 14414)

Handle (see page 14420)

73.1.3.4.21 TBitmap.ReleaseMaskHandle Method

Returns the handle to the bitmap's mask so that the TBitmap (see page 14396) object no longer knows about the mask handle.

Pascal

```
function ReleaseMaskHandle: HBITMAP;
```

C++

```
__fastcall HBITMAP ReleaseMaskHandle();
```

Description

Use ReleaseMaskHandle to disassociate the bitmap object from the bitmap mask handle.

See Also

ReleaseHandle (see page 14413)

Handle (see page 14420)

Mask (see page 14412)

73.1.3.4.22 TBitmap.ReleasePalette Method

Returns the handle to the bitmap's palette and disassociates the palette from the TBitmap (see page 14396) object.

Pascal

```
function ReleasePalette: HPALETTE;
```

C++

```
__fastcall HPALETTE ReleasePalette();
```

Description

Use ReleasePalette to disassociate the palette from the bitmap image.

73.1.3.4.23 TBitmap.SaveToClipboardFormat Method

Creates a local copy of the bitmap in Clipboard format.

Pascal

```
procedure SaveToClipboardFormat(var Format: Word; var Data: THandle; var APalette: HPALETTE);
override;
```

C++

```
virtual __fastcall SaveToClipboardFormat(Word Format, THandle Data, HPALETTE APalette);
```

Description

Use SaveToClipboardFormat to copy the bitmap to a Clipboard format. The bitmap's palette is returned in the APalette parameter, the format in the AFormat parameter, and a handle to the data in the AData parameter. Before the bitmap can be saved, an application must have registered the format with the TBitmap (see page 14396) object using the RegisterClipboardFormat method.

C++ Examples:

```
/*
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
*/
#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClipboard *cb = Clipboard();
  if (cb->HasFormat(CF_BITMAP))
  {
    Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
    try
    {
```

```
      Bitmap->LoadFromClipboardFormat(CF_BITMAP, cb->GetAsHandle(CF_BITMAP), 0);
      Canvas->Draw(5,5,Bitmap);
    }
    catch (...)
    {
      MessageBeep(0);
      ShowMessage("Error reading image from clipboard!");
    }
    delete Bitmap;
    cb->Clear();
  }
  else
  {
    MessageBeep(0);
    ShowMessage("Cannot find image in clipboard!");
  }
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  unsigned int DataHandle;
  HPALETTE APalette;
  unsigned short MyFormat;
  Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
  try
  {
    Bitmap->LoadFromFile("C:\\Program Files\\Common Files\\CodeGear
Shared\\Images\\Splash\\256Color\\FACTORY.BMP");
    // generate a clipboard format, with data and palette
    Bitmap->SaveToClipboardFormat(
      MyFormat,
      DataHandle,
      APalette);
    // save the data to the clipboard using that format and
    // the generated data
    Clipboard()->SetAsHandle(MyFormat,DataHandle);
  }
  catch (...)
  {
     ShowMessage("Failed to copy image to clipboard!");
  }
  delete Bitmap;
}
```

Delphi Examples:

```
{
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitmap;
  s : string;
  Icon: TIcon;
begin
 Bitmap := TBitMap.Create;
 try
   Image1.Picture.RegisterClipboardFormat(cf_BitMap,TIcon);
   Bitmap.LoadFromClipBoardFormat(
     cf_BitMap,ClipBoard.GetAsHandle(cf_Bitmap),0);
   Canvas.draw(0,0,Bitmap);
 finally
   Bitmap.free;
```

```
    Clipboard.Clear;
  end;
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  MyFormat : Word;
  Bitmap : TBitMap;
  AData : THandle;
  APalette : HPALETTE;
begin
  Bitmap := TBitmap.Create;
  try
    Bitmap.LoadFromFile('c:\Program Files\Common Files\CodeGear
Shared\Images\Splash\256color\factory.bmp');
    Bitmap.SaveToClipBoardFormat(
      MyFormat,
      AData,
      APalette);
    ClipBoard.SetAsHandle(MyFormat,AData);
  finally
    Bitmap.Free;
  end;
end;
```

See Also

RegisterClipboardFormat (see page 14592)

LoadFromClipboardFormat (see page 14408)

73.1.3.4.24 TBitmap.SaveToStream Method

Saves the bitmap to a stream.

Pascal

```
procedure SaveToStream(Stream: TStream); override;
```

C++

```
virtual __fastcall SaveToStream(TStream Stream);
```

Description

Use SaveToStream to write the bitmap image to the stream specified by the Stream parameter. For example, specify a TBlobStream object as the Stream parameter to save the bitmap image to a graphic field in a dataset.

See Also

LoadFromStream (see page 14412)

73.1.3.4.25 TBitmap.SetHeight Method

Pascal

```
procedure SetHeight(Value: Integer); override;
```

C++

```
virtual __fastcall SetHeight(int Value);
```

Description

This is SetHeight, a member of class TBitmap.

73.1.3.4.26 TBitmap.SetPalette Method

Pascal

```
procedure SetPalette(Value: HPALETTE); override;
```

C++

```
virtual __fastcall SetPalette(HPALETTE Value);
```

Description

This is SetPalette, a member of class TBitmap.

73.1.3.4.27 TBitmap.SetSize Method

Specifies the size of the bitmap.

Pascal

```
procedure SetSize(AWidth: Integer; AHeight: Integer); override;
```

C++

```
virtual __fastcall SetSize(int AWidth, int AHeight);
```

Description

Use the SetSize method to set both the height and width of the bitmap. This results in better performance than setting the height and width separately.

73.1.3.4.28 TBitmap.SetWidth Method

Pascal

```
procedure SetWidth(Value: Integer); override;
```

C++

```
virtual __fastcall SetWidth(int Value);
```

Description

This is SetWidth, a member of class TBitmap.

73.1.3.4.29 TBitmap.WriteData Method

Pascal

```
procedure WriteData(Stream: TStream); override;
```

C++

```
virtual __fastcall WriteData(TStream Stream);
```

Description

This is WriteData, a member of class TBitmap.

73.1.3.5 TBitmap Properties

The properties of the TBitmap class are listed here.

Public Properties

	Name	Description
R	Canvas (see page 14419)	Provides access to a drawing surface that represents the bitmap.
	Handle (see page 14420)	Provides access to the Windows GDI bitmap handle for accessing the GDI bitmap object.
	HandleType (see page 14420)	Indicates whether the bitmap is a device-dependent bitmap, or a device-independent bitmap.
	IgnorePalette (see page 14421)	Determines whether the bitmap realizes its palette when drawing its image.
	MaskHandle (see page 14421)	Provides access to the Windows GDI bitmap handle for accessing the GDI bitmap object.
	Monochrome (see page 14421)	Determines whether the bitmap displays its image in monochrome.
	PixelFormat (see page 14423)	Indicates the bit format of the bitmap image, specifying how the image is displayed and how the pixels of the bitmap image are stored in memory.
R	ScanLine (see page 14425)	Provides indexed access to each line of pixels.
	TransparentColor (see page 14427)	Determines which color of the bitmap is to be transparent when the bitmap is drawn.
	TransparentMode (see page 14428)	Determines whether the TransparentColor (see page 14427) property's value is automatically calculated or stored with the bitmap object.

73.1.3.5.1 TBitmap.Canvas Property

Provides access to a drawing surface that represents the bitmap.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Canvas allows drawing on the bitmap by providing a T Canvas object for this purpose. Drawing on the canvas effectively modifies the underlying bitmap image pixels. Any canvas operation is valid on a bitmap (not just Draw (see page 14405) and StretchDraw) including line drawing, rectangles, and circles. The bitmap object is passed as a parameter to these methods.

A canvas object is created automatically for the bitmap and the property is read-only.

C++ Examples:

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *bitmap = new Graphics::TBitmap();
  try
  {
    bitmap->LoadFromFile("..\\FACTORY.BMP ");
    bitmap->Transparent = true;
    bitmap->TransparentColor = bitmap->Canvas->Pixels[50][50];
    Form1->Canvas->Draw( 0, 0, bitmap);
    bitmap->TransparentMode = tmAuto;
    Form1->Canvas->Draw(50, 50, bitmap);
  }
  catch (...)
  {
    ShowMessage("Could not load or display bitmap");
  }
  delete bitmap;
```

Delphi Examples:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitMap;
```

```
begin
  Bitmap := TBitmap.Create;
  try
    with Bitmap do begin
      LoadFromFile('factory.bmp');
      Transparent := True;
      TransParentColor := BitMap.canvas.pixels[50,50];
      Form1.Canvas.Draw(0,0,BitMap);
      TransparentMode := tmAuto;
      Form1.Canvas.Draw(50,50,BitMap);
    end;
  finally
    Bitmap.Free;
  end;
end;
```

See Also

TCanvas (see page 14441)

Draw (see page 14454)

StretchDraw (see page 14472)

73.1.3.5.2 TBitmap.Handle Property

Provides access to the Windows GDI bitmap handle for accessing the GDI bitmap object.

Pascal

```
property Handle: HBITMAP;
```

C++

```
__property HBITMAP Handle;
```

Description

Use Handle to call a Windows API function that requires the handle of a bitmap object. Pass Handle as the bitmap handle parameter to these functions.

Handle is the HBITMAP encapsulated by the bitmap object. Avoid grabbing the handle directly since it causes the HBITMAP to be copied if more than one TBitmap (see page 14396) shares the handle.

Warning: Be careful when giving the handle to an object or routine. If the receiver takes ownership (and destroys) the bitmap handle, call TBitmap (see page 14396).::ReleaseHandle (see page 14413).

See Also

HandleType (see page 14420)

MaskHandle (see page 14421)

HandleAllocated (see page 14407)

73.1.3.5.3 TBitmap.HandleType Property

Indicates whether the bitmap is a device-dependent bitmap, or a device-independent bitmap.

Pascal

```
property HandleType: TBitmapHandleType;
```

C++

```
__property TBitmapHandleType HandleType;
```

Description

HandleType is used to find or modify the type of the bitmap. Device-dependent bitmaps (DDBs) may be faster to draw on the screen, but may be stored in memory in a device-specific format. Device-independent bitmaps (DIBs) are stored in memory in a standard format supported by all devices (including printers).

See Also

Handle (see page 14420)

73.1.3.5.4 TBitmap.IgnorePalette Property

Determines whether the bitmap realizes its palette when drawing its image.

Pascal

```
property IgnorePalette: Boolean;
```

C++

```
__property Boolean IgnorePalette;
```

Description

Use IgnorePalette when speed of drawing is a priority. When IgnorePalette is true, the bitmap does not realize its palette when drawing itself, resulting in lower picture quality on 256-color video drivers, but faster drawing of the bitmap image.

Note:

See Also

TBitmapImage (see page 14429)

TDBCtrlGrid (see page 8168)

TDBImage (see page 8813)

73.1.3.5.5 TBitmap.MaskHandle Property

Provides access to the Windows GDI bitmap handle for accessing the GDI bitmap object.

Pascal

```
property MaskHandle: HBITMAP;
```

C++

```
__property HBITMAP MaskHandle;
```

Description

Use MaskHandle to call a Windows API function that requires the handle of a bitmap object. Pass MaskHandle as the bitmap handle parameter to these functions. MaskHandle is the HBITMAP encapsulated by the bitmap object's mask.

See Also

Handle (see page 14420)

ReleaseMaskHandle (see page 14414)

73.1.3.5.6 TBitmap.Monochrome Property

Determines whether the bitmap displays its image in monochrome.

Pascal

```
property Monochrome: Boolean;
```

C++

```
__property Boolean Monochrome;
```

Description

If Monochrome is true if the bitmap displays as a monochrome bitmap. Monochrome is false if the bitmap displays in color, that is, if it contains more than one bit per pixel.

Note:

C++ Examples:

```
/*
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
Note: For the C++ Builder, capitalization matters for the file
name and path.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *Bitmap1 = new Graphics::TBitmap();
  Graphics::TBitmap *Bitmap2 = new Graphics::TBitmap();
  try
  {
    Bitmap1->LoadFromFile("..\\FACTORY.BMP");
    Bitmap2->Assign(Bitmap1);     // Copy Bitmap1 into Bitmap2
    Bitmap2->Dormant();           // Free up GDI resources
    Bitmap2->FreeImage();         // Free up Memory.
    Canvas->Draw(20,20,Bitmap2);  // Note that previous calls don't lose the image
    Bitmap2->Monochrome = true;
    Canvas->Draw(80,80,Bitmap2);
    Bitmap2->ReleaseHandle();       // This will actually lose the bitmap;
  }
  catch (...)
  {
    MessageBeep(0);
  }
  delete Bitmap1;
  delete Bitmap2;
}
```

Delphi Examples:

```
{
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
}
procedure TForm1.Button1Click(Sender: TObject);
var
 BitMap1,BitMap2 : TBitMap;
 MyFormat : Word;
begin
   BitMap2 := TBitMap.Create;
   BitMap1 := TBitMap.Create;
try
   BitMap1.LoadFromFile('factory.bmp');
   BitMap2.Assign(BitMap1);     // Copy BitMap1 into BitMap2
```

```
    BitMap2.Dormant;             // Free up GDI resources
    BitMap2.FreeImage;           // Free up Memory.
    Canvas.Draw(20,20,BitMap2);  // Note that previous calls don't lose the image
    BitMap2.Monochrome := true;
    Canvas.Draw(80,80,BitMap2);
    BitMap2.ReleaseHandle;       // This will actually lose the bitmap;
  finally
    BitMap1.Free;
    BitMap2.Free;
  end;
end;
```

73.1.3.5.7 TBitmap.PixelFormat Property

Indicates the bit format of the bitmap image, specifying how the image is displayed and how the pixels of the bitmap image are stored in memory.

Pascal

```
property PixelFormat: TPixelFormat;
```

C++

```
__property TPixelFormat PixelFormat;
```

Description

Use PixelFormat to change a TBitmap (see page 14396)'s internal image to a particular memory format and color depth, or to find out what memory format and color depth a TBitmap (see page 14396) is using.

For example, PixelFormat can be used to set the pixel format of the bitmap image to 8-bit for video drivers that cannot display the native format of a bitmap image.

Note: The PixelFormat of a JPEG image object applies to the bitmap if the JPEG image is copied to it.

Changing the pixel format is most commonly used with ScanLine (see page 14425), because your code must decode the pixel data accessed by ScanLine (see page 14425). Image-editing tools usually use one pixel for all internal image operations and copy the results to the screen (in whatever format) as the last step.

C++ Examples:

```
/*
This example shows how to draw directly to a Bitmap.  It
loads a bitmap from a file and then copies it to another
bitmap twice it's size.  Then the two bitmaps are
displayed on the form canvas.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
  Graphics::TBitmap *BigBitmap = new Graphics::TBitmap();
  TRGBTriple *ptr, *bigPtr;   // use a (byte *) for pf8bit color
  TPixelFormat pixForm, bigpixForm;
  try
  {
    Bitmap->LoadFromFile("../littlefac.bmp");
    pixForm = Bitmap->PixelFormat;
    bigpixForm  = BigBitmap->PixelFormat;
    Bitmap->PixelFormat = pf24bit;
    BigBitmap->PixelFormat = pf24bit;
    BigBitmap->Height = Bitmap->Height * 2;
    BigBitmap->Width = Bitmap->Width * 2;
    for (int y = 0; y < Bitmap->Height; y++)
    {
      ptr = (TRGBTriple *)Bitmap->ScanLine[y];
      for (int x = 0; x < Bitmap->Width; x++)
```

```
        {
          int bx = x * 2;
          int by = y * 2;
          bigPtr = (TRGBTriple *)BigBitmap->ScanLine[by];
          bigPtr[bx] = ptr[x];
          bigPtr[bx + 1] = ptr[x];
          bigPtr = (TRGBTriple *)BigBitmap->ScanLine[by + 1];
          bigPtr[bx] = ptr[x];
          bigPtr[bx + 1] = ptr[x];
        }
      }
      Canvas->Draw(0, 0, Bitmap);
      Canvas->Draw(200, 200, BigBitmap);
    }
    catch (...)
    {
      ShowMessage("Could not load or alter bitmap");
    }
    delete Bitmap;
    delete BigBitmap;
  }
```

Delphi Examples:

```
{
This example shows how to draw directly to a Bitmap.  It
loads a bitmap from a file and then copies it to another
bitmap twice it's size.  Then the two bitmaps are
displayed on the form canvas.
}
procedure TForm1.Button1Click(Sender: TObject);
type
  TRGBTripleArray = ARRAY[Word] of TRGBTriple;
  pRGBTripleArray = ^TRGBTripleArray; // use a PByteArray for pf8bit color
var
  x,y : Integer;
  bx, by : Integer;
  BitMap, BigBitMap : TBitMap;
  P, bigP : pRGBTripleArray;
  pixForm, bigpixForm : TPixelFormat;
begin
  BitMap := TBitMap.create;
  BigBitMap := TBitMap.create;
  try
    BitMap.LoadFromFile('littlefac.bmp');
    pixForm := BitMap.PixelFormat;
    bigpixForm := BigBitMap.PixelFormat;
    BitMap.PixelFormat := pf24bit;
    BigBitMap.PixelFormat := pf24bit;
    BigBitMap.Height := BitMap.Height * 2;
    BigBitMap.Width := BitMap.Width * 2;
    for y := 0 to BitMap.Height - 1 do
    begin
      P := BitMap.ScanLine[y];
      for x := 0 to BitMap.Width - 1 do
      begin
        bx := x * 2;
        by := y * 2;
        bigP := BigBitMap.ScanLine[by];
        bigP[bx] := P[x];
        bigP[bx + 1] := P[x];
        bigP := BigBitMap.ScanLine[by + 1];
        bigP[bx] := P[x];
        bigP[bx + 1] := P[x];
      end;
    end;
    Canvas.Draw(0, 0, BitMap);
```

```
    Canvas.Draw(200, 200, BigBitMap);
  finally
    BitMap.Free;
    BigBitMap.Free;
  end;
end;
```

See Also

PixelFormat (see page 15703)

ScanLine (see page 14425)

HandleType (see page 14420)

73.1.3.5.8 TBitmap.ScanLine Property

Provides indexed access to each line of pixels.

Pascal

```
property ScanLine [Row: Integer]: Pointer;
```

C++

```
__property void * ScanLine[int Row];
```

Description

ScanLine is used only with DIBs (Device Independent Bitmaps) for image editing tools that do low-level pixel work.

C++ Examples:

```
/*
This example shows how to draw directly to a Bitmap.  It
loads a bitmap from a file and then copies it to another
bitmap twice it's size.  Then the two bitmaps are
displayed on the form canvas.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
  Graphics::TBitmap *BigBitmap = new Graphics::TBitmap();
  TRGBTriple *ptr, *bigPtr;   // use a (byte *) for pf8bit color
  TPixelFormat pixForm, bigpixForm;
  try
  {
    Bitmap->LoadFromFile("../littlefac.bmp");
    pixForm = Bitmap->PixelFormat;
    bigpixForm  = BigBitmap->PixelFormat;
    Bitmap->PixelFormat = pf24bit;
    BigBitmap->PixelFormat = pf24bit;
    BigBitmap->Height = Bitmap->Height * 2;
    BigBitmap->Width = Bitmap->Width * 2;
    for (int y = 0; y < Bitmap->Height; y++)
    {
      ptr = (TRGBTriple *)Bitmap->ScanLine[y];
      for (int x = 0; x < Bitmap->Width; x++)
      {
        int bx = x * 2;
        int by = y * 2;
        bigPtr = (TRGBTriple *)BigBitmap->ScanLine[by];
        bigPtr[bx] = ptr[x];
        bigPtr[bx + 1] = ptr[x];
        bigPtr = (TRGBTriple *)BigBitmap->ScanLine[by + 1];
        bigPtr[bx] = ptr[x];
        bigPtr[bx + 1] = ptr[x];
```

```
      }
    }
    Canvas->Draw(0, 0, Bitmap);
    Canvas->Draw(200, 200, BigBitmap);
  }
  catch (...)
  {
    ShowMessage("Could not load or alter bitmap");
  }
  delete Bitmap;
  delete BigBitmap;
}
```

Delphi Examples:

```
{
This example shows how to draw directly to a Bitmap.  It
loads a bitmap from a file and then copies it to another
bitmap twice it's size.  Then the two bitmaps are
displayed on the form canvas.
}
procedure TForm1.Button1Click(Sender: TObject);
type
  TRGBTripleArray = ARRAY[Word] of TRGBTriple;
  pRGBTripleArray = ^TRGBTripleArray; // use a PByteArray for pf8bit color
var
  x,y : Integer;
  bx, by : Integer;
  BitMap, BigBitMap : TBitMap;
  P, bigP : pRGBTripleArray;
  pixForm, bigpixForm : TPixelFormat;
begin
  BitMap := TBitMap.create;
  BigBitMap := TBitMap.create;
  try
    BitMap.LoadFromFile('littlefac.bmp');
    pixForm := BitMap.PixelFormat;
    bigpixForm := BigBitMap.PixelFormat;
    BitMap.PixelFormat := pf24bit;
    BigBitMap.PixelFormat := pf24bit;
    BigBitMap.Height := BitMap.Height * 2;
    BigBitMap.Width := BitMap.Width * 2;
    for y := 0 to BitMap.Height - 1 do
    begin
      P := BitMap.ScanLine[y];
      for x := 0 to BitMap.Width - 1 do
      begin
        bx := x * 2;
        by := y * 2;
        bigP := BigBitMap.ScanLine[by];
        bigP[bx] := P[x];
        bigP[bx + 1] := P[x];
        bigP := BigBitMap.ScanLine[by + 1];
        bigP[bx] := P[x];
        bigP[bx + 1] := P[x];
      end;
    end;
    Canvas.Draw(0, 0, BitMap);
    Canvas.Draw(200, 200, BigBitMap);
  finally
    BitMap.Free;
    BigBitMap.Free;
  end;
end;
```

See Also

PixelFormat (see page 14423)

73.1.3.5.9 TBitmap.TransparentColor Property

Determines which color of the bitmap is to be transparent when the bitmap is drawn.

Pascal

```
property TransparentColor: TColor;
```

C++

```
__property TColor TransparentColor;
```

Description

Use TransparentColor to determine how to draw the bitmap transparently. When the TransparentMode (see page 14428) property is set to tmAuto (default), TransparentColor returns the color of the first pixel in the bitmap image data. For "bottom-up" bitmaps, the first pixel is the bottom leftmost pixel shown onscreen. For "top-down" bitmaps (less common), the first pixel is in the top left corner shown onscreen.

If TransparentColor is assigned, the TransparentMode (see page 14428) is automatically set to tmFixed so that the new transparent color can be used later. If you want TransparentColor to disregard any assignments and return the bottom leftmost pixel color again, set TransparentMode (see page 14428) to tmAuto.

C++ Examples:

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *bitmap = new Graphics::TBitmap();
  try
  {
    bitmap->LoadFromFile("..\\FACTORY.BMP ");
    bitmap->Transparent = true;
    bitmap->TransparentColor = bitmap->Canvas->Pixels[50][50];
    Form1->Canvas->Draw( 0, 0, bitmap);
    bitmap->TransparentMode = tmAuto;
    Form1->Canvas->Draw(50, 50, bitmap);
  }
  catch (...)
  {
    ShowMessage("Could not load or display bitmap");
  }
  delete bitmap;
```

Delphi Examples:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitMap;
begin
  Bitmap := TBitmap.Create;
  try
    with Bitmap do begin
      LoadFromFile('factory.bmp');
      Transparent := True;
      TransParentColor := BitMap.canvas.pixels[50,50];
      Form1.Canvas.Draw(0,0,BitMap);
      TransparentMode := tmAuto;
      Form1.Canvas.Draw(50,50,BitMap);
    end;
  finally
    Bitmap.Free;
```

```
    end;
  end;
```

See Also

TransparentMode (see page 14428)

73.1.3.5.10 TBitmap.TransparentMode Property

Determines whether the TransparentColor (see page 14427) property's value is automatically calculated or stored with the bitmap object.

Pascal

```
property TransparentMode: TTransparentMode;
```

C++

```
__property TTransparentMode TransparentMode;
```

Description

When TransparentMode is set to tmAuto (the default), the TransparentColor (see page 14427) property returns the color of the bottom-leftmost pixel of the bitmap image. When TransparentMode is set to tmFixed, the TransparentColor (see page 14427) property refers to the color stored in the bitmap object.

C++ Examples:

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *bitmap = new Graphics::TBitmap();
  try
  {
    bitmap->LoadFromFile("..\\FACTORY.BMP ");
    bitmap->Transparent = true;
    bitmap->TransparentColor = bitmap->Canvas->Pixels[50][50];
    Form1->Canvas->Draw( 0, 0, bitmap);
    bitmap->TransparentMode = tmAuto;
    Form1->Canvas->Draw(50, 50, bitmap);
  }
  catch (...)
  {
    ShowMessage("Could not load or display bitmap");
  }
  delete bitmap;
```

Delphi Examples:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitMap;
begin
  Bitmap := TBitmap.Create;
  try
    with Bitmap do begin
      LoadFromFile('factory.bmp');
      Transparent := True;
      TransParentColor := BitMap.canvas.pixels[50,50];
      Form1.Canvas.Draw(0,0,BitMap);
      TransparentMode := tmAuto;
      Form1.Canvas.Draw(50,50,BitMap);
    end;
  finally
    Bitmap.Free;
  end;
end;
```

See Also

TransparentColor (see page 14427)

73.1.4 TBitmapImage Class

TBitmapImage is the internal representation of the bitmap image for a TBitmap (see page 14396) object.

Class Hierarchy

Pascal

```
TBitmapImage = class(TSharedImage);
```

C++

```
class TBitmapImage : public TSharedImage;
```

File

Graphics

Description

TBitmapImage is used only for internal implementation of the TBitmap (see page 14396) component that is defined in the Graphics (see page 14387) unit. It represents the internal image of the bitmap. All of the data and methods introduced in TBitmapImage are private. They contain information about the specific Windows bitmap resource, including pointers to the standard HBITMAP structures defined by Windows. TBitmapImage is referenced in the constructor of the TBitmap (see page 14396) object when the bitmap image is created.

Note: TBitmapImage is how TBitmap (see page 14396) does reference counting and handle sharing. Multiple instances can refer to the same TBitmap (see page 14396) image. TBitmapImage is the actual owner of the bitmap handle.

See Also

TBitmap (see page 14396)

73.1.4.1 TBitmapImage Members

The following tables list the members exposed by TBitmapImage.

Protected Methods

	Name	Description
V	FreeHandle (see page 14430)	This is FreeHandle, a member of class TBitmapImage.
	Reference (see page 14604)	This is Reference, a member of class TSharedImage.
	Release (see page 14604)	This is Release, a member of class TSharedImage.

Protected Properties

	Name	Description
R	RefCount (see page 14605)	This is RefCount, a member of class TSharedImage.

Public Methods

	Name	Description
V	Destroy (see page 14430)	Frees the memory associated with the TBitmapImage (see page 14429) object.

73.1.4.2 TBitmapImage.Destroy Destructor

Frees the memory associated with the TBitmapImage (see page 14429) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBitmapImage();
```

Description

Do not call Destroy. The bitmap object automatically destroys the bitmap image.

See Also

Free (see page 22300)

delete

73.1.4.3 TBitmapImage Methods

The methods of the TBitmapImage class are listed here.

Protected Methods

	Name	Description
	FreeHandle (see page 14430)	This is FreeHandle, a member of class TBitmapImage.

73.1.4.3.1 TBitmapImage.FreeHandle Method

Pascal

```
procedure FreeHandle; override;
```

C++

```
virtual __fastcall FreeHandle();
```

Description

This is FreeHandle, a member of class TBitmapImage.

73.1.5 TBrush Class

TBrush represents the color and pattern used to fill solid shapes.

Class Hierarchy

Pascal

```
TBrush = class(TGraphicsObject);
```

C++

```
class TBrush : public TGraphicsObject;
```

File

Graphics

Description

TBrush encapsulates the Windows brush object (HBRUSH) and is used to fill solid shapes, such as rectangles and ellipses, with a color or pattern.

See Also

TCanvas (see page 14441)

TPen (see page 14571)

Shapes

Using the Main VCL

73.1.5.1 TBrush Members

The following tables list the members exposed by TBrush.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 14534)	Generates an OnChange (see page 14536) event when the properties of the graphics object change.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetBitmap (see page 14434)	This is GetBitmap, a member of class TBrush.
	GetColor (see page 14434)	This is GetColor, a member of class TBrush.
	GetHandle (see page 14434)	This is GetHandle, a member of class TBrush.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetStyle (see page 14434)	This is GetStyle, a member of class TBrush.
	Lock (see page 14534)	Blocks other execution threads from using the associated canvas until the Unlock (see page 14535) method is called.
	SetBitmap (see page 14434)	This is SetBitmap, a member of class TBrush.
	SetColor (see page 14435)	This is SetColor, a member of class TBrush.
	SetHandle (see page 14435)	This is SetHandle, a member of class TBrush.
	SetStyle (see page 14435)	This is SetStyle, a member of class TBrush.
	Unlock (see page 14535)	Releases the lock on execution threads set by the Lock (see page 14534) method.

Public Events

	Name	Description
	OnChange (see page 14536)	Occurs immediately after the graphics object changes.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 14433)	Copies the contents of the brush to another brush.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.

	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 14432)	Creates and initializes a TBrush (see page 14430) instance.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 14433)	Destroys the TBrush (see page 14430) instance and frees its memory.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	HandleAllocated (see page 14534)	Indicates whether the TGraphicsObject (see page 14532) object has acquired a handle to the underlying GDI object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Bitmap (see page 14436)	Specifies an external bitmap image that defines a pattern for the brush.
	Handle (see page 14438)	Provides access to the handle of a system brush.
	OwnerCriticalSection (see page 14536)	Points to information about the critical section that the canvas which draws with this graphics object uses to lock out other threads.

Published Properties

	Name	Description
	Color (see page 14437)	Indicates the color of the brush.
	Style (see page 14438)	Specifies the pattern for the brush.

73.1.5.2 TBrush.Create Constructor

Creates and initializes a TBrush (see page 14430) instance.

Pascal

```
constructor Create;
```

C++

```
__fastcall TBrush();
```

Description

Create generates a new TBrush (see page 14430) instance.

73.1.5.3 TBrush.Destroy Destructor

Destroys the TBrush (see page 14430) instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TBrush();
```

Description

Do not call Destroy directly in an application. Call Free instead. Free verifies that the TBrush (see page 14430) instance is not nil before calling Destroy.

See Also

Free (see page 22300)

73.1.5.4 TBrush Methods

The methods of the TBrush class are listed here.

Protected Methods

	Name	Description
	GetBitmap (see page 14434)	This is GetBitmap, a member of class TBrush.
	GetColor (see page 14434)	This is GetColor, a member of class TBrush.
	GetHandle (see page 14434)	This is GetHandle, a member of class TBrush.
	GetStyle (see page 14434)	This is GetStyle, a member of class TBrush.
	SetBitmap (see page 14434)	This is SetBitmap, a member of class TBrush.
	SetColor (see page 14435)	This is SetColor, a member of class TBrush.
	SetHandle (see page 14435)	This is SetHandle, a member of class TBrush.
	SetStyle (see page 14435)	This is SetStyle, a member of class TBrush.

Public Methods

	Name	Description
	Assign (see page 14433)	Copies the contents of the brush to another brush.

73.1.5.4.1 TBrush.Assign Method

Copies the contents of the brush to another brush.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Assign copies the brush's properties from another TBrush (see page 14430) instance.

See Also

Assign (see page 2930)

73.1.5.4.2 TBrush.GetBitmap Method

Pascal

```
function GetBitmap: TBitmap;
```

C++

```
__fastcall TBitmap GetBitmap();
```

Description

This is GetBitmap, a member of class TBrush.

73.1.5.4.3 TBrush.GetColor Method

Pascal

```
function GetColor: TColor;
```

C++

```
__fastcall TColor GetColor();
```

Description

This is GetColor, a member of class TBrush.

73.1.5.4.4 TBrush.GetHandle Method

Pascal

```
function GetHandle: HBrush;
```

C++

```
__fastcall HBrush GetHandle();
```

Description

This is GetHandle, a member of class TBrush.

73.1.5.4.5 TBrush.GetStyle Method

Pascal

```
function GetStyle: TBrushStyle;
```

C++

```
__fastcall TBrushStyle GetStyle();
```

Description

This is GetStyle, a member of class TBrush.

73.1.5.4.6 TBrush.SetBitmap Method

Pascal

```
procedure SetBitmap(Value: TBitmap);
```

C++

```
__fastcall SetBitmap(TBitmap Value);
```

Description

This is SetBitmap, a member of class TBrush.

73.1.5.4.7 TBrush.SetColor Method

Pascal

```
procedure SetColor(Value: TColor);
```

C++

```
__fastcall SetColor(TColor Value);
```

Description

This is SetColor, a member of class TBrush.

73.1.5.4.8 TBrush.SetHandle Method

Pascal

```
procedure SetHandle(Value: HBrush);
```

C++

```
__fastcall SetHandle(HBrush Value);
```

Description

This is SetHandle, a member of class TBrush.

73.1.5.4.9 TBrush.SetStyle Method

Pascal

```
procedure SetStyle(Value: TBrushStyle);
```

C++

```
__fastcall SetStyle(TBrushStyle Value);
```

Description

This is SetStyle, a member of class TBrush.

73.1.5.5 TBrush Properties

The properties of the TBrush class are listed here.

Public Properties

	Name	Description
	Bitmap (see page 14436)	Specifies an external bitmap image that defines a pattern for the brush.
	Handle (see page 14438)	Provides access to the handle of a system brush.

Published Properties

	Name	Description
	Color (see page 14437)	Indicates the color of the brush.
	Style (see page 14438)	Specifies the pattern for the brush.

73.1.5.5.1 TBrush.Bitmap Property

Specifies an external bitmap image that defines a pattern for the brush.

Pascal

```
property Bitmap: TBitmap;
```

C++

```
__property TBitmap Bitmap;
```

Description

Bitmap points to a TBitmap (see page 14396) object that holds a bitmap image. If Bitmap is nonempty, the bitmap image (rather than the Style (see page 14438) property) defines the brush's pattern. If the image is larger than eight pixels by eight pixels, only the top left eight-by-eight region is used.

Changing the image does not affect the brush until the TBitmap (see page 14396) is reassigned to the Bitmap property. Be sure to free the TBitmap (see page 14396) after finishing with the brush, since TBrush (see page 14430) will not free it.

C++ Examples:

```
/*
The following code loads a bitmap from a file and assigns it
to the Brush of the Canvas of Form1:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *BrushBmp = new Graphics::TBitmap;
  try
  {
    BrushBmp->LoadFromFile("../bm1.BMP");
    Form1->Canvas->Brush->Bitmap = BrushBmp;
    Form1->Canvas->FillRect(Rect(0,0,100,100));
  }
  __finally
  {
    Form1->Canvas->Brush->Bitmap = NULL;
    delete BrushBmp;
  }
}
```

Delphi Examples:

```
{
The following code loads a bitmap from a file and assigns it
to the Brush of the Canvas of Form1:
}
var
  Bitmap: TBitmap;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Bitmap := TBitmap.Create;
  try
    Bitmap.LoadFromFile('bm1.BMP');
    Form1.Canvas.Brush.Bitmap := Bitmap;
    Form1.Canvas.FillRect(Rect(0,0,100,100));
  finally
    Form1.Canvas.Brush.Bitmap := nil;
    Bitmap.Free;
  end;
end;
```

See Also

TBitmap (see page 14396)

Style (see page 14438)

73.1.5.5.2 TBrush.Color Property

Indicates the color of the brush.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

The Color property determines the color of the brush. This is the color that is used to draw the pattern represented by the Style (see page 14438) property, not the background color of the brush (unless Style (see page 14438) is bsSolid).

Note: If the value of the Style (see page 14438) property is bsClear, the Color property is ignored. Further, any value assigned to the Color property is lost when Style (see page 14438) is set to bsClear.

C++ Examples:

```
/*
The following example paints a cross-hatched ellipse onto
Image1 which is a TImage on the form when the user clicks on
Button1.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TCanvas *pCanvas = Image1->Canvas;
  pCanvas->Brush->Color = clRed;
  pCanvas->Brush->Style = bsDiagCross;
  pCanvas->Ellipse(0, 0, Image1->Width, Image1->Height);
}
```

Delphi Examples:

```
{
The following example paints a cross-hatched ellipse onto
Image1 which is a TImage on the form when the user clicks on
Button1.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  with Image1 do begin
    Canvas.Brush.Color := clRed;
    Canvas.Brush.Style := bsDiagCross;
    Canvas.Ellipse(0, 0, Image1.Width, Image1.Height);
  end;
end;
```

See Also

Style (see page 14438)

73.1.5.5.3 TBrush.Handle Property

Provides access to the handle of a system brush.

Pascal

```
property Handle: HBrush;
```

C++

```
__property HBrush Handle;
```

Description

The Handle property provides access to the Windows GDI object handle. TBrush (see page 14430) encapsulates the Windows brush object (HBRUSH) and is used to fill solid shapes, such as rectangles and ellipses, with a color or pattern.

73.1.5.5.4 TBrush.Style Property

Specifies the pattern for the brush.

Pascal

```
property Style: TBrushStyle;
```

C++

```
__property TBrushStyle Style;
```

Description

The Style property determines the pattern painted by the brush, unless a value is assigned to Bitmap (see page 14436).

Tip: Set the Style property to bsClear to eliminate flicker when the object repaints.

C++ Examples:

```
/*
The following example paints a cross-hatched ellipse onto
Image1 which is a TImage on the form when the user clicks on
Button1.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TCanvas *pCanvas = Image1->Canvas;
  pCanvas->Brush->Color = clRed;
  pCanvas->Brush->Style = bsDiagCross;
  pCanvas->Ellipse(0, 0, Image1->Width, Image1->Height);
}
```

Delphi Examples:

```
{
The following example paints a cross-hatched ellipse onto
Image1 which is a TImage on the form when the user clicks on
Button1.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  with Image1 do begin
    Canvas.Brush.Color := clRed;
    Canvas.Brush.Style := bsDiagCross;
    Canvas.Ellipse(0, 0, Image1.Width, Image1.Height);
  end;
end;
```

Bitmap (see page 14436)

Color (see page 14437)

73.1.6 TBrushRecall Class

TBrushRecall saves and restores a TBrush (see page 14430) object.

Class Hierarchy

Pascal

```
TBrushRecall = class(TRecall);
```

C++

```
class TBrushRecall : public TRecall;
```

File

Graphics

Description

Use TBrushRecall to store the current state of a TBrush (see page 14430) object. You are then free to change the current state of the brush object. To restore the brush object to its original state, all that is necessary is to free the TBrushRecall object and the brush object is automatically restored to the saved property values.

You can update the TBrushRecall instance to reflect the current properties of the TBrush (see page 14430) object by calling the Store method. You can prevent the TBrushRecall destructor from updating the TBrush (see page 14430) object by calling the Forget method.

See Also

TRecall (see page 2964)

TBrush (see page 14430)

Using Brushes

73.1.6.1 TBrushRecall Members

The following tables list the members exposed by TBrushRecall.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.

	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 14440)	Instantiates a TBrushRecall (see page 14439) object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2966)	Destroys the TRecall (see page 2964) instance, assigning the stored properties to the reference object.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Forget (see page 2967)	Discards the saved property values and prevents the TRecall (see page 2964) object from updating the reference object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Store (see page 2967)	Saves the current property settings of the reference object.

Public Properties

	Name	Description
R	Reference (see page 2968)	Indicates the reference object that is updated when you destroy the TRecall (see page 2964) instance.

73.1.6.2 TBrushRecall.Create Constructor

Instantiates a TBrushRecall (see page 14439) object.

Pascal

```
constructor Create(ABrush: TBrush);
```

C++

```
__fastcall TBrushRecall(TBrush ABrush);
```

Description

Call Create to instantiate a brush recall object at runtime. Create saves the current properties of the TBrush (see page 14430) object specified by ABrush, which becomes the value of the Reference property.

Subsequent calls to the Store method take snapshots of the properties of ABrush and save them, replacing the values saved by this constructor. When you destroy the TBrushRecall (see page 14439) instance, the most recently saved properties are assigned to ABrush, restoring it to a previous state.

Destroy (see page 2966)

Reference (see page 2968)

Store (see page 2967)

73.1.7 TCanvas Class

TCanvas provides an abstract drawing space for objects that must render their own images.

Class Hierarchy

Pascal

```
TCanvas = class(TPersistent);
```

C++

```
class TCanvas : public TPersistent;
```

File

Graphics

Description

Use TCanvas as a drawing surface for objects that draw an image of themselves. Standard window controls such as edit controls or list boxes do not require a canvas, as they are drawn by the system.

TCanvas provides properties, events and methods that assist in creating an image by

Specifying the type of brush, pen and font to use.

Drawing and filling a variety of shapes and lines.

Writing text.

Rendering graphic images.

Enabling a response to changes in the current image.

TCanvas has two descendants, TControlCanvas and TMetafileCanvas (see page 14564), which assist in drawing images of controls and in creating metafile images for objects.

See Also

TControlCanvas (see page 5903)

TMetafileCanvas (see page 14564)

73.1.7.1 TCanvas Members

The following tables list the members exposed by TCanvas.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 14450)	This is Changed, a member of class TCanvas.
	Changing (see page 14450)	This is Changing, a member of class TCanvas.
	CreateHandle (see page 14454)	This is CreateHandle, a member of class TCanvas.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.

	GetOwner (see page 2932)	Returns the owner of an object.
	RequiredState (see page 14470)	This is RequiredState, a member of class TCanvas.

Public Events

	Name	Description
	OnChange (see page 14496)	Occurs when the image has just changed.
	OnChanging (see page 14496)	Occurs just before a change is made to the image.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Arc (see page 14448)	Draws an arc on the image along the perimeter of the ellipse bounded by the specified rectangle.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BrushCopy (see page 14449)	Copies a portion of a bitmap onto a rectangle on the canvas, replacing one of the colors of the bitmap with the brush of the canvas.
	Chord (see page 14451)	Draws a closed figure represented by the intersection of a line and an ellipse.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CopyRect (see page 14452)	Copies part of an image from another canvas into the canvas.
	Create (see page 14443)	Creates an instance of TCanvas (see page 14441).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 14446)	Destroys an instance of TCanvas (see page 14441).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Draw (see page 14454)	Renders the graphic specified by the Graphic parameter on the canvas at the location given by the coordinates (X, Y).
	DrawFocusRect (see page 14455)	Draws a rectangle in the style used to indicate that the object inside the rectangle has focus.
	Ellipse (see page 14457)	This is the overview for the Ellipse method overload.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FillRect (see page 14458)	Fills the specified rectangle on the canvas using the current brush.
	FloodFill (see page 14459)	Fills an area of the canvas using the current brush.
	FrameRect (see page 14460)	Draws a rectangle using the Brush (see page 14484) of the canvas to draw the border.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	HandleAllocated (see page 14461)	Indicates whether the TCanvas (see page 14441) object has acquired a handle to a device context.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	LineTo (see page 14462)	Draws a line on the canvas from PenPos (see page 14494) to the point specified by X and Y, and sets the pen position to (X, Y).

	Lock (see page 14463)	Prevents other threads from drawing on the canvas.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MoveTo (see page 14463)	Changes the current drawing position to the point (X,Y).
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Pie (see page 14464)	Draws a pie-shaped the section of the ellipse bounded by the rectangle (X1, Y1) and (X2, Y2) on the canvas.
	PolyBezier (see page 14464)	Draws a set of Bezier curves.
	PolyBezierTo (see page 14465)	Draws a set of Bezier curves and updates the value of PenPos (see page 14494).
	Polygon (see page 14466)	Draws a series of lines on the canvas connecting the points passed in and closing the shape by drawing a line from the last point to the first point.
	Polyline (see page 14467)	Draws a series of lines on the canvas with the current pen, connecting each of the points passed to it in Points.
	Rectangle (see page 14468)	This is the overview for the Rectangle method overload.
	Refresh (see page 14470)	Deselects the Pen (see page 14492), Brush (see page 14484), and Font (see page 14488) from the device context.
	RoundRect (see page 14471)	Draws a rectangle with rounded corners on the canvas.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	StretchDraw (see page 14472)	Draws the graphic specified by the Graphic parameter in the rectangle specified by the Rect parameter.
	TextExtent (see page 14474)	Returns the width and height, in pixels, of a string rendered in the current font.
	TextHeight (see page 14474)	Returns the height, in pixels, of a string rendered in the current font.
	TextOut (see page 14475)	Writes a string on the canvas, starting at the point (X,Y), and then updates the PenPos (see page 14494) to the end of the string.
	TextRect (see page 14480)	This is the overview for the TextRect method overload.
	TextWidth (see page 14481)	Returns the width, in pixels, of a string rendered in the current font.
	TryLock (see page 14483)	Locks the canvas if it is currently unlocked.
	Unlock (see page 14483)	Decreases the LockCount (see page 14492) property, allowing other threads to execute when LockCount (see page 14492) reaches 0.

Public Properties

	Name	Description
R	CanvasOrientation (see page 14485)	Determines the orientation of the canvas as left-to-right or right-to-left.
R	ClipRect (see page 14486)	Read-only property that specifies the boundaries of the clipping rectangle.
	Handle (see page 14489)	Specifies the handle for this canvas.
R	LockCount (see page 14492)	Indicates the number of times the canvas has been locked to prevent interference from other threads.
	PenPos (see page 14494)	Specifies the current drawing position of the Pen (see page 14492).
	Pixels (see page 14494)	Specifies the color of the pixels within the current ClipRect (see page 14486).
	TextFlags (see page 14495)	Specifies how text is written to the canvas.

Published Properties

	Name	Description
	Brush (see page 14484)	Determines the color and pattern for filling graphical shapes and backgrounds.
	CopyMode (see page 14487)	Specifies how a graphical image is copied onto the canvas.
	Font (see page 14488)	Specifies the font to use when writing text on the image.
	Pen (see page 14492)	Specifies the kind of pen the canvas uses for drawing lines and outlining shapes.

73.1.7.2 TCanvas.Create Constructor

Creates an instance of TCanvas (see page 14441).

Pascal

```
constructor Create;
```

C++

```
__fastcall TCanvas();
```

Description

Call Create to instantiate a TCanvas (see page 14441) object at runtime. Create allocates memory for the instance of TCanvas (see page 14441) and creates the TFont (see page 14497), TBrush (see page 14430) and TPen (see page 14571) objects for the Font (see page 14488), Brush (see page 14484), and Pen (see page 14492) properties. Create also initializes the CopyMode (see page 14487) to cmSrcCopy (see page 14739).

C++ Examples:

```
/*
The GetFormImage allows you to easily obtain a bitmap of a
form. The following method can be added to a custom
TWinControl descendant to save itself as a bitmap.  Check the
produced BMP file to confirm.  Click the button and them
double click on the newly created foo.bmp file to view.
*/
class TMyControl : public TColorListBox
{
__published:    // IDE-managed Components
    void __fastcall SaveAsBmp(TFileName fileName);
private:    // User declarations
public:     // User declarations
    __fastcall TMyControl(TComponent* Owner);
};

TForm1 *Form1;
TMyControl *MyControl1;

__fastcall TForm1::TForm1(TComponent* Owner)
    : TForm(Owner)
{
}
__fastcall TMyControl::TMyControl(TComponent* Owner)
    : TColorListBox(Owner)
{
}

typedef struct {
  TLogPalette lpal;
  TPaletteEntry dummy[256];
} LogPal;

void __fastcall TMyControl::SaveAsBmp(TFileName fileName)
{
  TCanvas *tempCanvas = new TCanvas;
  try
  {
    HWND notUsed;
    tempCanvas->Handle = GetDeviceContext(notUsed);
    TImage *image2save = new TImage(Form1);
    try
    {
      image2save->Height = Height;
      image2save->Width = Width;
      TRect destRect = Rect(0,0,Width,Height);
      TRect sourceRect = destRect;
      image2save->Canvas->CopyRect(destRect, tempCanvas, sourceRect);
      LogPal SysPal;
      SysPal.lpal.palVersion = 0x300;
      SysPal.lpal.palNumEntries = 256;
      GetSystemPaletteEntries(tempCanvas->Handle,0,256,SysPal.lpal.palPalEntry);
      image2save->Picture->Bitmap->Palette = CreatePalette((const tagLOGPALETTE
```

```
*)&SysPal.lpal);
      image2save->Picture->SaveToFile(fileName);
    }
    __finally
    {
     delete image2save;
    }
  }
  __finally
  {
    delete tempCanvas;
  }
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  MyControl1->SaveAsBmp("../foo.bmp");
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MyControl1 = new TMyControl(Form1);
  MyControl1->Parent = Form1;
  MyControl1->Visible  = true;
}
```

Delphi Examples:

```
{
The GetFormImage allows you to easily obtain a bitmap of a
form. The following method can be added to a custom
TWinControl descendant to save itself as a bitmap.  Check the
produced BMP file to confirm.  Click the button and them
double click on the newly created foo.bmp file to view.
}

TFont (see page 14497)

TPen (see page 14571)

73.1.7.3 TCanvas.Destroy Destructor

Destroys an instance of TCanvas (see page 14441).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCanvas();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TCanvas (see page 14441) object is not nil and only then calls Destroy.

73.1.7.4 TCanvas Methods

The methods of the TCanvas class are listed here.

Protected Methods

	Name	Description
	Changed (see page 14450)	This is Changed, a member of class TCanvas.
	Changing (see page 14450)	This is Changing, a member of class TCanvas.
	CreateHandle (see page 14454)	This is CreateHandle, a member of class TCanvas.
	RequiredState (see page 14470)	This is RequiredState, a member of class TCanvas.

Public Methods

	Name	Description
	Arc (see page 14448)	Draws an arc on the image along the perimeter of the ellipse bounded by the specified rectangle.
	BrushCopy (see page 14449)	Copies a portion of a bitmap onto a rectangle on the canvas, replacing one of the colors of the bitmap with the brush of the canvas.
	Chord (see page 14451)	Draws a closed figure represented by the intersection of a line and an ellipse.
	CopyRect (see page 14452)	Copies part of an image from another canvas into the canvas.
	Draw (see page 14454)	Renders the graphic specified by the Graphic parameter on the canvas at the location given by the coordinates (X, Y).
	DrawFocusRect (see page 14455)	Draws a rectangle in the style used to indicate that the object inside the rectangle has focus.
	Ellipse (see page 14457)	This is the overview for the Ellipse method overload.
	FillRect (see page 14458)	Fills the specified rectangle on the canvas using the current brush.
	FloodFill (see page 14459)	Fills an area of the canvas using the current brush.
	FrameRect (see page 14460)	Draws a rectangle using the Brush (see page 14484) of the canvas to draw the border.
	HandleAllocated (see page 14461)	Indicates whether the TCanvas (see page 14441) object has acquired a handle to a device context.
	LineTo (see page 14462)	Draws a line on the canvas from PenPos (see page 14494) to the point specified by X and Y, and sets the pen position to (X, Y).
	Lock (see page 14463)	Prevents other threads from drawing on the canvas.
	MoveTo (see page 14463)	Changes the current drawing position to the point (X,Y).

	Pie (see page 14464)	Draws a pie-shaped the section of the ellipse bounded by the rectangle (X1, Y1) and (X2, Y2) on the canvas.
	PolyBezier (see page 14464)	Draws a set of Bezier curves.
	PolyBezierTo (see page 14465)	Draws a set of Bezier curves and updates the value of PenPos (see page 14494).
	Polygon (see page 14466)	Draws a series of lines on the canvas connecting the points passed in and closing the shape by drawing a line from the last point to the first point.
	Polyline (see page 14467)	Draws a series of lines on the canvas with the current pen, connecting each of the points passed to it in Points.
	Rectangle (see page 14468)	This is the overview for the Rectangle method overload.
	Refresh (see page 14470)	Deselects the Pen (see page 14492), Brush (see page 14484), and Font (see page 14488) from the device context.
	RoundRect (see page 14471)	Draws a rectangle with rounded corners on the canvas.
	StretchDraw (see page 14472)	Draws the graphic specified by the Graphic parameter in the rectangle specified by the Rect parameter.
	TextExtent (see page 14474)	Returns the width and height, in pixels, of a string rendered in the current font.
	TextHeight (see page 14474)	Returns the height, in pixels, of a string rendered in the current font.
	TextOut (see page 14475)	Writes a string on the canvas, starting at the point (X,Y), and then updates the PenPos (see page 14494) to the end of the string.
	TextRect (see page 14480)	This is the overview for the TextRect method overload.
	TextWidth (see page 14481)	Returns the width, in pixels, of a string rendered in the current font.
	TryLock (see page 14483)	Locks the canvas if it is currently unlocked.
	Unlock (see page 14483)	Decreases the LockCount (see page 14492) property, allowing other threads to execute when LockCount (see page 14492) reaches 0.

73.1.7.4.1 TCanvas.Arc Method

Draws an arc on the image along the perimeter of the ellipse bounded by the specified rectangle.

Pascal

```
procedure Arc(X1: Integer; Y1: Integer; X2: Integer; Y2: Integer; X3: Integer; Y3: Integer;
X4: Integer; Y4: Integer);
```

C++

```
__fastcall Arc(int X1, int Y1, int X2, int Y2, int X3, int Y3, int X4, int Y4);
```

Description

Use Arc to draw an elliptically curved line with the current Pen (see page 14492). The arc traverses the perimeter of an ellipse that is bounded by the points (X1,Y1) and (X2,Y2). The arc is drawn following the perimeter of the ellipse, counterclockwise, from the starting point to the ending point. The starting point is defined by the intersection of the ellipse and a line defined by the center of the ellipse and (X3,Y3). The ending point is defined by the intersection of the ellipse and a line defined by the center of the ellipse and (X4, Y4).

Note: On Windows 9x or Windows ME, the sums X1 + X2 and Y1 + Y2 cannot exceed 32768. Also, the sum X1 + X2 + Y1 + Y2 cannot exceed 32768.

On NT or Windows 2000, the drawing direction can be changed to clockwise using the Windows API call SetArcDirection.

C++ Examples:

```
/*
The following lines of code draw the top quarter of an arc
bounded by the current window:
*/
void __fastcall TForm1::FormPaint(TObject *Sender)
{
  TRect R = GetClientRect();  // Gets the rectangular
                              // coordinates of
                              // the current window.
  Canvas->Arc(R.Left, R.Top, R.Right, R.Bottom, R.Right, R.Top, R.Left, R.Top);
```

```
}
```

Delphi Examples:

```
{
The following lines of code draw the top quarter of an arc
bounded by the current window:
}
procedure TForm1.FormPaint(Sender: TObject);
var
  R: TRect;
begin
  R := GetClientRect;   { Gets the boundaries of the current window }
  Canvas.Arc(R.Left, R.Top, R.Right, R.Bottom, R.Right, R.Top, R.Left, R.Top);
end;
```

See Also

Ellipse (see page 14457)

Pen (see page 14492)

73.1.7.4.2 TCanvas.BrushCopy Method

Copies a portion of a bitmap onto a rectangle on the canvas, replacing one of the colors of the bitmap with the brush of the canvas.

Pascal

```
procedure BrushCopy(const Dest: TRect; Bitmap: TBitmap; const Source: TRect; Color: TColor);
```

C++

```
__fastcall BrushCopy(const TRect Dest, TBitmap Bitmap, const TRect Source, TColor Color);
```

Description

Use BrushCopy to achieve special effects such as making the copied image partially transparent. BrushCopy is provided mainly for backward compatibility. Use a TImageList instead of BrushCopy.

Dest specifies the rectangular portion of the canvas that will receive the copy of the bitmap. Bitmap specifies the graphic to copy from. Source specifies the rectangular area of Bitmap to copy. Color specifies the color in Bitmap to replace with the Brush (see page 14484) of the canvas.

To use BrushCopy to make the copied image partially transparent, specify the color of the surface of the canvas (clBackground (see page 14666) for example) as the Color of the Brush (see page 14484) property, then call BrushCopy.

C++ Examples:

```
/*
The following code illustrates the differences between
CopyRect and BrushCopy. The bitmap graphic 'FACTORY.BMP' is
loaded into Bitmap and displayed on the Canvas of Form1.
BrushCopy replaces the color black in the graphic with the
brush of the canvas, while CopyRect leaves the colors intact.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
Graphics::TBitmap *Bitmap;
TRect   MyRect, MyOther;
MyRect = Rect(10,10,100,100);
MyOther = Rect(10,111,100, 201);
Bitmap = new Graphics::TBitmap;
Bitmap->LoadFromFile("c:/Program Files/Common Files/CodeGear
Shared/Images/Splash/256color/factory.bmp");
Form1->Canvas->BrushCopy(MyRect, Bitmap, MyRect, clBlack);
```

```
Form1->Canvas->CopyRect(MyOther, Bitmap->Canvas, MyRect);
delete Bitmap;
}
```

Delphi Examples:

```
{
The following code illustrates the differences between
CopyRect and BrushCopy. The bitmap graphic 'FACTORY.BMP' is
loaded into Bitmap and displayed on the Canvas of Form1.
BrushCopy replaces the color black in the graphic with the
brush of the canvas, while CopyRect leaves the colors intact.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap: TBitmap;
  MyRect, MyOther: TRect;
begin
  MyRect := Rect(10,10,150,150);
  MyOther := Rect(10,161,150,301);
  Bitmap := TBitmap.Create;
  Bitmap.LoadFromFile(
    'c:\Program Files\Common Files\CodeGear Shared\Images\Splash\256color\factory.bmp');
  Form1.Canvas.BrushCopy(MyRect, Bitmap, MyRect, clBlack);
  Form1.Canvas.CopyRect(MyOther,Bitmap.Canvas,MyRect);
  Bitmap.Free;
end;
```

73.1.7.4.3 TCanvas.Changed Method

Pascal

```
procedure Changed; virtual;
```

C++

```
virtual __fastcall Changed();
```

Description

This is Changed, a member of class TCanvas.

73.1.7.4.4 TCanvas.Changing Method

Pascal

```
procedure Changing; virtual;
```

C++

```
virtual __fastcall Changing();
```

Description

This is Changing, a member of class TCanvas.

73.1.7.4.5 TCanvas.Chord Method

Draws a closed figure represented by the intersection of a line and an ellipse.

Pascal

```
procedure Chord(X1: Integer; Y1: Integer; X2: Integer; Y2: Integer; X3: Integer; Y3: Integer;
X4: Integer; Y4: Integer);
```

C++

```
__fastcall Chord(int X1, int Y1, int X2, int Y2, int X3, int Y3, int X4, int Y4);
```

Description

Use Chord to create a shape that is defined by an arc and a line that joins the endpoints of the arc. The chord consists of a portion of an ellipse that is bounded by the points (X1,Y1) and (X2,Y2). The ellipse is bisected by a line that runs between the points (X3,Y3) and (X4,Y4).

The perimeter of the chord runs counter clockwise from (X3, Y3), counterclockwise along the ellipse to (X4,Y4), and straight back to (X3,Y3). If (X3,Y3) and (X4,Y4) are not on the surface of the ellipse, the corresponding corners on the chord are the closest points on the perimeter that intersect the line. The outline of the chord is drawn using the value of Pen (see page 14492), and the shape is filled using the value of Brush (see page 14484).

Note: On Windows 9x or Windows ME, the sums X1 + X2 and Y1 + Y2 cannot exceed 32768. Also, the sum X1 + X2 + Y1 + Y2 cannot exceed 32768.

On NT, the drawing direction can be changed to clockwise using the Windows API call SetArcDirection.

C++ Examples:

```
/*
This code draws a chord on the top of an ellipse bounded by
the current window.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TRect R = GetClientRect();  //Get coordinates of the current window.
  Canvas->Chord(R.Left, R.Top, R.Right, R.Bottom, R.Right, R.Top, R.Left, R.Top);
}
```

Delphi Examples:

```
{
This code draws a chord on the top of an ellipse bounded by
the current window.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  R: TRect;
begin
  R := GetClientRect;  { Get coordinates of the current window. }
  Canvas.Chord(R.Left, R.Top, R.Right, R.Bottom, R.Right, R.Top, R.Left, R.Top);
end;
```

73.1.7.4.6 TCanvas.CopyRect Method

Copies part of an image from another canvas into the canvas.

Pascal

```
procedure CopyRect(const Dest: TRect; Canvas: TCanvas; const Source: TRect);
```

C++

```
__fastcall CopyRect(const TRect Dest, TCanvas Canvas, const TRect Source);
```

Description

Use CopyRect to transfer part of the image on another canvas to the image of the TCanvas (see page 14441) object. Dest specifies the rectangle on the canvas where the source image will be copied. The Canvas parameter specifies the canvas with the source image. Source specifies a rectangle bounding the portion of the source canvas that will be copied.

The portion of the source canvas is copied using the mode specified by CopyMode (see page 14487).

C++ Examples:

```
/*
The following code illustrates the differences between
CopyRect and BrushCopy. The bitmap graphic 'FACTORY.BMP' is
loaded into Bitmap and displayed on the Canvas of Form1.
BrushCopy replaces the color black in the graphic with the
brush of the canvas, while CopyRect leaves the colors intact.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
Graphics::TBitmap *Bitmap;
TRect   MyRect, MyOther;
MyRect = Rect(10,10,100,100);
MyOther = Rect(10,111,100, 201);
Bitmap = new Graphics::TBitmap;
Bitmap->LoadFromFile("c:/Program Files/Common Files/CodeGear
Shared/Images/Splash/256color/factory.bmp");
Form1->Canvas->BrushCopy(MyRect, Bitmap, MyRect, clBlack);
Form1->Canvas->CopyRect(MyOther, Bitmap->Canvas, MyRect);
delete Bitmap;
}
/*
The following example uses the CopyMode of an image's canvas
to blank out the image when the user chooses the "Cut" menu
item.  This example requires a Main menu with a Copy and a
Cut menu item that have their OnClick error handlers populated.
Note: CopyMode and CopyRect are members of the destination
canvas.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
    TRect SrcRect, DstRect;
    Image2->Canvas->CopyMode = cmSrcCopy;
    DstRect = Rect(0, 0, Image2->Width, Image2->Height);
    SrcRect = Rect(0, 0, Image1->Width, Image1->Height);
    Image2->Canvas->CopyRect(DstRect, Image1->Canvas, SrcRect);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
 TRect r;
 Copy1Click(Sender); // Do the same thing as the copy menu item.
 Image1->Canvas->CopyMode = cmWhiteness;
```

```
 r = Rect(0, 0, Image1->Width, Image1->Height);
 Image1->Canvas->CopyRect(r, Image1->Canvas, r);
 Image1->Canvas->CopyMode = cmSrcCopy; // Restore the copy mode.
}
```

Delphi Examples:

```
{
The following code illustrates the differences between
CopyRect and BrushCopy. The bitmap graphic 'FACTORY.BMP' is
loaded into Bitmap and displayed on the Canvas of Form1.
BrushCopy replaces the color black in the graphic with the
brush of the canvas, while CopyRect leaves the colors intact.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap: TBitmap;
  MyRect, MyOther: TRect;
begin
  MyRect := Rect(10,10,150,150);
  MyOther := Rect(10,161,150,301);
  Bitmap := TBitmap.Create;
  Bitmap.LoadFromFile(
    'c:\Program Files\Common Files\CodeGear Shared\Images\Splash\256color\factory.bmp');
  Form1.Canvas.BrushCopy(MyRect, Bitmap, MyRect, clBlack);
  Form1.Canvas.CopyRect(MyOther,Bitmap.Canvas,MyRect);
  Bitmap.Free;
end;
{
The following example uses the CopyMode of an image's canvas
to blank out the image when the user chooses the "Cut" menu
item.  This example requires a Main menu with a Copy and a
Cut menu item that have their OnClick error handlers populated.
Note: CopyMode and CopyRect are members of the destination
canvas.
}
procedure TForm1.Copy1Click(Sender: TObject);
var
  DstRect, SrcRect: TRect;
begin
  with Image2.Canvas do
  begin
    CopyMode := cmSrcCopy;
    DstRect := Rect(0, 0, Image2.Width, Image2.Height);
    SrcRect := Rect(0, 0, Image1.Width, Image1.Height);
    CopyRect(DstRect, Image1.Canvas, SrcRect);
  end;
end;

procedure TForm1.Cut1Click(Sender: TObject);
var
  ARect: TRect;
begin
  Copy1Click(Sender); { do the same thing as the copy menu item }
  with Image1.Canvas do
  begin
    CopyMode := cmWhiteness;
    ARect := Rect(0, 0, Image1.Width, Image1.Height);
    CopyRect(ARect, Image1.Canvas, ARect);
    CopyMode := cmSrcCopy; { restore the copy mode }
  end;
end;
```

73.1.7.4.7 TCanvas.CreateHandle Method

Pascal

```
procedure CreateHandle; virtual;
```

C++

```
virtual __fastcall CreateHandle();
```

Description

This is CreateHandle, a member of class TCanvas.

73.1.7.4.8 TCanvas.Draw Method

Renders the graphic specified by the Graphic parameter on the canvas at the location given by the coordinates (X, Y).

Pascal

```
procedure Draw(X: Integer; Y: Integer; Graphic: TGraphic);
```

C++

```
__fastcall Draw(int X, int Y, TGraphic Graphic);
```

Description

Call Draw to draw a graphic on the canvas. Draw calls the Draw method of the graphic. The image is rendered into a rectangle determined by the size of the graphic, with the upper left corner at the point (X, Y).

Graphics (see page 14387) can be bitmaps, icons, or metafiles. If the graphic is a TBitmap (see page 14396) object, the bitmap is rendered using the value of CopyMode (see page 14487).

C++ Examples:

```
/*
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PaintBox1->Canvas->Draw(0,0, Image1->Picture->Graphic);
}
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *bitmap = new Graphics::TBitmap();
  try
  {
    bitmap->LoadFromFile("..\\FACTORY.BMP ");
    bitmap->Transparent = true;
    bitmap->TransparentColor = bitmap->Canvas->Pixels[50][50];
    Form1->Canvas->Draw( 0, 0, bitmap);
    bitmap->TransparentMode = tmAuto;
    Form1->Canvas->Draw(50, 50, bitmap);
  }
  catch (...)
  {
    ShowMessage("Could not load or display bitmap");
  }
  delete bitmap;
```

Delphi Examples:

```
{
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  PaintBox1.Canvas.Draw(0,0, Image1.Picture.Graphic);
end;
procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitMap;
begin
  Bitmap := TBitmap.Create;
  try
    with Bitmap do begin
      LoadFromFile('factory.bmp');
      Transparent := True;
      TransParentColor := BitMap.canvas.pixels[50,50];
      Form1.Canvas.Draw(0,0,BitMap);
      TransparentMode := tmAuto;
      Form1.Canvas.Draw(50,50,BitMap);
    end;
  finally
    Bitmap.Free;
  end;
end;
```

73.1.7.4.9 TCanvas.DrawFocusRect Method

Draws a rectangle in the style used to indicate that the object inside the rectangle has focus.

Pascal

```
procedure DrawFocusRect(const Rect: TRect);
```

C++

```
__fastcall DrawFocusRect(const TRect Rect);
```

Description

Call DrawFocusRect for the perimeter of the image of a control when the control gets or loses input focus. Because DrawFocusRect uses an XOR function, calling it a second time while specifying the same rectangle removes the rectangle from the screen.

The rectangle this function draws cannot be scrolled. To scroll an area containing a rectangle drawn by DrawFocusRect, call DrawFocusRect to remove the rectangle from the screen, scroll the area, and then call DrawFocusRect to draw the rectangle in the new position.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
```

```
  component to draw the contents of each cell in a draw grid.
  It draws a focus rectangle around the cell that has focus.
  goDrawFocusSelect in the DrawGrid Options parameter must be
  True to set focus on a cell.  The ImageList Draw method must
  be called after DrawFocusRect. The OnSelectCell event handler
  must implemented to return true.
  */
  void __fastcall TForm1::DrawGrid1DrawCell(
    TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
  {
    long index = ARow * DrawGrid1->ColCount + ACol;
    DrawGrid1->Canvas->Brush->Color = clBackground;
    DrawGrid1->Canvas->FillRect(Rect);
    ImageList1->Draw(DrawGrid1->Canvas,Rect.Left,Rect.Top,index);
    if (State.Contains(gdFocused))
    {
      DrawGrid1->Canvas->DrawFocusRect(Rect);
      Label1->Caption = "Cell " + IntToStr(index) + " has the focus.";
    }
    ImageList1->Draw(
      DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
  }
  //---------------------------------------------------------------------------
  void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
        bool &CanSelect)
  {
    CanSelect= True;
  }
```

Delphi Examples:

```
  {
  The following code uses the bitmaps in an image list
  component to draw the contents of each cell in a draw grid.
  It draws a focus rectangle around the cell that has focus.
  goDrawFocusSelect in the DrawGrid Options parameter must be
  True to set focus on a cell.  The ImageList Draw method must
  be called after DrawFocusRect. The OnSelectCell event handler
  must implemented to return true.
  }
  procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
    Rect: TRect; State: TGridDrawState);
  var
    index: Integer;
  begin
    index := ARow * DrawGrid1.ColCount + ACol;
    DrawGrid1.Canvas.Brush.Color := clWhite;
    DrawGrid1.Canvas.FillRect(Rect);
    if (gdFocused in State) then
    begin
      DrawGrid1.Canvas.DrawFocusRect(Rect);
      Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
    end;
    ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  end;

  procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
    var CanSelect: Boolean);
  begin
    CanSelect:= True;
  end;
```

73.1.7.4.10 Ellipse Method

This is the overview for the Ellipse method overload.

Overload List

	Name	Description
	TCanvas.Ellipse (Integer, Integer, Integer, Integer) (see page 14457)	Draws the ellipse defined by a bounding rectangle on the canvas.
	TCanvas.Ellipse (TRect) (see page 14457)	Draws the ellipse defined by a bounding rectangle on the canvas.

73.1.7.4.10.1 TCanvas.Ellipse Method (Integer, Integer, Integer, Integer)

Draws the ellipse defined by a bounding rectangle on the canvas.

Pascal

```
procedure Ellipse(X1: Integer; Y1: Integer; X2: Integer; Y2: Integer); overload;
procedure Ellipse(const Rect: TRect); overload;
```

C++

```
__fastcall Ellipse(int X1, int Y1, int X2, int Y2);
__fastcall Ellipse(const TRect Rect);
```

Description

Call Ellipse to draw a circle or ellipse on the canvas. Specify the bounding rectangle either by giving

The top left point at pixel coordinates (X1, Y1) and the bottom right point at (X2, Y2).

A TRect value.

If the bounding rectangle is a square, a circle is drawn.

The ellipse is outlined using the value of Pen (see page 14492), and filled using the value of Brush (see page 14484).

Note: On Windows 9x or Windows ME, the sums X1 + X2 and Y1 + Y2 cannot exceed 32768. Also, the sum X1 + X2 + Y1 + Y2 cannot exceed 32768.

C++ Examples:

```
/*
The following example paints a cross-hatched ellipse onto
Image1 which is a TImage on the form when the user clicks on
Button1.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TCanvas *pCanvas = Image1->Canvas;
  pCanvas->Brush->Color = clRed;
  pCanvas->Brush->Style = bsDiagCross;
  pCanvas->Ellipse(0, 0, Image1->Width, Image1->Height);
}
```

Delphi Examples:

```
{
The following example paints a cross-hatched ellipse onto
Image1 which is a TImage on the form when the user clicks on
Button1.
```

```
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  with Image1 do begin
    Canvas.Brush.Color := clRed;
    Canvas.Brush.Style := bsDiagCross;
    Canvas.Ellipse(0, 0, Image1.Width, Image1.Height);
  end;
end;
```

73.1.7.4.11 TCanvas.FillRect Method

Fills the specified rectangle on the canvas using the current brush.

Pascal

```
procedure FillRect(const Rect: TRect);
```

C++

```
__fastcall FillRect(const TRect Rect);
```

Description

Use FillRect to fill a rectangular region using the current brush. The region is filled including the top and left sides of the rectangle, but excluding the bottom and right edges.

C++ Examples:

```
/*
The following code loads a bitmap from a file and assigns it
to the Brush of the Canvas of Form1:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *BrushBmp = new Graphics::TBitmap;
  try
  {
    BrushBmp->LoadFromFile("../bm1.BMP");
    Form1->Canvas->Brush->Bitmap = BrushBmp;
    Form1->Canvas->FillRect(Rect(0,0,100,100));
  }
  __finally
  {
    Form1->Canvas->Brush->Bitmap = NULL;
    delete BrushBmp;
  }
}
```

Delphi Examples:

```
{
The following code loads a bitmap from a file and assigns it
to the Brush of the Canvas of Form1:
}
var
  Bitmap: TBitmap;
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
  Bitmap := TBitmap.Create;
  try
    Bitmap.LoadFromFile('bm1.BMP');
    Form1.Canvas.Brush.Bitmap := Bitmap;
    Form1.Canvas.FillRect(Rect(0,0,100,100));
  finally
    Form1.Canvas.Brush.Bitmap := nil;
    Bitmap.Free;
  end;
end;
```

See Also

FloodFill (see page 14459)

73.1.7.4.12 TCanvas.FloodFill Method

Fills an area of the canvas using the current brush.

Pascal

```
procedure FloodFill(X: Integer; Y: Integer; Color: TColor; FillStyle: TFillStyle);
```

C++

```
__fastcall FloodFill(int X, int Y, TColor Color, TFillStyle FillStyle);
```

Description

Use FloodFill to fill a possibly non-rectangular region of the image with the value of Brush (see page 14484). The boundaries of the region to be filled are determined by moving outward from the point (X,Y) until a color boundary involving the Color parameter is encountered.

X and X are the coordinates on the canvas where filling starts.

Color is the color that defines the boundary of the region to fill. Its interpretation depends on the value of FillStyle.

FillStyle specifies whether the region is defined by all pixels with the same value as Color, or all points with a different value.

Tip: Use the Pixels (see page 14494) property to get the exact value of the color at the point (X,Y) when using a FillStyle of fsSurface. Similarly, when FillStyle is fsBorder, use Pixels (see page 14494) to get the exact value of the boundary color if a point on the boundary is known.

C++ Examples:

```
/*
The following code floodfills from the center point of
Form1's client area until the color black is encountered:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Canvas->Brush->Color = clBlue;
  Canvas->Brush->Style = bsDiagCross;
  Canvas->FloodFill(
    ClientWidth/2, ClientHeight/2, clBlack, fsBorder);
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  int ewidth = 400;
  int eheight = 200;
```

```
  Canvas->Brush->Color = clRed;
  Canvas->Pen->Color = clBlack;
  Canvas->Ellipse(
    (ClientWidth - ewidth)/2,
    (ClientHeight - eheight)/2,
    ewidth, eheight);
}
```

Delphi Examples:

```
{
The following code floodfills from the center point of
Form1's client area until the color black is encountered:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Canvas.Brush.Color := clBlue;
  Canvas.Brush.Style := bsDiagCross;
  Canvas.FloodFill(
    ClientWidth div 2, ClientHeight div 2, clBlack, fsBorder);
end;

procedure TForm1.Button2Click(Sender: TObject);
var ewidth, eheight: integer;
begin
  ewidth := 400;
  eheight := 200;
  Canvas.Brush.Color := clRed;
  Canvas.Pen.Color := clBlack;
  Canvas.Ellipse(
    (ClientWidth - ewidth) div 2,
    (ClientHeight - eheight) div 2,
    ewidth, eheight);
end;
```

See Also

FillRect (see page 14458)

Pixels (see page 14494)

73.1.7.4.13 TCanvas.FrameRect Method

Draws a rectangle using the Brush (see page 14484) of the canvas to draw the border.

Pascal

```
procedure FrameRect(const Rect: TRect);
```

C++

```
__fastcall FrameRect(const TRect Rect);
```

Description

Use FrameRect to draw a 1 pixel wide border around a rectangular region. FrameRect does not fill the interior of the rectangle with the Brush (see page 14484) pattern.

To draw a boundary using the Pen (see page 14492) instead, use the Polygon (see page 14466) method.

C++ Examples:

```
/*
The following code displays the text "Hello, world!" in a
rectangle defined by the coordinates (10, 10) and (100, 100).
After displaying the text with the TextRect method, the code
draws a black, vertical line frame around the rectangle.
```

```
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TRect TheRect = Rect(10,10,100,100);
  Canvas->TextRect(TheRect, 10, 10, "Hello World");
  Canvas->Brush->Color = clBlack;
  Canvas->FrameRect(TheRect);
}
```

Delphi Examples:

```
{
The following code displays the text "Hello, world!" in a
rectangle defined by the coordinates (10, 10) and (100, 100).
After displaying the text with the TextRect method, the code
draws a black, vertical line frame around the rectangle.
}
procedure TForm1.Button1Click(Sender: TObject);
var TheRect: TRect;
begin
  TheRect := Rect(10,10,100,100);
  Form1.Canvas.TextRect(TheRect,10,10,'Hello, world!');
  Form1.Canvas.Brush.Color := clBlack;
  Form1.Canvas.FrameRect(TheRect);
end;
```

Rectangle (see page 14468)

RoundRect (see page 14471)

73.1.7.4.14 TCanvas.HandleAllocated Method

Indicates whether the TCanvas (see page 14441) object has acquired a handle to a device context.

Pascal

```
function HandleAllocated: Boolean;
```

C++

```
__fastcall Boolean HandleAllocated();
```

Description

Use HandleAllocated to determine whether the Handle (see page 14489) property is set to an HDC value. HandleAllocated indicates whether the canvas has acquired a device context. Use HandleAllocated rather than reading the Handle (see page 14489) property. When an application reads the Handle (see page 14489) property, TCanvas (see page 14441) automatically allocates a new device context and returns its handle if the property had not been previously set.

See Also

Handle (see page 14489)

73.1.7.4.15 TCanvas.LineTo Method

Draws a line on the canvas from PenPos (see page 14494) to the point specified by X and Y, and sets the pen position to (X, Y).

Pascal

```
procedure LineTo(X: Integer; Y: Integer);
```

C++

```
__fastcall LineTo(int X, int Y);
```

Description

Use LineTo to draw a line from PenPos (see page 14494) up to, but not including the point (X,Y). LineTo changes the value of PenPos (see page 14494) to (X,Y).

The line is drawn using Pen (see page 14492).

Note: If the current Pen (see page 14492) does not have a style of psSolid, the line is drawn with a background specified by the current brush.

C++ Examples:

```
/*
The following code draws a line from the upper left corner
of a form to the mouse position when the mouse is moved,
creating a "rubber band" effect.
*/
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  /* first call FillRect to paint the surface of the form.
  this removes any previously drawn lines (and anything else!) */
  Canvas->FillRect(ClientRect);
  Canvas->MoveTo(0, 0);
  Canvas->LineTo(X, Y);
}
```

Delphi Examples:

```
{
The following code draws a line from the upper left corner
of a form to the mouse position when the mouse is moved,
creating a "rubber band" effect.
}
procedure TForm1.FormMouseMove(
  Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  { first call FillRect to paint the surface of the form.
  this removes any previously drawn lines (and anything else!) }
  Canvas.FillRect(ClientRect);
  Canvas.MoveTo(0, 0);
  Canvas.LineTo(X, Y);
end;
```

Pen (see page 14492)

PenPos (see page 14494)

Polyline (see page 14467)

Style (see page 14579)

Brush (see page 14484)

73.1.7.4.16 TCanvas.Lock Method

Prevents other threads from drawing on the canvas.

Pascal

```
procedure Lock;
```

C++

```
__fastcall Lock();
```

Description

Call Lock in a multithreaded application to prevent other threads from drawing on the canvas. Lock prevents other cooperating threads in the application from executing until the Unlock (see page 14483) method is called. Nested calls to Lock increment the LockCount (see page 14492) property so that the canvas is not unlocked until the last lock is released.

In multi-threaded applications that use Lock to protect a canvas, all calls that use the canvas must be protected by a call to Lock. Any thread that does not lock the canvas before using it will introduce potential bugs.

Because Lock prevents other threads from executing, it can adversely affect performance. Do not call Lock unless there is a danger that another thread might interfere with drawing on the canvas.

See Also

LockCount (see page 14492)

TryLock (see page 14483)

Unlock (see page 14483)

Locking Objects

73.1.7.4.17 TCanvas.MoveTo Method

Changes the current drawing position to the point (X,Y).

Pascal

```
procedure MoveTo(X: Integer; Y: Integer);
```

C++

```
__fastcall MoveTo(int X, int Y);
```

Description

Use MoveTo to set the value of PenPos (see page 14494) before calling LineTo (see page 14462). Calling MoveTo is equivalent to setting the PenPos (see page 14494) property.

C++ Examples:

```
/*
The following code draws a line from the upper left corner
of a form to the mouse position when the mouse is moved,
creating a "rubber band" effect.
*/
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  /* first call FillRect to paint the surface of the form.
  this removes any previously drawn lines (and anything else!) */
  Canvas->FillRect(ClientRect);
  Canvas->MoveTo(0, 0);
```

```
  Canvas->LineTo(X, Y);
}
```

Delphi Examples:

```
{
The following code draws a line from the upper left corner
of a form to the mouse position when the mouse is moved,
creating a "rubber band" effect.
}
procedure TForm1.FormMouseMove(
  Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  { first call FillRect to paint the surface of the form.
  this removes any previously drawn lines (and anything else!) }
  Canvas.FillRect(ClientRect);
  Canvas.MoveTo(0, 0);
  Canvas.LineTo(X, Y);
end;
```

See Also

LineTo (see page 14462)

PenPos (see page 14494)

73.1.7.4.18 TCanvas.Pie Method

Draws a pie-shaped the section of the ellipse bounded by the rectangle (X1, Y1) and (X2, Y2) on the canvas.

Pascal

```
procedure Pie(X1: Integer; Y1: Integer; X2: Integer; Y2: Integer; X3: Integer; Y3: Integer;
X4: Integer; Y4: Integer);
```

C++

```
__fastcall Pie(int X1, int Y1, int X2, int Y2, int X3, int Y3, int X4, int Y4);
```

Description

Use Pie to draw a pie-shaped wedge on the image. The wedge is defined by the ellipse bounded by the rectangle determined by the points (X1, Y1) and X2, Y2). The section drawn is determined by two lines radiating from the center of the ellipse through the points (X3, Y3) and (X4, Y4).

The wedge is outlined using Pen (see page 14492), and filled using Brush (see page 14484).

Note: On Windows 9x or Windows ME, the sums X1 + X2 and Y1 + Y2 cannot exceed 32768. Also, the sum X1 + X2 + Y1 + Y2 cannot exceed 32768.

Brush (see page 14484)

Chord (see page 14451)

Pen (see page 14492)

73.1.7.4.19 TCanvas.PolyBezier Method

Draws a set of Bezier curves.

Pascal

```
procedure PolyBezier(const Points: array of TPoint);
```

C++

```
__fastcall PolyBezier(const array of TPoint Points);
```

Description

Use PolyBezier to draw cubic Bezier curves using the endpoints and control points specified by the Points parameter. The first curve is drawn from the first point to the fourth point, using the second and third points as control points. Each subsequent curve in the sequence needs exactly three more points: the ending point of the previous curve is used as the starting point, the next two points in the sequence are control points, and the third is the ending point.

The Points parameter gives the endpoints to use when generating the Bezier curves.

Note: The Points_Size parameter is the index of the last point in the array (one less than the total number of points).

This procedure draws lines by using the current pen.

Note: In Delphi, you can use the Slice function to pass a portion of an array of points to the PolyBezier method. For example, to form a Bezier curve using the first ten points from an array of 100 points, use the Slice function as follows:

```
Canvas.PolyBezier(Slice(PointArray, 10));
```

Control points after a[Index+3] are ignored. Nothing happens if there aren't enough control points.

See Also

Polyline (see page 14467)

PolyBezierTo (see page 14465)

Pen (see page 14492)

73.1.7.4.20 TCanvas.PolyBezierTo Method

Draws a set of Bezier curves and updates the value of PenPos (see page 14494).

Pascal

```
procedure PolyBezierTo(const Points: array of TPoint);
```

C++

```
__fastcall PolyBezierTo(const array of TPoint Points);
```

Description

Use PolyBezierTo to draw cubic Bezier curves using the endpoints and control points specified by the Points parameter. The first curve is drawn from the first point to the fourth point, using the second and third points as control points. Each subsequent curve in the sequence needs exactly three more points: the ending point of the previous curve is used as the starting point, the next two points in the sequence are control points, and the third is the ending point.

The Points parameter gives the endpoints to use when generating the Bezier curves.

Note: The Points_Size parameter is the index of the last point in the array (one less than the total number of points).

This procedure draws lines by using the current pen and updates the value of PenPos (see page 14494) to the value of the last endpoint.

Note: In Delphi, you can use the Slice function to pass a portion of an array of points to the PolyBezierTo method. For example, to form a Bezier curve using the first ten points from an array of 100 points, use the Slice function as follows:

```
Canvas.PolyBezierTo(Slice(PointArray, 10));
```

See Also

Polyline (see page 14467)

PolyBezier (see page 14464)

Pen (see page 14492)

PenPos (see page 14494)

73.1.7.4.21 TCanvas.Polygon Method

Draws a series of lines on the canvas connecting the points passed in and closing the shape by drawing a line from the last point to the first point.

Pascal

```
procedure Polygon(const Points: array of TPoint);
```

C++

```
__fastcall Polygon(const array of TPoint Points);
```

Description

Use Polygon to draw a closed, many-sided shape on the canvas, using the value of Pen (see page 14492). After drawing the complete shape, Polygon fills the shape using the value of Brush (see page 14484).

The Points parameter is an array of points that give the vertices of the polygon.

Note: The Points_Size parameter is the index of the last point in the array (one less than the total number of points).

The first point is always connected to the last point.

Note: In Delphi, you can use the Slice function to pass a portion of an array of points to the Polygon method. For example, to form a polygon using the first ten points from an array of 100 points, use the Slice function as follows:

```
Canvas.Polygon(Slice(PointArray, 10));
```

To draw a polygon on the canvas, without filling it, use the Polyline (see page 14467) method, specifying the first point a second time at the end.

C++ Examples:

```
/*
This example draws a polygon in the specified shape, and
fills it with the color teal.
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
  TPoint points[4];
  points[0] = Point(10,10);
  points[1] = Point(30,10);
  points[2] = Point(130,30);
  points[3] = Point(240,120);
  ((TPaintBox *)Sender)->Canvas->Brush->Color = clTeal;
  ((TPaintBox *)Sender)->Canvas->Polygon(points, 3);
}
```

Delphi Examples:

```
{
This example draws a polygon in the specified shape, and
fills it with the color teal.
}
procedure TForm1.FormPaint(Sender: TObject);
begin
  Canvas.Brush.Color := clTeal;
  Canvas.Polygon([Point(10, 10), Point(30, 10),
    Point(130, 30), Point(240, 120)]);
end;
```

See Also

Brush (see page 14484)

Pen (see page 14492)

Polyline (see page 14467)

Slice (see page 22529)

73.1.7.4.22 TCanvas.Polyline Method

Draws a series of lines on the canvas with the current pen, connecting each of the points passed to it in Points.

Pascal

```
procedure Polyline(const Points: array of TPoint);
```

C++

```
__fastcall Polyline(const array of TPoint Points);
```

Description

Use Polyline to connect a set of points on the canvas. If you specify only two points, Polyline draws a single line.

The Points parameter is an array of points to be connected.

Note: The Points_Size parameter is the index of the last point in the array (one less than the total number of points).

Note: In Delphi, you can use the Slice function to pass a portion of an array of points to the Polyline method. For example, to form a line connecting the first ten points from an array of 100 points, use the Slice function as follows:

```
Canvas.Polyline(Slice(PointArray, 10));
```

Calling the MoveTo (see page 14463) function with the value of the first point, and then repeatedly calling LineTo (see page 14462) with all subsequent points will draw the same image on the canvas. However, unlike LineTo (see page 14462), Polyline does not change the value of PenPos (see page 14494).

C++ Examples:

```
/*
This example paints a white five-pointed star in a paintbox
control:
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
  TPaintBox *pPB = (TPaintBox *)Sender;
  TPoint points[6];
  pPB->Canvas->Pen->Color = clWhite;
  points[0].x = 40;
  points[0].y = 10;
```

```
  points[1].x = 20;
  points[1].y = 60;
  points[2].x = 70;
  points[2].y = 30;
  points[3].x = 10;
  points[3].y = 30;
  points[4].x = 60;
  points[4].y = 60;
  points[5].x = 40;
  points[5].y = 10;
  pPB->Canvas->Polyline(points,5);
}
```

Delphi Examples:

```
{
This example paints a white five-pointed star in a paintbox
control:
}
procedure TForm1.PaintBox1Paint(Sender: TObject);
begin
  with Sender as TPaintBox do
  begin
    Canvas.Pen.Color := clWhite;
    Canvas.Polyline([Point(40, 10), Point(20, 60), Point(70, 30),
    Point(10, 30), Point(60, 60), Point(40, 10)]);
  end;
end;
```

73.1.7.4.23 Rectangle Method

This is the overview for the Rectangle method overload.

Overload List

	Name	Description
	TCanvas.Rectangle (Integer, Integer, Integer, Integer) (see page 14468)	Draws a rectangle on the canvas.
	TCanvas.Rectangle (TRect) (see page 14468)	Draws a rectangle on the canvas.

73.1.7.4.23.1 TCanvas.Rectangle Method (Integer, Integer, Integer, Integer)

Draws a rectangle on the canvas.

Pascal

```
procedure Rectangle(X1: Integer; Y1: Integer; X2: Integer; Y2: Integer); overload;
procedure Rectangle(const Rect: TRect); overload;
```

C++

```
__fastcall Rectangle(int X1, int Y1, int X2, int Y2);
__fastcall Rectangle(const TRect Rect);
```

Description

Use Rectangle to draw a rectangle using Pen (see page 14492) and fill it with Brush (see page 14484). Specify the rectangle's coordinates in one of two ways:

Giving four coordinates that define the upper left corner at the point (X1, Y1) and the lower right corner at the point (X2, Y2).

Using a TRect type.

To fill a rectangular region without drawing the boundary in the current pen, use FillRect (see page 14458). To outline a rectangular region without filling it, use FrameRect (see page 14460) or Polygon (see page 14466). To draw a rectangle with rounded corners, use RoundRect (see page 14471).

C++ Examples:

```
/*
This example draws many rectangles of various sizes and
colors on a form maximized to fill the entire screen. To run
the code, drop a TTimer component on the form and use the
object inspector to create the OnTimer and OnActivate event
handlers.
*/
int x, y;

void __fastcall TForm1::FormActivate(TObject *Sender)
{
  WindowState = wsMaximized;
  Timer1->Interval = 50;
  randomize();
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  x = random(Screen->Width - 10);
  y = random(Screen->Height - 10);
  Canvas->Pen->Color = (Graphics::TColor) random(65535);
  switch (random(5))
  {
    case 0: Canvas->Pen->Style = psSolid; break;
    case 1: Canvas->Pen->Style = psDash; break;
    case 2: Canvas->Pen->Style = psDot; break;
    case 3: Canvas->Pen->Style = psDashDot; break;
    case 4: Canvas->Pen->Style = psDashDotDot; break;
  }
  Canvas->Rectangle(x, y, x + random(400), y + random(400));
}
```

Delphi Examples:

```
{
This example draws many rectangles of various sizes and
colors on a form maximized to fill the entire screen. To run
the code, drop a TTimer component on the form and use the
object inspector to create the OnTimer and OnActivate event
handlers.
}
var
  X, Y: Integer;
procedure TForm1.FormActivate(Sender: TObject);
begin
  WindowState := wsMaximized;
  Timer1.Interval := 50;
```

```
    Randomize;
  end;

  procedure TForm1.Timer1Timer(Sender: TObject);
  begin
    X := Random(Screen.Width - 10);
    Y := Random(Screen.Height - 10);
    Canvas.Pen.Color := Random(65535);
    case Random(5) of
      0: Canvas.Pen.Style := psSolid;
      1: Canvas.Pen.Style := psDash;
      2: Canvas.Pen.Style := psDot;
      3: Canvas.Pen.Style := psDashDot;
      4: Canvas.Pen.Style := psDashDotDot;
    end;
    Canvas.Rectangle(X, Y, X + Random(400), Y + Random(400));
  end;
```

FillRect (see page 14458)

FrameRect (see page 14460)

Pen (see page 14492)

Polygon (see page 14466)

RoundRect (see page 14471)

73.1.7.4.24 TCanvas.Refresh Method

Deselects the Pen (see page 14492), Brush (see page 14484), and Font (see page 14488) from the device context.

Pascal

```
procedure Refresh;
```

C++

```
__fastcall Refresh();
```

Description

Call Refresh to return the HDC used by the canvas to a default state. Refresh does not change the values of the Font (see page 14488), Brush (see page 14484), or Pen (see page 14492) properties. Calling any of the drawing methods of the canvas after calling Refresh will reselect the Font (see page 14488), Brush (see page 14484), or Pen (see page 14492) into the HDC if it is used by the drawing method.

See Also

Brush (see page 14484)

Font (see page 14488)

Handle (see page 14489)

Pen (see page 14492)

73.1.7.4.25 TCanvas.RequiredState Method

Pascal

```
procedure RequiredState(ReqState: TCanvasState);
```

C++

```
__fastcall RequiredState(TCanvasState ReqState);
```

Description

This is RequiredState, a member of class TCanvas.

73.1.7.4.26 TCanvas.RoundRect Method

Draws a rectangle with rounded corners on the canvas.

Pascal

```
procedure RoundRect(X1: Integer; Y1: Integer; X2: Integer; Y2: Integer; X3: Integer; Y3:
Integer);
```

C++

```
__fastcall RoundRect(int X1, int Y1, int X2, int Y2, int X3, int Y3);
```

Description

Use RoundRect to draw a rounded rectangle using Pen (see page 14492) and fill it with Brush (see page 14484). The rectangle will have edges defined by the points (X1,Y1), (X2,Y1), (X2,Y2), (X1,Y2), but the corners will be shaved to create a rounded appearance. The curve of the rounded corners matches the curvature of an ellipse with width X3 and height Y3.

To draw an ellipse instead, use Ellipse (see page 14457). To draw a true rectangle, use Rectangle (see page 14468).

C++ Examples:

```
/*
This example draws many rounded rectangles of various sizes
and colors on a form maximized to fill the entire screen:
*/
int x, y;

void __fastcall TForm1::FormActivate(TObject *Sender)
{
  WindowState = wsMaximized;
  Timer1->Interval = 50;
  randomize();
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  x = random(Screen->Width - 10);
  y = random(Screen->Height - 10);
  Canvas->Pen->Color = (Graphics::TColor) random(65535);
  Canvas->Pen->Width = random(7);
  int Dx = random(400);
  int Dy = random(400);
  Canvas->RoundRect(x, y, x + Dx, y + Dy, Dx/2, Dy/2);
}
```

Delphi Examples:

```
{
This example draws many rounded rectangles of various sizes
and colors on a form maximized to fill the entire screen:
}
var
  X, Y, DX, DY: Integer;
procedure TForm1.FormActivate(Sender: TObject);
begin
  WindowState := wsMaximized;
  Timer1.Interval := 50;
```

```
    Randomize;
  end;

  procedure TForm1.Timer1Timer(Sender: TObject);
  begin
    X := Random(Screen.Width - 10);
    Y := Random(Screen.Height - 10);
    Canvas.Pen.Color := Random(65535);
    Canvas.Pen.Width := Random(7);
    DX := Random(400);
    DY := Random(400);
    Canvas.RoundRect(X, Y, X + DX, Y + DY, DX div 2, DY div 2);
  end;
```

See Also

Brush (see page 14484)

Ellipse (see page 14457)

Pen (see page 14492)

Rectangle (see page 14468)

73.1.7.4.27 TCanvas.StretchDraw Method

Draws the graphic specified by the Graphic parameter in the rectangle specified by the Rect parameter.

Pascal

```
procedure StretchDraw(const Rect: TRect; Graphic: TGraphic);
```

C++

```
__fastcall StretchDraw(const TRect Rect, TGraphic Graphic);
```

Description

Call StretchDraw to draw a graphic on the canvas so that the image fits in the specified rectangle. StretchDraw calls the Draw (see page 14454) method of the graphic. The graphic object determines how to fit into the rectangle. This may involve changing magnification and/or aspect ratio.

To render the graphic in its natural size, use the Draw (see page 14454) method, instead.

If the graphic is a TBitmap (see page 14396) object, the bitmap is rendered using the value of CopyMode (see page 14487).

Note: If the graphic is an icon, it is not stretched.

C++ Examples:

```
/*
The following example is taken from the custom draw demo. It
shows how the OnCustomDraw event handler draws the
background for the tree view before the items and lines are
drawn.
*/
void __fastcall TCustomDrawForm::TVCustomDraw(TCustomTreeView *Sender,
      const TRect &ARect, bool &DefaultDraw)
{
/*
This event should be used to draw any background colors or
images.  ARect represents the entire client area of the TreeView.
Use the TreeView's canvas to do the drawing.
Note that drawing a background bitmap is not really
supported by CustomDraw, so scrolling can get messy. Best to
```

```
subclass the TreeView and handle scrolling messages.
*/
  if (None1 != NULL)
  {
    if (None1->Checked) //no picture
    {
      TV->Canvas->Brush->Color = BkgColorDialog->Color;
      TV->Canvas->Brush->Style = FBrushStyle;
      TV->Canvas->FillRect(ARect);
    }
    else if (Tile1->Checked) //tile bitmap
    {
      TV->Canvas->Brush->Bitmap = Image1->Picture->Bitmap;
      TV->Canvas->FillRect(ARect);
    }
    else //Stretch across the canvas.
      TV->Canvas->StretchDraw(ARect, Image1->Picture->Bitmap);
  };
  DefaultDraw = FDefaultDraw;
  // Setting DefaultDraw to false here prevents all calls to
  // OnCustomDrawItem.
}
```

Delphi Examples:

```
{
The following example is taken from the custom draw demo. It
shows how the OnCustomDraw event handler draws the
background for the tree view before the items and lines are
drawn.
}
procedure TCustomDrawForm.TVCustomDraw(Sender: TCustomTreeView; const ARect: TRect;
  var DefaultDraw: Boolean);
begin
{
This event should be used to draw any background colors or
images.  ARect represents the entire client area of the TreeView.
Use the TreeView's canvas to do the drawing.
Note that drawing a background bitmap is not really
supported by CustomDraw, so scrolling can get messy. Best to
subclass the TreeView and handle scrolling messages.
}
  with TV.Canvas do
  begin
    if None1 <> nil then
    begin
      if None1.Checked then //no picture
      begin
        Brush.Color := BkgColorDialog.Color;
        Brush.Style := FBrushStyle;
        FillRect(ARect);
      end else
        if Tile1.Checked then //tile bitmap
        begin
          Brush.Bitmap := Image1.Picture.Bitmap;
            FillRect(ARect);
          end else //Stretch across the canvas.
              StretchDraw(ARect, Image1.Picture.Bitmap);
    end;
  end;
  DefaultDraw := FDefaultDraw;
  // Setting DefaultDraw to false here prevents all calls to
  // OnCustomDrawItem.
end;
```

CopyMode (see page 14487)

CopyRect (see page 14452)

Draw (see page 14454)

73.1.7.4.28 TCanvas.TextExtent Method

Returns the width and height, in pixels, of a string rendered in the current font.

Pascal

```
function TextExtent(const Text: string): TSize;
```

C++

```
__fastcall TSize TextExtent(const AnsiString Text);
```

Description

Use TextExtent to determine the space a string will occupy in the image. Other elements in the image such as lines, boxes, or additional lines of text can be positioned to accommodate the size of the text. TextExtent returns the width and height of the rectangle that bounds the text on the canvas.

To check only the height, call TextHeight (see page 14474). To check only the width, call TextWidth (see page 14481).

See Also

Font (see page 14488)

TextHeight (see page 14474)

TextOut (see page 14475)

TextWidth (see page 14481)

73.1.7.4.29 TCanvas.TextHeight Method

Returns the height, in pixels, of a string rendered in the current font.

Pascal

```
function TextHeight(const Text: string): Integer;
```

C++

```
__fastcall int TextHeight(const AnsiString Text);
```

Description

Use TextHeight to determine the height a string will occupy in the image. Other elements in the image such as lines, boxes, or additional lines of text can be positioned to accommodate the height of the text. TextHeight returns the height of the font, the ascenders plus the descenders, not the actual height of the specified string. If Font.Height is negative, then TextHeight is equal to abs(Font.Height) plus the internal leading of the font. If Font.Height is positive, then TextHeight equals Font.Height.

TextHeight returns the same value as TextExtent (see page 14474)(Text).cy.

C++ Examples:

```
/*
This project requires a TPageControl and several TTabPages.
To add new pages, right-click the TPageControl and select
New Page.  During the form creation the width and height of
```

```
all tabs on the Page Control becomes double the largest
previous value. So if there are three tabs with captions that
are 12, 23, and 19 characters long, the TabWidth would be the
number of pixels required to fit 46 characters.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < PageControl1->PageCount; i++)
  {
     AnsiString s = PageControl1->Pages[i]->Caption;
     if (Canvas->TextWidth(s) * 2 > PageControl1->TabWidth)
        PageControl1->TabWidth = Canvas->TextWidth(s) * 2;
      if (Canvas->TextHeight(s) * 2 > PageControl1->TabHeight)
        PageControl1->TabHeight = Canvas->TextHeight(s) * 2;
  }
}
```

Delphi Examples:

```
{
This project requires a TPageControl and several TTabPages.
To add new pages, right-click the TPageControl and select
New Page.  During the form creation the width and height of
all tabs on the Page Control becomes double the largest
previous value. So if there are three tabs with captions that
are 12, 23, and 19 characters long, the TabWidth would be the
number of pixels required to fit 46 characters.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  with PageControl1 do
  begin
    for i := 0 to PageCount - 1 do
    begin
      if (Canvas.TextWidth(Pages[i].Caption) * 2) > TabWidth then
        TabWidth := Canvas.TextWidth(Pages[i].Caption) * 2;
      if (Canvas.TextHeight(Pages[i].Caption) * 2) > TabHeight then
        TabHeight := Canvas.TextHeight(Pages[i].Caption) * 2;
    end;
  end;
end;
```

TextExtent (see page 14474)

TextOut (see page 14475)

TextWidth (see page 14481)

73.1.7.4.30 TCanvas.TextOut Method

Writes a string on the canvas, starting at the point (X,Y), and then updates the PenPos (see page 14494) to the end of the string.

Pascal

```
procedure TextOut(X: Integer; Y: Integer; const Text: string);
```

C++

```
__fastcall TextOut(int X, int Y, const AnsiString Text);
```

Description

Use TextOut to write a string onto the canvas. The string will be written using the current value of Font (see page 14488). Use the TextExtent (see page 14474) method to determine the space occupied by the text in the image. To write only the text that fits within a clipping rectangle, use TextRect (see page 14480) instead.

After a call to TextOut, the PenPos (see page 14494) property indicates the point at the top right of the text on the canvas.

C++ Examples:

```
/*
Add a THeaderControl to the form and call
HeaderControl1DrawSection for the OnDrawSection event.
*/
void __fastcall TForm1::HeaderControl1DrawSection(THeaderControl *HeaderControl,
      THeaderSection *Section, const TRect &Rect, bool Pressed)
{
  if (Pressed)
    HeaderControl->Canvas->Font->Color = clRed;
  else
    HeaderControl->Canvas->Font->Color = clBlue;
  HeaderControl->Canvas->TextOut(Rect.Left + HeaderControl->Canvas->Font->Size, Rect.Top + 2,
"Custom " + IntToStr(Section->Index));
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  THeaderSection *Section;
  for (int i = 0; i <= 4; i++)
  {
    Section = HeaderControl1->Sections->Add();
    Section->Text = "Section " + IntToStr(i);
    Section->MinWidth =
      (Section->Text).Length() *
      HeaderControl1->Font->Size;
    // Owner draw every other section
    if (i % 2 == 0)
      Section->Style = hsOwnerDraw;
    else
      Section->Style = hsText;
  }
}
/*

73.1.7.4.31 TextRect Method

This is the overview for the TextRect method overload.

Overload List

	Name	Description
	TCanvas.TextRect (TRect, Integer, Integer, string) (see page 14480)	Writes a string inside a clipping rectangle.
	TCanvas.TextRect (TRect, string, TTextFormat) (see page 14480)	Writes a string inside a clipping rectangle.

73.1.7.4.31.1 TCanvas.TextRect Method (TRect, Integer, Integer, string)

Writes a string inside a clipping rectangle.

Pascal

```
procedure TextRect(Rect: TRect; X: Integer; Y: Integer; const Text: string); overload;
procedure TextRect(var Rect: TRect; var Text: string; TextFormat: TTextFormat = []); overload;
```

C++

```
__fastcall TextRect(TRect Rect, int X, int Y, const AnsiString Text);
__fastcall TextRect(TRect Rect, AnsiString Text, TTextFormat TextFormat = []);
```

Description

Use TextRect to write a string within a limited rectangular region. Any portions of the string that fall outside the rectangle passed in the Rect parameter are clipped and don't appear. The upper left corner of the text is placed at the point (X, Y).

C++ Examples:

```
/*
The following code displays the text "Hello, world!" in a
rectangle defined by the coordinates (10, 10) and (100, 100).
After displaying the text with the TextRect method, the code
draws a black, vertical line frame around the rectangle.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TRect TheRect = Rect(10,10,100,100);
  Canvas->TextRect(TheRect, 10, 10, "Hello World");
  Canvas->Brush->Color = clBlack;
  Canvas->FrameRect(TheRect);
}
```

Delphi Examples:

```
{
The following code displays the text "Hello, world!" in a
rectangle defined by the coordinates (10, 10) and (100, 100).
After displaying the text with the TextRect method, the code
draws a black, vertical line frame around the rectangle.
}
procedure TForm1.Button1Click(Sender: TObject);
var TheRect: TRect;
begin
  TheRect := Rect(10,10,100,100);
  Form1.Canvas.TextRect(TheRect,10,10,'Hello, world!');
  Form1.Canvas.Brush.Color := clBlack;
  Form1.Canvas.FrameRect(TheRect);
end;
```

73.1.7.4.32 TCanvas.TextWidth Method

Returns the width, in pixels, of a string rendered in the current font.

Pascal

```
function TextWidth(const Text: string): Integer;
```

C++

```
__fastcall int TextWidth(const AnsiString Text);
```

Description

Use TextWidth to determine the length a string will occupy in the image. TextWidth indicates whether a given string will fit in the

available space. Other graphical elements in the image such as lines, or additional strings can be positioned to accommodate the width of the text.

TextWidth returns the same value as TextExtent (see page 14474)(Text).cx.

C++ Examples:

```
/*
This project requires a TPageControl and several TTabPages.
To add new pages, right-click the TPageControl and select
New Page.  During the form creation the width and height of
all tabs on the Page Control becomes double the largest
previous value. So if there are three tabs with captions that
are 12, 23, and 19 characters long, the TabWidth would be the
number of pixels required to fit 46 characters.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < PageControl1->PageCount; i++)
  {
     AnsiString s = PageControl1->Pages[i]->Caption;
     if (Canvas->TextWidth(s) * 2 > PageControl1->TabWidth)
        PageControl1->TabWidth = Canvas->TextWidth(s) * 2;
      if (Canvas->TextHeight(s) * 2 > PageControl1->TabHeight)
        PageControl1->TabHeight = Canvas->TextHeight(s) * 2;
  }
}
```

Delphi Examples:

```
{
This project requires a TPageControl and several TTabPages.
To add new pages, right-click the TPageControl and select
New Page.  During the form creation the width and height of
all tabs on the Page Control becomes double the largest
previous value. So if there are three tabs with captions that
are 12, 23, and 19 characters long, the TabWidth would be the
number of pixels required to fit 46 characters.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  with PageControl1 do
  begin
    for i := 0 to PageCount - 1 do
    begin
      if (Canvas.TextWidth(Pages[i].Caption) * 2) > TabWidth then
        TabWidth := Canvas.TextWidth(Pages[i].Caption) * 2;
      if (Canvas.TextHeight(Pages[i].Caption) * 2) > TabHeight then
        TabHeight := Canvas.TextHeight(Pages[i].Caption) * 2;
    end;
  end;
end;
```

73.1.7.4.33 TCanvas.TryLock Method

Locks the canvas if it is currently unlocked.

Pascal

```
function TryLock: Boolean;
```

C++

```
__fastcall Boolean TryLock();
```

Description

Call TryLock to prevent other threads from writing on the surface of the canvas until the Unlock (see page 14483) method is called. Unlike calls to the Lock (see page 14463) method, which nest so that every call to Lock (see page 14463) must be matched with a subsequent call to Unlock (see page 14483), TryLock need only be matched by a call to Unlock (see page 14483) if the canvas was not already locked.

If the canvas is unlocked, TryLock locks the canvas, sets the LockCount (see page 14492) property to 1, and returns true. If the canvas is already locked, TryLock returns false without making any changes.

Use TryLock before attempting changes to the canvas that could interfere with other code that is protected by a Lock (see page 14463)/Unlock (see page 14483) pair of method calls.

See Also

Lock (see page 14463)

LockCount (see page 14492)

Unlock (see page 14483)

73.1.7.4.34 TCanvas.Unlock Method

Decreases the LockCount (see page 14492) property, allowing other threads to execute when LockCount (see page 14492) reaches 0.

Pascal

```
procedure Unlock;
```

C++

```
__fastcall Unlock();
```

Description

Call Unlock at the end of a critical section begun with a call to the Lock (see page 14463) method. Every call to Lock (see page 14463) must be matched by a call to Unlock.

See Also

Lock (see page 14463)

LockCount (see page 14492)

Locking Objects

73.1.7.5 TCanvas Properties

The properties of the TCanvas class are listed here.

Public Properties

	Name	Description
R	CanvasOrientation (see page 14485)	Determines the orientation of the canvas as left-to-right or right-to-left.
R	ClipRect (see page 14486)	Read-only property that specifies the boundaries of the clipping rectangle.
	Handle (see page 14489)	Specifies the handle for this canvas.
R	LockCount (see page 14492)	Indicates the number of times the canvas has been locked to prevent interference from other threads.
	PenPos (see page 14494)	Specifies the current drawing position of the Pen (see page 14492).
	Pixels (see page 14494)	Specifies the color of the pixels within the current ClipRect (see page 14486).
	TextFlags (see page 14495)	Specifies how text is written to the canvas.

Published Properties

	Name	Description
	Brush (see page 14484)	Determines the color and pattern for filling graphical shapes and backgrounds.
	CopyMode (see page 14487)	Specifies how a graphical image is copied onto the canvas.
	Font (see page 14488)	Specifies the font to use when writing text on the image.
	Pen (see page 14492)	Specifies the kind of pen the canvas uses for drawing lines and outlining shapes.

73.1.7.5.1 TCanvas.Brush Property

Determines the color and pattern for filling graphical shapes and backgrounds.

Pascal

```
property Brush: TBrush;
```

C++

```
__property TBrush Brush;
```

Description

Set the Brush property to specify the color and pattern to use when drawing the background or filling in graphical shapes. The value of Brush is a TBrush (see page 14430) object. Set the properties of the TBrush (see page 14430) object to specify the color and pattern or bitmap to use when filling in spaces on the canvas.

Note: Setting the Brush property assigns the specified TBrush (see page 14430) object, rather than replacing the current TBrush (see page 14430) object.

C++ Examples:

```
/*
The following code loads a bitmap from a file and assigns it
to the Brush of the Canvas of Form1:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *BrushBmp = new Graphics::TBitmap;
  try
  {
    BrushBmp->LoadFromFile("../bm1.BMP");
    Form1->Canvas->Brush->Bitmap = BrushBmp;
    Form1->Canvas->FillRect(Rect(0,0,100,100));
  }
```

```
  __finally
  {
    Form1->Canvas->Brush->Bitmap = NULL;
    delete BrushBmp;
  }
}
```

Delphi Examples:

```
{
The following code loads a bitmap from a file and assigns it
to the Brush of the Canvas of Form1:
}
var
  Bitmap: TBitmap;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Bitmap := TBitmap.Create;
  try
    Bitmap.LoadFromFile('bm1.BMP');
    Form1.Canvas.Brush.Bitmap := Bitmap;
    Form1.Canvas.FillRect(Rect(0,0,100,100));
  finally
    Form1.Canvas.Brush.Bitmap := nil;
    Bitmap.Free;
  end;
end;
```

RoundRect (see page 14471)

73.1.7.5.2 TCanvas.CanvasOrientation Property

Determines the orientation of the canvas as left-to-right or right-to-left.

Pascal

```
property CanvasOrientation: TCanvasOrientation;
```

C++

```
__property TCanvasOrientation CanvasOrientation;
```

Description

CanvasOrientation is a read-only property used for bi-directional support. It indicates whether the orientation of the canvas is left-to-right (coLeftToRight) or right-to-left (coRightToLeft). The default is coLeftToRight, meaning that the 0,0 coordinate is at the top left corner of the canvas. In Middle eastern locales the orientation may be coRightToLeft, meaning that the 0,0 coordinate is at the top right corner of the canvas. This property is important for grid controls because it changes the grid's canvas orientation during drawing.

See Also

BiDiMode (see page 5803)

73.1.7.5.3 TCanvas.ClipRect Property

Read-only property that specifies the boundaries of the clipping rectangle.

Pascal

```
property ClipRect: TRect;
```

C++

```
__property TRect ClipRect;
```

Description

Use ClipRect to determine where the canvas needs painting. ClipRect limits the drawing region of the canvas so that any drawing that occurs at coordinates outside the ClipRect is clipped and does not appear in the image.

When handling a form's OnPaint event, the canvas' ClipRect property is set to the rectangle that needs to be painted. Portions of the image that do not overlap the ClipRect do not need to be drawn. Thus, OnPaint routines can use the value of ClipRect to optimize painting, speeding the overall performance of the application.

Note: ClipRect can be modified using the SelectClipRgn Win32 API.

C++ Examples:

```
/*
This example creates a region and selects this region as the
clipping rectangle for the Image component's canvas. It then
sets the canvas's brush color to red and calls FillRect
using the ClipRect as the area to fill. Lastly, the ClipRect
is reset to the original value that it contained by calling
SelectClipRect with nil as the second parameter and deletes
the region.  Place a TImage object in the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    HRGN MyRgn;

    MyRgn = ::CreateRectRgn(100,100,200,200);
    ::SelectClipRgn(Image1->Canvas->Handle,MyRgn);
    Image1->Canvas->Brush->Color = clRed;
    Image1->Canvas->FillRect(Image1->Canvas->ClipRect);
    Image1->Invalidate();
    ::SelectClipRgn(Image1->Canvas->Handle,NULL);
    ::DeleteObject(MyRgn);
}
```

Delphi Examples:

```
{
This example creates a region and selects this region as the
clipping rectangle for the Image component's canvas. It then
sets the canvas's brush color to red and calls FillRect
using the ClipRect as the area to fill. Lastly, the ClipRect
is reset to the original value that it contained by calling
SelectClipRect with nil as the second parameter and deletes
the region.  Place a TImage object in the form.
}
procedure TForm1.Button1Click(Sender: TObject);
var
```

```
    MyRgn: HRGN;
begin
    MyRgn := CreateRectRgn(100,100,200,200);
    SelectClipRgn(Image1.Canvas.Handle,MyRgn);
    Image1.Canvas.Brush.Color := clRed;
    Image1.Canvas.FillRect(Image1.Canvas.ClipRect);
    Image1.Invalidate;
    SelectClipRgn(Image1.Canvas.Handle, HRGN(nil));
    DeleteObject(MyRgn);
end;
```

OnPaint (see page 13975)

73.1.7.5.4 TCanvas.CopyMode Property

Specifies how a graphical image is copied onto the canvas.

Pascal

```
property CopyMode: TCopyMode;
```

C++

```
__property TCopyMode CopyMode;
```

Description

Set CopyMode to affect the way graphical images are drawn onto the canvas. The CopyMode is used when copying an image from another canvas using the CopyRect (see page 14452) method. CopyMode is also used by TBitmap (see page 14396) objects when they draw themselves to a canvas.

Use CopyMode to achieve a variety of affects when rendering an image. Achieve special effects like merged images and making parts of a bitmap transparent by combining multiple images with different CopyModes.

C++ Examples:

```
/*
The following example uses the CopyMode of an image's canvas
to blank out the image when the user chooses the "Cut" menu
item.  This example requires a Main menu with a Copy and a
Cut menu item that have their OnClick error handlers populated.
Note: CopyMode and CopyRect are members of the destination
canvas.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
    TRect SrcRect, DstRect;
    Image2->Canvas->CopyMode = cmSrcCopy;
    DstRect = Rect(0, 0, Image2->Width, Image2->Height);
    SrcRect = Rect(0, 0, Image1->Width, Image1->Height);
    Image2->Canvas->CopyRect(DstRect, Image1->Canvas, SrcRect);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
 TRect r;
 Copy1Click(Sender); // Do the same thing as the copy menu item.
 Image1->Canvas->CopyMode = cmWhiteness;
 r = Rect(0, 0, Image1->Width, Image1->Height);
 Image1->Canvas->CopyRect(r, Image1->Canvas, r);
 Image1->Canvas->CopyMode = cmSrcCopy; // Restore the copy mode.
}
```

Delphi Examples:

```
{
The following example uses the CopyMode of an image's canvas
to blank out the image when the user chooses the "Cut" menu
item.  This example requires a Main menu with a Copy and a
Cut menu item that have their OnClick error handlers populated.
Note: CopyMode and CopyRect are members of the destination
canvas.
}
procedure TForm1.Copy1Click(Sender: TObject);
var
  DstRect, SrcRect: TRect;
begin
  with Image2.Canvas do
  begin
    CopyMode := cmSrcCopy;
    DstRect := Rect(0, 0, Image2.Width, Image2.Height);
    SrcRect := Rect(0, 0, Image1.Width, Image1.Height);
    CopyRect(DstRect, Image1.Canvas, SrcRect);
  end;
end;

procedure TForm1.Cut1Click(Sender: TObject);
var
  ARect: TRect;
begin
  Copy1Click(Sender); { do the same thing as the copy menu item }
  with Image1.Canvas do
  begin
    CopyMode := cmWhiteness;
    ARect := Rect(0, 0, Image1.Width, Image1.Height);
    CopyRect(ARect, Image1.Canvas, ARect);
    CopyMode := cmSrcCopy; { restore the copy mode }
  end;
end;
```

73.1.7.5.5 TCanvas.Font Property

Specifies the font to use when writing text on the image.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

Set Font to specify the font to use for writing text on the image. The value of Font is a T Font object. Set the properties of the T Font object to specify the font face, color, size, style, and any other aspects of the font.

The Canvas.Font property is only guaranteed to equal the Font property if you have an owner-drawn listbox (where you are expected to use the canvas). Even in that case, it is only guaranteed to equal the Font property once the first paint message is underway. If you use a canvas inside an ownerdraw event, everything should work as expected. Using the canvas for a reason outside the scope of its intended usage may give unpredictable results.

Note: Setting the Font property assigns the specified T Font object, rather than replacing the current T Font object.

See Also

TextOut (see page 14475)

TextRect (see page 14480)

TFont (see page 14497)

Assign (see page 14500)

73.1.7.5.6 TCanvas.Handle Property

Specifies the handle for this canvas.

Pascal

```
property Handle: HDC;
```

C++

```
__property HDC Handle;
```

Description

The Handle property specifies the Windows GDI handle to the device context for this canvas.

Set Handle to the HDC for the device context the canvas must draw into. When a windowed control responds to a Windows paint message, the HDC for drawing is passed in to the PaintWindow method. In other cases, an HDC can be obtained for a window by calling the GetDeviceContext method of a control. Additionally, Windows provides API calls to obtain an HDC for a printer or for a memory image.

Read the Handle property to supplement the drawing services provided by the TCanvas (see page 14441) object with API calls that require a handle to a device context. Most of the Windows GDI calls require an HDC.

TCanvas (see page 14441) does not own the HDC. Applications must create an HDC and set the Handle property. Applications must release the HDC when the canvas no longer needs it. Setting the Handle property of a canvas that already has a valid HDC will not automatically release the initial HDC.

Note: Some descendants of TCanvas (see page 14441), such as TControlCanvas, do own the HDC. Do not set the Handle property for these objects. They fetch and free their own Handle.

C++ Examples:

```
/*
The GetFormImage allows you to easily obtain a bitmap of a
form. The following method can be added to a custom
TWinControl descendant to save itself as a bitmap.  Check the
produced BMP file to confirm.  Click the button and them
double click on the newly created foo.bmp file to view.
*/
class TMyControl : public TColorListBox
{
__published:    // IDE-managed Components
    void __fastcall SaveAsBmp(TFileName fileName);
private:    // User declarations
public:     // User declarations
    __fastcall TMyControl(TComponent* Owner);
};

TForm1 *Form1;
TMyControl *MyControl1;
```

```
__fastcall TForm1::TForm1(TComponent* Owner)
    : TForm(Owner)
{
}
__fastcall TMyControl::TMyControl(TComponent* Owner)
    : TColorListBox(Owner)
{
}

  MyControl1.Parent:= Form1;
  MyControl1.visible := true;
end;
```

See Also

GetDeviceContext (see page 5760)

PaintWindow (see page 6169)

73.1.7.5.7 TCanvas.LockCount Property

Indicates the number of times the canvas has been locked to prevent interference from other threads.

Pascal

```
property LockCount: Integer;
```

C++

```
__property int LockCount;
```

Description

Read LockCount to determine whether the canvas is locked. Whenever the Lock (see page 14463) method is called to block other threads from interfering with the canvas, LockCount increases. Whenever the Unlock (see page 14483) method is called at the end of a critical section, LockCount decreases. When LockCount is 0, other threads may draw on the canvas.

See Also

Lock (see page 14463)

TThread (see page 3108)

Unlock (see page 14483)

73.1.7.5.8 TCanvas.Pen Property

Specifies the kind of pen the canvas uses for drawing lines and outlining shapes.

Pascal

```
property Pen: TPen;
```

C++

```
__property TPen Pen;
```

Description

Set Pen to specify the pen to use for drawing lines and outlining shapes in the image. The value of Pen is a TPen (see page 14571) object. Set the properties of the TPen (see page 14571) object to specify the color, style, width, and mode of the pen.

Note: Setting the Pen property assigns the specified TPen (see page 14571) object, rather than replacing the current TPen (see page 14571) object.

C++ Examples:

```
/*
This example paints a white five-pointed star in a paintbox
control:
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
  TPaintBox *pPB = (TPaintBox *)Sender;
  TPoint points[6];
  pPB->Canvas->Pen->Color = clWhite;
  points[0].x = 40;
  points[0].y = 10;
  points[1].x = 20;
  points[1].y = 60;
  points[2].x = 70;
  points[2].y = 30;
  points[3].x = 10;
  points[3].y = 30;
  points[4].x = 60;
  points[4].y = 60;
  points[5].x = 40;
  points[5].y = 10;
  pPB->Canvas->Polyline(points,5);
}
```

Delphi Examples:

```
{
This example paints a white five-pointed star in a paintbox
control:
}
procedure TForm1.PaintBox1Paint(Sender: TObject);
begin
  with Sender as TPaintBox do
  begin
    Canvas.Pen.Color := clWhite;
    Canvas.Polyline([Point(40, 10), Point(20, 60), Point(70, 30),
    Point(10, 30), Point(60, 60), Point(40, 10)]);
  end;
end;
```

MoveTo (see page 14463)

PenPos (see page 14494)

Pie (see page 14464)

Polygon (see page 14466)

Polyline (see page 14467)

Rectangle (see page 14468)

RoundRect (see page 14471)

TPen (see page 14571)

Assign (see page 14574)

73.1.7.5.9 TCanvas.PenPos Property

Specifies the current drawing position of the Pen (see page 14492).

Pascal

```
property PenPos: TPoint;
```

C++

```
__property TPoint PenPos;
```

Description

Read PenPos to learn the current drawing position of the Pen (see page 14492). This is the starting point of a line drawn by the LineTo (see page 14462) method. Setting the PenPos property is equivalent to calling the MoveTo (see page 14463) method.

See Also

LineTo (see page 14462)

MoveTo (see page 14463)

Pen (see page 14492)

73.1.7.5.10 TCanvas.Pixels Property

Specifies the color of the pixels within the current ClipRect (see page 14486).

Pascal

```
property Pixels [X, Y: Integer]: TColor;
```

C++

```
__property TColor Pixels[int X, Y];
```

Description

Read Pixels to learn the color on the drawing surface at a specific pixel position within the current clipping region. If the position is outside the clipping rectangle, reading the value of Pixels returns -1.

Write Pixels to change the color of individual pixels on the drawing surface. Use Pixels for detailed effects on an image. Pixels may also be used to determine the color that should be used for the FillRect (see page 14458) method.

Not every device context supports the Pixels property. Reading the Pixels property for such a device context will return a value of -1. Setting the Pixels property for such a device context does nothing.

C++ Examples:

```
/*
This example draws a red line (very slowly) when the user
presses a button. Attach the following code to the button's
OnClick event handler:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 10; i <= 200; i++)
    Canvas->Pixels[i][10] = clRed;
}
```

Delphi Examples:

```
{
This example draws a red line (very slowly) when the user
```

```
  presses a button. Attach the following code to the button's
  OnClick event handler:
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    W: Word;
  begin
      for W := 10 to 200 do
        Canvas.Pixels[W, 10] := clRed;
  end;
```

See Also

ClipRect (see page 14486)

Handle (see page 14489)

FillRect (see page 14458)

73.1.7.5.11 TCanvas.TextFlags Property

Specifies how text is written to the canvas.

Pascal

```
property TextFlags: Longint;
```

C++

```
__property Longint TextFlags;
```

Description

Use TextFlags to influence the way text is drawn when calling the TextOut (see page 14475) or TextRect (see page 14480) method. TextFlags is an integer made by combining any of the following constants:

Constant	Meaning
ETO_CLIPPED	Only the text that fits within a specified rectangle is displayed. This flag is automatically added when calling the TextRect (see page 14480) method. When writing text using TextOut (see page 14475) method, this flag has no effect because the drawing boundaries are determined by the TextExtent (see page 14474) property.
ETO_OPAQUE	The text is drawn with an opaque background color. Using this flag improves performance but does not allow images behind the text rectangle to show.
ETO_RTLREADING	Text strings are displayed from right to left. This is available only with Mideast versions of Windows, where text is written from right to left. Often this is used in combination with a CanvasOrientation (see page 14485) of coRightToLeft.
ETO_GLYPH_INDEX	The text is an array of character placement codes that are parsed directly by the Windows GDI. Glyph indexing only applies to TrueType fonts, but the flag can be used with other fonts to indicate that the GDI should process the text string directly without language processing. See the Windows GDI documentation for more details.
ETO_IGNORELANGUAGE	This is an undocumented Microsoft flag. Check updates of Microsoft documentation for when information is provided.
ETO_NUMERICSLOCAL	All numbers in the text are displayed using digits specific to the current locale.
ETO_NUMERICSLATIN	All numbers in the text are displayed using European digits.
ETO_PDY	This flag is only relevant when using the Windows API ExtTextOut. When this is set, the array pointed to by lpDx contains pairs of values. The first value of each pair is, as usual, the distance between origins of adjacent character cells, but the second value is the displacement along the vertical direction of the font.

CanvasOrientation (see page 14485)

TextExtent (see page 14474)

TextOut (see page 14475)

TextRect (see page 14480)

73.1.7.6 TCanvas Events

The events of the TCanvas class are listed here.

Public Events

	Name	Description
	OnChange (see page 14496)	Occurs when the image has just changed.
	OnChanging (see page 14496)	Occurs just before a change is made to the image.

73.1.7.6.1 TCanvas.OnChange Event

Occurs when the image has just changed.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action whenever the image on the canvas changes. When an application calls one of the drawing methods of TCanvas (see page 14441), the following steps occur.

1An OnChanging (see page 14496) event occurs.

2The TCanvas (see page 14441) method makes a change to the image.

3An OnChange event occurs.

OnChange events occur on changes to the image, not changes to the properties of the canvas. Applications can respond to changes in the Font (see page 14488), Brush (see page 14484), and Pen (see page 14492) properties by assigning OnChange event handlers to the corresponding TFont (see page 14497), TBrush (see page 14430), and TPen (see page 14571) objects. However, TCanvas (see page 14441) assigns its own OnChange event handlers for those objects. Before assigning an OnChange event handler to one of these objects, read the existing event handler. Use that value to call the TCanvas (see page 14441) event handler from the new event handler.

See Also

OnChanging (see page 14496)

OnChange (see page 14536)

73.1.7.6.2 TCanvas.OnChanging Event

Occurs just before a change is made to the image.

Pascal

```
property OnChanging: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChanging;
```

Description

Write an OnChanging event handler to take specific action before the image on the canvas changes. When an application calls one of the drawing methods of TCanvas (see page 14441), the following steps occur.

1An OnChanging event occurs.

2The TCanvas (see page 14441) method makes a change to the image.

3An OnChange (see page 14496) event occurs.

See Also

OnChange (see page 14496)

73.1.8 TFont Class

TFont encapsulates a system font.

Class Hierarchy

Pascal

```
TFont = class(TGraphicsObject);
```

C++

```
class TFont : public TGraphicsObject;
```

File

Graphics

Description

TFont describes font characteristics used when displaying text. TFont defines a set of characters by specifying the height, font family (typeface), attributes (such as bold or italic) and so on.

TFont encapsulates a windows logical font.

See Also

TTextAttributes (see page 4982)

Using the Main VCL

73.1.8.1 TFont Members

The following tables list the members exposed by TFont.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 14502)	Generates an OnChange event when the properties of the graphics object change.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetCharset (see page 14502)	This is GetCharset, a member of class TFont.
	GetHandle (see page 14503)	This is GetHandle, a member of class TFont.
	GetHeight (see page 14503)	This is GetHeight, a member of class TFont.
	GetName (see page 14503)	This is GetName, a member of class TFont.
	GetOrientation (see page 14503)	This is GetOrientation, a member of class TFont.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPitch (see page 14503)	This is GetPitch, a member of class TFont.
	GetSize (see page 14504)	This is GetSize, a member of class TFont.
	GetStyle (see page 14504)	This is GetStyle, a member of class TFont.
	Lock (see page 14534)	Blocks other execution threads from using the associated canvas until the Unlock (see page 14535) method is called.
	SetCharset (see page 14504)	This is SetCharset, a member of class TFont.
	SetColor (see page 14504)	This is SetColor, a member of class TFont.
	SetHandle (see page 14505)	This is SetHandle, a member of class TFont.
	SetHeight (see page 14505)	This is SetHeight, a member of class TFont.
	SetName (see page 14505)	This is SetName, a member of class TFont.
	SetOrientation (see page 14505)	This is SetOrientation, a member of class TFont.
	SetPitch (see page 14505)	This is SetPitch, a member of class TFont.
	SetSize (see page 14506)	This is SetSize, a member of class TFont.
	SetStyle (see page 14506)	This is SetStyle, a member of class TFont.
	Unlock (see page 14535)	Releases the lock on execution threads set by the Lock (see page 14534) method.

Public Events

	Name	Description
	OnChange (see page 14536)	Occurs immediately after the graphics object changes.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 14500)	Copies the properties of another TFont (see page 14497) object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 14499)	Creates and initializes an instance of TFont (see page 14497).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 14500)	Destroys an instance of TFont (see page 14497).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.

	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	HandleAllocated (see page 14534)	Indicates whether the TGraphicsObject (see page 14532) object has acquired a handle to the underlying GDI object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	FontAdapter (see page 14508)	Designates an interface for providing the font information to ActiveX controls.
	Handle (see page 14509)	Provides access to the handle of a system font.
	OwnerCriticalSection (see page 14536)	Points to information about the critical section that the canvas which draws with this graphics object uses to lock out other threads.
	PixelsPerInch (see page 14512)	Indicates the conversion factor between logical inches and the pixels of the device (printer or screen) using the font.

Published Properties

	Name	Description
	Charset (see page 14506)	Specifies the character set of the font.
	Color (see page 14507)	Specifies the color of the text.
	Height (see page 14510)	Specifies the height of the font.
	Name (see page 14510)	Identifies the typeface of the font.
	Orientation (see page 14511)	Specifies text orientation.
	Pitch (see page 14512)	Specifies whether the characters in the font all have the same width.
	Size (see page 14513)	Specifies the height of the font in points.
	Style (see page 14513)	Determines whether the font is normal, italic, underlined, bold, and so on.

73.1.8.2 TFont.Create Constructor

Creates and initializes an instance of TFont (see page 14497).

Pascal

```
constructor Create;
```

C++

```
__fastcall TFont();
```

Description

Call Create to create a font object at runtime.

Create allocates memory for the font resource, and initializes the Color (see page 14507) property to clWindowText (see page 14733). Create also initializes the PixelsPerInch (see page 14512) property based on the screen resolution.

See Also

PixelsPerInch (see page 14512)

73.1.8.3 TFont.Destroy Destructor

Destroys an instance of TFont (see page 14497).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TFont();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TFont (see page 14497) reference is not nil, and only then calls Destroy. Destroy frees the resource identified by the Handle (see page 14509) property.

See Also

Handle (see page 14509)

Free (see page 22300)

73.1.8.4 TFont Methods

The methods of the TFont class are listed here.

Protected Methods

	Name	Description
	Changed (see page 14502)	Generates an OnChange event when the properties of the graphics object change.
	GetCharset (see page 14502)	This is GetCharset, a member of class TFont.
	GetHandle (see page 14503)	This is GetHandle, a member of class TFont.
	GetHeight (see page 14503)	This is GetHeight, a member of class TFont.
	GetName (see page 14503)	This is GetName, a member of class TFont.
	GetOrientation (see page 14503)	This is GetOrientation, a member of class TFont.
	GetPitch (see page 14503)	This is GetPitch, a member of class TFont.
	GetSize (see page 14504)	This is GetSize, a member of class TFont.
	GetStyle (see page 14504)	This is GetStyle, a member of class TFont.
	SetCharset (see page 14504)	This is SetCharset, a member of class TFont.
	SetColor (see page 14504)	This is SetColor, a member of class TFont.
	SetHandle (see page 14505)	This is SetHandle, a member of class TFont.
	SetHeight (see page 14505)	This is SetHeight, a member of class TFont.
	SetName (see page 14505)	This is SetName, a member of class TFont.
	SetOrientation (see page 14505)	This is SetOrientation, a member of class TFont.
	SetPitch (see page 14505)	This is SetPitch, a member of class TFont.
	SetSize (see page 14506)	This is SetSize, a member of class TFont.
	SetStyle (see page 14506)	This is SetStyle, a member of class TFont.

Public Methods

	Name	Description
	Assign (see page 14500)	Copies the properties of another TFont (see page 14497) object.

73.1.8.4.1 TFont.Assign Method

Copies the properties of another TFont (see page 14497) object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Call Assign to set the properties of the font to match the characteristics of the Source object. If Source is another TFont (see page 14497) object, Assign matches the font characteristics of the source. Assign does not copy the PixelsPerInch (see page 14512) property, so this method can be used to copy a screen font to a printer font, or vice versa.

If the Source parameter is not another TFont (see page 14497) object, Assign calls the inherited method so that the font can be copied from any object that can assign font properties in its AssignTo method.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
```

```
    FontDialog1.Execute;
  end;

  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    myActiveControl := ActiveControl;
  end;

  procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
  begin
    if myActiveControl is TEdit then
      with myActiveControl as TEdit do
         Font.Assign(TFontDialog(Sender).Font)
    else if myActiveControl is TRichEdit then
      with myActiveControl as TRichEdit do
        SelAttributes.Assign(TFontDialog(Sender).Font)
    else
      Beep;
  end;
```

See Also

PixelsPerInch (see page 14512)

AssignTo (see page 2931)

73.1.8.4.2 TFont.Changed Method

Generates an OnChange event when the properties of the graphics object change.

Pascal

```
procedure Changed; override;
```

C++

```
virtual __fastcall Changed();
```

Description

Descendants of TGraphicsObject call Changed after making changes to the properties encapsulated by the TGraphicsObject object.

See Also

OnChange (see page 14536)

73.1.8.4.3 TFont.GetCharset Method

Pascal

```
function GetCharset: TFontCharset;
```

C++

```
__fastcall TFontCharset GetCharset();
```

Description

This is GetCharset, a member of class TFont.

73.1.8.4.4 TFont.GetHandle Method

Pascal

```
function GetHandle: HFont;
```

C++

```
__fastcall HFont GetHandle();
```

Description

This is GetHandle, a member of class TFont.

73.1.8.4.5 TFont.GetHeight Method

Pascal

```
function GetHeight: Integer;
```

C++

```
__fastcall int GetHeight();
```

Description

This is GetHeight, a member of class TFont.

73.1.8.4.6 TFont.GetName Method

Pascal

```
function GetName: TFontName;
```

C++

```
__fastcall TFontName GetName();
```

Description

This is GetName, a member of class TFont.

73.1.8.4.7 TFont.GetOrientation Method

Pascal

```
function GetOrientation: Integer;
```

C++

```
__fastcall int GetOrientation();
```

Description

This is GetOrientation, a member of class TFont.

73.1.8.4.8 TFont.GetPitch Method

Pascal

```
function GetPitch: TFontPitch;
```

C++

```
__fastcall TFontPitch GetPitch();
```

Description

This is GetPitch, a member of class TFont.

73.1.8.4.9 TFont.GetSize Method

Pascal

```
function GetSize: Integer;
```

C++

```
__fastcall int GetSize();
```

Description

This is GetSize, a member of class TFont.

73.1.8.4.10 TFont.GetStyle Method

Pascal

```
function GetStyle: TFontStyles;
```

C++

```
__fastcall TFontStyles GetStyle();
```

Description

This is GetStyle, a member of class TFont.

73.1.8.4.11 TFont.SetCharset Method

Pascal

```
procedure SetCharset(const Value: TFontCharset);
```

C++

```
__fastcall SetCharset(const TFontCharset Value);
```

Description

This is SetCharset, a member of class TFont.

73.1.8.4.12 TFont.SetColor Method

Pascal

```
procedure SetColor(const Value: TColor);
```

C++

```
__fastcall SetColor(const TColor Value);
```

Description

This is SetColor, a member of class TFont.

73.1.8.4.13 TFont.SetHandle Method

Pascal

```
procedure SetHandle(const Value: HFont);
```

C++

```
__fastcall SetHandle(const HFont Value);
```

Description

This is SetHandle, a member of class TFont.

73.1.8.4.14 TFont.SetHeight Method

Pascal

```
procedure SetHeight(const Value: Integer);
```

C++

```
__fastcall SetHeight(const int Value);
```

Description

This is SetHeight, a member of class TFont.

73.1.8.4.15 TFont.SetName Method

Pascal

```
procedure SetName(const Value: TFontName);
```

C++

```
__fastcall SetName(const TFontName Value);
```

Description

This is SetName, a member of class TFont.

73.1.8.4.16 TFont.SetOrientation Method

Pascal

```
procedure SetOrientation(const Value: Integer);
```

C++

```
__fastcall SetOrientation(const int Value);
```

Description

This is SetOrientation, a member of class TFont.

73.1.8.4.17 TFont.SetPitch Method

Pascal

```
procedure SetPitch(const Value: TFontPitch);
```

C++

```
__fastcall SetPitch(const TFontPitch Value);
```

Description

This is SetPitch, a member of class TFont.

73.1.8.4.18 TFont.SetSize Method

Pascal

```
procedure SetSize(const Value: Integer);
```

C++

```
__fastcall SetSize(const int Value);
```

Description

This is SetSize, a member of class TFont.

73.1.8.4.19 TFont.SetStyle Method

Pascal

```
procedure SetStyle(const Value: TFontStyles);
```

C++

```
__fastcall SetStyle(const TFontStyles Value);
```

Description

This is SetStyle, a member of class TFont.

73.1.8.5 TFont Properties

The properties of the TFont class are listed here.

Public Properties

	Name	Description
	FontAdapter (see page 14508)	Designates an interface for providing the font information to ActiveX controls.
	Handle (see page 14509)	Provides access to the handle of a system font.
	PixelsPerInch (see page 14512)	Indicates the conversion factor between logical inches and the pixels of the device (printer or screen) using the font.

Published Properties

	Name	Description
	Charset (see page 14506)	Specifies the character set of the font.
	Color (see page 14507)	Specifies the color of the text.
	Height (see page 14510)	Specifies the height of the font.
	Name (see page 14510)	Identifies the typeface of the font.
	Orientation (see page 14511)	Specifies text orientation.
	Pitch (see page 14512)	Specifies whether the characters in the font all have the same width.
	Size (see page 14513)	Specifies the height of the font in points.
	Style (see page 14513)	Determines whether the font is normal, italic, underlined, bold, and so on.

73.1.8.5.1 TFont.Charset Property

Specifies the character set of the font.

Pascal

```
property Charset: TFontCharset;
```

C++

```
__property TFontCharset Charset;
```

Description

Set Charset to identify the character set of the font. Each typeface (specified by the Name (see page 14510) property) supports one or more character sets. Check the information supplied by the font vendor to determine what values of Charset are valid.

See Also

Name (see page 14510)

73.1.8.5.2 TFont.Color Property

Specifies the color of the text.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to specify the color of the text characters (as opposed to the background color). If Color is set to a dithered color, the text appears in the closest non-dithered value.

C++ Examples:

```
/*
Add a THeaderControl to the form and call
HeaderControl1DrawSection for the OnDrawSection event.
*/
void __fastcall TForm1::HeaderControl1DrawSection(THeaderControl *HeaderControl,
      THeaderSection *Section, const TRect &Rect, bool Pressed)
{
  if (Pressed)
    HeaderControl->Canvas->Font->Color = clRed;
  else
    HeaderControl->Canvas->Font->Color = clBlue;
  HeaderControl->Canvas->TextOut(Rect.Left + HeaderControl->Canvas->Font->Size, Rect.Top + 2,
"Custom " + IntToStr(Section->Index));
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  THeaderSection *Section;
  for (int i = 0; i <= 4; i++)
  {
    Section = HeaderControl1->Sections->Add();
    Section->Text = "Section " + IntToStr(i);
    Section->MinWidth =
      (Section->Text).Length() *
      HeaderControl1->Font->Size;
    // Owner draw every other section
    if (i % 2 == 0)
      Section->Style = hsOwnerDraw;
    else
      Section->Style = hsText;
```

```
  }
}
```

Delphi Examples:

```
{
Add a THeaderControl to the form and call
HeaderControl1DrawSection for the OnDrawSection event.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  HeaderSection: THeaderSection;
  I: Integer;
begin
  for I := 0 to 4 do
  begin
    HeaderSection := HeaderControl1.Sections.Add;
    HeaderSection.Text := 'Text Section ' + IntToStr(I);
    HeaderSection.MinWidth := length(HeaderSection.Text) * Font.Size;
    // Owner draw every other section
    if (I mod 2 = 0) then
      HeaderSection.Style := hsOwnerDraw
    else
      HeaderSection.Style := hsText;
  end;
end;

procedure TForm1.HeaderControl1DrawSection(HeaderControl: THeaderControl;
  Section: THeaderSection; const Rect: TRect; Pressed: Boolean);
begin
  with HeaderControl.Canvas do
  begin
    // highlight pressed sections
    if Pressed then
      Font.Color := clRed
    else
      Font.Color := clBlue;
    TextOut(Rect.Left + Font.Size, Rect.Top + 2, 'Owner Drawn text');
  end;
end;
```

See Also

Color (see page 5812)

73.1.8.5.3 TFont.FontAdapter Property

Designates an interface for providing the font information to ActiveX controls.

Pascal

```
property FontAdapter: IChangeNotifier;
```

C++

```
__property IChangeNotifier FontAdapter;
```

Description

Do not use the FontAdapter property. FontAdapter is used internally by ActiveX controls to communicate font information through an OLE interface.

See Also

TFontAdapter (see page 1583)

73.1.8.5.4 TFont.Handle Property

Provides access to the handle of a system font.

Pascal

```
property Handle: HFont;
```

C++

```
__property HFont Handle;
```

Description

The Handle property indicates the Windows GDI font object handle.

Use Handle as a parameter when calling Windows API functions that require a font handle. Set Handle to make the TFont (see page 14497) object represent the Windows font indicated by the font handle. Setting Handle releases the current Windows font resource.

Note: When possible, change a font by setting the other properties of TFont (see page 14497) rather than using the Handle property. Setting Handle does not reset the properties that describe the font. However, an OnChange (see page 14536) event does occur when Handle is set directly by an application.

C++ Examples:

```
/*
This example creates a rotated font and displays it on the
form by assigning the handle of the rotated to the Form's
Canvas Font via the Font's Handle property.  Rotating fonts
is a straightforward process, so long as the Windows Font
Mapper can supply a rotated font based on the font you
request. If you are using a TrueType font there is virtually
no reason for failure.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
    LOGFONT lf; // Windows native font structure

    Canvas->Brush->Style = bsClear; // set the brush style to transparent
    ZeroMemory(&lf, sizeof(LOGFONT));

    lf.lfHeight = 20;
    lf.lfEscapement = 10 * 45; // degrees to rotate
    lf.lfOrientation = 10 * 45;
    lf.lfCharSet = DEFAULT_CHARSET;
    strcpy(lf.lfFaceName, "Tahoma");

    Canvas->Font->Handle = CreateFontIndirect(&lf);
    Canvas->TextOut(10, 100, "Rotated text"); // output the rotated font
}
```

Delphi Examples:

```
{
This example creates a rotated font and displays it on the
form by assigning the handle of the rotated to the Form's
Canvas Font via the Font's Handle property.  Rotating fonts
is a straightforward process, so long as the Windows Font
Mapper can supply a rotated font based on the font you
request. If you are using a TrueType font there is virtually
no reason for failure.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  lf: LOGFONT; // Windows native font structure
begin
  Canvas.Brush.Style := bsClear; // set the brush style to transparent
  FillChar(lf, SizeOf(lf), Byte(0));
  lf.lfHeight := 20;
  lf.lfEscapement := 10 * 45; // degrees to rotate
  lf.lfOrientation := 10 * 45;
  lf.lfCharSet := DEFAULT_CHARSET;
  StrCopy(lf.lfFaceName, 'Tahoma');

  Canvas.Font.Handle := CreateFontIndirect(lf);
  Canvas.TextOut(10, 100, 'Rotated text'); // output the rotated font
end;
```

See Also

OnChange (see page 14536)

73.1.8.5.5 TFont.Height Property

Specifies the height of the font.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Use Height to specify the height of the font in pixels. If the value is negative, the internal leading that appears at the top of each line of text is not measured. If the value is positive, Height represents the height of the characters plus the internal leading.

To specify the size of the font in points, use the Size (see page 14513) property instead. Users usually specify font size in points, while applications may be concerned with the actual size of the font in pixels when displaying the font on the screen.

The value of Height can be obtained from the point size using this formula:

```
Font.Height = -Font.Size * Font.PixelsPerInch / 72
```

When the Height property has a positive value, the Size (see page 14513) property has a negative value. When the Size (see page 14513) property has a positive value, the Height property has a negative value.

See Also

Size (see page 14513)

73.1.8.5.6 TFont.Name Property

Identifies the typeface of the font.

Pascal

```
property Name: TFontName;
```

C++

```
__property TFontName Name;
```

Description

Use Name to specify the typeface of the font. If the font family described by Name includes multiple character sets, be sure to set the Charset (see page 14506) property as well.

Note: If the combination of font family (typeface) and attributes (such as bold or italic) specifies a font that is not available on the system, the system substitutes a different font.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

See Also

Charset (see page 14506)

Pitch (see page 14512)

Size (see page 14513)

73.1.8.5.7 TFont.Orientation Property

Specifies text orientation.

Pascal

```
property Orientation: Integer;
```

C++

```
__property int Orientation;
```

Description

Use Orientation to specify the orientation of text characters. It is the angle in tenths of degrees between the character's baseline and device x-axis. This is similar to the **lfOrientation** field of the Windows GDI **LOGFONT** structure that defines font attributes.

See Also

Color (see page 14507)

73.1.8.5.8 TFont.Pitch Property

Specifies whether the characters in the font all have the same width.

Pascal

```
property Pitch: TFontPitch;
```

C++

```
__property TFontPitch Pitch;
```

Description

Each typeface has an associated pitch. The characters in fixed-pitch fonts are all the same width. The characters in variable-pitch fonts differ in width. Fixed pitch fonts are generally used for representing source code, because they allow the indentation to line up properly. Variable pitch fonts are generally used to give text a more natural appearance

Here are the possible values for Pitch:

Value	Meaning
fpDefault	The font pitch is set to the default value, which depends on the font specified in the Name (see page 14510) property.
fpFixed	The font pitch is set to Fixed. All characters in the font have the same width.
fpVariable	The font pitch is set to Variable. The characters in the font have varying widths.

Setting the Pitch of a fixed-pitch font to fpVariable or a variable-pitch font to fpFixed will cause window system to find what it considers the best match to all of the font characteristics that have been specified. This might have no effect on the appearance of a font, or might cause the window system to substitute a different font with the appropriate pitch. For example, setting the pitch of Serif (a variable-pitch font) to fpFixed causes Courier to be displayed.

See Also

Name (see page 14510)

73.1.8.5.9 TFont.PixelsPerInch Property

Indicates the conversion factor between logical inches and the pixels of the device (printer or screen) using the font.

Pascal

```
property PixelsPerInch: Integer;
```

C++

```
__property int PixelsPerInch;
```

Description

PixelsPerInch is used to ensure that when a font is copied from the form's canvas to the printer, the font is the same size in points. The PixelsPerInch property affects printer fonts only and should not be modified.

To modify the size of a font, use the Size (see page 14513) or Height (see page 14510) properties.

See Also

Height (see page 14510)

Size (see page 14513)

73.1.8.5.10 TFont.Size Property

Specifies the height of the font in points.

Pascal

```
property Size: Integer;
```

C++

```
__property int Size;
```

Description

Use Size to specify the point size of the font. If the value is negative, the internal leading that appears at the top of each line of text is included. If the value is positive, Size represents the height of the characters but not the internal leading.

To determine the size of the font in pixels, use the Height (see page 14510) property instead. The value of Size can be obtained from the height in pixels using this formula:

```
Font.Size = -Font.Height * 72 / Font.PixelsPerInch
```

When the Size property has a positive value, the Height (see page 14510) property has a negative value. When the Height (see page 14510) property has a positive value, the Size property has a negative value.

See Also

Height (see page 14510)

73.1.8.5.11 TFont.Style Property

Determines whether the font is normal, italic, underlined, bold, and so on.

Pascal

```
property Style: TFontStyles;
```

C++

```
__property TFontStyles Style;
```

Description

Use Style to add special characteristics to characters that use the font. Style is a set containing zero or more values from the following:

Value	Meaning
fsBold	The font is boldfaced.
fsItalic	The font is italicized.
fsUnderline	The font is underlined.

fsStrikeOut	The font is displayed with a horizontal line through it.

C++ Examples:

```
/*
This example demonstrates how to set and clear font styles.
This example requires a button and a label that has text
with some styles set.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
   Label1->Font->Style = TFontStyles() << fsBold << fsUnderline;
}
/*
This example demonstrates how to clear any Styles that were previously set.
*/
void __fastcall TForm1::Button2Click(TObject *Sender)
{
   Label1->Font->Style = TFontStyles();
}
```

Delphi Examples:

```
{
This example demonstrates how to set and clear font styles.
This example requires a button and a label that has text
with some styles set.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   Label1.Font.Style := [fsBold, fsUnderline];
end;
{
This code demonstrates how to clear any Styles that were
previously set.
}
procedure TForm1.Button2Click(Sender: TObject);
begin
   Label1.Font.Style := [];
end;
```

73.1.9 TFontRecall Class

TFontRecall saves and restores the properties of a TFont (see page 14497) object.

Class Hierarchy

Pascal

```
TFontRecall = class(TRecall);
```

C++

```
class TFontRecall : public TRecall;
```

File

Graphics

Description

Use TFontRecall to store the current state of a TFont (see page 14497) object. You are then free to change the current state of the font object. To restore the font object to its original state, all that is necessary is to free the TFontRecall object and the TFont (see page 14497) object is automatically restored to the saved property values.

You can update the TFontRecall instance to reflect the current properties of the TFont (see page 14497) object by calling the Store method. You can prevent the TFontRecall destructor from updating the TFont (see page 14497) object by calling the Forget method.

See Also

TRecall (see page 2964)

TFont (see page 14497)

73.1.9.1 TFontRecall Members

The following tables list the members exposed by TFontRecall.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 14516)	Instantiates a TFontRecall (see page 14514) object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2966)	Destroys the TRecall (see page 2964) instance, assigning the stored properties to the reference object.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Forget (see page 2967)	Discards the saved property values and prevents the TRecall (see page 2964) object from updating the reference object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.

	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Store (see page 2967)	Saves the current property settings of the reference object.

Public Properties

	Name	Description
R	Reference (see page 2968)	Indicates the reference object that is updated when you destroy the TRecall (see page 2964) instance.

73.1.9.2 TFontRecall.Create Constructor

Instantiates a TFontRecall (see page 14514) object.

Pascal

```
constructor Create(AFont: TFont);
```

C++

```
__fastcall TFontRecall(TFont AFont);
```

Description

Call Create to instantiate a font recall object at runtime. Create saves the current properties of the TFont (see page 14497) object specified by AFont, which becomes the value of the Reference property.

Subsequent calls to the Store method take snapshots of the properties of AFont and save them, replacing the values saved by this constructor. When you destroy the TFontRecall (see page 14514) instance, the most recently-saved properties are assigned to AFont, restoring it to a previous state.

See Also

Destroy (see page 2966)

Reference (see page 2968)

Store (see page 2967)

73.1.10 TGraphic Class

TGraphic is the abstract base class type for objects such as icons, bitmaps, and metafiles that can store and display visual images.

Class Hierarchy

Pascal

```
TGraphic = class(TInterfacedPersistent, IStreamPersist);
```

C++

```
class TGraphic : public TInterfacedPersistent, public IStreamPersist;
```

File

Graphics

Description

TGraphic is an abstract class that cannot be instantiated. Descendant graphics objects override many of the methods of TGraphic to address the needs of their particular file format and graphical characteristics. TGraphic also introduces methods that work with TPicture (see page 14584) objects and the Clipboard. Properties of TGraphic provide information about the state and size of the graphic image.

When the type of graphic is known, store the graphic in its specific type object. Otherwise, use a TPicture (see page 14584) object that can hold any type of TGraphic.

See Also

TClipboard (see page 3328)

TBitmap (see page 14396)

TPicture (see page 14584)

TIcon (see page 14537)

Tmetafile

TJPEGImage (see page 15688)

TOleGraphic (see page 1587)

TImage (see page 12777)

Graphic Controls

73.1.10.1 TGraphic Members

The following tables list the members exposed by TGraphic.

Protected Methods

	Name	Description
	_AddRef (see page 2853)	Increments the reference count for the interfaced object's interface.
	_Release (see page 2854)	Decrements the reference count for the interfaced object's interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Changed (see page 14520)	This is Changed, a member of class TGraphic.
V	DefineProperties (see page 14520)	Provides an interface for a method that reads and writes otherwise unpublished data.
A	Draw (see page 14521)	This is Draw, a member of class TGraphic.
V	Equals (see page 14521)	This is Equals, a member of class TGraphic.
A	GetEmpty (see page 14521)	This is GetEmpty, a member of class TGraphic.
A	GetHeight (see page 14521)	This is GetHeight, a member of class TGraphic.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetPalette (see page 14522)	This is GetPalette, a member of class TGraphic.
V	GetTransparent (see page 14522)	This is GetTransparent, a member of class TGraphic.
A	GetWidth (see page 14522)	This is GetWidth, a member of class TGraphic.
	Progress (see page 14524)	This is Progress, a member of class TGraphic.
V	ReadData (see page 14524)	This is ReadData, a member of class TGraphic.
A	SetHeight (see page 14526)	This is SetHeight, a member of class TGraphic.
V	SetPalette (see page 14527)	This is SetPalette, a member of class TGraphic.
V	SetTransparent (see page 14527)	This is SetTransparent, a member of class TGraphic.

	SetWidth (see page 14527)	This is SetWidth, a member of class TGraphic.
	WriteData (see page 14527)	This is WriteData, a member of class TGraphic.

Public Events

	Name	Description
	OnChange (see page 14531)	Occurs whenever a graphical image changes.
	OnProgress (see page 14531)	Occurs when a graphical image is in the process of changing.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 2854)	Obtains a reference to the Owner's interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 14519)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	LoadFromClipboardFormat (see page 14522)	Introduces an abstract method that loads the image from a variable in Clipboard format.
	LoadFromFile (see page 14523)	Loads a graphic image stored in a file.
	LoadFromStream (see page 14524)	Introduces an abstract method that loads the image from a stream.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 2854)	Returns a reference to a specified interface if the object supports that interface.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SaveToClipboardFormat (see page 14525)	Introduces an abstract method that assigns the graphic to a variable in clipboard format.
	SaveToFile (see page 14525)	Saves a graphics image to a file.

	SaveToStream (see page 14526)	Introduces an abstract method that saves the graphic image to a stream.
	SetSize (see page 14527)	Specifies the size of the graphic.

Public Properties

	Name	Description
	Empty (see page 14528)	Indicates whether the graphics object contains a graphic.
	Height (see page 14528)	Specifies the vertical size of the graphic in pixels.
	Modified (see page 14528)	Indicates whether the graphics object has been changed or edited.
	Palette (see page 14529)	Indicates the color palette of the graphical image.
	PaletteModified (see page 14529)	Indicates whether the palette has changed.
	Transparent (see page 14529)	Indicates whether the image covers its rectangular area.
	Width (see page 14530)	Determines the maximum width of the graphics object in pixels.

73.1.10.2 TGraphic.Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create; virtual;
```

C++

```
virtual __fastcall TGraphic();
```

Description

System::TObject::Create constructs an object. The purpose, size, and behavior of objects differ greatly. The System::TObject::Create constructor defined by System::TObject::TObject allocates memory but does not initialize data.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

System::TObject::Destroy (see page 22287)

System::TObject::Free (see page 22300)

73.1.10.3 TGraphic Methods

The methods of the TGraphic class are listed here.

Protected Methods

	Name	Description
	Changed (see page 14520)	This is Changed, a member of class TGraphic.
	DefineProperties (see page 14520)	Provides an interface for a method that reads and writes otherwise unpublished data.
	Draw (see page 14521)	This is Draw, a member of class TGraphic.
	Equals (see page 14521)	This is Equals, a member of class TGraphic.
	GetEmpty (see page 14521)	This is GetEmpty, a member of class TGraphic.
	GetHeight (see page 14521)	This is GetHeight, a member of class TGraphic.
	GetPalette (see page 14522)	This is GetPalette, a member of class TGraphic.
	GetTransparent (see page 14522)	This is GetTransparent, a member of class TGraphic.
	GetWidth (see page 14522)	This is GetWidth, a member of class TGraphic.
	Progress (see page 14524)	This is Progress, a member of class TGraphic.
	ReadData (see page 14524)	This is ReadData, a member of class TGraphic.

	SetHeight (see page 14526)	This is SetHeight, a member of class TGraphic.
	SetPalette (see page 14527)	This is SetPalette, a member of class TGraphic.
	SetTransparent (see page 14527)	This is SetTransparent, a member of class TGraphic.
	SetWidth (see page 14527)	This is SetWidth, a member of class TGraphic.
	WriteData (see page 14527)	This is WriteData, a member of class TGraphic.

Public Methods

	Name	Description
	LoadFromClipboardFormat (see page 14522)	Introduces an abstract method that loads the image from a variable in Clipboard format.
	LoadFromFile (see page 14523)	Loads a graphic image stored in a file.
	LoadFromStream (see page 14524)	Introduces an abstract method that loads the image from a stream.
	SaveToClipboardFormat (see page 14525)	Introduces an abstract method that assigns the graphic to a variable in clipboard format.
	SaveToFile (see page 14525)	Saves a graphics image to a file.
	SaveToStream (see page 14526)	Introduces an abstract method that saves the graphic image to a stream.
	SetSize (see page 14527)	Specifies the size of the graphic.

73.1.10.3.1 TGraphic.Changed Method

Pascal

```
procedure Changed(Sender: TObject); virtual;
```

C++

```
virtual __fastcall Changed(TObject * Sender);
```

Description

This is Changed, a member of class TGraphic.

73.1.10.3.2 TGraphic.DefineProperties Method

Provides an interface for a method that reads and writes otherwise unpublished data.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

Descendants of TPersistent override DefineProperties to designate a method for storing the object's unpublished data to a stream such as a form file. By default, writing an object to a stream writes the values of all its published properties, and reading the object in reads those values and assigns them to the properties. Objects can also specify methods that read and write data other than published properties by overriding the DefineProperties method.

When overriding DefineProperties, consider including some or all of the following:

A call to the inherited method

Calls to the filer object's DefineProperty method

Calls to the filer object's DefineBinaryProperty method

DefineProperties is virtual, so descendant classes can override it as necessary but are not required to do so.

See Also

DefineProperties (see page 2771)

DefineBinaryProperty (see page 2837)

DefineProperty (see page 2838)

73.1.10.3.3 TGraphic.Draw Method

Pascal

```
procedure Draw(ACanvas: TCanvas; const Rect: TRect); virtual; abstract;
```

C++

```
virtual __fastcall Draw(TCanvas ACanvas, const TRect Rect) = 0;
```

Description

This is Draw, a member of class TGraphic.

73.1.10.3.4 TGraphic.Equals Method

Pascal

```
function Equals(Graphic: TGraphic): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean Equals(TGraphic Graphic);
```

Description

This is Equals, a member of class TGraphic.

73.1.10.3.5 TGraphic.GetEmpty Method

Pascal

```
function GetEmpty: Boolean; virtual; abstract;
```

C++

```
virtual __fastcall Boolean GetEmpty() = 0;
```

Description

This is GetEmpty, a member of class TGraphic.

73.1.10.3.6 TGraphic.GetHeight Method

Pascal

```
function GetHeight: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetHeight() = 0;
```

Description

This is GetHeight, a member of class TGraphic.

73.1.10.3.7 TGraphic.GetPalette Method

Pascal

```
function GetPalette: HPALETTE; virtual;
```

C++

```
virtual __fastcall HPALETTE GetPalette();
```

Description

This is GetPalette, a member of class TGraphic.

73.1.10.3.8 TGraphic.GetTransparent Method

Pascal

```
function GetTransparent: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetTransparent();
```

Description

This is GetTransparent, a member of class TGraphic.

73.1.10.3.9 TGraphic.GetWidth Method

Pascal

```
function GetWidth: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetWidth() = 0;
```

Description

This is GetWidth, a member of class TGraphic.

73.1.10.3.10 TGraphic.LoadFromClipboardFormat Method

Introduces an abstract method that loads the image from a variable in Clipboard format.

Pascal

```
procedure LoadFromClipboardFormat(AFormat: Word; AData: THandle; APalette: HPALETTE); virtual;
abstract;
```

C++

```
virtual __fastcall LoadFromClipboardFormat(Word AFormat, THandle AData, HPALETTE APalette) = 0;
```

Description

Each descendant graphic object defines a LoadFromClipboardFormat method that replaces the current graphic image with the graphic indicated by AData, which it loads from the Clipboard.

The format for the new graphic object must be registered with the Clipboard in the RegisterClipboardFormat method, or an exception is raised.

See Also

TClipboard (see page 3328)

RegisterClipboardFormat (see page 14592)

73.1.10.3.11 TGraphic.LoadFromFile Method

Loads a graphic image stored in a file.

Pascal

```
procedure LoadFromFile(const Filename: string); virtual;
```

C++

```
virtual __fastcall LoadFromFile(const AnsiString Filename);
```

Description

LoadFromFile reads the file specified in FileName and loads the data into the graphics object.

C++ Examples:

```
/*
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
Note: For the C++ Builder, capitalization matters for the file
name and path.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *Bitmap1 = new Graphics::TBitmap();
  Graphics::TBitmap *Bitmap2 = new Graphics::TBitmap();
  try
  {
    Bitmap1->LoadFromFile("..\\FACTORY.BMP");
    Bitmap2->Assign(Bitmap1);     // Copy Bitmap1 into Bitmap2
    Bitmap2->Dormant();           // Free up GDI resources
    Bitmap2->FreeImage();         // Free up Memory.
    Canvas->Draw(20,20,Bitmap2);  // Note that previous calls don't lose the image
    Bitmap2->Monochrome = true;
    Canvas->Draw(80,80,Bitmap2);
    Bitmap2->ReleaseHandle();       // This will actually lose the bitmap;
  }
  catch (...)
  {
    MessageBeep(0);
  }
  delete Bitmap1;
  delete Bitmap2;
}
```

Delphi Examples:

```
{
This example uses a button on a form and creates two bitmaps
dynamically.  One bitmap is monchrome, which means all
non-white colors become black.  The bitmap file path is
relative to the Debug directory.
}
procedure TForm1.Button1Click(Sender: TObject);
var
 BitMap1,BitMap2 : TBitMap;
 MyFormat : Word;
```

```
begin
   BitMap2 := TBitMap.Create;
   BitMap1 := TBitMap.Create;
try
   BitMap1.LoadFromFile('factory.bmp');
   BitMap2.Assign(BitMap1);     // Copy BitMap1 into BitMap2
   BitMap2.Dormant;             // Free up GDI resources
   BitMap2.FreeImage;           // Free up Memory.
   Canvas.Draw(20,20,BitMap2);  // Note that previous calls don't lose the image
   BitMap2.Monochrome := true;
   Canvas.Draw(80,80,BitMap2);
   BitMap2.ReleaseHandle;       // This will actually lose the bitmap;
 finally
   BitMap1.Free;
   BitMap2.Free;
 end;
end;
```

See Also

LoadFromStream (see page 14524)

73.1.10.3.12 TGraphic.LoadFromStream Method

Introduces an abstract method that loads the image from a stream.

Pascal

```
procedure LoadFromStream(Stream: TStream); virtual; abstract;
```

C++

```
virtual __fastcall LoadFromStream(TStream Stream) = 0;
```

Description

Each descendant graphic object defines a LoadFromStream method that loads a graphics object from Stream.

See Also

LoadFromFile (see page 14523)

TStream (see page 2973)

73.1.10.3.13 TGraphic.Progress Method

Pascal

```
procedure Progress(Sender: TObject; Stage: TProgressStage; PercentDone: Byte; RedrawNow:
Boolean; const R: TRect; const Msg: string); dynamic;
```

C++

```
__fastcall Progress(TObject * Sender, TProgressStage Stage, Byte PercentDone, Boolean
RedrawNow, const TRect R, const AnsiString Msg);
```

Description

This is Progress, a member of class TGraphic.

73.1.10.3.14 TGraphic.ReadData Method

Pascal

```
procedure ReadData(Stream: TStream); virtual;
```

C++

```
virtual __fastcall ReadData(TStream Stream);
```

Description

This is ReadData, a member of class TGraphic.

73.1.10.3.15 TGraphic.SaveToClipboardFormat Method

Introduces an abstract method that assigns the graphic to a variable in clipboard format.

Pascal

```
procedure SaveToClipboardFormat(var AFormat: Word; var AData: THandle; var APalette:
HPALETTE); virtual; abstract;
```

C++

```
virtual __fastcall SaveToClipboardFormat(Word AFormat, THandle AData, HPALETTE APalette) = 0;
```

Description

Each descendant graphic object defines a SaveToClipboardFormat method that saves that particular graphic image type to a Clipboard format. An application must have registered the format with the TGraphic (see page 14516) object using the RegisterClipboardFormat method.

See Also

TClipboard (see page 3328)

RegisterClipboardFormat (see page 14592)

73.1.10.3.16 TGraphic.SaveToFile Method

Saves a graphics image to a file.

Pascal

```
procedure SaveToFile(const Filename: string); virtual;
```

C++

```
virtual __fastcall SaveToFile(const AnsiString Filename);
```

Description

SaveToFile writes the graphic to a file, specified by Filename.

C++ Examples:

```
/*
This example converts a bitmap image to a jpeg file by using
the Assign method.  This example requires a button and two
images.  One image must have it's Picture property loaded
with a bitmap at design time.
*/

#include <Jpeg.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  //Requires "jpeg.hpp" to be included in the source file
  TJPEGImage *jp = new TJPEGImage();
  try
  {
    jp->Assign(Image1->Picture->Bitmap);
```

```
      jp->SaveToFile("..\\factory.jpg");
      Image2->Stretch = True;
      Image2->Picture->LoadFromFile("..\\factory.jpg");
    }
    __finally
    {
      delete jp;
    }
  }
```

Delphi Examples:

```
{
This example converts a bitmap image to a jpeg file by using
the Assign method.  This example requires a button and two
images.  One image must have it's Picture property loaded
with a bitmap at design time.
}
uses Jpeg;

procedure TForm1.Button1Click(Sender: TObject);
var
  jp: TJPEGImage;  //Requires the "jpeg" unit added to "uses" clause.
begin
  jp := TJPEGImage.Create;
  try
    with jp do
    begin
      Assign(Image1.Picture.Bitmap);
      SaveToFile('factory.jpg');
      Image2.Stretch := True;
      Image2.Picture.LoadFromFile('factory.jpg');
    end;
  finally
    jp.Free;
  end;
end;
```

73.1.10.3.17 TGraphic.SaveToStream Method

Introduces an abstract method that saves the graphic image to a stream.

Pascal

```
procedure SaveToStream(Stream: TStream); virtual; abstract;
```

C++

```
virtual __fastcall SaveToStream(TStream Stream) = 0;
```

Description

Each descendant graphic object defines a SaveToStream method that saves the object to a Stream.

73.1.10.3.18 TGraphic.SetHeight Method

Pascal

```
procedure SetHeight(Value: Integer); virtual; abstract;
```

C++

```
virtual __fastcall SetHeight(int Value) = 0;
```

Description

This is SetHeight, a member of class TGraphic.

73.1.10.3.19 TGraphic.SetPalette Method

Pascal

```
procedure SetPalette(Value: HPALETTE); virtual;
```

C++

```
virtual __fastcall SetPalette(HPALETTE Value);
```

Description

This is SetPalette, a member of class TGraphic.

73.1.10.3.20 TGraphic.SetSize Method

Specifies the size of the graphic.

Pascal

```
procedure SetSize(AWidth: Integer; AHeight: Integer); virtual;
```

C++

```
virtual __fastcall SetSize(int AWidth, int AHeight);
```

Description

Use the SetSize method to set both the height and width of the graphic. This results in better performance than setting the height and width separately.

73.1.10.3.21 TGraphic.SetTransparent Method

Pascal

```
procedure SetTransparent(Value: Boolean); virtual;
```

C++

```
virtual __fastcall SetTransparent(Boolean Value);
```

Description

This is SetTransparent, a member of class TGraphic.

73.1.10.3.22 TGraphic.SetWidth Method

Pascal

```
procedure SetWidth(Value: Integer); virtual; abstract;
```

C++

```
virtual __fastcall SetWidth(int Value) = 0;
```

Description

This is SetWidth, a member of class TGraphic.

73.1.10.3.23 TGraphic.WriteData Method

Pascal

```
procedure WriteData(Stream: TStream); virtual;
```

C++

```
virtual __fastcall WriteData(TStream Stream);
```

Description

This is WriteData, a member of class TGraphic.

73.1.10.4 TGraphic Properties

The properties of the TGraphic class are listed here.

Public Properties

	Name	Description
R	Empty (see page 14528)	Indicates whether the graphics object contains a graphic.
	Height (see page 14528)	Specifies the vertical size of the graphic in pixels.
	Modified (see page 14528)	Indicates whether the graphics object has been changed or edited.
	Palette (see page 14529)	Indicates the color palette of the graphical image.
	PaletteModified (see page 14529)	Indicates whether the palette has changed.
	Transparent (see page 14529)	Indicates whether the image covers its rectangular area.
	Width (see page 14530)	Determines the maximum width of the graphics object in pixels.

73.1.10.4.1 TGraphic.Empty Property

Indicates whether the graphics object contains a graphic.

Pascal

```
property Empty: Boolean;
```

C++

```
__property Boolean Empty;
```

Description

Use Empty to determine whether the graphic is bound to an image. Each descendant graphic object defines its own Get method to access the Empty property.

73.1.10.4.2 TGraphic.Height Property

Specifies the vertical size of the graphic in pixels.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Use Height to determine the height of the graphic image. Each descendant graphic object defines its own Get and Set methods to access the Height property.

73.1.10.4.3 TGraphic.Modified Property

Indicates whether the graphics object has been changed or edited.

Pascal

```
property Modified: Boolean;
```

C++

```
__property Boolean Modified;
```

Description

If Modified is true, the graphic object has changed. If Modified is false, the graphics object is in the same state as when the object was loaded.

The Modified property indicates only if bitmap objects have been modified. Modified is not true if the graphics object contains an icon or metafile graphic, even if they have been modified.

If the graphics object was modified, save the changes to a file with the SaveToFile (see page 14525) method. The next time the application runs, it can load the graphic from the file with the LoadFromFile (see page 14523) method.

73.1.10.4.4 TGraphic.Palette Property

Indicates the color palette of the graphical image.

Pascal

```
property Palette: HPALETTE;
```

C++

```
__property HPALETTE Palette;
```

Description

Use Palette to get the color palette of a graphical image. If the graphic does not need or does not use a palette, the Palette property is zero.

73.1.10.4.5 TGraphic.PaletteModified Property

Indicates whether the palette has changed.

Pascal

```
property PaletteModified: Boolean;
```

C++

```
__property Boolean PaletteModified;
```

Description

Use PaletteModified to determine if the palette used for a graphical image has changed. PaletteModified is used in the OnChange (see page 14531) event. PaletteModified remains true until whoever is responsible for realizing this new palette (for example, TImage) sets it to false.

73.1.10.4.6 TGraphic.Transparent Property

Indicates whether the image covers its rectangular area.

Pascal

```
property Transparent: Boolean;
```

C++

```
__property Boolean Transparent;
```

Description

Use Transparent to specify that the graphic be drawn transparently. Some descendants of TGraphic (see page 14516) such as TIcon (see page 14537) and TMetafile (see page 14549) are always transparent, so setting the property for those objects does not change their behavior. However, the TBitmap (see page 14396) graphic's drawing is affected by this property. The TImage component sets this property to be the same as its Transparent property to achieve transparent painting.

When the Transparent property is set to True, you can either specify a color as the transparent color or you can use the default color, which is the pixel in the lower left. The specified color is not displayed in the graphic, which lets the background show through. This can be useful in layering and for non-rectangular graphics.

C++ Examples:

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *bitmap = new Graphics::TBitmap();
  try
  {
    bitmap->LoadFromFile("..\\FACTORY.BMP ");
    bitmap->Transparent = true;
    bitmap->TransparentColor = bitmap->Canvas->Pixels[50][50];
    Form1->Canvas->Draw( 0, 0, bitmap);
    bitmap->TransparentMode = tmAuto;
    Form1->Canvas->Draw(50, 50, bitmap);
  }
  catch (...)
  {
    ShowMessage("Could not load or display bitmap");
  }
  delete bitmap;
```

Delphi Examples:

```
procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitMap;
begin
  Bitmap := TBitmap.Create;
  try
    with Bitmap do begin
      LoadFromFile('factory.bmp');
      Transparent := True;
      TransParentColor := BitMap.canvas.pixels[50,50];
      Form1.Canvas.Draw(0,0,BitMap);
      TransparentMode := tmAuto;
      Form1.Canvas.Draw(50,50,BitMap);
    end;
  finally
    Bitmap.Free;
  end;
end;
```

73.1.10.4.7 TGraphic.Width Property

Determines the maximum width of the graphics object in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Each descendant graphic object defines its own Get and Set methods to access the Width property.

73.1.10.5 TGraphic Events

The events of the TGraphic class are listed here.

Public Events

	Name	Description
	OnChange (see page 14531)	Occurs whenever a graphical image changes.
	OnProgress (see page 14531)	Occurs when a graphical image is in the process of changing.

73.1.10.5.1 TGraphic.OnChange Event

Occurs whenever a graphical image changes.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Use OnChange to write a handler to perform an action then the graphical image changes.

73.1.10.5.2 TGraphic.OnProgress Event

Occurs when a graphical image is in the process of changing.

Pascal

```
property OnProgress: TProgressEvent;
```

C++

```
__property TProgressEvent OnProgress;
```

Description

For certain descendants of TGraphic (see page 14516), OnProgress occurs during slow processes such as loading, storing, or transforming image data. OnProgress allows applications to provide feedback to the user about the progress of the slow process.

Component writers can generate OnProgress events for new descendants of TGraphic (see page 14516) by calling the protected Progress (see page 14524) method. These events are propagated to the TPicture (see page 14584) and TImage objects.

See Also

OnProgress (see page 12831)

OnProgress (see page 14603)

73.1.11 TGraphicsObject Class

TGraphicsObject is the abstract base class for objects which encapsulate a system graphics object: TBrush (see page 14430), TFont (see page 14497), and TPen (see page 14571).

Class Hierarchy

Pascal

```
TGraphicsObject = class(TPersistent);
```

C++

```
class TGraphicsObject : public TPersistent;
```

File

Graphics

Description

Create descendants of TGraphicsObject when drawing an image to a canvas (TCanvas (see page 14441)). Each TGraphicsObject object describes a system graphics object that is selected into the device context of the canvas.

TGraphicsObject introduces a mechanism for responding to changes in the properties of the graphics object.

See Also

TBrush (see page 14430)

TCanvas (see page 14441)

TFont (see page 14497)

TPen (see page 14571)

73.1.11.1 TGraphicsObject Members

The following tables list the members exposed by TGraphicsObject.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 14534)	Generates an OnChange (see page 14536) event when the properties of the graphics object change.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.
	Lock (see page 14534)	Blocks other execution threads from using the associated canvas until the Unlock (see page 14535) method is called.
	Unlock (see page 14535)	Releases the lock on execution threads set by the Lock (see page 14534) method.

Public Events

	Name	Description
	OnChange (see page 14536)	Occurs immediately after the graphics object changes.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	HandleAllocated (see page 14534)	Indicates whether the TGraphicsObject (see page 14532) object has acquired a handle to the underlying GDI object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	OwnerCriticalSection (see page 14536)	Points to information about the critical section that the canvas which draws with this graphics object uses to lock out other threads.

73.1.11.2 TGraphicsObject Methods

The methods of the TGraphicsObject class are listed here.

Protected Methods

	Name	Description
	Changed (see page 14534)	Generates an OnChange (see page 14536) event when the properties of the graphics object change.
	Lock (see page 14534)	Blocks other execution threads from using the associated canvas until the Unlock (see page 14535) method is called.

	Unlock (see page 14535)	Releases the lock on execution threads set by the Lock (see page 14534) method.

Public Methods

	Name	Description
	HandleAllocated (see page 14534)	Indicates whether the TGraphicsObject (see page 14532) object has acquired a handle to the underlying GDI object.

73.1.11.2.1 TGraphicsObject.Changed Method

Generates an OnChange (see page 14536) event when the properties of the graphics object change.

Pascal

```
procedure Changed; dynamic;
```

C++

```
__fastcall Changed();
```

Description

Descendants of TGraphicsObject (see page 14532) call Changed after making changes to the properties encapsulated by the TGraphicsObject (see page 14532) object.

See Also

OnChange (see page 14536)

73.1.11.2.2 TGraphicsObject.HandleAllocated Method

Indicates whether the TGraphicsObject (see page 14532) object has acquired a handle to the underlying GDI object.

Pascal

```
function HandleAllocated: Boolean;
```

C++

```
__fastcall Boolean HandleAllocated();
```

Description

Use HandleAllocated to determine whether the Handle property is set for the graphics object. HandleAllocated indicates whether the underlying GDI object has been acquired. Use HandleAllocated rather than reading the Handle property. When an application reads the Handle property, TGraphicsObject (see page 14532) descendants automatically create the underlying GDI object and return its handle if the property had not been previously set.

See Also

Handle (see page 14578)

Handle (see page 14509)

Handle (see page 14438)

73.1.11.2.3 TGraphicsObject.Lock Method

Blocks other execution threads from using the associated canvas until the Unlock (see page 14535) method is called.

Pascal

```
procedure Lock;
```

C++

```
__fastcall Lock();
```

Description

Call Lock in a multithreaded application before using the graphics object in a section of code that would not otherwise be thread-safe. Lock prevents other cooperating threads in the application from using the associated canvas until the Unlock (see page 14535) method is called. Calls to Lock can be nested so that the canvas is not unlocked until the last lock is released.

Because Lock prevents other threads from executing, it can adversely affect performance. Do not call Lock unless there is a danger that another thread might interfere with the drawing.

Note: Lock will do nothing unless the drawing surface sets the OwnerCriticalSection (see page 14536) property. TCanvas (see page 14441) objects automatically set the OwnerCriticalSection (see page 14536) property when they use graphics objects.

See Also

OwnerCriticalSection (see page 14536)

TCanvas (see page 14441)

TThread (see page 3108)

Unlock (see page 14535)

73.1.11.2.4 TGraphicsObject.Unlock Method

Releases the lock on execution threads set by the Lock (see page 14534) method.

Pascal

```
procedure Unlock;
```

C++

```
__fastcall Unlock();
```

Description

Call Unlock at the end of a thread-sensitive section of code that was started with a call to the Lock (see page 14534) method. When every call to Lock (see page 14534) is balanced by a call to Unlock, other threads are allowed to lock the associated canvas.

See Also

Lock (see page 14534)

TThread (see page 3108)

TCanvas (see page 14441)

73.1.11.3 TGraphicsObject Properties

The properties of the TGraphicsObject class are listed here.

Public Properties

	Name	Description
	OwnerCriticalSection (see page 14536)	Points to information about the critical section that the canvas which draws with this graphics object uses to lock out other threads.

73.1.11.3.1 TGraphicsObject.OwnerCriticalSection Property

Points to information about the critical section that the canvas which draws with this graphics object uses to lock out other threads.

Pascal

```
property OwnerCriticalSection: PRTLCriticalSection;
```

C++

```
__property PRTLCriticalSection OwnerCriticalSection;
```

Description

Use OwnerCriticalSection to obtain information about the thread locking state of the canvas that draws with this graphics object. The canvas sets OwnerCriticalSection when it creates the graphics object. Do not change this property while the canvas is using the graphics object.

If the graphics object is created on behalf of a drawing surface that is not a canvas, set OwnerCriticalSection to an initialized TRTLCriticalSection that is maintained by the drawing surface.

To use OwnerCriticalSection to block other execution threads, use the Lock (see page 14534) method.

See Also

Lock (see page 14534)

Unlock (see page 14535)

Lock (see page 14463)

73.1.11.4 TGraphicsObject Events

The events of the TGraphicsObject class are listed here.

Public Events

	Name	Description
	OnChange (see page 14536)	Occurs immediately after the graphics object changes.

73.1.11.4.1 TGraphicsObject.OnChange Event

Occurs immediately after the graphics object changes.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action when the graphics object changes. The properties of the graphics object reflect the new settings when OnChange occurs.

See Also

Changed (see page 14534)

73.1.12 TIcon Class

TIcon is an encapsulation of a Windows icon.

Class Hierarchy

Pascal

```
TIcon = class(TGraphic);
```

C++

```
class TIcon : public TGraphic;
```

File

Graphics

Description

Use TIcon to represent one of the icons in an image list. Assign (see page 14541) an icon to objects that have an Icon property, such as TForm or TPicture (see page 14584).

Icon objects represent the value loaded from a Windows icon file (.ICO file). Draw (see page 14542) an icon on a canvas, using the Draw (see page 14542) method of the TCanvas (see page 14441) object. Icons do not stretch, so do not use StretchDraw (TCanvas (see page 14441)) with an icon.

Note: TIcon can be used to display the value of a multi-resolution (>16 color) icon. However, it can not support the creation of multi-resolution icons, nor the resizing of the image after it is loaded from a file or stream.

See Also

TCanvas (see page 14441)

Icon

TImageList (see page 6078)

TPicture (see page 14584)

73.1.12.1 TIcon Members

The following tables list the members exposed by TIcon.

Protected Methods

	Name	Description
	_AddRef (see page 2853)	Increments the reference count for the interfaced object's interface.
	_Release (see page 2854)	Decrements the reference count for the interfaced object's interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Changed (see page 14520)	This is Changed, a member of class TGraphic.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 14520)	Provides an interface for a method that reads and writes otherwise unpublished data.

	Draw (see page 14542)	This is Draw, a member of class TIcon.
	Equals (see page 14521)	This is Equals, a member of class TGraphic.
	GetEmpty (see page 14542)	This is GetEmpty, a member of class TIcon.
	GetHeight (see page 14542)	This is GetHeight, a member of class TIcon.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 14522)	This is GetPalette, a member of class TGraphic.
	GetTransparent (see page 14522)	This is GetTransparent, a member of class TGraphic.
	GetWidth (see page 14542)	This is GetWidth, a member of class TIcon.
	Progress (see page 14524)	This is Progress, a member of class TGraphic.
	ReadData (see page 14524)	This is ReadData, a member of class TGraphic.
	SetHeight (see page 14545)	This is SetHeight, a member of class TIcon.
	SetPalette (see page 14527)	This is SetPalette, a member of class TGraphic.
	SetTransparent (see page 14546)	This is SetTransparent, a member of class TIcon.
	SetWidth (see page 14546)	This is SetWidth, a member of class TIcon.
	WriteData (see page 14527)	This is WriteData, a member of class TGraphic.

Public Events

	Name	Description
	OnChange (see page 14531)	Occurs whenever a graphical image changes.
	OnProgress (see page 14531)	Occurs when a graphical image is in the process of changing.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 2854)	Obtains a reference to the Owner's interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 14541)	Copies an icon image from another TIcon (see page 14537) object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 14539)	Creates an instance of TIcon (see page 14537).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 14541)	Destroys an instance of TIcon (see page 14537).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	HandleAllocated (see page 14543)	Indicates whether the TIcon (see page 14537) object has acquired a handle to the underlying GDI object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.

	LoadFromClipboardFormat (see page 14543)	Prevents applications from loading icons from the clipboard.
	LoadFromFile (see page 14523)	Loads a graphic image stored in a file.
	LoadFromResourceID (see page 14543)	This is LoadFromResourceID, a member of class TIcon.
	LoadFromResourceName (see page 14544)	Loads an icon resource into the icon object.
	LoadFromStream (see page 14544)	Loads the icon from a stream.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 2854)	Returns a reference to a specified interface if the object supports that interface.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReleaseHandle (see page 14544)	Releases the Windows GDI object represented by the icon.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SaveToClipboardFormat (see page 14545)	Prevents applications from saving icons to the clipboard.
	SaveToFile (see page 14525)	Saves a graphics image to a file.
	SaveToStream (see page 14545)	Saves the icon to a stream.
	SetSize (see page 14546)	Specifies the size of the icon.

Public Properties

	Name	Description
	Empty (see page 14528)	Indicates whether the graphics object contains a graphic.
	Handle (see page 14546)	Provides access to the Windows GDI icon handle.
	Height (see page 14528)	Specifies the vertical size of the graphic in pixels.
	Modified (see page 14528)	Indicates whether the graphics object has been changed or edited.
	Palette (see page 14529)	Indicates the color palette of the graphical image.
	PaletteModified (see page 14529)	Indicates whether the palette has changed.
	Transparent (see page 14529)	Indicates whether the image covers its rectangular area.
	Width (see page 14530)	Determines the maximum width of the graphics object in pixels.

73.1.12.2 TIcon.Create Constructor

Creates an instance of TIcon (see page 14537).

Pascal

```
constructor Create; override;
```

C++

```
virtual __fastcall TIcon();
```

Description

Call Create to create an empty icon object. Once an image has been read into the icon from a file or stream, or by assigning another icon object, the icon can be drawn on a canvas or added to an image list. Do not create an icon object for setting the icon property of a form or picture. These objects create a TIcon (see page 14537) object in their own constructors. Instead, use the LoadFromFile (see page 14523), LoadFromStream (see page 14544), or LoadFromClipboardFormat (see page 14543) method on the TIcon (see page 14537) object that you can obtain by reading the Icon property.

C++ Examples:

```
/*
This example converts a specified icon to a bitmap. To run
this example, add an image, a button, and an Open dialog to
a form. Name the button ConvertIcon2Bitmap, and add the
following code as its OnClick event handler.
*/
void __fastcall TForm1::ConvertIcon2BitmapClick(TObject *Sender)
{
```

```
    OpenDialog1->DefaultExt = ".ICO";
    OpenDialog1->Filter = "icons (*.ico)|*.ICO";
    OpenDialog1->Options << ofOverwritePrompt << ofFileMustExist << ofHideReadOnly;
    if (OpenDialog1->Execute())
    {
      TIcon *pi = new TIcon();
      try
      {
        AnsiString as;
        pi->LoadFromFile(OpenDialog1->FileName);
        as = ChangeFileExt(OpenDialog1->FileName,".BMP");
        Image1->Width = pi->Width;
        Image1->Height = pi->Height;
        Image1->Canvas->Draw(0,0,pi);
        Image1->Picture->SaveToFile(as);
        ShowMessage(OpenDialog1->FileName + " Saved to " + as);
      }
      __finally
      {
        delete pi;
      }
    }
  }
```

Delphi Examples:

```
{
This example converts a specified icon to a bitmap. To run
this example, add an image, a button, and an Open dialog to
a form. Name the button ConvertIcon2Bitmap, and add the
following code as its OnClick event handler.
}
procedure TForm1.ConvertIcon2BitmapClick(Sender: TObject);
var
  s : string;
  Icon: TIcon;
begin
  OpenDialog1.DefaultExt := '.ICO';
  OpenDialog1.Filter := 'icons (*.ico)|*.ICO';
  OpenDialog1.Options := [ofOverwritePrompt, ofFileMustExist, ofHideReadOnly ];
  if OpenDialog1.Execute then
  begin
    Icon := TIcon.Create;
    try
      Icon.Loadfromfile(OpenDialog1.FileName);
      s:= ChangeFileExt(OpenDialog1.FileName,'.BMP');
      Image1.Width := Icon.Width;
      Image1.Height := Icon.Height;
      Image1.Canvas.Draw(0,0,Icon);
      Image1.Picture.SaveToFile(s);
      ShowMessage(OpenDialog1.FileName + ' Saved to ' + s);
    finally
      Icon.Free;
    end;
  end;
end;
```

See Also

Empty

LoadFromClipboardFormat (see page 14522)

LoadFromFile (see page 14523)

LoadFromStream (see page 14544)

73.1.12.3 TIcon.Destroy Destructor

Destroys an instance of TIcon (see page 14537).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TIcon();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TIcon (see page 14537) reference is not nil, and only then calls Destroy.

See Also

Free (see page 22300)

ReleaseHandle (see page 14544)

73.1.12.4 TIcon Methods

The methods of the TIcon class are listed here.

Protected Methods

	Name	Description
	Draw (see page 14542)	This is Draw, a member of class TIcon.
	GetEmpty (see page 14542)	This is GetEmpty, a member of class TIcon.
	GetHeight (see page 14542)	This is GetHeight, a member of class TIcon.
	GetWidth (see page 14542)	This is GetWidth, a member of class TIcon.
	SetHeight (see page 14545)	This is SetHeight, a member of class TIcon.
	SetTransparent (see page 14546)	This is SetTransparent, a member of class TIcon.
	SetWidth (see page 14546)	This is SetWidth, a member of class TIcon.

Public Methods

	Name	Description
	Assign (see page 14541)	Copies an icon image from another TIcon (see page 14537) object.
	HandleAllocated (see page 14543)	Indicates whether the TIcon (see page 14537) object has acquired a handle to the underlying GDI object.
	LoadFromClipboardFormat (see page 14543)	Prevents applications from loading icons from the clipboard.
	LoadFromResourceID (see page 14543)	This is LoadFromResourceID, a member of class TIcon.
	LoadFromResourceName (see page 14544)	Loads an icon resource into the icon object.
	LoadFromStream (see page 14544)	Loads the icon from a stream.
	ReleaseHandle (see page 14544)	Releases the Windows GDI object represented by the icon.
	SaveToClipboardFormat (see page 14545)	Prevents applications from saving icons to the clipboard.
	SaveToStream (see page 14545)	Saves the icon to a stream.
	SetSize (see page 14546)	Specifies the size of the icon.

73.1.12.4.1 TIcon.Assign Method

Copies an icon image from another TIcon (see page 14537) object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Call Assign to copy another icon object. Assign copies the icon image from the Source parameter if it is another TIcon (see page 14537) object. Otherwise, Assign calls the inherited method, which copies the icon image from any source object that specifies how to copy to a TIcon (see page 14537) in its AssignTo method.

See Also

AssignTo (see page 2931)

73.1.12.4.2 TIcon.Draw Method

Pascal

```
procedure Draw(ACanvas: TCanvas; const Rect: TRect); override;
```

C++

```
virtual __fastcall Draw(TCanvas ACanvas, const TRect Rect);
```

Description

This is Draw, a member of class TIcon.

73.1.12.4.3 TIcon.GetEmpty Method

Pascal

```
function GetEmpty: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetEmpty();
```

Description

This is GetEmpty, a member of class TIcon.

73.1.12.4.4 TIcon.GetHeight Method

Pascal

```
function GetHeight: Integer; override;
```

C++

```
virtual __fastcall int GetHeight();
```

Description

This is GetHeight, a member of class TIcon.

73.1.12.4.5 TIcon.GetWidth Method

Pascal

```
function GetWidth: Integer; override;
```

C++

```
virtual __fastcall int GetWidth();
```

Description

This is GetWidth, a member of class TIcon.

73.1.12.4.6 TIcon.HandleAllocated Method

Indicates whether the TIcon (see page 14537) object has acquired a handle to the underlying GDI object.

Pascal

```
function HandleAllocated: Boolean;
```

C++

```
__fastcall Boolean HandleAllocated();
```

Description

Use HandleAllocated to determine whether the Handle (see page 14546) property is set to an HICON value. HandleAllocated indicates whether the underlying GDI object has already been created. Use HandleAllocated rather than reading the Handle (see page 14546) property. When an application reads the Handle (see page 14546) property, it automatically creates an icon and returns its handle if the underlying GDI object does not already exist.

See Also

Handle (see page 14546)

73.1.12.4.7 TIcon.LoadFromClipboardFormat Method

Prevents applications from loading icons from the clipboard.

Pascal

```
procedure LoadFromClipboardFormat(AFormat: Word; AData: THandle; APalette: HPALETTE); override;
```

C++

```
virtual __fastcall LoadFromClipboardFormat(Word AFormat, THandle AData, HPALETTE APalette);
```

Description

LoadFromClipboardFormat is overridden in TIcon (see page 14537) because the clipboard format is not supported.

See Also

RegisterClipboardFormat (see page 14592)

73.1.12.4.8 TIcon.LoadFromResourceID Method

Pascal

```
procedure LoadFromResourceID(Instance: THandle; ResID: Integer);
```

C++

```
__fastcall LoadFromResourceID(THandle Instance, int ResID);
```

Description

This is LoadFromResourceID, a member of class TIcon.

73.1.12.4.9 TIcon.LoadFromResourceName Method

Loads an icon resource into the icon object.

Pascal

```
procedure LoadFromResourceName(Instance: THandle; const ResName: String);
```

C++

```
__fastcall LoadFromResourceName(THandle Instance, const AnsiString ResName);
```

Description

LoadFromResourceName loads the specified icon resource from a module's executable file.

Instance is the handle of the module that contains the resource.

ResName is the name of the resource to load.

See Also

LoadFromMimeSource

LoadFromStream (see page 14544)

73.1.12.4.10 TIcon.LoadFromStream Method

Loads the icon from a stream.

Pascal

```
procedure LoadFromStream(Stream: TStream); override;
```

C++

```
virtual __fastcall LoadFromStream(TStream Stream);
```

Description

Use LoadFromStream to read the icon image from a stream. Set the Stream parameter to a stream object that provides access to the memory image of the icon. To load the icon from a .ico file, use the LoadFromFile (see page 14523) method. To load the icon from the Clipboard, use the LoadFromClipboardFormat (see page 14543) method.

See Also

LoadFromClipboardFormat (see page 14522)

LoadFromFile (see page 14523)

SaveToStream (see page 14545)

73.1.12.4.11 TIcon.ReleaseHandle Method

Releases the Windows GDI object represented by the icon.

Pascal

```
function ReleaseHandle: HICON;
```

C++

```
__fastcall HICON ReleaseHandle();
```

Description

Call ReleaseHandle to release the resources used to represent the icon. ReleaseHandle sets the Handle (see page 14546)

property to nil (Delphi) or NULL (C++).

ReleaseHandle informs the TIcon (see page 14537) instance that it is no longer responsible for destroying the icon handle.

See Also

Handle (see page 14546)

73.1.12.4.12 TIcon.SaveToClipboardFormat Method

Prevents applications from saving icons to the clipboard.

Pascal

```
procedure SaveToClipboardFormat(var Format: Word; var Data: THandle; var APalette: HPALETTE);
override;
```

C++

```
virtual __fastcall SaveToClipboardFormat(Word Format, THandle Data, HPALETTE APalette);
```

Description

SaveToClipboardFormat is overridden in TIcon (see page 14537) because the format is not supported for the Clipboard.

See Also

LoadFromClipboardFormat (see page 14543)

73.1.12.4.13 TIcon.SaveToStream Method

Saves the icon to a stream.

Pascal

```
procedure SaveToStream(Stream: TStream); override;
```

C++

```
virtual __fastcall SaveToStream(TStream Stream);
```

Description

Use SaveToStream to write the icon image to a stream. Specify the Stream parameter as the stream object that receives the memory image of the icon. To write the icon to a .ico file, use the SaveToFile (see page 14525) method. To write the icon to the Clipboard, use the SaveToClipboardFormat (see page 14545) method.

See Also

LoadFromStream (see page 14544)

SaveToClipboardFormat (see page 14525)

SaveToFile (see page 14525)

73.1.12.4.14 TIcon.SetHeight Method

Pascal

```
procedure SetHeight(Value: Integer); override;
```

C++

```
virtual __fastcall SetHeight(int Value);
```

Description

This is SetHeight, a member of class TIcon.

73.1.12.4.15 TIcon.SetSize Method

Specifies the size of the icon.

Pascal

```
procedure SetSize(AWidth: Integer; AHeight: Integer); override;
```

C++

```
virtual __fastcall SetSize(int AWidth, int AHeight);
```

Description

Use the SetSize method to set both the height and width of the icon. This results in better performance than setting the height and width separately.

73.1.12.4.16 TIcon.SetTransparent Method

Pascal

```
procedure SetTransparent(Value: Boolean); override;
```

C++

```
virtual __fastcall SetTransparent(Boolean Value);
```

Description

This is SetTransparent, a member of class TIcon.

73.1.12.4.17 TIcon.SetWidth Method

Pascal

```
procedure SetWidth(Value: Integer); override;
```

C++

```
virtual __fastcall SetWidth(int Value);
```

Description

This is SetWidth, a member of class TIcon.

73.1.12.5 TIcon Properties

The properties of the TIcon class are listed here.

Public Properties

	Name	Description
	Handle (see page 14546)	Provides access to the Windows GDI icon handle.

73.1.12.5.1 TIcon.Handle Property

Provides access to the Windows GDI icon handle.

Pascal

```
property Handle: HICON;
```

C++

```
__property HICON Handle;
```

Description

Use Handle to specify the icon when using a Windows API function that requires the handle of an icon object. The Handle property is nil (Delphi) or NULL (C++) if the icon has not been loaded.

Call the ReleaseHandle (see page 14544) method before changing the icon image by setting the Handle property. The icon image can also be loaded by assigning another icon object or using the LoadFromClipboardFormat (see page 14543), LoadFromFile (see page 14523), or LoadFromStream (see page 14544) method.

See Also

Assign (see page 14541)

Empty

LoadFromClipboardFormat (see page 14522)

LoadFromFile (see page 14523)

LoadFromStream (see page 14544)

ReleaseHandle (see page 14544)

73.1.13 TIconImage Class

TIconImage is the internal representation of the bitmap image for a TIcon (see page 14537) object.

Class Hierarchy

Pascal

```
TIconImage = class(TSharedImage);
```

C++

```
class TIconImage : public TSharedImage;
```

File

Graphics

Description

TIconImage is used for internal implementation only. It represents the internal image of the bitmap encapsulated by the TIcon (see page 14537) object. All of the data and methods introduced in TIconImage are private. They contain information about the specific icon resource, including pointers to the standard HICON structures defined by Windows. TIconImage is referenced in the constructor of the TIcon (see page 14537) object when the icon image is created.

See Also

TIcon (see page 14537)

73.1.13.1 TIconImage Members

The following tables list the members exposed by TIconImage.

Protected Methods

	Name	Description
V	FreeHandle (see page 14548)	This is FreeHandle, a member of class TIconImage.
	Reference (see page 14604)	This is Reference, a member of class TSharedImage.
	Release (see page 14604)	This is Release, a member of class TSharedImage.

Protected Properties

	Name	Description
R	RefCount (see page 14605)	This is RefCount, a member of class TSharedImage.

Public Methods

	Name	Description
V	Destroy (see page 14548)	Destroys the TIconImage (see page 14547) instance and frees its memory.

73.1.13.2 TIconImage.Destroy Destructor

Destroys the TIconImage (see page 14547) instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TIconImage();
```

Description

You do not need to destroy the icon image. The TIconImage (see page 14547) object is automatically destroyed by the icon object.

See Also

Free (see page 22300)

73.1.13.3 TIconImage Methods

The methods of the TIconImage class are listed here.

Protected Methods

	Name	Description
V	FreeHandle (see page 14548)	This is FreeHandle, a member of class TIconImage.

73.1.13.3.1 TIconImage.FreeHandle Method

Pascal

```
procedure FreeHandle; override;
```

C++

```
virtual __fastcall FreeHandle();
```

Description

This is FreeHandle, a member of class TIconImage.

73.1.14 TMetafile Class

TMetafile is an encapsulation of the Win32 Enhanced (see page 14562) metafile.

Class Hierarchy

Pascal

```
TMetafile = class(TGraphic);
```

C++

```
class TMetafile : public TGraphic;
```

File

Graphics

Description

TMetafile contains a metafile graphic (EMF file format).

Properties of TMetafile indicate the size and characteristics of the metafile.

To draw a metafile on a canvas, call the Draw (see page 14555) or StretchDraw methods of a TCanvas (see page 14441) object, passing a TMetafile as a parameter. The Enhanced (see page 14562) property determines how the metafile will be stored on disk. If Enhanced (see page 14562) is true, the metafile is stored as an .EMF (Win32 Enhanced (see page 14562) Metafile) file. If Enhanced (see page 14562) is false, the metafile is stored as a .WMF (Windows 3.1 Metafile, with Aldus header).

See Also

TMetafileImage (see page 14569)

Using the Main VCL

73.1.14.1 TMetafile Members

The following tables list the members exposed by TMetafile.

Protected Methods

	Name	Description
	_AddRef (see page 2853)	Increments the reference count for the interfaced object's interface.
	_Release (see page 2854)	Decrements the reference count for the interfaced object's interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	Changed (see page 14520)	This is Changed, a member of class TGraphic.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.

	DefineProperties (see page 14520)	Provides an interface for a method that reads and writes otherwise unpublished data.
	Draw (see page 14555)	This is Draw, a member of class TMetafile.
	Equals (see page 14521)	This is Equals, a member of class TGraphic.
	GetEmpty (see page 14555)	This is GetEmpty, a member of class TMetafile.
	GetHeight (see page 14555)	This is GetHeight, a member of class TMetafile.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 14556)	This is GetPalette, a member of class TMetafile.
	GetTransparent (see page 14522)	This is GetTransparent, a member of class TGraphic.
	GetWidth (see page 14556)	This is GetWidth, a member of class TMetafile.
	Progress (see page 14524)	This is Progress, a member of class TGraphic.
	ReadData (see page 14557)	This is ReadData, a member of class TMetafile.
	ReadEMFStream (see page 14557)	This is ReadEMFStream, a member of class TMetafile.
	ReadWMFStream (see page 14558)	This is ReadWMFStream, a member of class TMetafile.
	SetHeight (see page 14559)	This is SetHeight, a member of class TMetafile.
	SetPalette (see page 14527)	This is SetPalette, a member of class TGraphic.
	SetTransparent (see page 14560)	This is SetTransparent, a member of class TMetafile.
	SetWidth (see page 14560)	This is SetWidth, a member of class TMetafile.
	TestEMF (see page 14560)	This is TestEMF, a member of class TMetafile.
	WriteData (see page 14560)	This is WriteData, a member of class TMetafile.
	WriteEMFStream (see page 14561)	This is WriteEMFStream, a member of class TMetafile.
	WriteWMFStream (see page 14561)	This is WriteWMFStream, a member of class TMetafile.

Public Events

	Name	Description
	OnChange (see page 14531)	Occurs whenever a graphical image changes.
	OnProgress (see page 14531)	Occurs when a graphical image is in the process of changing.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 2854)	Obtains a reference to the Owner's interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 14554)	Copies an object to the metafile.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 14555)	Deletes the metafile image.
	Create (see page 14551)	Instantiates a metafile object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 14553)	Destroys an instance of a metafile object.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.

	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	HandleAllocated (see page 14556)	Indicates whether the TMetafile (see page 14549) object has acquired a handle to the underlying GDI object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	LoadFromClipboardFormat (see page 14556)	Loads a metafile from the Clipboard.
V	LoadFromFile (see page 14523)	Loads a graphic image stored in a file.
V	LoadFromStream (see page 14557)	Loads the metafile from a stream.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	QueryInterface (see page 2854)	Returns a reference to a specified interface if the object supports that interface.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReleaseHandle (see page 14558)	Releases the Windows GDI object represented by the metafile.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	SaveToClipboardFormat (see page 14558)	Saves a metafile to a Clipboard format.
V	SaveToFile (see page 14559)	Writes the metafile to disk.
V	SaveToStream (see page 14559)	Writes the metafile to a stream.
V	SetSize (see page 14560)	Specifies the size of the metafile.

Public Properties

	Name	Description
R	CreatedBy (see page 14561)	Specifies the name of the author or application used to create the metafile.
R	Description (see page 14562)	Provides an optional text description that is embedded in the metafile.
R	Empty (see page 14528)	Indicates whether the graphics object contains a graphic.
	Enhanced (see page 14562)	Determines how the metafile will be stored on disk.
	Handle (see page 14563)	Provides access to the Windows GDI metafile handle, for accessing the GDI metafile object.
	Height (see page 14528)	Specifies the vertical size of the graphic in pixels.
	Inch (see page 14563)	Returns the units per inch that are used for the metafile's coordinate mapping.
	MMHeight (see page 14563)	Contains the height of the metafile image in 0.01 millimeter units, the native scale used by enhanced metafiles.
	MMWidth (see page 14564)	Contains the width of the metafile image in 0.01 millimeter units, the native scale used by enhanced metafiles.
	Modified (see page 14528)	Indicates whether the graphics object has been changed or edited.
	Palette (see page 14529)	Indicates the color palette of the graphical image.
	PaletteModified (see page 14529)	Indicates whether the palette has changed.
	Transparent (see page 14529)	Indicates whether the image covers its rectangular area.
	Width (see page 14530)	Determines the maximum width of the graphics object in pixels.

73.1.14.2 TMetafile.Create Constructor

Instantiates a metafile object.

Pascal

```
constructor Create; override;
```

C++

```
virtual __fastcall TMetafile();
```

Description

Call Create to instantiate a metafile at runtime.

Create allocates memory for a metafile object, and calls the inherited Create. Then sets the Enhanced (see page 14562) and Transparent (see page 14529) properties to true.

To create a metafile image from scratch, draw the image in a metafile canvas. When the metafile canvas is destroyed, it transfers the image into the metafile object provided to the metafile canvas constructor. After the image is drawn on the canvas and the canvas is destroyed, the image is 'playable' in the metafile object.

C++ Examples:

```
/*
This example shows how to create or augment a metafile using
a metafile canvas object.  This metafile can then be used to
draw on the canvas of another object such as a paintbox or a
printer.
*/
TMetafile *MyMetafile;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
MyMetafile = new TMetafile;
TMetafileCanvas *canvas = new TMetafileCanvas(MyMetafile, 0);
canvas->Brush->Color = clRed;
canvas->Ellipse(0, 0, 100, 200);
// ...
delete canvas;
Form1->Canvas->Draw(0, -50, MyMetafile); //1 red circle
PaintBox1->Canvas->Draw(0, 0, MyMetafile); //1 red circle
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  if (MyMetafile == NULL) return;   // click Button1 first!
  TMetafileCanvas *canvas = new TMetafileCanvas(MyMetafile, 0);
  canvas->Draw(-50, 0, MyMetafile);
  canvas->Brush->Color = clBlue;
  canvas->Ellipse(100, 100, 300, 200);
  // ...
  delete canvas;
  Form1->Canvas->Draw(0, 0, MyMetafile); // 1 red circle and 1 blue circle
  PaintBox1->Canvas->Draw(0, 0, MyMetafile); // 1 red circle and 1 blue circle
}
```

Delphi Examples:

```
{
This example shows how to create or augment a metafile using
a metafile canvas object.  This metafile can then be used to
draw on the canvas of another object such as a paintbox or a
printer.
}

var
  MyMetafile: TMetafile;

procedure TForm1.Button1Click(Sender: TObject);
begin
  MyMetafile := TMetafile.Create;
  with TMetafileCanvas.Create(MyMetafile, 0) do
  try
    Brush.Color := clRed;
    Ellipse(0, 0, 100, 200);
    //  ...
```

```
    finally
      Free;
    end;
    Form1.Canvas.Draw(0, 0, MyMetafile); {1 red circle }
    PaintBox1.Canvas.Draw(0, -50, MyMetafile); {1 red circle }
  end;

  {
  To add to an existing metafile image, create a metafile
  canvas and play the source metafile into the metafile canvas:
  }
  procedure TForm1.Button2Click(Sender: TObject);
  begin
    if (MyMetafile = nil) then exit;  { click Button1 first! }

    with TMetafileCanvas.Create(MyMetafile, 0) do
    try
      Draw(-50, 0, MyMetafile);
      Brush.Color := clBlue;
      Ellipse(100, 100, 300, 200);
  // ...
    finally
      Free;
    end;
    Form1.Canvas.Draw(0, 0, MyMetafile); {1 red circle and 1 blue circle }
    PaintBox1.Canvas.Draw(0, 0, MyMetafile); {1 red circle and 1 blue circle }
  end;
```

See Also

Enhanced (see page 14562)

Create (see page 22287)

TMetafileCanvas (see page 14564)

TMetafileImage (see page 14569)

Transparent (see page 14529)

73.1.14.3 TMetafile.Destroy Destructor

Destroys an instance of a metafile object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TMetafile();
```

Description

Do not call Destroy directly in an application. Instead, an application should call Free. Free verifies that the TMetafile (see page 14549) reference is not nil before it calls Destroy.

Destroy releases the image, which frees the image and the handle when the reference count on the metafile image is zero. Then Destroy calls the inherited Destroy.

See Also

Free (see page 22300)

TMetafileImage (see page 14569)

Destroy (see page 22287)

73.1.14.4 TMetafile Methods

The methods of the TMetafile class are listed here.

Protected Methods

	Name	Description
	Draw (see page 14555)	This is Draw, a member of class TMetafile.
	GetEmpty (see page 14555)	This is GetEmpty, a member of class TMetafile.
	GetHeight (see page 14555)	This is GetHeight, a member of class TMetafile.
	GetPalette (see page 14556)	This is GetPalette, a member of class TMetafile.
	GetWidth (see page 14556)	This is GetWidth, a member of class TMetafile.
	ReadData (see page 14557)	This is ReadData, a member of class TMetafile.
	ReadEMFStream (see page 14557)	This is ReadEMFStream, a member of class TMetafile.
	ReadWMFStream (see page 14558)	This is ReadWMFStream, a member of class TMetafile.
	SetHeight (see page 14559)	This is SetHeight, a member of class TMetafile.
	SetTransparent (see page 14560)	This is SetTransparent, a member of class TMetafile.
	SetWidth (see page 14560)	This is SetWidth, a member of class TMetafile.
	TestEMF (see page 14560)	This is TestEMF, a member of class TMetafile.
	WriteData (see page 14560)	This is WriteData, a member of class TMetafile.
	WriteEMFStream (see page 14561)	This is WriteEMFStream, a member of class TMetafile.
	WriteWMFStream (see page 14561)	This is WriteWMFStream, a member of class TMetafile.

Public Methods

	Name	Description
	Assign (see page 14554)	Copies an object to the metafile.
	Clear (see page 14555)	Deletes the metafile image.
	HandleAllocated (see page 14556)	Indicates whether the TMetafile (see page 14549) object has acquired a handle to the underlying GDI object.
	LoadFromClipboardFormat (see page 14556)	Loads a metafile from the Clipboard.
	LoadFromStream (see page 14557)	Loads the metafile from a stream.
	ReleaseHandle (see page 14558)	Releases the Windows GDI object represented by the metafile.
	SaveToClipboardFormat (see page 14558)	Saves a metafile to a Clipboard format.
	SaveToFile (see page 14559)	Writes the metafile to disk.
	SaveToStream (see page 14559)	Writes the metafile to a stream.
	SetSize (see page 14560)	Specifies the size of the metafile.

73.1.14.4.1 TMetafile.Assign Method

Copies an object to the metafile.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Assign copies the Enhanced (see page 14562) and Palette (see page 14529) properties of an object to the metafile. If the metafile is nil (Delphi) or NULL (C++), Assign creates one. Otherwise, Assign calls the inherited method. For assignment, metafiles are polymorphic with other TGraphic (see page 14516) objects, and with TPicture (see page 14584).

See Also

Enhanced (see page 14562)

Palette

Assign (see page 2930)

Assign (see page 14587)

Graphic (see page 14600)

73.1.14.4.2 TMetafile.Clear Method

Deletes the metafile image.

Pascal

```
procedure Clear;
```

C++

```
__fastcall Clear();
```

Description

Use Clear to release the old metafile image, create a new image, and increment a reference count on it.

See Also

TMetafileImage (see page 14569)

73.1.14.4.3 TMetafile.Draw Method

Pascal

```
procedure Draw(ACanvas: TCanvas; const Rect: TRect); override;
```

C++

```
virtual __fastcall Draw(TCanvas ACanvas, const TRect Rect);
```

Description

This is Draw, a member of class TMetafile.

73.1.14.4.4 TMetafile.GetEmpty Method

Pascal

```
function GetEmpty: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetEmpty();
```

Description

This is GetEmpty, a member of class TMetafile.

73.1.14.4.5 TMetafile.GetHeight Method

Pascal

```
function GetHeight: Integer; override;
```

C++

```
virtual __fastcall int GetHeight();
```

Description

This is GetHeight, a member of class TMetafile.

73.1.14.4.6 TMetafile.GetPalette Method

Pascal

```
function GetPalette: HPALETTE; override;
```

C++

```
virtual __fastcall HPALETTE GetPalette();
```

Description

This is GetPalette, a member of class TMetafile.

73.1.14.4.7 TMetafile.GetWidth Method

Pascal

```
function GetWidth: Integer; override;
```

C++

```
virtual __fastcall int GetWidth();
```

Description

This is GetWidth, a member of class TMetafile.

73.1.14.4.8 TMetafile.HandleAllocated Method

Indicates whether the TMetafile (see page 14549) object has acquired a handle to the underlying GDI object.

Pascal

```
function HandleAllocated: Boolean;
```

C++

```
__fastcall Boolean HandleAllocated();
```

Description

Use HandleAllocated to determine whether the Handle (see page 14563) property is set to an HMETAFILE (see page 14646) value. HandleAllocated indicates whether the underlying GDI object has already been created. Use HandleAllocated rather than reading the Handle (see page 14563) property. When an application reads the Handle (see page 14563) property, it automatically creates a metafile and returns its handle if the underlying GDI object does not already exist.

See Also

Handle (see page 14563)

73.1.14.4.9 TMetafile.LoadFromClipboardFormat Method

Loads a metafile from the Clipboard.

Pascal

```
procedure LoadFromClipboardFormat(AFormat: Word; AData: THandle; APalette: HPALETTE); override;
```

C++

```
virtual __fastcall LoadFromClipboardFormat(Word AFormat, THandle AData, HPALETTE APalette);
```

Description

LoadFromClipboardFormat replaces the current image with the data in the clipboard. LoadFromClipboardFormat ignores the AData and APalette parameters.

See Also

RegisterClipboardFormat (see page 14592)

73.1.14.4.10 TMetafile.LoadFromStream Method

Loads the metafile from a stream.

Pascal

```
procedure LoadFromStream(Stream: TStream); override;
```

C++

```
virtual __fastcall LoadFromStream(TStream Stream);
```

Description

Use LoadFromStream by specifying the stream from which the metafile is loaded as the value of Stream. LoadFromStream reads a metafile from a stream and replaces the current image with it.

See Also

SaveToStream (see page 14559)

73.1.14.4.11 TMetafile.ReadData Method

Pascal

```
procedure ReadData(Stream: TStream); override;
```

C++

```
virtual __fastcall ReadData(TStream Stream);
```

Description

This is ReadData, a member of class TMetafile.

73.1.14.4.12 TMetafile.ReadEMFStream Method

Pascal

```
procedure ReadEMFStream(Stream: TStream);
```

C++

```
__fastcall ReadEMFStream(TStream Stream);
```

Description

This is ReadEMFStream, a member of class TMetafile.

73.1.14.4.13 TMetafile.ReadWMFStream Method

Pascal

```
procedure ReadWMFStream(Stream: TStream; Length: Longint);
```

C++

```
__fastcall ReadWMFStream(TStream Stream, Longint Length);
```

Description

This is ReadWMFStream, a member of class TMetafile.

73.1.14.4.14 TMetafile.ReleaseHandle Method

Releases the Windows GDI object represented by the metafile.

Pascal

```
function ReleaseHandle: HENHMETAFILE;
```

C++

```
__fastcall HENHMETAFILE ReleaseHandle();
```

Description

Call ReleaseHandle to release the resources used to represent the metafile. ReleaseHandle sets the Handle (see page 14563) property to nil. NULL.

Call ReleaseHandle before setting the Handle (see page 14563) property, so that the resources associated with the metafile are not lost.

See Also

Handle (see page 14563)

73.1.14.4.15 TMetafile.SaveToClipboardFormat Method

Saves a metafile to a Clipboard format.

Pascal

```
procedure SaveToClipboardFormat(var AFormat: Word; var AData: THandle; var APalette:
HPALETTE); override;
```

C++

```
virtual __fastcall SaveToClipboardFormat(Word AFormat, THandle AData, HPALETTE APalette);
```

Description

Use SaveToClipboardFormat to copy the metafile to a Clipboard format. The resulting values can then be copied to the Windows clipboard using the clipboard's SetAsHandle method.

The metafile's palette is returned in the APalette parameter, the format in the AFormat parameter, and a handle to the data in the AData parameter. Before the metafile can be saved, an application must have registered the format with the metafile object using the RegisterClipboardFormat method.

To save a metafile to a file, call SaveToFile (see page 14559).

See Also

LoadFromClipboardFormat (see page 14556)

SaveToFile (see page 14559)

SetAsHandle (see page 3343)

73.1.14.4.16 TMetafile.SaveToFile Method

Writes the metafile to disk.

Pascal

```
procedure SaveToFile(const Filename: String); override;
```

C++

```
virtual __fastcall SaveToFile(const AnsiString Filename);
```

Description

Use SaveToFile to save the metafile to a file provided by the Filename parameter. To load a metafile from a file, call the LoadFromFile (see page 14523) method.

See Also

SaveToStream (see page 14559)

LoadFromFile (see page 14523)

73.1.14.4.17 TMetafile.SaveToStream Method

Writes the metafile to a stream.

Pascal

```
procedure SaveToStream(Stream: TStream); override;
```

C++

```
virtual __fastcall SaveToStream(TStream Stream);
```

Description

Use SaveToStream to save the metafile to the stream specified by the value of the Stream parameter.

See Also

LoadFromStream (see page 14557)

SaveToFile (see page 14559)

73.1.14.4.18 TMetafile.SetHeight Method

Pascal

```
procedure SetHeight(Value: Integer); override;
```

C++

```
virtual __fastcall SetHeight(int Value);
```

Description

This is SetHeight, a member of class TMetafile.

73.1.14.4.19 TMetafile.SetSize Method

Specifies the size of the metafile.

Pascal

```
procedure SetSize(AWidth: Integer; AHeight: Integer); override;
```

C++

```
virtual __fastcall SetSize(int AWidth, int AHeight);
```

Description

Use the SetSize method to set both the height and width of the metafile. This results in better performance than setting the height and width separately.

73.1.14.4.20 TMetafile.SetTransparent Method

Pascal

```
procedure SetTransparent(Value: Boolean); override;
```

C++

```
virtual __fastcall SetTransparent(Boolean Value);
```

Description

This is SetTransparent, a member of class TMetafile.

73.1.14.4.21 TMetafile.SetWidth Method

Pascal

```
procedure SetWidth(Value: Integer); override;
```

C++

```
virtual __fastcall SetWidth(int Value);
```

Description

This is SetWidth, a member of class TMetafile.

73.1.14.4.22 TMetafile.TestEMF Method

Pascal

```
function TestEMF(Stream: TStream): Boolean;
```

C++

```
__fastcall Boolean TestEMF(TStream Stream);
```

Description

This is TestEMF, a member of class TMetafile.

73.1.14.4.23 TMetafile.WriteData Method

Pascal

```
procedure WriteData(Stream: TStream); override;
```

C++

```
virtual __fastcall WriteData(TStream Stream);
```

Description

This is WriteData, a member of class TMetafile.

73.1.14.4.24 TMetafile.WriteEMFStream Method

Pascal

```
procedure WriteEMFStream(Stream: TStream);
```

C++

```
__fastcall WriteEMFStream(TStream Stream);
```

Description

This is WriteEMFStream, a member of class TMetafile.

73.1.14.4.25 TMetafile.WriteWMFStream Method

Pascal

```
procedure WriteWMFStream(Stream: TStream);
```

C++

```
__fastcall WriteWMFStream(TStream Stream);
```

Description

This is WriteWMFStream, a member of class TMetafile.

73.1.14.5 TMetafile Properties

The properties of the TMetafile class are listed here.

Public Properties

	Name	Description
R	CreatedBy (see page 14561)	Specifies the name of the author or application used to create the metafile.
R	Description (see page 14562)	Provides an optional text description that is embedded in the metafile.
	Enhanced (see page 14562)	Determines how the metafile will be stored on disk.
	Handle (see page 14563)	Provides access to the Windows GDI metafile handle, for accessing the GDI metafile object.
	Inch (see page 14563)	Returns the units per inch that are used for the metafile's coordinate mapping.
	MMHeight (see page 14563)	Contains the height of the metafile image in 0.01 millimeter units, the native scale used by enhanced metafiles.
	MMWidth (see page 14564)	Contains the width of the metafile image in 0.01 millimeter units, the native scale used by enhanced metafiles.

73.1.14.5.1 TMetafile.CreatedBy Property

Specifies the name of the author or application used to create the metafile.

Pascal

```
property CreatedBy: String;
```

C++

```
__property AnsiString CreatedBy;
```

Description

Use CreatedBy to set the string to an optional name of the author or application used to create the metafile. To set the CreatedBy string of a new metafile, call the TMetaFileCanvas CreateWithComment constructor (Delphi) or the TMetafileCanvas (see page 14564) constructor that takes a comment (C++).

See Also

TMetafileCanvas (see page 14564)

CreateWithComment (see page 14568)

Create_c

73.1.14.5.2 TMetafile.Description Property

Provides an optional text description that is embedded in the metafile.

Pascal

```
property Description: String;
```

C++

```
__property AnsiString Description;
```

Description

Set the Description string of a new metafile by calling the TMetaFileCanvas CreateWithComment constructor (Delphi) or the TMetafileCanvas (see page 14564) constructor that takes a comment (C++)..

See Also

TMetafileCanvas (see page 14564)

CreateWithComment (see page 14568)

Create_c

73.1.14.5.3 TMetafile.Enhanced Property

Determines how the metafile will be stored on disk.

Pascal

```
property Enhanced: Boolean;
```

C++

```
__property Boolean Enhanced;
```

Description

Use Enhanced to determine how the metafile is stored on disk. If Enhanced is true, the metafile is stored as an .EMF (Win32 Enhanced Metafile). If Enhanced is false, the metafile is stored as a .WMF (Windows 3.1 Metafile, with Aldus header).

The in-memory format is always EMF. WMF has very limited capabilities; storing as WMF will lose information that would be retained by EMF. This property is set to match the metafile type when loaded from a stream or file. If loaded as WMF, then save as WMF.

73.1.14.5.4 TMetafile.Handle Property

Provides access to the Windows GDI metafile handle, for accessing the GDI metafile object.

Pascal

```
property Handle: HENHMETAFILE;
```

C++

```
__property HENHMETAFILE Handle;
```

Description

Use Handle when calling a Windows API function that requires the handle of a metafile object. Pass the handle from the Handle property of the metafile object to the function.

See Also

DestroyMetaPict (see page 18011)

73.1.14.5.5 TMetafile.Inch Property

Returns the units per inch that are used for the metafile's coordinate mapping.

Pascal

```
property Inch: Word;
```

C++

```
__property Word Inch;
```

Description

Use Inch to find the units per inch assumed by a WMF metafile, and to alter scale when writing as WMF, but otherwise this property is obsolete. Enhanced (see page 14562) metafiles maintain complete scale information internally. For example, if the metafile was created in a Twips coordinate system (using MM_TWIPS mapping), the value of Inch is 1440.

73.1.14.5.6 TMetafile.MMHeight Property

Contains the height of the metafile image in 0.01 millimeter units, the native scale used by enhanced metafiles.

Pascal

```
property MMHeight: Integer;
```

C++

```
__property int MMHeight;
```

Description

MMHeight is used for a more accurate reading of the vertical size of the graphic. The Height (see page 14528) property, by contrast, is always in screen device pixel units; to avoid loss of precision in converting between device pixels and millimeters, set or read the dimensions in millimeters with MMHeight.

See Also

MMWidth (see page 14564)

73.1.14.5.7 TMetafile.MMWidth Property

Contains the width of the metafile image in 0.01 millimeter units, the native scale used by enhanced metafiles.

Pascal

```
property MMWidth: Integer;
```

C++

```
__property int MMWidth;
```

Description

MMWidth is used for a more accurate reading of the horizontal size of the graphic. The Width (see page 14530) property, by contrast, is always in screen device pixel units; to avoid loss of precision in converting between device pixels and millimeters, set or read the dimensions in millimeters with MMWidth.

The MMWidth property is always in screen device pixel units.

See Also

MMHeight (see page 14563)

73.1.15 TMetafileCanvas Class

TMetafileCanvas allows applications to create metafile images from scratch.

Class Hierarchy

Pascal

```
TMetafileCanvas = class(TCanvas);
```

C++

```
class TMetafileCanvas : public TCanvas;
```

File

Graphics

Description

Use TMetafileCanvas as a surface on which to draw a metafile image. When the canvas is destroyed, it transfers the image into the metafile object provided to the canvas constructor. After the image is drawn on the canvas and the canvas is destroyed, the image is 'playable' in the metafile object.

See Also

TMetafile (see page 14549)

73.1.15.1 TMetafileCanvas Members

The following tables list the members exposed by TMetafileCanvas.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 14450)	This is Changed, a member of class TCanvas.
	Changing (see page 14450)	This is Changing, a member of class TCanvas.
	CreateHandle (see page 14454)	This is CreateHandle, a member of class TCanvas.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.
	RequiredState (see page 14470)	This is RequiredState, a member of class TCanvas.

Public Events

	Name	Description
	OnChange (see page 14496)	Occurs when the image has just changed.
	OnChanging (see page 14496)	Occurs just before a change is made to the image.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Arc (see page 14448)	Draws an arc on the image along the perimeter of the ellipse bounded by the specified rectangle.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BrushCopy (see page 14449)	Copies a portion of a bitmap onto a rectangle on the canvas, replacing one of the colors of the bitmap with the brush of the canvas.
	Chord (see page 14451)	Draws a closed figure represented by the intersection of a line and an ellipse.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	CopyRect (see page 14452)	Copies part of an image from another canvas into the canvas.
	Create (see page 14567)	Creates an instance of TMetafileCanvas (see page 14564) and acquires a handle to a metafile device context.
	CreateWithComment (see page 14568)	Creates an instance of TMetafileCanvas (see page 14564) and acquires a handle to a metafile device context with a comment string.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 14569)	Destroys an instance of the TMetafileCanvas (see page 14564) after transferring the image to the TMetafile (see page 14549) object that was passed to the constructor.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Draw (see page 14454)	Renders the graphic specified by the Graphic parameter on the canvas at the location given by the coordinates (X, Y).
	DrawFocusRect (see page 14455)	Draws a rectangle in the style used to indicate that the object inside the rectangle has focus.
	Ellipse (see page 14457)	This is the overview for the Ellipse method overload.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FillRect (see page 14458)	Fills the specified rectangle on the canvas using the current brush.
	FloodFill (see page 14459)	Fills an area of the canvas using the current brush.
	FrameRect (see page 14460)	Draws a rectangle using the Brush (see page 14484) of the canvas to draw the border.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.

	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	HandleAllocated (see page 14461)	Indicates whether the TCanvas (see page 14441) object has acquired a handle to a device context.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	LineTo (see page 14462)	Draws a line on the canvas from PenPos (see page 14494) to the point specified by X and Y, and sets the pen position to (X, Y).
	Lock (see page 14463)	Prevents other threads from drawing on the canvas.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MoveTo (see page 14463)	Changes the current drawing position to the point (X,Y).
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Pie (see page 14464)	Draws a pie-shaped the section of the ellipse bounded by the rectangle (X1, Y1) and (X2, Y2) on the canvas.
	PolyBezier (see page 14464)	Draws a set of Bezier curves.
	PolyBezierTo (see page 14465)	Draws a set of Bezier curves and updates the value of PenPos (see page 14494).
	Polygon (see page 14466)	Draws a series of lines on the canvas connecting the points passed in and closing the shape by drawing a line from the last point to the first point.
	Polyline (see page 14467)	Draws a series of lines on the canvas with the current pen, connecting each of the points passed to it in Points.
	Rectangle (see page 14468)	This is the overview for the Rectangle method overload.
	Refresh (see page 14470)	Deselects the Pen (see page 14492), Brush (see page 14484), and Font (see page 14488) from the device context.
	RoundRect (see page 14471)	Draws a rectangle with rounded corners on the canvas.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	StretchDraw (see page 14472)	Draws the graphic specified by the Graphic parameter in the rectangle specified by the Rect parameter.
	TextExtent (see page 14474)	Returns the width and height, in pixels, of a string rendered in the current font.
	TextHeight (see page 14474)	Returns the height, in pixels, of a string rendered in the current font.
	TextOut (see page 14475)	Writes a string on the canvas, starting at the point (X,Y), and then updates the PenPos (see page 14494) to the end of the string.
	TextRect (see page 14480)	This is the overview for the TextRect method overload.
	TextWidth (see page 14481)	Returns the width, in pixels, of a string rendered in the current font.
	TryLock (see page 14483)	Locks the canvas if it is currently unlocked.
	Unlock (see page 14483)	Decreases the LockCount (see page 14492) property, allowing other threads to execute when LockCount (see page 14492) reaches 0.

Public Properties

	Name	Description
R	CanvasOrientation (see page 14485)	Determines the orientation of the canvas as left-to-right or right-to-left.
R	ClipRect (see page 14486)	Read-only property that specifies the boundaries of the clipping rectangle.
	Handle (see page 14489)	Specifies the handle for this canvas.
R	LockCount (see page 14492)	Indicates the number of times the canvas has been locked to prevent interference from other threads.
	PenPos (see page 14494)	Specifies the current drawing position of the Pen (see page 14492).
	Pixels (see page 14494)	Specifies the color of the pixels within the current ClipRect (see page 14486).
	TextFlags (see page 14495)	Specifies how text is written to the canvas.

Published Properties

	Name	Description
	Brush (see page 14484)	Determines the color and pattern for filling graphical shapes and backgrounds.

	CopyMode (see page 14487)	Specifies how a graphical image is copied onto the canvas.
	Font (see page 14488)	Specifies the font to use when writing text on the image.
	Pen (see page 14492)	Specifies the kind of pen the canvas uses for drawing lines and outlining shapes.

73.1.15.2 TMetafileCanvas.Create Constructor

Creates an instance of TMetafileCanvas (see page 14564) and acquires a handle to a metafile device context.

Pascal

```
constructor Create(AMetafile: TMetafile; ReferenceDevice: HDC);
```

C++

```
__fastcall TMetafileCanvas(TMetafile AMetafile, HDC ReferenceDevice);
```

Description

Call Create to create an instantiate a TMetafileCanvas (see page 14564) object. Pass in the associated metafile whose image is about to be drawn as the AMetafile parameter. Pass in a handle to a device context on which to base the metafile's device context as the ReferenceDevice parameter. In most cases, this is the device context for a window on which the image is normally drawn.

Create sets the size of the TMetafile (see page 14549) object from ReferenceDevice if it does not already have the MMHeight and MMWidth properties set. Create then creates a metafile device context, and sets the Handle (see page 14489) property to its handle. All subsequent drawing methods will draw to the metafile device context.

When the TMetafileCanvas (see page 14564) is destroyed, The CreatedBy and Description strings will be used to set the properties of the same name in the TMetafile (see page 14549) object.

C++ Examples:

```
/*
This example shows how to create or augment a metafile using
a metafile canvas object.  This metafile can then be used to
draw on the canvas of another object such as a paintbox or a
printer.
*/
TMetafile *MyMetafile;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
MyMetafile = new TMetafile;
TMetafileCanvas *canvas = new TMetafileCanvas(MyMetafile, 0);
canvas->Brush->Color = clRed;
canvas->Ellipse(0, 0, 100, 200);
// ...
delete canvas;
Form1->Canvas->Draw(0, -50, MyMetafile); //1 red circle
PaintBox1->Canvas->Draw(0, 0, MyMetafile); //1 red circle
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  if (MyMetafile == NULL) return;   // click Button1 first!
  TMetafileCanvas *canvas = new TMetafileCanvas(MyMetafile, 0);
  canvas->Draw(-50, 0, MyMetafile);
  canvas->Brush->Color = clBlue;
  canvas->Ellipse(100, 100, 300, 200);
  // ...
  delete canvas;
  Form1->Canvas->Draw(0, 0, MyMetafile); // 1 red circle and 1 blue circle
  PaintBox1->Canvas->Draw(0, 0, MyMetafile); // 1 red circle and 1 blue circle
```

```
}
```

Delphi Examples:

```
{
This example shows how to create or augment a metafile using
a metafile canvas object.  This metafile can then be used to
draw on the canvas of another object such as a paintbox or a
printer.
}

var
  MyMetafile: TMetafile;

procedure TForm1.Button1Click(Sender: TObject);
begin
  MyMetafile := TMetafile.Create;
  with TMetafileCanvas.Create(MyMetafile, 0) do
  try
    Brush.Color := clRed;
    Ellipse(0, 0, 100, 200);
    //  ...
  finally
    Free;
  end;
  Form1.Canvas.Draw(0, 0, MyMetafile); {1 red circle }
  PaintBox1.Canvas.Draw(0, -50, MyMetafile); {1 red circle }
end;

{
To add to an existing metafile image, create a metafile
canvas and play the source metafile into the metafile canvas:
}
procedure TForm1.Button2Click(Sender: TObject);
begin
  if (MyMetafile = nil) then exit;  { click Button1 first! }

  with TMetafileCanvas.Create(MyMetafile, 0) do
  try
    Draw(-50, 0, MyMetafile);
    Brush.Color := clBlue;
    Ellipse(100, 100, 300, 200);
// ...
  finally
    Free;
  end;
  Form1.Canvas.Draw(0, 0, MyMetafile); {1 red circle and 1 blue circle }
  PaintBox1.Canvas.Draw(0, 0, MyMetafile); {1 red circle and 1 blue circle }
end;
```

See Also

CreateWithComment (see page 14568)

73.1.15.3 TMetafileCanvas.CreateWithComment Constructor

Creates an instance of TMetafileCanvas (see page 14564) and acquires a handle to a metafile device context with a comment string.

Pascal

```
constructor CreateWithComment(AMetafile: TMetafile; ReferenceDevice: HDC; const CreatedBy:
String; const Description: String);
```

C++

```
__fastcall TMetafileCanvas(TMetafile AMetafile, HDC ReferenceDevice, const AnsiString
CreatedBy, const AnsiString Description);
```

Description

Call CreateWithComment to create an instantiate a TMetafileCanvas (see page 14564) object for a metafile that will receive the CreatedBy and Description strings. CreateWithComment sets the size of the TMetafile (see page 14549) object from the ReferenceDevice if it does not already have the MMHeight and MMWidth properties set. Create (see page 14567) then creates a metafile device context using the CreatedBy and Description strings as a description, and sets the Handle (see page 14489) property to its handle. All subsequent drawing methods will draw to the metafile device context.

When the TMetafileCanvas (see page 14564) is destroyed, the CreatedBy and Description strings are used to set the properties of the same name in the TMetafile (see page 14549) object.

See Also

Description (see page 14562)

73.1.15.4 TMetafileCanvas.Destroy Destructor

Destroys an instance of the TMetafileCanvas (see page 14564) after transferring the image to the TMetafile (see page 14549) object that was passed to the constructor.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TMetafileCanvas();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TMetafileCanvas (see page 14564) reference is not nil, and only then calls Destroy.

Destroy sets the Handle (see page 14489) property of the TMetafile (see page 14549) object that was passed to the constructor before freeing the memory associated with the object.

See Also

Free (see page 22300)

Handle (see page 14563)

73.1.16 TMetafileImage Class

TMetafileImage is the internal representation of the metafile image for a TMetafile (see page 14549) object.

Class Hierarchy

Pascal

```
TMetafileImage = class(TSharedImage);
```

C++

```
class TMetafileImage : public TSharedImage;
```

File

Graphics

Description

TMetafileImage is used for internal implementation only. It represents the internal image of the metafile encapsulated by the TMetafile (see page 14549) object. All of the data and methods introduced in TMetafileImage are private. They contain information about the specific metafile image, including pointers to the standard HENHMETAFILE (see page 14645) (enhanced metafile handle) and HPALETTE (handle to palette) structures defined by Windows.

See Also

TMetafile (see page 14549)

TMetafileCanvas (see page 14564)

73.1.16.1 TMetafileImage Members

The following tables list the members exposed by TMetafileImage.

Protected Methods

	Name	Description
V	FreeHandle (see page 14571)	This is FreeHandle, a member of class TMetafileImage.
	Reference (see page 14604)	This is Reference, a member of class TSharedImage.
	Release (see page 14604)	This is Release, a member of class TSharedImage.

Protected Properties

	Name	Description
R	RefCount (see page 14605)	This is RefCount, a member of class TSharedImage.

Public Methods

	Name	Description
V	Destroy (see page 14570)	Disposes of the instance of a metafile image.

73.1.16.2 TMetafileImage.Destroy Destructor

Disposes of the instance of a metafile image.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TMetafileImage();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TMetafileImage (see page 14569) reference is not nil before it calls Destroy.

Destroy frees the metafile handle and palette before calling the inherited Destroy.

See Also

Destroy (see page 22287)

Free (see page 22300)

73.1.16.3 TMetafileImage Methods

The methods of the TMetafileImage class are listed here.

Protected Methods

	Name	Description
	FreeHandle (see page 14571)	This is FreeHandle, a member of class TMetafileImage.

73.1.16.3.1 TMetafileImage.FreeHandle Method

Pascal

```
procedure FreeHandle; override;
```

C++

```
virtual __fastcall FreeHandle();
```

Description

This is FreeHandle, a member of class TMetafileImage.

73.1.17 TPen Class

TPen is used to draw lines or outline shapes on a canvas.

Class Hierarchy

Pascal

```
TPen = class(TGraphicsObject);
```

C++

```
class TPen : public TGraphicsObject;
```

File

Graphics

Description

Use TPen to describe the attributes of a Windows pen when drawing an image to a canvas (TCanvas (see page 14441)). TPen encapsulates the pen properties that are selected into the device context of the canvas.

See Also

TPen

TCanvas (see page 14441)

Using the Main VCL

73.1.17.1 TPen Members

The following tables list the members exposed by TPen.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 14534)	Generates an OnChange (see page 14536) event when the properties of the graphics object change.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetColor (see page 14575)	This is GetColor, a member of class TPen.
	GetHandle (see page 14575)	This is GetHandle, a member of class TPen.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetStyle (see page 14575)	This is GetStyle, a member of class TPen.
	GetWidth (see page 14575)	This is GetWidth, a member of class TPen.
	Lock (see page 14534)	Blocks other execution threads from using the associated canvas until the Unlock (see page 14535) method is called.
	SetColor (see page 14575)	This is SetColor, a member of class TPen.
	SetHandle (see page 14576)	This is SetHandle, a member of class TPen.
	SetMode (see page 14576)	This is SetMode, a member of class TPen.
	SetStyle (see page 14576)	This is SetStyle, a member of class TPen.
	SetWidth (see page 14576)	This is SetWidth, a member of class TPen.
	Unlock (see page 14535)	Releases the lock on execution threads set by the Lock (see page 14534) method.

Public Events

	Name	Description
	OnChange (see page 14536)	Occurs immediately after the graphics object changes.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 14574)	Assigns the properties of the pen from another TPen (see page 14571) object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 14573)	Creates an instance of TPen (see page 14571).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 14573)	Destroys an instance of TPen (see page 14571).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.

	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	HandleAllocated (see page 14534)	Indicates whether the TGraphicsObject (see page 14532) object has acquired a handle to the underlying GDI object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Handle (see page 14578)	Specifies the Windows pen object handle.
	OwnerCriticalSection (see page 14536)	Points to information about the critical section that the canvas which draws with this graphics object uses to lock out other threads.

Published Properties

	Name	Description
	Color (see page 14577)	Determines the color used to draw lines on the canvas.
	Mode (see page 14579)	Determines how the pen draws lines on the canvas.
	Style (see page 14579)	Determines the style in which the pen draws lines.
	Width (see page 14580)	Specifies the width of the pen in pixels.

73.1.17.2 TPen.Create Constructor

Creates an instance of TPen (see page 14571).

Pascal

```
constructor Create;
```

C++

```
__fastcall TPen();
```

Description

Call Create to create a TPen (see page 14571) object for assigning the pen property of a canvas. The pen for the canvas is created automatically in the constructor for the TCanvas (see page 14441) object.

Create allocates memory for the TPen (see page 14571) object and initializes the Mode (see page 14579) property to pmCopy.

See Also

Mode (see page 14579)

Pen (see page 14492)

73.1.17.3 TPen.Destroy Destructor

Destroys an instance of TPen (see page 14571).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TPen();
```

Description

Do not call Destroy directly from an application. Instead, call Free. Free verifies that the TPen (see page 14571) reference is not nil, and only then calls Destroy.Destroy frees the resource identified by the Handle (see page 14578) property.

See Also

Free (see page 22300)

73.1.17.4 TPen Methods

The methods of the TPen class are listed here.

Protected Methods

	Name	Description
	GetColor (see page 14575)	This is GetColor, a member of class TPen.
	GetHandle (see page 14575)	This is GetHandle, a member of class TPen.
	GetStyle (see page 14575)	This is GetStyle, a member of class TPen.
	GetWidth (see page 14575)	This is GetWidth, a member of class TPen.
	SetColor (see page 14575)	This is SetColor, a member of class TPen.
	SetHandle (see page 14576)	This is SetHandle, a member of class TPen.
	SetMode (see page 14576)	This is SetMode, a member of class TPen.
	SetStyle (see page 14576)	This is SetStyle, a member of class TPen.
	SetWidth (see page 14576)	This is SetWidth, a member of class TPen.

Public Methods

	Name	Description
	Assign (see page 14574)	Assigns the properties of the pen from another TPen (see page 14571) object.

73.1.17.4.1 TPen.Assign Method

Assigns the properties of the pen from another TPen (see page 14571) object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

If the Source parameter identifies another TPen (see page 14571) object, Assign copies the Color (see page 14577), Width (see page 14580), Style (see page 14579), and Mode (see page 14579) properties of the source pen. Otherwise, the inherited method copies the properties from any object that can write to a TPen (see page 14571) object in its AssignTo method.

See Also

Color (see page 14577)

Mode (see page 14579)

Style (see page 14579)

AssignTo (see page 2931)

Width (see page 14580)

73.1.17.4.2 TPen.GetColor Method

Pascal

```
function GetColor: TColor;
```

C++

```
__fastcall TColor GetColor();
```

Description

This is GetColor, a member of class TPen.

73.1.17.4.3 TPen.GetHandle Method

Pascal

```
function GetHandle: HPen;
```

C++

```
__fastcall HPen GetHandle();
```

Description

This is GetHandle, a member of class TPen.

73.1.17.4.4 TPen.GetStyle Method

Pascal

```
function GetStyle: TPenStyle;
```

C++

```
__fastcall TPenStyle GetStyle();
```

Description

This is GetStyle, a member of class TPen.

73.1.17.4.5 TPen.GetWidth Method

Pascal

```
function GetWidth: Integer;
```

C++

```
__fastcall int GetWidth();
```

Description

This is GetWidth, a member of class TPen.

73.1.17.4.6 TPen.SetColor Method

Pascal

```
procedure SetColor(Value: TColor);
```

C++

```
__fastcall SetColor(TColor Value);
```

Description

This is SetColor, a member of class TPen.

73.1.17.4.7 TPen.SetHandle Method

Pascal

```
procedure SetHandle(Value: HPen);
```

C++

```
__fastcall SetHandle(HPen Value);
```

Description

This is SetHandle, a member of class TPen.

73.1.17.4.8 TPen.SetMode Method

Pascal

```
procedure SetMode(Value: TPenMode);
```

C++

```
__fastcall SetMode(TPenMode Value);
```

Description

This is SetMode, a member of class TPen.

73.1.17.4.9 TPen.SetStyle Method

Pascal

```
procedure SetStyle(Value: TPenStyle);
```

C++

```
__fastcall SetStyle(TPenStyle Value);
```

Description

This is SetStyle, a member of class TPen.

73.1.17.4.10 TPen.SetWidth Method

Pascal

```
procedure SetWidth(Value: Integer);
```

C++

```
__fastcall SetWidth(int Value);
```

Description

This is SetWidth, a member of class TPen.

73.1.17.5 TPen Properties

The properties of the TPen class are listed here.

Public Properties

	Name	Description
	Handle (see page 14578)	Specifies the Windows pen object handle.

Published Properties

	Name	Description
	Color (see page 14577)	Determines the color used to draw lines on the canvas.
	Mode (see page 14579)	Determines how the pen draws lines on the canvas.
	Style (see page 14579)	Determines the style in which the pen draws lines.
	Width (see page 14580)	Specifies the width of the pen in pixels.

73.1.17.5.1 TPen.Color Property

Determines the color used to draw lines on the canvas.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Set Color to change the color used to draw lines or outline shapes. The way the color is used by the pen depends on the Mode (see page 14579) and Style (see page 14579) properties.

C++ Examples:

```
/*
This example draws many rectangles of various sizes and
colors on a form maximized to fill the entire screen. To run
the code, drop a TTimer component on the form and use the
object inspector to create the OnTimer and OnActivate event
handlers.
*/
int x, y;

void __fastcall TForm1::FormActivate(TObject *Sender)
{
  WindowState = wsMaximized;
  Timer1->Interval = 50;
  randomize();
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  x = random(Screen->Width - 10);
  y = random(Screen->Height - 10);
  Canvas->Pen->Color = (Graphics::TColor) random(65535);
  switch (random(5))
  {
    case 0: Canvas->Pen->Style = psSolid; break;
    case 1: Canvas->Pen->Style = psDash; break;
    case 2: Canvas->Pen->Style = psDot; break;
    case 3: Canvas->Pen->Style = psDashDot; break;
```

```
    case 4: Canvas->Pen->Style = psDashDotDot; break;
  }
  Canvas->Rectangle(x, y, x + random(400), y + random(400));
}
```

Delphi Examples:

```
{
This example draws many rectangles of various sizes and
colors on a form maximized to fill the entire screen. To run
the code, drop a TTimer component on the form and use the
object inspector to create the OnTimer and OnActivate event
handlers.
}
var
  X, Y: Integer;
procedure TForm1.FormActivate(Sender: TObject);
begin
  WindowState := wsMaximized;
  Timer1.Interval := 50;
  Randomize;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  X := Random(Screen.Width - 10);
  Y := Random(Screen.Height - 10);
  Canvas.Pen.Color := Random(65535);
  case Random(5) of
    0: Canvas.Pen.Style := psSolid;
    1: Canvas.Pen.Style := psDash;
    2: Canvas.Pen.Style := psDot;
    3: Canvas.Pen.Style := psDashDot;
    4: Canvas.Pen.Style := psDashDotDot;
  end;
  Canvas.Rectangle(X, Y, X + Random(400), Y + Random(400));
end;
```

See Also

Mode (see page 14579)

Style (see page 14579)

73.1.17.5.2 TPen.Handle Property

Specifies the Windows pen object handle.

Pascal

```
property Handle: HPen;
```

C++

```
__property HPen Handle;
```

Description

The Handle property provides access to the Windows GDI object handle. TPen (see page 14571) encapsulates the Windows pen object (HPEN). Use Handle when making a Windows API function call that requires the handle of a pen object. Handle is the Windows handle currently selected into the device context of the canvas.

See Also

Handle (see page 14489)

73.1.17.5.3 TPen.Mode Property

Determines how the pen draws lines on the canvas.

Pascal

```
property Mode: TPenMode;
```

C++

```
__property TPenMode Mode;
```

Description

Set Mode to determine how the color of the pen interacts with the color on the canvas.

See Also

Color (see page 14577)

TCanvas (see page 14441)

73.1.17.5.4 TPen.Style Property

Determines the style in which the pen draws lines.

Pascal

```
property Style: TPenStyle;
```

C++

```
__property TPenStyle Style;
```

Description

Use Style to draw a dotted or dashed line, or to omit the line that appears as a frame around shapes.

Note: Only the psInsideFrame style will produce a dithered color to match a Color (see page 14577) property that is not in the color table. All others choose the closest color from the Windows color table.

Note: Dotted or dashed pen styles are not available when the Width (see page 14580) property is not 1.

C++ Examples:

```
/*
This example draws many rectangles of various sizes and
colors on a form maximized to fill the entire screen. To run
the code, drop a TTimer component on the form and use the
object inspector to create the OnTimer and OnActivate event
handlers.
*/
int x, y;

void __fastcall TForm1::FormActivate(TObject *Sender)
{
  WindowState = wsMaximized;
  Timer1->Interval = 50;
  randomize();
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
```

```
    x = random(Screen->Width - 10);
    y = random(Screen->Height - 10);
    Canvas->Pen->Color = (Graphics::TColor) random(65535);
    switch (random(5))
    {
      case 0: Canvas->Pen->Style = psSolid; break;
      case 1: Canvas->Pen->Style = psDash; break;
      case 2: Canvas->Pen->Style = psDot; break;
      case 3: Canvas->Pen->Style = psDashDot; break;
      case 4: Canvas->Pen->Style = psDashDotDot; break;
    }
    Canvas->Rectangle(x, y, x + random(400), y + random(400));
  }
```

Delphi Examples:

```
{
This example draws many rectangles of various sizes and
colors on a form maximized to fill the entire screen. To run
the code, drop a TTimer component on the form and use the
object inspector to create the OnTimer and OnActivate event
handlers.
}
var
  X, Y: Integer;
procedure TForm1.FormActivate(Sender: TObject);
begin
  WindowState := wsMaximized;
  Timer1.Interval := 50;
  Randomize;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  X := Random(Screen.Width - 10);
  Y := Random(Screen.Height - 10);
  Canvas.Pen.Color := Random(65535);
  case Random(5) of
    0: Canvas.Pen.Style := psSolid;
    1: Canvas.Pen.Style := psDash;
    2: Canvas.Pen.Style := psDot;
    3: Canvas.Pen.Style := psDashDot;
    4: Canvas.Pen.Style := psDashDotDot;
  end;
  Canvas.Rectangle(X, Y, X + Random(400), Y + Random(400));
end;
```

See Also

Color (see page 14577)

Width (see page 14580)

73.1.17.5.5 TPen.Width Property

Specifies the width of the pen in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Use Width to give the line greater weight. If you attempt to set Width to a value less than 0, the new value is ignored.

Note: The value of Width influences which values of Style (see page 14579) are valid.

C++ Examples:

```
/*
This example draws many rounded rectangles of various sizes
and colors on a form maximized to fill the entire screen:
*/
int x, y;

void __fastcall TForm1::FormActivate(TObject *Sender)
{
  WindowState = wsMaximized;
  Timer1->Interval = 50;
  randomize();
}

void __fastcall TForm1::Timer1Timer(TObject *Sender)
{
  x = random(Screen->Width - 10);
  y = random(Screen->Height - 10);
  Canvas->Pen->Color = (Graphics::TColor) random(65535);
  Canvas->Pen->Width = random(7);
  int Dx = random(400);
  int Dy = random(400);
  Canvas->RoundRect(x, y, x + Dx, y + Dy, Dx/2, Dy/2);
}
```

Delphi Examples:

```
{
This example draws many rounded rectangles of various sizes
and colors on a form maximized to fill the entire screen:
}
var
  X, Y, DX, DY: Integer;
procedure TForm1.FormActivate(Sender: TObject);
begin
  WindowState := wsMaximized;
  Timer1.Interval := 50;
  Randomize;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  X := Random(Screen.Width - 10);
  Y := Random(Screen.Height - 10);
  Canvas.Pen.Color := Random(65535);
  Canvas.Pen.Width := Random(7);
  DX := Random(400);
  DY := Random(400);
  Canvas.RoundRect(X, Y, X + DX, Y + DY, DX div 2, DY div 2);
end;
```

Style (see page 14579)

73.1.18 TPenRecall Class

TPenRecall saves and restores the properties of a TPen (see page 14571) object.

Class Hierarchy

Pascal

```
TPenRecall = class(TRecall);
```

C++

```
class TPenRecall : public TRecall;
```

File

Graphics

Description

Use TPenRecall to store the current state of a TPen (see page 14571) object. You are then free to change the current state of the pen object. To restore the pen object to its original state, all that is necessary is to destroy the TPenRecall object and the pen object is automatically restored to the saved property values.

You can update the TPenRecall instance to reflect the current properties of the TPen (see page 14571) object by calling the Store method. You can prevent the TPenRecall destructor from updating the TPen (see page 14571) object by calling the Forget method.

TRecall (see page 2964)

TPen (see page 14571)

Using Pens

73.1.18.1 TPenRecall Members

The following tables list the members exposed by TPenRecall.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 14583)	Instantiates a TPenRecall (see page 14582) object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2966)	Destroys the TRecall (see page 2964) instance, assigning the stored properties to the reference object.

V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Forget (see page 2967)	Discards the saved property values and prevents the TRecall (see page 2964) object from updating the reference object.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	Store (see page 2967)	Saves the current property settings of the reference object.

Public Properties

	Name	Description
R	Reference (see page 2968)	Indicates the reference object that is updated when you destroy the TRecall (see page 2964) instance.

73.1.18.2 TPenRecall.Create Constructor

Instantiates a TPenRecall (see page 14582) object.

Pascal

```
constructor Create(APen: TPen);
```

C++

```
__fastcall TPenRecall(TPen APen);
```

Description

Call Create to instantiate a pen recall object at runtime. Create saves the current properties of the TPen (see page 14571) object specified by APen, which becomes the value of the Reference property.

Subsequent calls to the Store method take snapshots of the properties of APen and save them, replacing the values saved by this constructor. When you destroy the TPenRecall (see page 14582) instance, the most recently-saved properties are assigned to APen, restoring it to a previous state.

See Also

Destroy (see page 2966)

Reference (see page 2968)

Store (see page 2967)

73.1.19 TPicture Class

TPicture contains a bitmap, icon, metafile graphic, or user-defined graphic.

Class Hierarchy

Pascal

```
TPicture = class(TInterfacedPersistent, IStreamPersist);
```

C++

```
class TPicture : public TInterfacedPersistent, public IStreamPersist;
```

File

Graphics

Description

TPicture is a TGraphic (see page 14516) container, used to hold a graphic, the type of which is specified in the Graphic (see page 14600) property. It is used in place of a TGraphic (see page 14516) if the graphic can be of any TGraphic (see page 14516) class. LoadFromFile (see page 14591) and SaveToFile (see page 14595) are polymorphic. For example, if the TPicture is holding an Icon (see page 14601), it is valid to LoadFromFile (see page 14591) a bitmap file, where the class TIcon (see page 14537) can only read .ICO files.

If the TPicture contains a bitmap graphic, the Bitmap (see page 14598) property specifies the graphic. If the TPicture contains an icon graphic, the Icon (see page 14601) property specifies the graphic. If the TPicture contains a metafile graphic, the Metafile (see page 14601) property specifies the graphic.

The properties of TPicture indicate the type of graphic that the picture object contains, and its size. The methods of TPicture are used to load, save, and manipulate graphics.

To load or save a picture to the Clipboard, use the Assign (see page 14587) method of a TClipboard object.

To draw a picture on a canvas, call the Draw or StretchDraw methods of a TCanvas (see page 14441) object, passing the Graphic (see page 14600) property of a TPicture as a parameter.

See Also

TCanvas (see page 14441)

TClipboard (see page 3328)

73.1.19.1 TPicture Members

The following tables list the members exposed by TPicture.

Protected Methods

	Name	Description
	_AddRef (see page 2853)	Increments the reference count for the interfaced object's interface.
	_Release (see page 2854)	Decrements the reference count for the interfaced object's interface.
	AssignTo (see page 14589)	Copies the properties of an object to a destination object.

	Changed (see page 14590)	This is Changed, a member of class TPicture.
	DefineProperties (see page 14590)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetOwner (see page 2932)	Returns the owner of an object.
	LoadFromStream (see page 14591)	Reads the picture from a Stream.
	Progress (see page 14592)	This is Progress, a member of class TPicture.
	SaveToStream (see page 14597)	Saves the picture to a stream.

Public Events

	Name	Description
	OnChange (see page 14602)	Occurs when the specific graphics item encapsulated by the picture object changes.
	OnProgress (see page 14603)	Occurs periodically during slow operations that affect the graphic.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 2854)	Obtains a reference to the Owner's interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 14587)	Copies one object to another by copying the contents of that object to the other.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 14586)	Creates a TPicture (see page 14584) object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 14586)	Destroys an instance of a picture object.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	LoadFromClipboardFormat (see page 14590)	Reads the picture from the handle provided in the given Clipboard format.
	LoadFromFile (see page 14591)	Reads the file specified in Filename and loads the data into the TPicture (see page 14584) object.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 2854)	Returns a reference to a specified interface if the object supports that interface.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.

	RegisterClipboardFormat (see page 14592)	Registers a new TGraphic (see page 14516) class for use in the LoadFromClipboardFormat (see page 14590) method.
	RegisterFileFormat (see page 14594)	Registers a new TGraphic (see page 14516) class for use in LoadFromFile (see page 14591).
	RegisterFileFormatRes (see page 14594)	Registers a new TGraphic (see page 14516) class for use in the LoadFromFile (see page 14591) method.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SaveToClipboardFormat (see page 14595)	Allocates a global handle and writes the picture in its native Clipboard format (CF_BITMAP for bitmaps, CF_METAFILE for metafiles, and so on).
	SaveToFile (see page 14595)	Writes the picture to disk.
	SupportsClipboardFormat (see page 14597)	Indicates if the given Clipboard format is supported by the LoadFromClipboardFormat (see page 14590) method.
	UnregisterGraphicClass (see page 14597)	This is UnregisterGraphicClass, a member of class TPicture.

Public Properties

	Name	Description
	Bitmap (see page 14598)	Specifies the contents of the picture object as a bitmap graphic (.BMP file format).
	Graphic (see page 14600)	Specifies the graphic that the picture contains.
R	Height (see page 14600)	Specifies the vertical size (in pixels) of the graphic.
	Icon (see page 14601)	Specifies the contents of the TPicture (see page 14584) object as an icon graphic (.ICO file format).
	Metafile (see page 14601)	Specifies the contents of the picture object as an Enhanced Windows metafile graphic (.EMF file format).
	PictureAdapter (see page 14601)	Represents an OLE interface for the picture.
R	Width (see page 14602)	Specifies the horizontal size (in pixels) of the picture.

73.1.19.2 TPicture.Create Constructor

Creates a TPicture (see page 14584) object.

Pascal

```
constructor Create;
```

C++

```
__fastcall TPicture();
```

Description

Call Create to create an instance of TPicture (see page 14584) at runtime. Create allocates the memory for the picture object and initializes its internal formats. After creating the TPicture (see page 14584) object, use the LoadFromClipboardFormat (see page 14590) or LoadFromFile (see page 14591) method to assign a graphical image to the picture, so that it is available to the application.

See Also

LoadFromClipboardFormat (see page 14590)

LoadFromFile (see page 14591)

73.1.19.3 TPicture.Destroy Destructor

Destroys an instance of a picture object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TPicture();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TPicture (see page 14584) reference is not nil before it calls Destroy.

Destroy frees the graphic image it contains before calling the inherited Destroy.

See Also

Free (see page 22300)

Destroy (see page 22287)

73.1.19.4 TPicture Methods

The methods of the TPicture class are listed here.

Protected Methods

	Name	Description
	AssignTo (see page 14589)	Copies the properties of an object to a destination object.
	Changed (see page 14590)	This is Changed, a member of class TPicture.
	DefineProperties (see page 14590)	Provides an interface for a method that reads and writes otherwise unpublished data.
	LoadFromStream (see page 14591)	Reads the picture from a Stream.
	Progress (see page 14592)	This is Progress, a member of class TPicture.
	SaveToStream (see page 14597)	Saves the picture to a stream.

Public Methods

	Name	Description
	Assign (see page 14587)	Copies one object to another by copying the contents of that object to the other.
	LoadFromClipboardFormat (see page 14590)	Reads the picture from the handle provided in the given Clipboard format.
	LoadFromFile (see page 14591)	Reads the file specified in Filename and loads the data into the TPicture (see page 14584) object.
	RegisterClipboardFormat (see page 14592)	Registers a new TGraphic (see page 14516) class for use in the LoadFromClipboardFormat (see page 14590) method.
	RegisterFileFormat (see page 14594)	Registers a new TGraphic (see page 14516) class for use in LoadFromFile (see page 14591).
	RegisterFileFormatRes (see page 14594)	Registers a new TGraphic (see page 14516) class for use in the LoadFromFile (see page 14591) method.
	SaveToClipboardFormat (see page 14595)	Allocates a global handle and writes the picture in its native Clipboard format (CF_BITMAP for bitmaps, CF_METAFILE for metafiles, and so on).
	SaveToFile (see page 14595)	Writes the picture to disk.
	SupportsClipboardFormat (see page 14597)	Indicates if the given Clipboard format is supported by the LoadFromClipboardFormat (see page 14590) method.
	UnregisterGraphicClass (see page 14597)	This is UnregisterGraphicClass, a member of class TPicture.

73.1.19.4.1 TPicture.Assign Method

Copies one object to another by copying the contents of that object to the other.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

When Source is a object type that is valid for the Graphic (see page 14600) property, Assign makes that graphic the value of the Graphic (see page 14600) property.

The actions performed by Assign depend on the actual types of the TPicture (see page 14584) Graphic (see page 14600) property and Source. For example, if the Graphic (see page 14600) property and Source are bitmaps (TBitmap (see page 14396)), the bitmap contained in Source is copied into the Graphic (see page 14600) property. Similar conversions are valid, for example, for TIcon (see page 14537) or TMetafile (see page 14549).

If the Source parameter is not a valid object for the Graphic (see page 14600) property, Assign calls the inherited method so that the picture can be copied from any object with which it is compatible.

C++ Examples:

```
/*
This example uses an image, a button, and a shape component
on a form. When the user clicks the button, an image of the
form is stored in the FormImage variable and copied to the
Clipboard. The image of the form is then copied back to
the image component, producing an interesting result,
especially if the button is clicked multiple times.  Add
ExtCtrls, StdCtrls, and Clipbrd to the uses clause.
}
*/

#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Graphics::TBitmap *FormImage = GetFormImage();
  try
  {
    Clipboard()->Assign(FormImage);
    Image1->Picture->Assign(Clipboard());
  }
  __finally
  {
    delete FormImage;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Shape1->Shape = stEllipse;
  Shape1->Brush->Color = clLime;
  Image1->Stretch = true;
}
```

Delphi Examples:

```
{
This example uses an image, a button, and a shape component
on a form. When the user clicks the button, an image of the
form is stored in the FormImage variable and copied to the
Clipboard. The image of the form is then copied back to
the image component, producing an interesting result,
especially if the button is clicked multiple times.  Add
ExtCtrls, StdCtrls, and Clipbrd to the uses clause.
}
procedure TForm1.Button1Click(Sender: TObject);
var
```

```
  FormImage: TBitmap;
begin
  FormImage := GetFormImage;
  try
    Clipboard.Assign(FormImage);
    Image1.Picture.Assign(Clipboard);
  finally
    FormImage.Free;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Shape1.Shape := stEllipse;
  Shape1.Brush.Color := clLime;
  Image1.Stretch := True;
end;
```

See Also

Graphic (see page 14600)

Assign (see page 2930)

73.1.19.4.2 TPicture.AssignTo Method

Copies the properties of an object to a destination object.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Override the AssignTo method to extend the functionality of the Assign method of destination objects so that they handle newly created object classes. When defining a new object class, override the Assign method for every existing object class that should be able to copy its properties to the new class. Override the AssignTo method for every existing class to which the new class can copy.

The Assign method of TPersistent calls AssignTo if the descendant object does not succeed in copying the properties of a source object. The AssignTo method defined by TPersistent raises an EConvertError exception.

For example, given the following code in which A and B are instance variables:

```
A.Assign(B); {Delphi}
A->Assign(B); // C++
```

if A knows how to handle B, then it does so and returns. If A doesn't know how to handle B's type, execution will trickle to the TPersistent version of Assign, which calls:

```
B.AssignTo(A); {Delphi}
B->AssignTo(A); // C++
```

If B knows how to copy to A, the assignment succeeds. Otherwise, TPersistent raises an exception.

See Also

Assign (see page 2930)

EConvertError (see page 22724)

73.1.19.4.3 TPicture.Changed Method

Pascal

```
procedure Changed(Sender: TObject); dynamic;
```

C++

```
__fastcall Changed(TObject * Sender);
```

Description

This is Changed, a member of class TPicture.

73.1.19.4.4 TPicture.DefineProperties Method

Provides an interface for a method that reads and writes otherwise unpublished data.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

Descendants of TPersistent override DefineProperties to designate a method for storing the object's unpublished data to a stream such as a form file. By default, writing an object to a stream writes the values of all its published properties, and reading the object in reads those values and assigns them to the properties. Objects can also specify methods that read and write data other than published properties by overriding the DefineProperties method.

When overriding DefineProperties, consider including some or all of the following:

A call to the inherited method

Calls to the filer object's DefineProperty method

Calls to the filer object's DefineBinaryProperty method

DefineProperties is virtual, so descendant classes can override it as necessary but are not required to do so.

See Also

DefineProperties (see page 2771)

DefineBinaryProperty (see page 2837)

DefineProperty (see page 2838)

73.1.19.4.5 TPicture.LoadFromClipboardFormat Method

Reads the picture from the handle provided in the given Clipboard format.

Pascal

```
procedure LoadFromClipboardFormat(AFormat: Word; AData: THandle; APalette: HPALETTE);
```

C++

```
__fastcall LoadFromClipboardFormat(Word AFormat, THandle AData, HPALETTE APalette);
```

Description

Use LoadFromClipboardFormat to read in a graphic from the Clipboard. If the format is not supported, an EInvalidGraphic (see

page 14395) exception is raised.

See Also

EInvalidGraphic (see page 14395)

RegisterClipboardFormat (see page 14592)

TClipboard (see page 3328)

73.1.19.4.6 TPicture.LoadFromFile Method

Reads the file specified in Filename and loads the data into the TPicture (see page 14584) object.

Pascal

```
procedure LoadFromFile(const Filename: string);
```

C++

```
__fastcall LoadFromFile(const AnsiString Filename);
```

Description

Use LoadFromFile to read a picture from disk. The TGraphic (see page 14516) class created is determined by the file extension of the file. If the file extension is not recognized an EInvalidGraphic (see page 14395) exception is raised.

See Also

EInvalidGraphic (see page 14395)

RegisterFileFormat (see page 14594)

TGraphic (see page 14516)

73.1.19.4.7 TPicture.LoadFromStream Method

Reads the picture from a Stream.

Pascal

```
procedure LoadFromStream(Stream: TStream);
```

C++

```
__fastcall LoadFromStream(TStream Stream);
```

Description

Use LoadFromStream to read a picture from a TStream object. The TGraphic (see page 14516) class created is determined by the type of data contained in the stream.

The data in the stream should be previously written by a call to the SaveToStream (see page 14597) method of another TPicture (see page 14584) or of a TGraphic (see page 14516) descendant.

See Also

EInvalidGraphic (see page 14395)

LoadFromMimeSource

LoadFromFile (see page 14591)

SaveToStream (see page 14597)

SaveToStream (see page 14526)

73.1.19.4.8 TPicture.Progress Method

Pascal

```
procedure Progress(Sender: TObject; Stage: TProgressStage; PercentDone: Byte; RedrawNow:
Boolean; const R: TRect; const Msg: string); dynamic;
```

C++

```
__fastcall Progress(TObject * Sender, TProgressStage Stage, Byte PercentDone, Boolean
RedrawNow, const TRect R, const AnsiString Msg);
```

Description

This is Progress, a member of class TPicture.

73.1.19.4.9 TPicture.RegisterClipboardFormat Method

Registers a new TGraphic (see page 14516) class for use in the LoadFromClipboardFormat (see page 14590) method.

Pascal

```
class procedure RegisterClipboardFormat(AFormat: Word; AGraphicClass: TGraphicClass);
```

C++

```
__fastcall RegisterClipboardFormat(Word AFormat, TGraphicClass AGraphicClass);
```

Description

Use RegisterClipboardFormat register a new graphic format with TPicture (see page 14584) so that it can be used with the LoadFromClipboardFormat (see page 14590) method.

C++ Examples:

```
/*
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
*/
#include <Clipbrd.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClipboard *cb = Clipboard();
  if (cb->HasFormat(CF_BITMAP))
  {
    Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
    try
    {
      Bitmap->LoadFromClipboardFormat(CF_BITMAP, cb->GetAsHandle(CF_BITMAP), 0);
      Canvas->Draw(5,5,Bitmap);
    }
    catch (...)
    {
      MessageBeep(0);
      ShowMessage("Error reading image from clipboard!");
    }
    delete Bitmap;
    cb->Clear();
  }
  else
  {
    MessageBeep(0);
    ShowMessage("Cannot find image in clipboard!");
```

```
  }
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  unsigned int DataHandle;
  HPALETTE APalette;
  unsigned short MyFormat;
  Graphics::TBitmap *Bitmap = new Graphics::TBitmap();
  try
  {
    Bitmap->LoadFromFile("C:\\Program Files\\Common Files\\CodeGear
Shared\\Images\\Splash\\256Color\\FACTORY.BMP");
    // generate a clipboard format, with data and palette
    Bitmap->SaveToClipboardFormat(
      MyFormat,
      DataHandle,
      APalette);
    // save the data to the clipboard using that format and
    // the generated data
    Clipboard()->SetAsHandle(MyFormat,DataHandle);
  }
  catch (...)
  {
     ShowMessage("Failed to copy image to clipboard!");
  }
  delete Bitmap;
}
```

Delphi Examples:

```
{
The following code draws a bitmap image from the Clipboard
when a button is pressed.  The SaveToClipboard button must
be selected before the LoadFromClipboard button in order to
place the icon on the clipboard.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  Bitmap : TBitmap;
  s : string;
  Icon: TIcon;
begin
 Bitmap := TBitMap.Create;
 try
   Image1.Picture.RegisterClipboardFormat(cf_BitMap,TIcon);
   Bitmap.LoadFromClipBoardFormat(
     cf_BitMap,ClipBoard.GetAsHandle(cf_Bitmap),0);
   Canvas.draw(0,0,Bitmap);
 finally
   Bitmap.free;
   Clipboard.Clear;
 end;
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  MyFormat : Word;
  Bitmap : TBitMap;
  AData : THandle;
  APalette : HPALETTE;
begin
  Bitmap := TBitmap.Create;
  try
    Bitmap.LoadFromFile('c:\Program Files\Common Files\CodeGear
Shared\Images\Splash\256color\factory.bmp');
```

```
      Bitmap.SaveToClipBoardFormat(
        MyFormat,
        AData,
        APalette);
      ClipBoard.SetAsHandle(MyFormat,AData);
    finally
      Bitmap.Free;
    end;
  end;
```

See Also

LoadFromClipboardFormat (see page 14590)

TClipboard (see page 3328)

UnRegisterGraphicClass (see page 14597)

73.1.19.4.10 TPicture.RegisterFileFormat Method

Registers a new TGraphic (see page 14516) class for use in LoadFromFile (see page 14591).

Pascal

```
class procedure RegisterFileFormat(const AExtension: string; const ADescription: string;
AGraphicClass: TGraphicClass);
```

C++

```
__fastcall RegisterFileFormat(const AnsiString AExtension, const AnsiString ADescription,
TGraphicClass AGraphicClass);
```

Description

Use RegisterFileFormat to register a graphic file format with TPicture (see page 14584) so that it can be used with a Open or Save dialog box.

The AExtension parameter specifies the three-character system file extension to associate with the graphic class (for example, "bmp" is associated with TBitmap (see page 14396)). The ADescription parameter specifies the description of the graphic to appear in the drop down list of the dialog box (for example, "Bitmaps" is the description of TBitmap (see page 14396)). The AGraphicClass parameter registers the new graphic class to associate with the file format.

See Also

LoadFromFile (see page 14591)

UnRegisterGraphicClass (see page 14597)

73.1.19.4.11 TPicture.RegisterFileFormatRes Method

Registers a new TGraphic (see page 14516) class for use in the LoadFromFile (see page 14591) method.

Pascal

```
class procedure RegisterFileFormatRes(const AExtension: String; ADescriptionResID: Integer;
AGraphicClass: TGraphicClass);
```

C++

```
__fastcall RegisterFileFormatRes(const AnsiString AExtension, int ADescriptionResID,
TGraphicClass AGraphicClass);
```

Description

Use RegisterFileFormatRes by specifying a string resource.

The AExtension parameter specifies the three-character system file extension to associate with the graphic class (for example, "bmp" is associated with TBitmap (see page 14396)).

The ADescriptionResID parameter specifies the resource ID for a description of the graphic, which then appears in the drop down list of the dialog box (for example, "Bitmaps" is the description of TBitmap (see page 14396)).

The AGraphicClass parameter registers the new graphic class to associate with the file format.

See Also

LoadFromFile (see page 14591)

UnRegisterGraphicClass (see page 14597)

73.1.19.4.12 TPicture.SaveToClipboardFormat Method

Allocates a global handle and writes the picture in its native Clipboard format (CF_BITMAP for bitmaps, CF_METAFILE for metafiles, and so on).

Pascal

```
procedure SaveToClipboardFormat(var AFormat: Word; var AData: THandle; var APalette: HPALETTE);
```

C++

```
__fastcall SaveToClipboardFormat(Word AFormat, THandle AData, HPALETTE APalette);
```

Description

Use SaveToClipboardFormat to copy the picture to a Clipboard format. The resulting values can then be copied to the Windows clipboard using the clipboard's SetAsHandle method.

The picture's palette is returned in the APalette parameter, the format in the AFormat parameter, and a handle to the data in the AData parameter. Before the picture can be saved, an application must have registered the format using the RegisterClipboardFormat (see page 14592) method.

See Also

Formats (see page 3348)

RegisterClipboardFormat (see page 14592)

73.1.19.4.13 TPicture.SaveToFile Method

Writes the picture to disk.

Pascal

```
procedure SaveToFile(const Filename: string);
```

C++

```
__fastcall SaveToFile(const AnsiString Filename);
```

Description

Use SaveToFile to save a TPicture (see page 14584) object to the file specified in Filename.

The saved picture can be loaded to another TPicture (see page 14584) or to an appropriate TGraphic (see page 14516) descendant by calling its LoadFromFile (see page 14591) method.

C++ Examples:

```
/*
This example converts a specified icon to a bitmap. To run
```

```
this example, add an image, a button, and an Open dialog to
a form. Name the button ConvertIcon2Bitmap, and add the
following code as its OnClick event handler.
*/
void __fastcall TForm1::ConvertIcon2BitmapClick(TObject *Sender)
{
  OpenDialog1->DefaultExt = ".ICO";
  OpenDialog1->Filter = "icons (*.ico)|*.ICO";
  OpenDialog1->Options << ofOverwritePrompt << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    TIcon *pi = new TIcon();
    try
    {
      AnsiString as;
      pi->LoadFromFile(OpenDialog1->FileName);
      as = ChangeFileExt(OpenDialog1->FileName,".BMP");
      Image1->Width = pi->Width;
      Image1->Height = pi->Height;
      Image1->Canvas->Draw(0,0,pi);
      Image1->Picture->SaveToFile(as);
      ShowMessage(OpenDialog1->FileName + " Saved to " + as);
    }
    __finally
    {
      delete pi;
    }
  }
}
```

Delphi Examples:

```
{
This example converts a specified icon to a bitmap. To run
this example, add an image, a button, and an Open dialog to
a form. Name the button ConvertIcon2Bitmap, and add the
following code as its OnClick event handler.
}
procedure TForm1.ConvertIcon2BitmapClick(Sender: TObject);
var
  s : string;
  Icon: TIcon;
begin
  OpenDialog1.DefaultExt := '.ICO';
  OpenDialog1.Filter := 'icons (*.ico)|*.ICO';
  OpenDialog1.Options := [ofOverwritePrompt, ofFileMustExist, ofHideReadOnly ];
  if OpenDialog1.Execute then
  begin
    Icon := TIcon.Create;
    try
      Icon.Loadfromfile(OpenDialog1.FileName);
      s:= ChangeFileExt(OpenDialog1.FileName,'.BMP');
      Image1.Width := Icon.Width;
      Image1.Height := Icon.Height;
      Image1.Canvas.Draw(0,0,Icon);
      Image1.Picture.SaveToFile(s);
      ShowMessage(OpenDialog1.FileName + ' Saved to ' + s);
    finally
      Icon.Free;
    end;
  end;
end;
```

See Also

LoadFromFile (see page 14591)

LoadFromFile (see page 14523)

73.1.19.4.14 TPicture.SaveToStream Method

Saves the picture to a stream.

Pascal

```
procedure SaveToStream(Stream: TStream);
```

C++

```
__fastcall SaveToStream(TStream Stream);
```

Description

Use SaveToStream to save a picture to the TStream object specified by the Stream parameter.

The saved picture can be loaded to another TPicture (see page 14584) or to an appropriate TGraphic (see page 14516) descendant by calling its LoadFromStream (see page 14591) method.

See Also

LoadFromStream (see page 14591)

LoadFromStream (see page 14524)

73.1.19.4.15 TPicture.SupportsClipboardFormat Method

Indicates if the given Clipboard format is supported by the LoadFromClipboardFormat (see page 14590) method.

Pascal

```
class function SupportsClipboardFormat(AFormat: Word): Boolean;
```

C++

```
__fastcall Boolean SupportsClipboardFormat(Word AFormat);
```

Description

If the LoadFromClipboardFormat (see page 14590) method supports the Clipboard format specified as the value of AFormat, SupportsClipboardFormat returns true. If the format is not supported, the method returns false.

See Also

LoadFromClipboardFormat (see page 14590)

73.1.19.4.16 TPicture.UnregisterGraphicClass Method

Pascal

```
class procedure UnregisterGraphicClass(AClass: TGraphicClass);
```

C++

```
__fastcall UnregisterGraphicClass(TGraphicClass AClass);
```

Description

This is UnregisterGraphicClass, a member of class TPicture.

73.1.19.5 TPicture Properties

The properties of the TPicture class are listed here.

Public Properties

	Name	Description
	Bitmap (see page 14598)	Specifies the contents of the picture object as a bitmap graphic (.BMP file format).
	Graphic (see page 14600)	Specifies the graphic that the picture contains.
R	Height (see page 14600)	Specifies the vertical size (in pixels) of the graphic.
	Icon (see page 14601)	Specifies the contents of the TPicture (see page 14584) object as an icon graphic (.ICO file format).
	Metafile (see page 14601)	Specifies the contents of the picture object as an Enhanced Windows metafile graphic (.EMF file format).
	PictureAdapter (see page 14601)	Represents an OLE interface for the picture.
R	Width (see page 14602)	Specifies the horizontal size (in pixels) of the picture.

73.1.19.5.1 TPicture.Bitmap Property

Specifies the contents of the picture object as a bitmap graphic (.BMP file format).

Pascal

```
property Bitmap: TBitmap;
```

C++

```
__property TBitmap Bitmap;
```

Description

Use Bitmap to reference the picture object when it contains a bitmap. If Bitmap is referenced when the picture contains a Metafile (see page 14601) or Icon (see page 14601) graphic, the graphic won't be converted. Instead, the original contents of the picture are discarded and Bitmap returns a new, blank bitmap.

Note: When assigning the Bitmap property, TPicture (see page 14584) assigns the properties of a another TBitmap (see page 14396) object. It does not take ownership of the specified value.

C++ Examples:

```
/*
The following example is taken from the custom draw demo. It
shows how the OnCustomDraw event handler draws the
background for the tree view before the items and lines are
drawn.
*/
void __fastcall TCustomDrawForm::TVCustomDraw(TCustomTreeView *Sender,
      const TRect &ARect, bool &DefaultDraw)
{
/*
This event should be used to draw any background colors or
images.  ARect represents the entire client area of the TreeView.
Use the TreeView's canvas to do the drawing.
Note that drawing a background bitmap is not really
supported by CustomDraw, so scrolling can get messy. Best to
subclass the TreeView and handle scrolling messages.
*/
  if (None1 != NULL)
  {
    if (None1->Checked) //no picture
```

```
      {
        TV->Canvas->Brush->Color = BkgColorDialog->Color;
        TV->Canvas->Brush->Style = FBrushStyle;
        TV->Canvas->FillRect(ARect);
      }
      else if (Tile1->Checked) //tile bitmap
      {
        TV->Canvas->Brush->Bitmap = Image1->Picture->Bitmap;
        TV->Canvas->FillRect(ARect);
      }
      else //Stretch across the canvas.
        TV->Canvas->StretchDraw(ARect, Image1->Picture->Bitmap);
    };
    DefaultDraw = FDefaultDraw;
    // Setting DefaultDraw to false here prevents all calls to
    // OnCustomDrawItem.
  }
```

Delphi Examples:

```
{
The following example is taken from the custom draw demo. It
shows how the OnCustomDraw event handler draws the
background for the tree view before the items and lines are
drawn.
}
procedure TCustomDrawForm.TVCustomDraw(Sender: TCustomTreeView; const ARect: TRect;
  var DefaultDraw: Boolean);
begin
{
This event should be used to draw any background colors or
images.  ARect represents the entire client area of the TreeView.
Use the TreeView's canvas to do the drawing.
Note that drawing a background bitmap is not really
supported by CustomDraw, so scrolling can get messy. Best to
subclass the TreeView and handle scrolling messages.
}
  with TV.Canvas do
  begin
    if None1 <> nil then
    begin
      if None1.Checked then //no picture
      begin
        Brush.Color := BkgColorDialog.Color;
        Brush.Style := FBrushStyle;
        FillRect(ARect);
      end else
        if Tile1.Checked then //tile bitmap
        begin
          Brush.Bitmap := Image1.Picture.Bitmap;
            FillRect(ARect);
          end else //Stretch across the canvas.
              StretchDraw(ARect, Image1.Picture.Bitmap);
    end;
  end;
  DefaultDraw := FDefaultDraw;
  // Setting DefaultDraw to false here prevents all calls to
  // OnCustomDrawItem.
end;
```

See Also

Graphic (see page 14600)

73.1.19.5.2 TPicture.Graphic Property

Specifies the graphic that the picture contains.

Pascal

```
property Graphic: TGraphic;
```

C++

```
__property TGraphic Graphic;
```

Description

Use Graphic to specify what graphic the TPicture (see page 14584) object contains. The graphic can be a bitmap, icon, metafile, or user-defined graphic class.

Note: When assigning the Graphic property, TPicture (see page 14584) assigns the properties of a another TGraphic (see page 14516) object. It does not take ownership of the specified object.

C++ Examples:

```
/*
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  PaintBox1->Canvas->Draw(0,0, Image1->Picture->Graphic);
}
```

Delphi Examples:

```
{
The following code draws the graphic in Picture1 in the
top-left corner PaintBox1.  Place a TPaintBox in the form
and a TImage in the form that contains a picture.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  PaintBox1.Canvas.Draw(0,0, Image1.Picture.Graphic);
end;
```

See Also

Bitmap (see page 14598)

Icon (see page 14601)

Metafile (see page 14601)

73.1.19.5.3 TPicture.Height Property

Specifies the vertical size (in pixels) of the graphic.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Use Height to find the height of the graphic image contained in the picture object. Height is the native, unstretched, height of the picture.

See Also

Width (see page 14602)

73.1.19.5.4 TPicture.Icon Property

Specifies the contents of the TPicture (see page 14584) object as an icon graphic (.ICO file format).

Pascal

```
property Icon: TIcon;
```

C++

```
__property TIcon Icon;
```

Description

If Icon is referenced when the TPicture (see page 14584) contains a Bitmap (see page 14598) or Metafile (see page 14601) graphic, the graphic won't be converted. Instead, the original contents of the TPicture (see page 14584) are discarded and Icon returns a new, blank icon.

Note: When assigning the Icon property, TPicture (see page 14584) assigns the properties of a another Icon object. It does not take ownership of the specified value.

See Also

Graphic (see page 14600)

73.1.19.5.5 TPicture.Metafile Property

Specifies the contents of the picture object as an Enhanced Windows metafile graphic (.EMF file format).

Pascal

```
property Metafile: TMetafile;
```

C++

```
__property TMetafile Metafile;
```

Description

If Metafile is referenced when the TPicture (see page 14584) contains a Bitmap (see page 14598) or Icon (see page 14601) graphic, the graphic won't be converted. Instead, the original contents of the TPicture (see page 14584) are discarded and Metafile returns a new, blank metafile.

Note: When assigning the Metafile property, TPicture (see page 14584) assigns the properties of a another TMetafile (see page 14549) object. It does not take ownership of the specified value.

See Also

Graphic (see page 14600)

73.1.19.5.6 TPicture.PictureAdapter Property

Represents an OLE interface for the picture.

Pascal

```
property PictureAdapter: IChangeNotifier;
```

C++

```
__property IChangeNotifier PictureAdapter;
```

Description

PictureAdapter is for internal use only.

See Also

TPictureAdapter (see page 1599)

73.1.19.5.7 TPicture.Width Property

Specifies the horizontal size (in pixels) of the picture.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Use Width to find the width of a graphic image. Width contains the native, unstretched, width of the picture.

See Also

Height (see page 14600)

73.1.19.6 TPicture Events

The events of the TPicture class are listed here.

Public Events

	Name	Description
	OnChange (see page 14602)	Occurs when the specific graphics item encapsulated by the picture object changes.
	OnProgress (see page 14603)	Occurs periodically during slow operations that affect the graphic.

73.1.19.6.1 TPicture.OnChange Event

Occurs when the specific graphics item encapsulated by the picture object changes.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Use OnChange to write an event handler to process an action when the graphic is modified.

73.1.19.6.2 TPicture.OnProgress Event

Occurs periodically during slow operations that affect the graphic.

Pascal

```
property OnProgress: TProgressEvent;
```

C++

```
__property TProgressEvent OnProgress;
```

Description

OnProgress is generated by the particular graphic that the picture object contains. Whether OnProgress occurs depends upon the type of graphic in the Graphic (see page 14600) property. Some graphics generate this event, others do not. Jpeg images, for example, generate an OnProgress event.

Write an OnProgress event handler to provide the user with feedback during slow operations such as loading large compressed images. TImage, for example, hooks the OnProgress event of TPicture (see page 14584).

Note: The PercentDone parameter on the event handler is only an approximation. With some image formats, the value of PercentDone may actually decrease from the value in previous events, as the graphic object discovers there is more work to do.

See Also

Graphic (see page 14600)

OnProgress (see page 12831)

73.1.20 TSharedImage Class

TSharedImage is the base class for classes that contain images used for graphics objects.

Class Hierarchy

Graphics.TSharedImage

Pascal

```
TSharedImage = class;
```

C++

```
class TSharedImage;
```

File

Graphics

Description

TSharedImage is used as a base class for classes that hold the internal representation of graphical images such as bitmaps and icons. TSharedImage is an abstract class. Its descendant classes are used internally by graphics objects, and are automatically created by their associated graphics objects.

See Also

TGraphic (see page 14516)

73.1.20.1 TSharedImage Members

The following tables list the members exposed by TSharedImage.

Protected Methods

	Name	Description
	FreeHandle (see page 14604)	This is FreeHandle, a member of class TSharedImage.
	Reference (see page 14604)	This is Reference, a member of class TSharedImage.
	Release (see page 14604)	This is Release, a member of class TSharedImage.

Protected Properties

	Name	Description
	RefCount (see page 14605)	This is RefCount, a member of class TSharedImage.

73.1.20.2 TSharedImage Methods

The methods of the TSharedImage class are listed here.

Protected Methods

	Name	Description
	FreeHandle (see page 14604)	This is FreeHandle, a member of class TSharedImage.
	Reference (see page 14604)	This is Reference, a member of class TSharedImage.
	Release (see page 14604)	This is Release, a member of class TSharedImage.

73.1.20.2.1 TSharedImage.FreeHandle Method

Pascal

```
procedure FreeHandle; virtual; abstract;
```

C++

```
virtual __fastcall FreeHandle() = 0;
```

Description

This is FreeHandle, a member of class TSharedImage.

73.1.20.2.2 TSharedImage.Reference Method

Pascal

```
procedure Reference;
```

C++

```
__fastcall Reference();
```

Description

This is Reference, a member of class TSharedImage.

73.1.20.2.3 TSharedImage.Release Method

Pascal

```
procedure Release;
```

C++

```
__fastcall Release();
```

Description

This is Release, a member of class TSharedImage.

73.1.20.3 TSharedImage Properties

The properties of the TSharedImage class are listed here.

Protected Properties

	Name	Description
	RefCount (see page 14605)	This is RefCount, a member of class TSharedImage.

73.1.20.3.1 TSharedImage.RefCount Property

Pascal

```
property RefCount: Integer;
```

C++

```
__property int RefCount;
```

Description

This is RefCount, a member of class TSharedImage.

73.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IChangeNotifier (see page 14606)	IChangeNotifier is the interface used for responding to status changes.

73.2.1 IChangeNotifier Interface

IChangeNotifier is the interface used for responding to status changes.

Class Hierarchy

Graphics.IChangeNotifier

Pascal

```
IChangeNotifier = interface;
```

C++

```
__interface IChangeNotifier;
```

File

Graphics

Description

IChangeNotifier introduces one method, Changed (see page 14607) that is invoked when the status of the implementing class changes.

See Also

Changed (see page 14607)

73.2.1.1 IChangeNotifier Members

The following tables list the members exposed by IChangeNotifier.

Public Methods

	Name	Description
	Changed (see page 14607)	Called when a change occurs in the implementing class.

73.2.1.2 IChangeNotifier Methods

The methods of the IChangeNotifier class are listed here.

Public Methods

	Name	Description
	Changed (see page 14607)	Called when a change occurs in the implementing class.

73.2.1.2.1 IChangeNotifier.Changed Method

Called when a change occurs in the implementing class.

Pascal

```
procedure Changed;
```

C++

```
__fastcall Changed();
```

Description

Changed is principally used internally by TFont (see page 14497) class TFontAdapter property and TPicture (see page 14584) class TPictureAdapter property.

See Also

TFontAdapter

TPictureAdapter

73.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AllocPatternBitmap (see page 14608)	Creates a TBitmap (see page 14396) filled with a pattern.
	BytesPerScanline (see page 14609)	This is function Graphics.BytesPerScanline.
	CharsetToIdent (see page 14609)	Obtains the name of a character set.
	ColorToIdent (see page 14610)	Provides the symbolic name of a TColor (see page 14648) value.
	ColorToRGB (see page 14610)	Converts a TColor (see page 14648) value into an RGB representation of the color.
	ColorToString (see page 14611)	Returns a string that represents the name of a TColor (see page 14648) value.
	CopyPalette (see page 14612)	Creates a new palette object that matches an existing palette.
	CreateGrayMappedBmp (see page 14612)	Remaps the standard gray colors in a bitmap with the system grays.
	CreateGrayMappedRes (see page 14613)	Remaps the standard gray colors in a bitmap resource with the system grays.
	CreateMappedBmp (see page 14614)	Changes the color table in a bitmap.
	CreateMappedRes (see page 14614)	Changes the color table in a bitmap resource.
	FreeMemoryContexts (see page 14615)	This is function Graphics.FreeMemoryContexts.
	GetCharsetValues (see page 14615)	Passes the name of every predefined character set string to a callback function.
	GetColorValues (see page 14619)	Passes the name of every predefined color constant to a callback function.
	GetDefFontCharSet (see page 14619)	Returns the character set of the default system font.
	GetDIB (see page 14620)	Returns the info header and image for a device independent bitmap.
	GetDIBSizes (see page 14620)	Returns the size of the info header and of the image for a device independent bitmap.
	GraphicExtension (see page 14621)	Returns the default file-name extension of a graphics object.
	GraphicFileMask (see page 14624)	Returns a file mask that specifies the valid extensions for a graphic class.
	GraphicFilter (see page 14624)	Returns a file filter compatible with the Filter property of an Open or Save dialog.
	IdentToCharset (see page 14627)	Translates the name of a character set constant to the corresponding character set.
	IdentToColor (see page 14627)	Translates the name of a color constant to the corresponding TColor (see page 14648) value.
	PaletteChanged (see page 14628)	This is function Graphics.PaletteChanged.
	StringToColor (see page 14628)	Translates a string representation of a color to the corresponding TColor (see page 14648) value.
	TransparentStretchBlt (see page 14629)	This is function Graphics.TransparentStretchBlt.

73.3.1 Graphics.AllocPatternBitmap Function

Creates a TBitmap (see page 14396) filled with a pattern.

Pascal

```
function AllocPatternBitmap(BkColor: TColor; FgColor: TColor): TBitmap;
```

C++

```
TBitmap AllocPatternBitmap(TColor BkColor, TColor FgColor);
```

File

Graphics

Description

AllocPatternBitmap returns a reference to an 8 by 8 pixel TBitmap (see page 14396) that is filled with a pattern. Pixels alternate between **BkColor** and **FgColor** colors horizontally and vertically in a quilt pattern.

See Also

TBitmap (see page 14396)

TColor (see page 14648)

73.3.2 Graphics.BytesPerScanline Function

Pascal

```
function BytesPerScanline(PixelsPerScanline: Longint; BitsPerPixel: Longint; Alignment:
Longint): Longint;
```

C++

```
Longint BytesPerScanline(Longint PixelsPerScanline, Longint BitsPerPixel, Longint Alignment);
```

File

Graphics

Description

This is function Graphics.BytesPerScanline.

73.3.3 Graphics.CharsetToIdent Function

Obtains the name of a character set.

Pascal

```
function CharsetToIdent(Charset: Longint; var Ident: string): Boolean;
```

C++

```
Boolean CharsetToIdent(Longint Charset, AnsiString Ident);
```

File

Graphics

Description

Call CharsetToIdent to obtain the symbolic name for the character set of a font. CharsetToIdent returns true if the Ident parameter is successfully given an identifying name for the character set.

Note: The return value of CharsetToIdent does not indicate whether the Charset parameter is valid for a given font. Many fonts support only a limited number of character sets. Some fonts may support less common character sets that can't be mapped to identifiers by CharsetToIdent.

See Also

TFont (see page 14497)

73.3.4 Graphics.ColorToIdent Function

Provides the symbolic name of a TColor (see page 14648) value.

Pascal

```
function ColorToIdent(Color: Longint; var Ident: string): Boolean;
```

C++

```
Boolean ColorToIdent(Longint Color, AnsiString Ident);
```

File

Graphics

Description

Call ColorToIdent to obtain the name of the symbolic constant that represents a TColor (see page 14648) value, such as clBlack (see page 14666) or clWindow (see page 14732). The Ident parameter is set to the symbolic name. If there is no symbolic constant defined for the color, ColorToIdent returns false.

See Also

ColorToString (see page 14611)

TColor (see page 14648)

IdentToColor (see page 14627)

73.3.5 Graphics.ColorToRGB Function

Converts a TColor (see page 14648) value into an RGB representation of the color.

Pascal

```
function ColorToRGB(Color: TColor): Longint;
```

C++

```
Longint ColorToRGB(TColor Color);
```

File

Graphics

Description

Call ColorToRGB to obtain an RGB representation of a color for using with Windows API calls. ColorToRGB strips away the information that is stored in the highest order bits about which palette to use for colors that are not always available.

Delphi Examples:

```
{
The following code converts the color of the current form,
Form1, to a Windows RGB value:
}
const
  NumPaletteEntries = 20;
var
  FPaletteEntries: array[0..NumPaletteEntries - 1] of TPaletteEntry;
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
  Result: Integer;
  RealColor, paletteColor: TColor;
begin
  Result := 0;
  I := 0;
  RealColor := Graphics.ColorToRGB(Form1.Color);
  while I < NumPaletteEntries do
  begin
    with FPaletteEntries[I] do
    begin
      paletteColor:= TColor(RGB(peRed, peGreen, peBlue));
      if RealColor = paletteColor then
      begin
        Label1.Caption := IntToStr(I);
        RedEdit.Text:= IntToStr(peRed);
        GreenEdit.Text:= IntToStr(peGreen);
        BlueEdit.Text:= IntToStr(peBlue);
        Exit;
      end;
    end;
    Inc(I)
  end;
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  Form1.Color:=
    StrToInt(RedEdit.Text) shl 16 +
    StrToInt(GreenEdit.Text) shl 8 +
    StrToInt(BlueEdit.Text);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  GetPaletteEntries(GetStockObject(DEFAULT_PALETTE), 0, NumPaletteEntries,
    FPaletteEntries);
  Form1.Color:= clMoneyGreen;
end;
```

See Also

ColorToIdent (see page 14610)

73.3.6 Graphics.ColorToString Function

Returns a string that represents the name of a TColor (see page 14648) value.

Pascal

```
function ColorToString(Color: TColor): string;
```

C++

```
AnsiString ColorToString(TColor Color);
```

File

Graphics

Description

Call ColorToString to obtain a string that represents a TColor (see page 14648) value. If there is a symbolic constant defined for the color (such as clBlack (see page 14666) or clHighlightText (see page 14674)), ColorToString returns the name of the constant. Otherwise, ColorToString returns the hex value of the color, formatted as a string such as "$02FF8800" (Delphi) or "0x02FF8800" (C++).

See Also

ColorToIdent (see page 14610)

StringToColor (see page 14628)

73.3.7 Graphics.CopyPalette Function

Creates a new palette object that matches an existing palette.

Pascal

```
function CopyPalette(Palette: HPALETTE): HPALETTE;
```

C++

```
HPALETTE CopyPalette(HPALETTE Palette);
```

File

Graphics

Description

Call CopyPalette to create a new Windows palette object that exactly matches an existing palette. If the Palette parameter does not refer to a valid Windows palette, or if a problem occurs while copying the palette, CopyPalette returns 0.

73.3.8 Graphics.CreateGrayMappedBmp Function

Remaps the standard gray colors in a bitmap with the system grays.

Pascal

```
function CreateGrayMappedBmp(Handle: HBITMAP): HBITMAP;
```

C++

```
HBITMAP CreateGrayMappedBmp(HBITMAP Handle);
```

File

Graphics

Description

Call CreateGrayMappedBmp to create a bitmap that uses the system gray colors (clBtnHightlight, clBtnFace (see page 14667), clBtnShadow (see page 14668) and clBtnText (see page 14668)) from a bitmap that uses standard gray scale colors (clWhite (see page 14732), clSilver (see page 14683), clGray (see page 14672), and clBlack (see page 14666)). This allows an application to dynamically create images that match the user's control panel settings, given a base image.

CreateGrayMappedBmp creates a new bitmap. It does not alter the original bitmap, which has the handle specified by the Handle parameter.

Note: CreateGrayMappedBmp does not work with bitmaps that have more than 256 colors. For bitmaps with more than 256 colors (8bpp), this function returns the original bitmap.

See Also

TBitmap (see page 14396)

CreateMappedBmp (see page 14614)

CreateGrayMappedRes (see page 14613)

Graphics

73.3.9 Graphics.CreateGrayMappedRes Function

Remaps the standard gray colors in a bitmap resource with the system grays.

Pascal

```
function CreateGrayMappedRes(Instance: THandle; ResName: PChar): HBITMAP;
```

C++

```
HBITMAP CreateGrayMappedRes(THandle Instance, const char * ResName);
```

File

Graphics

Description

Call CreateGrayMappedRes to create a bitmap that uses the system gray colors (clBtnHightlight, clBtnFace (see page 14667), clBtnShadow (see page 14668) and clBtnText (see page 14668)) from a resourced bitmap that uses standard gray scale colors (clWhite (see page 14732), clSilver (see page 14683), clGray (see page 14672), and clBlack (see page 14666)). This allows an application to dynamically create images that match the user's control panel settings, by creating a base image as a bitmap resource.

Use the Instance and ResName parameters to identify the bitmap resource whose color table should be changed

Note: CreateMappedRes (see page 14614) does not work with bitmaps that have more than 256 colors. For bitmaps with more than 256 colors (8bpp), this function returns an instance of the original bitmap without color modifications.

See Also

TBitmap (see page 14396)

CreateGrayMappedBmp (see page 14612)

FindResourceHInstance

Hinstance

CreateMappedRes (see page 14614)

Graphics

73.3.10 Graphics.CreateMappedBmp Function

Changes the color table in a bitmap.

Pascal

```
function CreateMappedBmp(Handle: HBITMAP; const OldColors: array of TColor; const NewColors:
array of TColor): HBITMAP;
```

C++

```
HBITMAP CreateMappedBmp(HBITMAP Handle, const array of TColor OldColors, const array of TColor
NewColors);
```

File

Graphics

Description

Call CreateMappedBmp to make selective changes to the color map of a bitmap. This function replaces the colors specified by the OldColors parameter with the colors specified by the NewColors parameter and returns the handle for a new device dependent bitmap (DDB) that uses the new color table. Handle is the handle to the bitmap whose color table should be changed. In C++, specify the size of the color arrays in OldColors_Size and NewColors_Size. This value should be the index of the last entry in the corresponding array. The OldColors and NewColors arrays should contain the same number of elements.

CreateMappedBmp creates a new bitmap. It does not alter the original bitmap, which has the handle specified by the Handle parameter.

Note: CreateMappedBmp does not work with bitmaps that have more than 256 colors. For bitmaps with more than 256 colors (8bpp), this function returns the original bitmap.

See Also

TBitmap (see page 14396)

CreateMappedRes (see page 14614)

CreateGrayMappedBmp (see page 14612)

73.3.11 Graphics.CreateMappedRes Function

Changes the color table in a bitmap resource.

Pascal

```
function CreateMappedRes(Instance: THandle; ResName: PChar; const OldColors: array of TColor;
const NewColors: array of TColor): HBITMAP;
```

C++

```
HBITMAP CreateMappedRes(THandle Instance, const char * ResName, const array of TColor
OldColors, const array of TColor NewColors);
```

File

Graphics

Description

Call CreateMappedRes to make selective changes to the color map of a resourced bitmap. This function replaces the colors specified by the OldColors parameter with the colors specified by the NewColors parameter and returns the handle for a new device dependent bitmap (DDB) that uses the new color table. Use the Instance and ResName parameters to identify the bitmap resource whose color table should be changed. In C++, indicate the number of elements in the color arrays by the OldColors_Size and NewColors_Size parameters. These values should be the index of the last element in the corresponding color array, not the number of entries. The OldColors and NewColors arrays should contain the same number of elements.

Note: CreateMappedRes does not work with bitmaps that have more than 256 colors. For bitmaps with more than 256 colors (8bpp), this function returns an instance of the original bitmap without color modifications.

See Also

TBitmap (see page 14396)

CreateMappedBmp (see page 14614)

FindResourceHInstance

Hinstance

CreateGrayMappedRes (see page 14613)

73.3.12 Graphics.FreeMemoryContexts Function

Pascal

```
procedure FreeMemoryContexts;
```

C++

```
FreeMemoryContexts();
```

File

Graphics

Description

This is function Graphics.FreeMemoryContexts.

73.3.13 Graphics.GetCharsetValues Function

Passes the name of every predefined character set string to a callback function.

Pascal

```
procedure GetCharsetValues(Proc: TGetStrProc);
```

C++

```
GetCharsetValues(TGetStrProc Proc);
```

File

Graphics

Description

Call GetCharsetValues to execute a callback for every character set name that has a corresponding constant defined in the application. The Proc parameter is the callback function that is called for every character set constant name.

Note: To convert the strings that are passed to the callback into the TFontCharset (see page 14651) type, use the IdentToCharset (see page 14627) function.

C++ Examples:

```
/*
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.
Note:   This OnKeyPress event handler does not deal with the
case when the user types the Delete key. That case must be
caught in the OnKeyDown event handler instead.
*/
void __fastcall TForm1::ComboBox1KeyPress(TObject *Sender, char &Key)
{
  // first, process the keystroke to obtain the current string
  // This code requires all items in list to be uppercase
  if (Key >= 'a' && Key <= 'z')
    Key -= 32; // Force Uppercase only!
  TComboBox *pCB = (TComboBox *)Sender;
  AnsiString TmpStr;
  bool BackSpace = (Key == (char)VK_BACK);
  if (BackSpace && pCB->SelLength)
    TmpStr = pCB->Text.SubString(1,pCB->SelStart)+
             pCB->Text.SubString(pCB->SelLength+pCB->SelStart+1,255);
  else if (BackSpace) // SelLength == 0
    TmpStr = pCB->Text.SubString(1,pCB->SelStart-1)+
             pCB->Text.SubString(pCB->SelStart+1,255);
  else //Key is a visible character
    TmpStr = pCB->Text.SubString(1,pCB->SelStart)+ Key +
             pCB->Text.SubString(pCB->SelLength+pCB->SelStart+1,255);
  if (TmpStr.IsEmpty())
    return;
  // set SelSt to the current insertion point
  int SelSt = pCB->SelStart;
  if (BackSpace && SelSt > 0)
    SelSt--;
  else if (!BackSpace)
    SelSt++;
  Key = 0; // indicate that key was handled
  if (SelSt == 0)
  {
    pCB->Text = "";
    return;
  }
  // Now that TmpStr is the currently typed string, see if we can locate a match
  bool Found = false;
  for (int i = 1; i < pCB->Items->Count; i++)
    if (TmpStr == pCB->Items->Strings[i-1].SubString(1,TmpStr.Length()))
    {
      pCB->Text = pCB->Items->Strings[i-1]; // update to the match that was found
      pCB->ItemIndex = i-1;
      Found = true;
      break;
    }
  if (Found) // select the untyped end of the string
  {
```

```
    pCB->SelStart = SelSt;
    pCB->SelLength = pCB->Text.Length() - SelSt;
  }
  else Beep();
}
//---------------------------------------------------------------------------
TStringList *CharSetList;

void __fastcall TForm1::AddCharacterSet(AnsiString S)
{
  CharSetList->Add(S);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
CharSetList = new TStringList();
GetCharsetValues(AddCharacterSet);
CharSetList->Sort();
ComboBox1->Items = CharSetList;
}
```

Delphi Examples:

```
{
The following uses the GetCharsetValues procedure to fill a
string list with the names of all the available character
set constants. This string list can then be used to allow
the user to select a character set.  Here is the callback
that adds the character sets to the string list:
}
var
  CharSetList : TStringList;

procedure TForm1.AddCharacterSet(const S: string);
begin
  CharSetList.Add(S);
end;
{
Here is the code that creates the string list, fills it, and sorts the character set names.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  CharSetList := TStringList.Create;
  Graphics.GetCharsetValues(AddCharacterSet);
  CharSetList.Sort;
  ListBox1.Items := CharSetList;
  CharSetList.Destroy;
end;
{
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.
Note:   This OnKeyPress event handler does not deal with the
case when the user types the Delete key. That case must be
caught in the OnKeyDown event handler instead.
Note: Set the TComboBox AutoComplete to false to turn off
default auto completion.
}
procedure TForm1.ComboBox1KeyPress(Sender: TObject; var Key: Char);
var
  Found: boolean;
  i, ct, SelSt: Integer;
  TmpStr: string;
begin
  { first, process the keystroke to obtain the current string }
```

```

TFontCharset (see page 14651)

73.3.14 Graphics.GetColorValues Function

Passes the name of every predefined color constant to a callback function.

Pascal

```
procedure GetColorValues(Proc: TGetStrProc);
```

C++

```
GetColorValues(TGetStrProc Proc);
```

File

Graphics

Description

Call GetColorValues to execute a callback for every TColor (see page 14648) constant defined in the application. The Proc parameter is the callback function that is called for every color constant name.

Note: To convert the strings that are passed to the callback into the TColor (see page 14648) type, use the IdentToColor (see page 14627) function.

See Also

TColor (see page 14648)

IdentToColor (see page 14627)

73.3.15 Graphics.GetDefFontCharSet Function

Returns the character set of the default system font.

Pascal

```
function GetDefFontCharSet: TFontCharSet;
```

C++

```
TFontCharSet GetDefFontCharSet();
```

File

Graphics

Description

Call GetDefFontCharSet to determine the character set that is used when a font is not explicitly assigned to a control. This character set can be used to initialize a font that is specified by font name only, to best match the characters for the locale of the machine on which the application is running.

See Also

TFont (see page 14497)

73.3.16 Graphics.GetDIB Function

Returns the info header and image for a device independent bitmap.

Pascal

```
function GetDIB(Bitmap: HBITMAP; Palette: HPALETTE; var BitmapInfo; var Bits): Boolean;
```

C++

```
Boolean GetDIB(HBITMAP Bitmap, HPALETTE Palette,  BitmapInfo,  Bits);
```

File

Graphics

Description

Call GetDIB to convert a device dependent bitmap into a device independent bitmap (DIB). Pass the handle to a device dependent bitmap and a handle to its palette as the Bitmap and Palette parameters. GetDIB fills in the BitmapInfo and Bits parameters with the info header and image of the corresponding DIB. GetDIB returns true if the bitmap was successfully converted into a DIB, false otherwise.

Before calling GetDIB, the memory for the info header and image must be allocated. Call GetDIBSizes (see page 14620) to determine the amount of memory that must be allocated for the info header and image.

See Also

GetDIBSizes (see page 14620)

73.3.17 Graphics.GetDIBSizes Function

Returns the size of the info header and of the image for a device independent bitmap.

Pascal

```
procedure GetDIBSizes(Bitmap: HBITMAP; var InfoHeaderSize: DWORD; var ImageSize: DWORD);
```

C++

```
GetDIBSizes(HBITMAP Bitmap, DWORD InfoHeaderSize, DWORD ImageSize);
```

File

Graphics

Description

Call GetDIBSizes to determine the amount of memory needed to convert a device dependent bitmap into a device independent bitmap (DIB). Pass the handle to a device dependent bitmap as the Bitmap parameter. GetDIBSizes returns the sizes of the info header and image of the corresponding DIB as the InfoHeaderSize parameter and the ImageSize parameter, respectively.

Call GetDIBSizes to determine the amount of memory that must be allocated before calling GetDIB (see page 14620) to convert a device dependent bitmap into a device independent bitmap.

See Also

GetDIB (see page 14620)

73.3.18 Graphics.GraphicExtension Function

Returns the default file-name extension of a graphics object.

Pascal

```
function GraphicExtension(GraphicClass: TGraphicClass): string;
```

C++

```
AnsiString GraphicExtension(TGraphicClass GraphicClass);
```

File

Graphics

Description

Call GraphicExtension to obtain a default extension value for the DefaultExt property of an Open, Open Picture, Save Picture or Save dialog. GraphicExtension returns the default extension for the type of graphics object specified by the GraphicClass parameter. In Delphi, the TGraphicClass (see page 14654) type is the class type for descendants TGraphic (see page 14516).

These are the file extensions returned for each built-in graphics class:

Graphic class	File extension returned
TBitmap (see page 14396)	bmp
TIcon (see page 14537)	ico
TMetafile (see page 14549)	emf

If custom graphics classes register a file extension, GraphicExtension will return that extension when passed the custom graphics class as an argument.

C++ Examples:

```
/*
The following example allows users to type the name of a
graphics class into an edit control and when a button is
pressed, the name of the default extension for that class is
displayed in another edit control.  In the form's OnCreate
event handler (or a similar place) you must register the
graphics classes so that GetClass can find them.
*/
TMetaClass *MetaClass;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClassFinder *myClassFinder = new TClassFinder(MetaClass, False);
  TGraphicClass mygraphclass = (TGraphicClass) (myClassFinder->GetClass(Edit2->Text));
//  TGraphicClass mygraphclass = (TGraphicClass) GetClass(Edit2->Text);
  Edit1->Text = GraphicExtension(mygraphclass);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MetaClass = __classid(TIcon); // ico
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(Graphics::TBitmap); // bmp
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TMetafile); // emf
```

```
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TShape);  // nographic extension
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TImage); // nographic extension
  RegisterClasses(&MetaClass, 0);
}
/*
This code displays a Save Picture dialog box with the
TBitmap default extension that is added automatically to
files that are given no extension. Confirm that the
bitmap file has been saved under the filename and path
specified.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString NewFileName, OldFileName;
  TFileStream *NewFile, *OldFile;
  SavePictureDialog1->DefaultExt = GraphicExtension(__classid(Graphics::TBitmap));
  SavePictureDialog1->Filter = GraphicFilter(__classid(Graphics::TBitmap));
  OldFileName = "factory.bmp";
  if (SavePictureDialog1->Execute())
  {
    NewFileName = SavePictureDialog1->FileName;
    OldFile = new TFileStream(OldFileName, (fmOpenRead | fmShareDenyWrite));
    try
    {
      NewFile = new TFileStream(NewFileName, (fmCreate | fmShareDenyRead));
      try
      {
        NewFile->CopyFrom(OldFile, OldFile->Size);
      }
      __finally
      {
        FreeAndNil(&NewFile);
      };
    }
    __finally
    {
      FreeAndNil(&OldFile);
    };
  };
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Image1->Picture->LoadFromFile("../factory.bmp");
}
```

Delphi Examples:

```
{
The following example allows users to type the name of a
graphics class into an edit control and when a button is
pressed, the name of the default extension for that class is
displayed in another edit control.  In the form’s OnCreate
event handler (or a similar place) you must register the
graphics classes so that GetClass can find them.
}

uses ExtCtrls;

procedure TForm1.Button1Click(Sender: TObject);
var
  myClassFinder: TClassFinder;
  mygraphclass: TGraphicClass;
begin
  { make sure the classes are registered so that GetClass will work -- }
```

```
    { Usually, this goes in the initialization section where it is only executed once }
    RegisterClasses([TIcon, TBitmap, TButton, TShape, TImage, TMetafile]);
    try
      myClassFinder := TClassFinder.Create(TIcon, False);
      mygraphclass := TGraphicClass(myClassFinder.GetClass(Edit2.Text));
//      mygraphclass := TGraphicClass(GetClass(Edit2.Text));  // works as well
      Edit1.Text := GraphicExtension(mygraphclass);
    except
      on EAccessViolation do
        MessageDlg('Invalid class name.', mtError, [mbOK], 0)
    end;
  end;
  {
  This code displays a Save Picture dialog box with the
  TBitmap default extension that is added automatically to
  files that are given no extension. Confirm that the
  bitmap file has been saved under the filename and path
  specified.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var NewFileName, OldFileName: string;
      NewFile, OldFile: TFileStream;
  begin
    SavePictureDialog1.DefaultExt := GraphicExtension(TBitmap);
    SavePictureDialog1.Filter := GraphicFilter(TBitmap);
    OldFileName := 'factory.bmp';
    if SavePictureDialog1.Execute then
    begin
      NewFileName := SavePictureDialog1.FileName;
      OldFile := TFileStream.Create(
        OldFileName, fmOpenRead or fmShareDenyWrite);
      try
        NewFile := TFileStream.Create(
          NewFileName, fmCreate or fmShareDenyRead);
        try
          NewFile.CopyFrom(OldFile, OldFile.Size);
        finally
          FreeAndNil(NewFile);
        end;
      finally
        FreeAndNil(OldFile);
      end;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Image1.Picture.LoadFromFile('factory.bmp');
  end;
```

73.3.19 Graphics.GraphicFileMask Function

Returns a file mask that specifies the valid extensions for a graphic class.

Pascal

```
function GraphicFileMask(GraphicClass: TGraphicClass): string;
```

C++

```
AnsiString GraphicFileMask(TGraphicClass GraphicClass);
```

File

Graphics

Description

Call GraphicFileMask to obtain a mask to determine the file extensions associated with a graphic class. The GraphicClass parameter can specify one of these values: TBitmap (see page 14396), TGraphic (see page 14516), TIcon (see page 14537), TMetafile (see page 14549), or a user-defined descendant of TGraphic (see page 14516). These are the strings that are returned for each built-in graphics class:

Graphic class	Filter string returned
TBitmap (see page 14396)	*.bmp
TIcon (see page 14537)	*.ico
TMetafile (see page 14549)	*.emf;*.wmf
TGraphic (see page 14516)	*.bmp;*.ico;*.emf;*.wmf
TGraphic (see page 14516)	;*.bmp;*.png;*.xpm*.ico

See Also

GraphicExtension (see page 14621)

GraphicFilter (see page 14624)

TFilterComboBox

TPicture (see page 14584)

73.3.20 Graphics.GraphicFilter Function

Returns a file filter compatible with the Filter property of an Open or Save dialog.

Pascal

```
function GraphicFilter(GraphicClass: TGraphicClass): string;
```

C++

```
AnsiString GraphicFilter(TGraphicClass GraphicClass);
```

File

Graphics

Description

Call GraphicFilter to obtain a value for the Filter property of an Open, Open Picture, Save Picture or Save dialog box. The GraphicClass parameter can specify one of these values: TBitmap (see page 14396), TGraphic (see page 14516), TIcon (see page 14537), TMetafile (see page 14549), or a user-defined descendant of TGraphic (see page 14516).

These are the strings that are returned for each built-in graphics class when the AllFilter parameter is true. (When AllFilter is false, the section labelled "All" is omitted):

Graphic class	Filter string returned
TBitmap (see page 14396)	Bitmaps (*.bmp;*.png;*.xpm)|*.bmp;*.png;*.xpm
TIcon (see page 14537)	Icons (*.ico)|*.ico
TGraphic (see page 14516)	All (*.bmp;*.png;*.xpm*.ico)|*.bmp;*.png;*.xpm*.ico|Bitmaps (*.bmp;*.png;*.xpm)|*.bmp;*.png;*.xpm|Icons (*.ico)|*.ico
TBitmap (see page 14396)	Bitmaps (*.bmp)|*.bmp
TIcon (see page 14537)	Icons (*.ico)|*.ico
TMetafile (see page 14549)	All (*.emf;*.wmf)|*.emf;*.wmf|Enhanced Metafiles (*.emf)|*.emf|Metafiles(*.wmf)|*.wmf
TGraphic (see page 14516)	All (*.bmp;*.ico;*.emf;*.wmf)|*.bmp;*.ico;*.emf; *.wmf|Bitmaps (*.bmp)|*.bmp|Icons (*.ico)|*.ico|Enhanced Metafiles (*.emf)|*.emf|Metafiles(*.wmf)|*.wmf

Graphic class	Filter string returned
TBitmap (see page 14396)	Bitmaps (*.bmp)|*.bmp
TIcon (see page 14537)	Icons (*.ico)|*.ico
TMetafile (see page 14549)	All (*.emf;*.wmf)|*.emf;*.wmf|Enhanced Metafiles (*.emf)|*.emf|Metafiles(*.wmf)|*.wmf
TGraphic (see page 14516)	All (*.bmp;*.ico;*.emf;*.wmf)|*.bmp;*.ico;*.emf; *.wmf|Bitmaps (*.bmp)|*.bmp|Icons (*.ico)|*.ico|Enhanced Metafiles (*.emf)|*.emf|Metafiles(*.wmf)|*.wmf

C++ Examples:

```
/*
This code displays a Save Picture dialog box with the
TBitmap default extension that is added automatically to
files that are given no extension. Confirm that the
bitmap file has been saved under the filename and path
specified.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString NewFileName, OldFileName;
  TFileStream *NewFile, *OldFile;
  SavePictureDialog1->DefaultExt = GraphicExtension(__classid(Graphics::TBitmap));
  SavePictureDialog1->Filter = GraphicFilter(__classid(Graphics::TBitmap));
  OldFileName = "factory.bmp";
  if (SavePictureDialog1->Execute())
  {
```

```
    NewFileName = SavePictureDialog1->FileName;
    OldFile = new TFileStream(OldFileName, (fmOpenRead | fmShareDenyWrite));
    try
    {
      NewFile = new TFileStream(NewFileName, (fmCreate | fmShareDenyRead));
      try
      {
        NewFile->CopyFrom(OldFile, OldFile->Size);
      }
      __finally
      {
        FreeAndNil(&NewFile);
      };
    }
    __finally
    {
      FreeAndNil(&OldFile);
    };
  };
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Image1->Picture->LoadFromFile("../factory.bmp");
}
```

Delphi Examples:

```
{
This code displays a Save Picture dialog box with the
TBitmap default extension that is added automatically to
files that are given no extension. Confirm that the
bitmap file has been saved under the filename and path
specified.
}
procedure TForm1.Button1Click(Sender: TObject);
var NewFileName, OldFileName: string;
    NewFile, OldFile: TFileStream;
begin
  SavePictureDialog1.DefaultExt := GraphicExtension(TBitmap);
  SavePictureDialog1.Filter := GraphicFilter(TBitmap);
  OldFileName := 'factory.bmp';
  if SavePictureDialog1.Execute then
  begin
    NewFileName := SavePictureDialog1.FileName;
    OldFile := TFileStream.Create(
      OldFileName, fmOpenRead or fmShareDenyWrite);
    try
      NewFile := TFileStream.Create(
        NewFileName, fmCreate or fmShareDenyRead);
      try
        NewFile.CopyFrom(OldFile, OldFile.Size);
      finally
        FreeAndNil(NewFile);
      end;
    finally
      FreeAndNil(OldFile);
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Image1.Picture.LoadFromFile('factory.bmp');
end;
```

73.3.21 Graphics.IdentToCharset Function

Translates the name of a character set constant to the corresponding character set.

Pascal

```
function IdentToCharset(const Ident: string; var Charset: Longint): Boolean;
```

C++

```
Boolean IdentToCharset(const AnsiString Ident, Longint Charset);
```

File

Graphics

Description

Call IdentToCharset to reverse the translation performed by CharsetToIdent (see page 14609). This method is useful for converting the strings generated by GetCharsetValues (see page 14615) into useable character sets. IdentToCharset returns true if the Ident parameter is successfully converted into a character set that is returned by the Charset parameter. IdentToCharset returns false if the Ident parameter is not the name of one of the TFontCharset (see page 14651) constants.

See Also

TFont (see page 14497)

GetCharsetValues (see page 14615)

CharSetToIdent

TFontCharset (see page 14651)

73.3.22 Graphics.IdentToColor Function

Translates the name of a color constant to the corresponding TColor (see page 14648) value.

Pascal

```
function IdentToColor(const Ident: string; var Color: Longint): Boolean;
```

C++

```
Boolean IdentToColor(const AnsiString Ident, Longint Color);
```

File

Graphics

Description

Call IdentToColor to reverse the translation performed by ColorToIdent (see page 14610). This method is useful for converting the strings generated by GetColorValues (see page 14619) into useable TColor (see page 14648) values. IdentToColor returns true if the Ident parameter is successfully converted into a color that is returned by the Color parameter. IdentToColor returns false if the Ident parameter is not the name of one of the TColor (see page 14648) constants.

Note: If the string identifier for a color may represent either a hex value or a color constant, use the StringToColor (see page 14628) function instead.

See Also

TColor (see page 14648)

GetColorValues (see page 14619)

ColorToIdent (see page 14610)

StringToColor (see page 14628)

73.3.23 Graphics.PaletteChanged Function

Pascal

```
procedure PaletteChanged;
```

C++

```
PaletteChanged();
```

File

Graphics

Description

This is function Graphics.PaletteChanged.

73.3.24 Graphics.StringToColor Function

Translates a string representation of a color to the corresponding TColor (see page 14648) value.

Pascal

```
function StringToColor(const S: string): TColor;
```

C++

```
TColor StringToColor(const AnsiString S);
```

File

Graphics

Description

Call StringToColor to reverse the translation performed by ColorToString (see page 14611). This method is useful for

converting the strings entered by the user into useable TColor (see page 14648) values.

The S parameter can be either the name of a built-in color constant, such as "clBtnFace (see page 14667)" (Windows) or "clBtnText (see page 14668)" (cross-platform), or the string representation of a valid TColor (see page 14648) value such as "$02FF8800" (Delphi) or "0x02FF8800" (C++). StringToColor returns the TColor (see page 14648) value that corresponds to the S parameter.

Note: If the string identifier can only be the name of a color constant, use IdentToColor (see page 14627) instead.

See Also

ColorToString (see page 14611)

IdentToColor (see page 14627)

73.3.25 Graphics.TransparentStretchBlt Function

Pascal

```
function TransparentStretchBlt(DstDC: HDC; DstX: Integer; DstY: Integer; DstW: Integer; DstH:
Integer; SrcDC: HDC; SrcX: Integer; SrcY: Integer; SrcW: Integer; SrcH: Integer; MaskDC: HDC;
MaskX: Integer; MaskY: Integer): Boolean;
```

C++

```
Boolean TransparentStretchBlt(HDC DstDC, int DstX, int DstY, int DstW, int DstH, HDC SrcDC,
int SrcX, int SrcY, int SrcW, int SrcH, HDC MaskDC, int MaskX, int MaskY);
```

File

Graphics

Description

This is function Graphics.TransparentStretchBlt.

73.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TBitmapHandleType (see page 14630)	TBitmapHandleType indicates the format used to store the in-memory image of a bitmap.
	TBrushStyle (see page 14631)	TBrushStyle specifies the pattern on a brush.
	TCanvasOrientation (see page 14632)	TCanvasOrientation specifies the pixel coordinate system that a canvas uses.
	TCanvasStates (see page 14633)	This is record Graphics.TCanvasStates.
	TFillMode (see page 14634)	This is record Graphics.TFillMode.
	TFillStyle (see page 14634)	TFillStyle indicates the type of color change defines the boundary of a possibly non-rectangular region n a canvas.
	TFontPitch (see page 14635)	TFontPitch indicates whether the characters in a font have the same width.
	TFontStyle (see page 14636)	TFontStyle and TFontStyles (see page 14653) specify style characteristics of a font.
	TPenMode (see page 14637)	TPenMode indicates how the color of a pen interacts with the color of a canvas.
	TPenStyle (see page 14639)	TPenStyle indicates the type of line a pen draws.
	TPixelFormat (see page 14640)	TPixelFormat specifies the format of a bitmap.
	TProgressStage (see page 14641)	TProgressStage indicates the stage of a lengthy operation.
	TTextFormats (see page 14642)	This is record Graphics.TTextFormats.
	TTransparentMode (see page 14643)	TTransparentMode indicates how the transparent color of a bitmap is determined.

Records

	Name	Description
	TBrushData (see page 14631)	This is record Graphics.TBrushData.
	TCursorOrIcon (see page 14633)	This is record Graphics.TCursorOrIcon.
	TFontData (see page 14635)	This is record Graphics.TFontData.
	TIconRec (see page 14636)	This is record Graphics.TIconRec.
	TPenData (see page 14637)	This is record Graphics.TPenData.
	TResData (see page 14641)	This is record Graphics.TResData.
	TResource (see page 14642)	This is record Graphics.TResource.

73.4.1 Graphics.TBitmapHandleType Enumeration

TBitmapHandleType indicates the format used to store the in-memory image of a bitmap.

Pascal

```
TBitmapHandleType = (
  bmDIB,
  bmDDB
);
```

C++

```
enum TBitmapHandleType {
  bmDIB,
  bmDDB
};
```

File

Graphics

Description

TBitmapHandleType can be any of the following values:

Value	Description
bmDIB	device-independent bitmap (DIB)
bmDDB	device-dependent bitmap (DDB)

73.4.2 Graphics.TBrushData Record

Pascal

```
TBrushData = record
  Handle: HBrush;
  Color: TColor;
  Bitmap: TBitmap;
  Style: TBrushStyle;
  OwnsBitmap: Boolean;
end;
```

C++

```
struct TBrushData {
  HBrush Handle;
  TColor Color;
  TBitmap Bitmap;
  TBrushStyle Style;
  Boolean OwnsBitmap;
};
```

File

Graphics

Description

This is record Graphics.TBrushData.

73.4.3 Graphics.TBrushStyle Enumeration

TBrushStyle specifies the pattern on a brush.

Pascal

```
TBrushStyle = (
  bsSolid,
  bsClear,
  bsHorizontal,
  bsVertical,
  bsFDiagonal,
  bsBDiagonal,
  bsCross,
  bsDiagCross
);
```

C++

```
enum TBrushStyle {
  bsSolid,
  bsClear,
  bsHorizontal,
  bsVertical,
  bsFDiagonal,
  bsBDiagonal,
  bsCross,
  bsDiagCross
};
```

File

Graphics

Description

The possible values of TBrushStyle are

ValuePatternValuePattern

Value	Pattern
bsSolid	bsCross
bsClear	bsDiagCross
bsBDiagonal	bsHorizontal
bsFDiagonal	bsVertical

See Also

TBrush (see page 14430)

73.4.4 Graphics.TCanvasOrientation Enumeration

TCanvasOrientation specifies the pixel coordinate system that a canvas uses.

Pascal

```
TCanvasOrientation = (
  coLeftToRight,
  coRightToLeft
);
```

C++

```
enum TCanvasOrientation {
  coLeftToRight,
  coRightToLeft
};
```

File

Graphics

Description

TCanvasOrientation determines where the (0,0) point falls on a canvas, and whether pixel coordinates are interpreted in a right-to-left or left-to-right manner.

The following table describes the possible values:

Value	Meaning
coLeftToRight	The origin (0,0) appears in the top-left corner. Pixel coordinates get larger as you move left or down.
coRightToLeft	The origin (0,0) appears in the top-right corner. Pixel coordinates get larger as you move right or down.

73.4.5 Graphics.TCanvasStates Enumeration

Pascal

```
TCanvasStates = (
  csHandleValid,
  csFontValid,
  csPenValid,
  csBrushValid
);
```

C++

```
enum TCanvasStates {
  csHandleValid,
  csFontValid,
  csPenValid,
  csBrushValid
};
```

File

Graphics

Description

This is record Graphics.TCanvasStates.

73.4.6 Graphics.TCursorOrIcon Record

Pascal

```
TCursorOrIcon = packed record
  Reserved: Word;
  wType: Word;
  Count: Word;
end;
```

C++

```
struct TCursorOrIcon {
  Word Reserved;
  Word wType;
  Word Count;
};
```

File

Graphics

Description

This is record Graphics.TCursorOrIcon.

73.4.7 Graphics.TFillMode Enumeration

Pascal

```
TFillMode = (
  fmAlternate,
  fmWinding
);
```

C++

```
enum TFillMode {
  fmAlternate,
  fmWinding
};
```

File

Graphics

Description

This is record Graphics.TFillMode.

73.4.8 Graphics.TFillStyle Enumeration

TFillStyle indicates the type of color change defines the boundary of a possibly non-rectangular region n a canvas.

Pascal

```
TFillStyle = (
  fsSurface,
  fsBorder
);
```

C++

```
enum TFillStyle {
  fsSurface,
  fsBorder
};
```

File

Graphics

Description

TFillStyle values determine what type of color changes define the boundaries of a (possibly) non-rectangular region of a canvas, as indicated in the following table.

Value	Meaning
fsSurface	The region is defined as all area that has a specified color. When another color is encountered, it is taken as the boundary of the region.
fsBorder	The region is defined as all area that does not have a specified color. When the specified color is encountered, it is taken as the boundary of the region.

73.4.9 Graphics.TFontData Record

Pascal

```
TFontData = record
  Handle: HFont;
  Height: Integer;
  Orientation: Integer;
  Pitch: TFontPitch;
  Style: TFontStylesBase;
  Charset: TFontCharset;
  Name: TFontDataName;
end;
```

C++

```
struct TFontData {
  HFont Handle;
  int Height;
  int Orientation;
  TFontPitch Pitch;
  TFontStylesBase Style;
  TFontCharset Charset;
  TFontDataName Name;
};
```

File

Graphics

Description

This is record Graphics.TFontData.

73.4.10 Graphics.TFontPitch Enumeration

TFontPitch indicates whether the characters in a font have the same width.

Pascal

```
TFontPitch = (
  fpDefault,
  fpVariable,
  fpFixed
);
```

C++

```
enum TFontPitch {
  fpDefault,
  fpVariable,
  fpFixed
};
```

File

Graphics

Description

The following table lists the possible values of the TFontPitch type:

Value	Meaning
fpDefault	The font pitch is set to the default value, which depends on the font specified in the font object's Name property.
fpFixed	The font pitch is set to fixed. All characters in the font have the same width.
fpVariable	The font pitch is set to variable. The characters in the font have different widths.

73.4.11 Graphics.TFontStyle Enumeration

TFontStyle and TFontStyles (see page 14653) specify style characteristics of a font.

Pascal

```
TFontStyle = (
  fsBold,
  fsItalic,
  fsUnderline,
  fsStrikeOut
);
```

C++

```
enum TFontStyle {
  fsBold,
  fsItalic,
  fsUnderline,
  fsStrikeOut
};
```

File

Graphics

Description

TFontStyles (see page 14653) is a set of TFontStyle values. The following table lists the possible values of the TFontStyle type:

Value	Meaning
fsBold	The font is boldfaced.
fsItalic	The font is italicized.
fsUnderline	The font is underlined.
fsStrikeOut	The font is displayed with a horizontal line through it.

73.4.12 Graphics.TIconRec Record

Pascal

```
TIconRec = packed record
  Width: Byte;
  Height: Byte;
  Colors: Word;
  Reserved1: Word;
```

```
    Reserved2: Word;
    DIBSize: Longint;
    DIBOffset: Longint;
  end;
```

C++

```
  struct TIconRec {
    Byte Width;
    Byte Height;
    Word Colors;
    Word Reserved1;
    Word Reserved2;
    Longint DIBSize;
    Longint DIBOffset;
  };
```

File

Graphics

Description

This is record Graphics.TIconRec.

73.4.13 Graphics.TPenData Record

Pascal

```
  TPenData = record
    Handle: HPen;
    Color: TColor;
    Width: Integer;
    Style: TPenStyle;
  end;
```

C++

```
  struct TPenData {
    HPen Handle;
    TColor Color;
    int Width;
    TPenStyle Style;
  };
```

File

Graphics

Description

This is record Graphics.TPenData.

73.4.14 Graphics.TPenMode Enumeration

TPenMode indicates how the color of a pen interacts with the color of a canvas.

Pascal

```
  TPenMode = (
    pmBlack,
    pmWhite,
```

```
    pmNop,
    pmNot,
    pmCopy,
    pmNotCopy,
    pmMergePenNot,
    pmMaskPenNot,
    pmMergeNotPen,
    pmMaskNotPen,
    pmMerge,
    pmNotMerge,
    pmMask,
    pmNotMask,
    pmXor,
    pmNotXor
  );
```

C++

```
  enum TPenMode {
    pmBlack,
    pmWhite,
    pmNop,
    pmNot,
    pmCopy,
    pmNotCopy,
    pmMergePenNot,
    pmMaskPenNot,
    pmMergeNotPen,
    pmMaskNotPen,
    pmMerge,
    pmNotMerge,
    pmMask,
    pmNotMask,
    pmXor,
    pmNotXor
  };
```

File

Graphics

Description

TPenMode indicates how a pen color interacts with the color of the canvas it is writing on. The following table lists the possible values:

Mode	Pixel color
pmBlack	Always black
pmWhite	Always white
pmNop	Unchanged
pmNot	Inverse of canvas background color
pmCopy	Pen color specified in Color property
pmNotCopy	Inverse of pen color
pmMergePenNot	Combination of pen color and inverse of canvas background
pmMaskPenNot	Combination of colors common to both pen and inverse of canvas background.
pmMergeNotPen	Combination of canvas background color and inverse of pen color
pmMaskNotPen	Combination of colors common to both canvas background and inverse of pen
pmMerge	Combination of pen color and canvas background color
pmNotMerge	Inverse of pmMerge: combination of pen color and canvas background color

pmMask	Combination of colors common to both pen and canvas background
pmNotMask	Inverse of pmMask: combination of colors common to both pen and canvas background
pmXor	Combination of colors in either pen or canvas background, but not both
pmNotXor	Inverse of pmXor: combination of colors in either pen or canvas background, but not both

73.4.15 Graphics.TPenStyle Enumeration

TPenStyle indicates the type of line a pen draws.

Pascal

```
TPenStyle = (
  psSolid,
  psDash,
  psDot,
  psDashDot,
  psDashDotDot,
  psClear,
  psInsideFrame,
  psUserStyle,
  psAlternate
);
```

C++

```
enum TPenStyle {
  psSolid,
  psDash,
  psDot,
  psDashDot,
  psDashDotDot,
  psClear,
  psInsideFrame,
  psUserStyle,
  psAlternate
};
```

File

Graphics

Description

TPenStyle can have one of the following values:

Value	Meaning
psSolid	A solid line.
psDash	A line made up of a series of dashes.
psDot	A line made up of a series of dots.
psDashDot	A line made up of alternating dashes and dots.
psDashDotDot	A line made up of a series of dash-dot-dot combinations.
psClear	No line is drawn (used to omit the line around shapes that draw an outline using the current pen).
psInsideFrame	A solid line, but one that may use a dithered color if Width is greater than 1.

psAlternate	The pen sets every other pixel. (This style is applicable only for cosmetic pens.) This style is only valid for pens created with the `ExtCreatePen` API function. (See MS Windows SDK docs.) This applies to both VCL and VCL.NET.
psUserStyle	The pen uses a styling array supplied by the user. Thus style is only valid for pens created with the `ExtCreatePen` API function. (See MS Windows SDK docs.) This applies to both VCL and VCL.NET.

73.4.16 Graphics.TPixelFormat Enumeration

TPixelFormat specifies the format of a bitmap.

Pascal

```
TPixelFormat = (
  pfDevice,
  pf1bit,
  pf4bit,
  pf8bit,
  pf15bit,
  pf16bit,
  pf24bit,
  pf32bit,
  pfCustom
);
```

C++

```
enum TPixelFormat {
  pfDevice,
  pf1bit,
  pf4bit,
  pf8bit,
  pf15bit,
  pf16bit,
  pf24bit,
  pf32bit,
  pfCustom
};
```

File

Graphics

Description

TPixelFormat can have one of the following values:

Value	Meaning
pfDevice	The bitmap is stored as a device-dependent bitmap.
pf1bit	The bitmap is a device-independent bitmap with one bit per pixel (black and white palette)
pf4bit	The bitmap is a device-independent bitmap that uses a 16-color palette.
pf8bit	The bitmap is a device-independent bitmap that uses a 256color palette.
pf15bit	The bitmap is a device-independent true-color bitmap that uses 15 bits per pixel (RGB compression).
pf16bit	The bitmap is a device-independent true-color bitmap that uses 16 bits per pixel (bitfield compression).
pf24bit	The bitmap is a device-independent true-color bitmap that uses 24 bits per pixel.

pf32bit	The bitmap is a device-independent true-color bitmap that uses 32 bits per pixel (RGB compression).
pfCustom	The bitmap uses some other format. TBitmap (see page 14396) does not support pfCustom.

73.4.17 Graphics.TProgressStage Enumeration

TProgressStage indicates the stage of a lengthy operation.

Pascal

```
TProgressStage = (
  psStarting,
  psRunning,
  psEnding
);
```

C++

```
enum TProgressStage {
  psStarting,
  psRunning,
  psEnding
};
```

File

Graphics

Description

The following table lists the possible values:

Value	Meaning
psStarting	The operation is about to begin.
psRunning	The operation is underway and has not yet completed.
psEnding	The operation has just completed.

73.4.18 Graphics.TResData Record

Pascal

```
TResData = record
  Handle: THandle;
end;
```

C++

```
struct TResData {
  THandle Handle;
};
```

File

Graphics

Description

This is record Graphics.TResData.

73.4.19 Graphics.TResource Record

Pascal

```
TResource = record
  Next: PResource;
  RefCount: Integer;
  Handle: THandle;
  HashCode: Word;
  case Integer of
    0: (Data: TResData;);
    1: (Font: TFontData;);
    2: (Pen: TPenData;);
    3: (Brush: TBrushData;);
end;
```

C++

```
struct TResource {
  PResource Next;
  int RefCount;
  THandle Handle;
  Word HashCode;
  TResData Data;
  TFontData Font;
  TPenData Pen;
  TBrushData Brush;
};
```

File

Graphics

Description

This is record Graphics.TResource.

73.4.20 Graphics.TTextFormats Enumeration

Pascal

```
TTextFormats = (
  tfBottom,
  tfCalcRect,
  tfCenter,
  tfEditControl,
  tfEndEllipsis,
  tfPathEllipsis,
  tfExpandTabs,
  tfExternalLeading,
  tfLeft,
  tfModifyString,
  tfNoClip,
  tfNoPrefix,
  tfRight,
  tfRtlReading,
```

```
    tfSingleLine,
    tfTop,
    tfVerticalCenter,
    tfWordBreak
  );
```

C++

```
  enum TTextFormats {
    tfBottom,
    tfCalcRect,
    tfCenter,
    tfEditControl,
    tfEndEllipsis,
    tfPathEllipsis,
    tfExpandTabs,
    tfExternalLeading,
    tfLeft,
    tfModifyString,
    tfNoClip,
    tfNoPrefix,
    tfRight,
    tfRtlReading,
    tfSingleLine,
    tfTop,
    tfVerticalCenter,
    tfWordBreak
  };
```

File

Graphics

Description

This is record Graphics.TTextFormats.

73.4.21 Graphics.TTransparentMode Enumeration

TTransparentMode indicates how the transparent color of a bitmap is determined.

Pascal

```
  TTransparentMode = (
    tmAuto,
    tmFixed
  );
```

C++

```
  enum TTransparentMode {
    tmAuto,
    tmFixed
  };
```

File

Graphics

Description

The following table lists the possible values:

Value	Meaning
tmAuto	The transparent color is determined by the bottom-leftmost pixel of the bitmap image.
tmFixed	The transparent color is explicitly assigned and stored in the bitmap object.

73.5 Types

The following table lists types in this documentation.

Types

Name	Description
HENHMETAFILE (see page 14645)	Meta file handle type.
HMETAFILE (see page 14646)	This is type Graphics.HMETAFILE.
PColor (see page 14646)	PColor is a pointer to a TColor (see page 14648) type.
PCursorOrIcon (see page 14646)	This is type Graphics.PCursorOrIcon.
PIconRec (see page 14647)	This is type Graphics.PIconRec.
PResource (see page 14647)	This is type Graphics.PResource.
TCanvasState (see page 14647)	This is type Graphics.TCanvasState.
TColor (see page 14648)	TColor is used to specify the color of a Windows-only control.
TCopyMode (see page 14650)	TCopyMode specifies how a graphical image is copied onto a canvas.
TFontCharset (see page 14651)	TFontCharset represents the character set of a font.
TFontDataName (see page 14652)	This is type Graphics.TFontDataName.
TFontName (see page 14653)	TFontName is a string that holds the typeface name of a font.
TFontStyles (see page 14653)	TFontStyle (see page 14636) and TFontStyles specify style characteristics of a font.
TFontStylesBase (see page 14653)	This is type Graphics.TFontStylesBase.
TGraphicClass (see page 14654)	TGraphicClass defines the metaclass for TGraphic (see page 14516).
TProgressEvent (see page 14655)	TProgressEvent is the type of event handlers that provide feedback during lengthy operations.
TTextFormat (see page 14656)	TTextFormat indicates how a text viewer control displays its contents.

73.5.1 Graphics.HENHMETAFILE Type

Meta file handle type.

Pascal

```
HENHMETAFILE = THandle;
```

C++

```
THandle HENHMETAFILE;
```

File

Graphics

Description

ReleaseHandle is called to release the resources used to represent the metafile. HENHMETAFILE is the data type passed to that method.

See Also

ReleaseHandle

73.5.2 Graphics.HMETAFILE Type

Pascal

```
HMETAFILE = THandle;
```

C++

```
THandle HMETAFILE;
```

File

Graphics

Description

This is type Graphics.HMETAFILE.

73.5.3 Graphics.PColor Type

PColor is a pointer to a TColor (see page 14648) type.

Pascal

```
PColor = ^TColor;
```

C++

```
^TColor PColor;
```

File

Graphics

Description

The TColor (see page 14648) type represents a color as an integer.

Note: Static arrays are declared with an immutable size.

See Also

TColor (see page 14648)

73.5.4 Graphics.PCursorOrIcon Type

Pascal

```
PCursorOrIcon = ^TCursorOrIcon;
```

C++

```
^TCursorOrIcon PCursorOrIcon;
```

File

Graphics

Description

This is type Graphics.PCursorOrIcon.

73.5.5 Graphics.PIconRec Type

Pascal

```
PIconRec = ^TIconRec;
```

C++

```
^TIconRec PIconRec;
```

File

Graphics

Description

This is type Graphics.PIconRec.

73.5.6 Graphics.PResource Type

Pascal

```
PResource = ^TResource;
```

C++

```
^TResource PResource;
```

File

Graphics

Description

This is type Graphics.PResource.

73.5.7 Graphics.TCanvasState Type

Pascal

```
TCanvasState = set of TCanvasStates;
```

C++

```
TCanvasStates TCanvasState;
```

File

Graphics

Description

This is type Graphics.TCanvasState.

73.5.8 Graphics.TColor Type

TColor is used to specify the color of a Windows-only control.

Pascal

```
TColor = -$7FFFFFFF-1..$7FFFFFFF;
```

C++

```
-$7FFFFFFF-1..$7FFFFFFF TColor;
```

File

Graphics

Description

TColor is used to specify the color of a Windows-only control. It is used by the Color property of many components and by a number of other properties that specify color values.

The Graphics (see page 14387) unit contains definitions of useful constants for TColor. These constants map either directly to the closest matching color in the system palette (for example, clBlue (see page 14666) maps to blue) or to the corresponding system screen element color defined in the Color section of the Windows Control panel (for example, clBtnFace (see page 14667) maps to the system color for button faces).

If you specify TColor as a specific 4-byte hexadecimal number instead of using the constants defined in the Graphics (see page 14387) unit, the low three bytes represent RGB color intensities for blue, green, and red, respectively. The value $00FF0000 (Delphi) or 0x00FF0000 (C++) represents full-intensity, pure blue, $0000FF00 (Delphi) or 0x0000FF00 (C++) is pure green, and $000000FF (Delphi) or 0x000000FF (C++) is pure red. $00000000 (Delphi) or 0x00000000 (C++) is black and $00FFFFFF (Delphi) or 0x00FFFFFF (C++) is white.

If the highest-order byte is zero, the color obtained is the closest matching color in the system palette. If the highest-order byte is one ($01 or 0x01), the color obtained is the closest matching color in the currently realized palette. If the highest-order byte is two ($02 or 0x02), the value is matched with the nearest color in the logical palette of the current device context.

The following tables lists the color constants from the Graphics (see page 14387) unit. The first two columns list the colors that map to the closest matching color in the system palette, while the last two columns list the colors that are defined in the Windows Control panel.

Value	Meaning	Value	Meaning
clNone (see page 14681)	White on Windows 9x, Black on NT.	clScrollBar (see page 14683)	Current color for the of scroll bar track.
clAqua (see page 14665)	Aqua	clBackground (see page 14666)	Current background color of the Windows desktop
clBlack (see page 14666)	Black	clActiveCaption (see page 14664)	Current color of the title bar of the active window
clBlue (see page 14666)	Blue	clInactiveCaption (see page 14675)	Current color of the title bar of inactive windows

clCream (see page 14669)	Cream	clMenu (see page 14679)	Current background color of menus
clDkGray (see page 14670)	Dark Gray	clWindow (see page 14732)	Current background color of windows
clFuchsia (see page 14670)	Fuchsia	clWindowFrame (see page 14733)	Current color of window frames
clGray (see page 14672)	Gray	clMenuText (see page 14680)	Current color of text on menus
clGreen (see page 14673)	Green	clWindowText (see page 14733)	Current color of text in windows
clLime (see page 14677)	Lime green	clCaptionText (see page 14669)	Current color of the text on the title bar of the active window
clLtGray (see page 14677)	Light Gray	clActiveBorder (see page 14664)	Current border color of the active window
clMaroon (see page 14678)	Maroon	clInactiveBorder (see page 14675)	Current border color of inactive windows
clMedGray (see page 14678)	Medium Gray	clAppWorkSpace (see page 14665)	Current color of the application workspace
clMoneyGreen (see page 14680)	Mint green	clHighlight (see page 14673)	Current background color of selected text
clNavy (see page 14681)	Navy blue	clHightlightText	Current color of selected text
clOlive (see page 14682)	Olive green	clBtnFace (see page 14667)	Current color of a button face
clPurple (see page 14682)	Purple	clBtnShadow (see page 14668)	Current color of a shadow cast by a button
clRed (see page 14683)	Red	clGrayText (see page 14672)	Current color of text that is dimmed
clSilver (see page 14683)	Silver	clBtnText (see page 14668)	Current color of text on a button
clSkyBlue (see page 14684)	Sky blue	clInactiveCaptionText (see page 14675)	Current color of the text on the title bar of an inactive window
clTeal (see page 14685)	Teal	clBtnHighlight (see page 14667)	Current color of the highlighting on a button

clWhite (see page 14732)	White	cl3DDkShadow (see page 14663)	Windows 95 or NT 4.0 only: Dark shadow for three-dimensional display elements
clYellow (see page 14734)	Yellow	cl3DLight (see page 14663)	Windows 95 or NT 4.0 only: Light color for three-dimensional display elements (for edges facing the light source)
		clInfoText (see page 14676)	Windows 95 or NT 4.0 only: Text color for tool tip controls
		clInfoBk (see page 14676)	Windows 95 or NT 4.0 only: Background color for tool tip controls
		clGradientActiveCaption (see page 14671)	Windows 98 or Windows 2000: Right side color in the color gradient of an active window's title bar. clActiveCaption (see page 14664) specifies the left side color.
		clGradientInactiveCaption (see page 14671)	Windows 98 or Windows 2000: Right side color in the color gradient of an inactive window's title bar. clInactiveCaption (see page 14675) specifies the left side color.
		clDefault (see page 14670)	The default color for the control to which the color is assigned.

73.5.9 Graphics.TCopyMode Type

TCopyMode specifies how a graphical image is copied onto a canvas.

Pascal

```
TCopyMode = Longint;
```

C++

```
Longint TCopyMode;
```

File

Graphics

Description

TCopyMode values describe how to combine the colors of a source bitmap and a destination bitmap.

The Windows unit defines the following constants for TCopyMode values:

Value	Meaning
cmBlackness (see page 14734)	Fills the destination rectangle on the canvas with black.
cmDstInvert (see page 14735)	Inverts the image on the canvas and ignores the source.
cmMergeCopy (see page 14735)	Combines the image on the canvas and the source bitmap by using the Boolean AND operator.
cmMergePaint (see page 14736)	Combines the inverted source bitmap with the image on the canvas by using the Boolean OR operator.

cmNotSrcCopy (see page 14736)	Copies the inverted source bitmap to the canvas.
cmNotSrcErase (see page 14737)	Combines the image on the canvas and the source bitmap by using the Boolean OR operator, and inverts the result.
cmPatCopy (see page 14737)	Copies the source pattern to the canvas.
cmPatInvert (see page 14738)	Combines the source pattern with the image on the canvas using the Boolean XOR operator
cmPatPaint (see page 14738)	Combines the inverted source bitmap with the source pattern by using the Boolean OR operator. Combines the result of this operation with the image on the canvas by using the Boolean OR operator.
cmSrcAnd (see page 14739)	Combines the image on the canvas and source bitmap by using the Boolean AND operator.
cmSrcCopy (see page 14739)	Copies the source bitmap to the canvas.
cmSrcErase (see page 14740)	Inverts the image on the canvas and combines the result with the source bitmap by using the Boolean AND operator.
cmSrcInvert (see page 14740)	Combines the image on the canvas and the source bitmap by using the Boolean XOR operator.
cmSrcPaint (see page 14741)	Combines the image on the canvas and the source bitmap by using the Boolean OR operator.
cmWhiteness (see page 14741)	Fills the destination rectangle on the canvas with white.

73.5.10 Graphics.TFontCharset Type

TFontCharset represents the character set of a font.

Pascal

```
TFontCharset = 0..255;
```

C++

```
0..255 TFontCharset;
```

File

Graphics

Description

Each Windows typeface supports one or more character sets, which indicate what characters can be written using the font. For

example, most fonts that can represent japanese characters use a particular multi-byte character set.

Each font supports its own, unique set of character sets. Check with the font vendor to determine which character sets are supported.

The following table lists the predefined constants provided for standard character sets:

Constant	Value	Description
ANSI_CHARSET	0	ANSI characters.
DEFAULT_CHARSET	1	Font is chosen based solely on Name and Size. If the described font is not available on the system, Windows will substitute another font.
SYMBOL_CHARSET	2	Standard symbol set.
MAC_CHARSET	77	Macintosh characters. Not available on NT 3.51.
SHIFTJIS_CHARSET	128	Japanese shift-JIS characters.
HANGEUL_CHARSET	129	Korean characters (Wansung).
JOHAB_CHARSET	130	Korean characters (Johab). Not available on NT 3.51
GB2312_CHARSET	134	Simplified Chinese characters (mainland china).
CHINESEBIG5_CHARSET	136	Traditional Chinese characters (Taiwanese).
GREEK_CHARSET	161	Greek characters. Not available on NT 3.51.
TURKISH_CHARSET	162	Turkish characters. Not available on NT 3.51
VIETNAMESE_CHARSET	163	Vietnamese characters. Not available on NT 3.51.
HEBREW_CHARSET	177	Hebrew characters. Not available on NT 3.51
ARABIC_CHARSET	178	Arabic characters. Not available on NT 3.51
BALTIC_CHARSET	186	Baltic characters. Not available on NT 3.51.
RUSSIAN_CHARSET	204	Cyrillic characters. Not available on NT 3.51.
THAI_CHARSET	222	Thai characters. Not available on NT 3.51
EASTEUROPE_CHARSET	238	Includes diacritical marks for eastern european countries. Not available on NT 3.51.
OEM_CHARSET	255	Depends on the codepage of the operating system.

73.5.11 Graphics.TFontDataName Type

Pascal

```
TFontDataName = string[LF_FACESIZE - 1];
```

C++

```
string[LF_FACESIZE - 1] TFontDataName;
```

File

Graphics

Description

This is type Graphics.TFontDataName.

73.5.12 Graphics.TFontName Type

TFontName is a string that holds the typeface name of a font.

Pascal

```
TFontName = type string;
```

C++

```
type string TFontName;
```

File

Graphics

Description

TFontName maps to a string. It is the type for representing the typeface name of a font.

73.5.13 Graphics.TFontStyles Type

TFontStyle (see page 14636) and TFontStyles specify style characteristics of a font.

Pascal

```
TFontStyles = set of TFontStyle;
```

C++

```
TFontStyle TFontStyles;
```

File

Graphics

Description

TFontStyles is a set of TFontStyle (see page 14636) values. The following table lists the possible values of the TFontStyle (see page 14636) type:

Value	Meaning
fsBold	The font is boldfaced.
fsItalic	The font is italicized.
fsUnderline	The font is underlined.
fsStrikeOut	The font is displayed with a horizontal line through it.

73.5.14 Graphics.TFontStylesBase Type

Pascal

```
TFontStylesBase = set of TFontStyle;
```

C++

```
TFontStyle TFontStylesBase;
```

File

Graphics

Description

This is type Graphics.TFontStylesBase.

73.5.15 Graphics.TGraphicClass Type

TGraphicClass defines the metaclass for TGraphic (see page 14516).

Pascal

```
TGraphicClass = class of TGraphic;
```

C++

```
TGraphic TGraphicClass;
```

File

Graphics

Description

TGraphicClass is the metaclass for TGraphic (see page 14516). Its value is the class reference for TGraphic (see page 14516) or for one of its descendants.

C++ Examples:

```
/*
The following example allows users to type the name of a
graphics class into an edit control and when a button is
pressed, the name of the default extension for that class is
displayed in another edit control.  In the form's OnCreate
event handler (or a similar place) you must register the
graphics classes so that GetClass can find them.
*/
TMetaClass *MetaClass;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClassFinder *myClassFinder = new TClassFinder(MetaClass, False);
  TGraphicClass mygraphclass = (TGraphicClass) (myClassFinder->GetClass(Edit2->Text));
//  TGraphicClass mygraphclass = (TGraphicClass) GetClass(Edit2->Text);
  Edit1->Text = GraphicExtension(mygraphclass);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MetaClass = __classid(TIcon); // ico
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(Graphics::TBitmap); // bmp
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TMetafile); // emf
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TShape);  // nographic extension
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TImage); // nographic extension
  RegisterClasses(&MetaClass, 0);
```

```
}
```

Delphi Examples:

```
{
The following example allows users to type the name of a
graphics class into an edit control and when a button is
pressed, the name of the default extension for that class is
displayed in another edit control.  In the form's OnCreate
event handler (or a similar place) you must register the
graphics classes so that GetClass can find them.
}

uses ExtCtrls;

procedure TForm1.Button1Click(Sender: TObject);
var
  myClassFinder: TClassFinder;
  mygraphclass: TGraphicClass;
begin
  { make sure the classes are registered so that GetClass will work -- }
  { Usually, this goes in the initialization section where it is only executed once }
  RegisterClasses([TIcon, TBitmap, TButton, TShape, TImage, TMetafile]);
  try
    myClassFinder := TClassFinder.Create(TIcon, False);
    mygraphclass := TGraphicClass(myClassFinder.GetClass(Edit2.Text));
//    mygraphclass := TGraphicClass(GetClass(Edit2.Text));  // works as well
    Edit1.Text := GraphicExtension(mygraphclass);
  except
    on EAccessViolation do
      MessageDlg('Invalid class name.', mtError, [mbOK], 0)
  end;
end;
```

73.5.16 Graphics.TProgressEvent Type

TProgressEvent is the type of event handlers that provide feedback during lengthy operations.

Pascal

```
TProgressEvent = procedure (Sender: TObject; Stage: TProgressStage; PercentDone: Byte;
RedrawNow: Boolean; const R: TRect; const Msg: string) of object;
```

C++

```
(Sender: TObject; Stage: TProgressStage; PercentDone: Byte; RedrawNow: Boolean; const R:
TRect; const Msg: string) ( TProgressEvent)();
```

File

Graphics

Description

Sender is the object that receives the event notification. This is typically the component that initiated the lengthy operation.

Stage indicates whether the operation is beginning, continuing, or ending. If the event handler displays an indicator such as a progress bar, the indicator can be created when Stage is psStarting, updated while Stage is psRunning, and removed when Stage is psEnding.

PercentDone is an approximation of how much of the operation has completed. Use PercentDone to update the position of a progress bar or other indicator.

RedrawNow indicates whether the partial results of the operation can safely be drawn on screen at this point.

R gives the dimensions of the portion of the display that has changed and needs to be redrawn.

Msg contains one or two words that describe what operation is occurring. For example, the value of Msg could be a string such as Loading, Storing, or Reducing colors. The Msg string can also be empty.

73.5.17 Graphics.TTextFormat Type

TTextFormat indicates how a text viewer control displays its contents.

Pascal

```
TTextFormat = set of TTextFormats;
```

C++

```
TTextFormats TTextFormat;
```

File

Graphics

Description

TTextFormat has the following values:

Value	Meaning
tfAutoText	The control attempts to determine whether Text contains rich text. If a valid tag is seen on the first line, Text is assumed to be a rich text document. Otherwise, Text is displayed as plain text.
tfText	The control assumes that Text contains rich text, even if no tags are present. Note that in rich text, any sequence consisting entirely of spaces, tabs, and line breaks counts as a single space.
tfPlainText	The control assumes that Text contains plain text.

73.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
DDBsOnly (see page 14657)	Determines whether bitmap handles are created as device-dependent bitmaps (DDB).
DefFontData (see page 14658)	This is variable Graphics.DefFontData.
SystemPalette16 (see page 14658)	Contains the 16 VGA system colors.

73.6.1 Graphics.DDBsOnly Variable

Determines whether bitmap handles are created as device-dependent bitmaps (DDB).

Pascal

```
DDBsOnly: Boolean = False;
```

C++

```
Boolean DDBsOnly = False;
```

File

Graphics

Description

Set DDBsOnly to force all bitmap handles to be created as device-dependent bitmaps (DDB). The default bitmap handle format is DIB (device-independent bitmap).

Setting DDBsOnly to true undercuts much of the graphics architecture; it should not be used unless it is absolutely required. Examples of when to set it to true are:

A graphics-intensive application does bitmap operations that Windows does not support with DIBs; you can either set each bitmap object to DDB before you access its handle property, or you can set this global variable to Truetrue.

An application uses hundreds of very small bitmaps. Each DIB consumes a separate 4k memory page. DIBs are less efficient for storing many small images than DDBs. Before resorting to changing the DDBsOnly flag to address this, however, consider switching your code to use image lists instead of individual tiny bitmaps. Image lists are more efficient than DIBs and DDBs for storing many same-size small images.

Note: Setting DDBsOnly to true introduces the issue of image alteration. When a BMP file or resource is loaded into a DDB, the color information in the original image is changed to fit the pixel format of the current video device and mode. If you read an image, touch its handle, and write it out, you will not get the same file you read in. DIBs solve this problem. Do not change DDBsOnly unless you have a specific need for device-dependent bitmaps and are willing to accept the image-altering DDB side effects.

73.6.2 Graphics.DefFontData Variable

Pascal

```
DefFontData: TFontData = ( Handle: 0; Height: 0; Orientation: 0; Pitch: fpDefault; Style: [];
Charset : DEFAULT_CHARSET; Name: 'MS Sans Serif');
```

C++

```
TFontData DefFontData = ( Handle: 0; Height: 0; Orientation: 0; Pitch: fpDefault; Style: [];
Charset : DEFAULT_CHARSET; Name: 'MS Sans Serif');
```

File

Graphics

Description

This is variable Graphics.DefFontData.

73.6.3 Graphics.SystemPalette16 Variable

Contains the 16 VGA system colors.

Pascal

```
SystemPalette16: HPalette;
```

C++

```
HPalette SystemPalette16;
```

File

Graphics

Description

SystemPalette16 holds a palette handle that contains the 16 VGA system colors. This palette is built at runtime from the system colors defined by the current video card and driver. The actual color values of the stock VGA palette can vary from one video card vendor to the next. Therefore it is not safe to assume, for example, that clGray (see page 14672) will be RGB(128,128,128) on all systems.

This handle is available as a convenience. This is the palette that VCL forces on all 16 color bitmaps that are loaded from files or resources.

Note: Using custom 16-color palettes does not work on 16-color video systems. It is problematic on many 256 color drivers because the variation in colors interferes with transparency operations.

73.7 Constants

The following table lists constants in this documentation.

Constants

Name	Description
cl3DDkShadow (see page 14663)	Represents the dark shadow of 3D components.
cl3DLight (see page 14663)	Represents the light part of 3D components.
clActiveBorder (see page 14664)	Represents the default border color of an active window.
clActiveCaption (see page 14664)	Represents the default color of the title bar of an active window.
clAppWorkSpace (see page 14665)	Represents the default Application WorkSpace color.
clAqua (see page 14665)	Represents the color Aqua.
clBackground (see page 14666)	Represents the default Windows background color.
clBlack (see page 14666)	Represents the color black.
clBlue (see page 14666)	Represents the color blue.
clBtnFace (see page 14667)	Represents the color of the face of a button.
clBtnHighlight (see page 14667)	Represents the color of the highlighting on a button.
clBtnShadow (see page 14668)	Represents the color of the shadow cast by of a button.
clBtnText (see page 14668)	Represents the default color of the text on a button.
clCaptionText (see page 14669)	Represents the default color of the text on the title bar of an active window.
clCream (see page 14669)	Represents the color cream.
clDefault (see page 14670)	Specifies the default color of a component.
clDkGray (see page 14670)	Represents the color dark gray.
clFuchsia (see page 14670)	Represents the color fuchsia.
clGradientActiveCaption (see page 14671)	Right side color in the color gradient of an active window's title bar.
clGradientInactiveCaption (see page 14671)	Right side color in the color gradient of an inactive window's title bar.
clGray (see page 14672)	Represents the color gray.
clGrayText (see page 14672)	Represents the color of text that is grayed out.
clGreen (see page 14673)	Represents the color green.
clHighlight (see page 14673)	Represents the color of the background of a block of selected text.
clHighlightText (see page 14674)	Represents the color of selected text.
clHotLight (see page 14674)	This is constant Graphics.clHotLight.
clInactiveBorder (see page 14675)	Represents the default border color of an inactive window.
clInactiveCaption (see page 14675)	Represents the default color of the title bar of an inactive window.
clInactiveCaptionText (see page 14675)	Represents the default color of the title text in an inactive window.
clInfoBk (see page 14676)	Represents the color of the background of a tool tip.
clInfoText (see page 14676)	Represents the color of tool tip text.
clLime (see page 14677)	Represents the color lime.
clLtGray (see page 14677)	Represents the color light gray.
clMaroon (see page 14678)	Represents the color maroon.
clMedGray (see page 14678)	Represents the color medium gray.
clMenu (see page 14679)	Represents the color of the background of an unselected menu sub item.
clMenuBar (see page 14679)	Represents the color of the background of an unselected main menu item.
clMenuHighlight (see page 14679)	Represents the color of the background of a selected menu item.
clMenuText (see page 14680)	Represents the default menu text color.
clMoneyGreen (see page 14680)	Represents the color money green.
clNavy (see page 14681)	Represents the color navy.
clNone (see page 14681)	Represents no selected color.
clOlive (see page 14682)	Represents the color olive.
clPurple (see page 14682)	Represents the color purple.

clRed (see page 14683)	Represents the color red.
clScrollBar (see page 14683)	This is constant Graphics.clScrollBar.
clSilver (see page 14683)	Represents the color silver.
clSkyBlue (see page 14684)	Represents the color sky blue.
clSystemColor (see page 14684)	Is a mask used to identify the set of system colors.
clTeal (see page 14685)	Represents the color teal.
clWebAliceBlue (see page 14685)	This is constant Graphics.clWebAliceBlue.
clWebAntiqueWhite (see page 14686)	This is constant Graphics.clWebAntiqueWhite.
clWebAqua (see page 14686)	This is constant Graphics.clWebAqua.
clWebAquamarine (see page 14686)	This is constant Graphics.clWebAquamarine.
clWebAzure (see page 14687)	This is constant Graphics.clWebAzure.
clWebBeige (see page 14687)	This is constant Graphics.clWebBeige.
clWebBisque (see page 14687)	This is constant Graphics.clWebBisque.
clWebBlack (see page 14688)	This is constant Graphics.clWebBlack.
clWebBlanchedAlmond (see page 14688)	This is constant Graphics.clWebBlanchedAlmond.
clWebBlue (see page 14688)	This is constant Graphics.clWebBlue.
clWebBlueViolet (see page 14689)	This is constant Graphics.clWebBlueViolet.
clWebBrown (see page 14689)	This is constant Graphics.clWebBrown.
clWebBurlywood (see page 14689)	This is constant Graphics.clWebBurlywood.
clWebCadetBlue (see page 14690)	This is constant Graphics.clWebCadetBlue.
clWebChartreuse (see page 14690)	This is constant Graphics.clWebChartreuse.
clWebChocolate (see page 14690)	This is constant Graphics.clWebChocolate.
clWebCoral (see page 14691)	This is constant Graphics.clWebCoral.
clWebCornFlowerBlue (see page 14691)	This is constant Graphics.clWebCornFlowerBlue.
clWebCornSilk (see page 14691)	This is constant Graphics.clWebCornSilk.
clWebCrimson (see page 14692)	This is constant Graphics.clWebCrimson.
clWebCyan (see page 14692)	This is constant Graphics.clWebCyan.
clWebDarkBlue (see page 14692)	This is constant Graphics.clWebDarkBlue.
clWebDarkCyan (see page 14693)	This is constant Graphics.clWebDarkCyan.
clWebDarkGoldenRod (see page 14693)	This is constant Graphics.clWebDarkGoldenRod.
clWebDarkGray (see page 14693)	This is constant Graphics.clWebDarkGray.
clWebDarkgreen (see page 14694)	This is constant Graphics.clWebDarkgreen.
clWebDarkKhaki (see page 14694)	This is constant Graphics.clWebDarkKhaki.
clWebDarkMagenta (see page 14694)	This is constant Graphics.clWebDarkMagenta.
clWebDarkOliveGreen (see page 14695)	This is constant Graphics.clWebDarkOliveGreen.
clWebDarkOrange (see page 14695)	This is constant Graphics.clWebDarkOrange.
clWebDarkOrchid (see page 14695)	This is constant Graphics.clWebDarkOrchid.
clWebDarkRed (see page 14696)	This is constant Graphics.clWebDarkRed.
clWebDarkSalmon (see page 14696)	This is constant Graphics.clWebDarkSalmon.
clWebDarkSeaGreen (see page 14696)	This is constant Graphics.clWebDarkSeaGreen.
clWebDarkSlateBlue (see page 14697)	This is constant Graphics.clWebDarkSlateBlue.
clWebDarkSlategray (see page 14697)	This is constant Graphics.clWebDarkSlategray.
clWebDarkTurquoise (see page 14697)	This is constant Graphics.clWebDarkTurquoise.
clWebDarkViolet (see page 14698)	This is constant Graphics.clWebDarkViolet.
clWebDeepPink (see page 14698)	This is constant Graphics.clWebDeepPink.
clWebDeepskyBlue (see page 14698)	This is constant Graphics.clWebDeepskyBlue.
clWebDimGray (see page 14699)	This is constant Graphics.clWebDimGray.
clWebDodgerBlue (see page 14699)	This is constant Graphics.clWebDodgerBlue.
clWebFirebrick (see page 14699)	This is constant Graphics.clWebFirebrick.
clWebFloralWhite (see page 14700)	This is constant Graphics.clWebFloralWhite.
clWebForestGreen (see page 14700)	This is constant Graphics.clWebForestGreen.
clWebFuchsia (see page 14700)	This is constant Graphics.clWebFuchsia.
clWebGainsboro (see page 14701)	This is constant Graphics.clWebGainsboro.
clWebGhostWhite (see page 14701)	This is constant Graphics.clWebGhostWhite.

clWebGold (see page 14701)	This is constant Graphics.clWebGold.
clWebGoldenRod (see page 14702)	This is constant Graphics.clWebGoldenRod.
clWebGray (see page 14702)	This is constant Graphics.clWebGray.
clWebGreen (see page 14702)	This is constant Graphics.clWebGreen.
clWebGreenYellow (see page 14703)	This is constant Graphics.clWebGreenYellow.
clWebHoneydew (see page 14703)	This is constant Graphics.clWebHoneydew.
clWebHotPink (see page 14703)	This is constant Graphics.clWebHotPink.
clWebIndianRed (see page 14704)	This is constant Graphics.clWebIndianRed.
clWebIndigo (see page 14704)	This is constant Graphics.clWebIndigo.
clWebIvory (see page 14704)	This is constant Graphics.clWebIvory.
clWebKhaki (see page 14705)	This is constant Graphics.clWebKhaki.
clWebLavender (see page 14705)	This is constant Graphics.clWebLavender.
clWebLavenderBlush (see page 14705)	This is constant Graphics.clWebLavenderBlush.
clWebLawnGreen (see page 14706)	This is constant Graphics.clWebLawnGreen.
clWebLemonChiffon (see page 14706)	This is constant Graphics.clWebLemonChiffon.
clWebLightBlue (see page 14706)	This is constant Graphics.clWebLightBlue.
clWebLightCoral (see page 14707)	This is constant Graphics.clWebLightCoral.
clWebLightCyan (see page 14707)	This is constant Graphics.clWebLightCyan.
clWebLightGoldenrodYellow (see page 14707)	This is constant Graphics.clWebLightGoldenrodYellow.
clWebLightGreen (see page 14708)	This is constant Graphics.clWebLightGreen.
clWebLightgrey (see page 14708)	This is constant Graphics.clWebLightgrey.
clWebLightPink (see page 14708)	This is constant Graphics.clWebLightPink.
clWebLightSalmon (see page 14709)	This is constant Graphics.clWebLightSalmon.
clWebLightSeaGreen (see page 14709)	This is constant Graphics.clWebLightSeaGreen.
clWebLightSkyBlue (see page 14709)	This is constant Graphics.clWebLightSkyBlue.
clWebLightSlateGray (see page 14710)	This is constant Graphics.clWebLightSlateGray.
clWebLightSteelBlue (see page 14710)	This is constant Graphics.clWebLightSteelBlue.
clWebLightYellow (see page 14710)	This is constant Graphics.clWebLightYellow.
clWebLime (see page 14711)	This is constant Graphics.clWebLime.
clWebLimeGreen (see page 14711)	This is constant Graphics.clWebLimeGreen.
clWebLinen (see page 14711)	This is constant Graphics.clWebLinen.
clWebMagenta (see page 14712)	This is constant Graphics.clWebMagenta.
clWebMaroon (see page 14712)	This is constant Graphics.clWebMaroon.
clWebMediumAquamarine (see page 14712)	This is constant Graphics.clWebMediumAquamarine.
clWebMediumBlue (see page 14713)	This is constant Graphics.clWebMediumBlue.
clWebMediumOrchid (see page 14713)	This is constant Graphics.clWebMediumOrchid.
clWebMediumPurple (see page 14713)	This is constant Graphics.clWebMediumPurple.
clWebMediumSeaGreen (see page 14714)	This is constant Graphics.clWebMediumSeaGreen.
clWebMediumSlateBlue (see page 14714)	This is constant Graphics.clWebMediumSlateBlue.
clWebMediumSpringGreen (see page 14714)	This is constant Graphics.clWebMediumSpringGreen.
clWebMediumTurquoise (see page 14715)	This is constant Graphics.clWebMediumTurquoise.
clWebMediumVioletRed (see page 14715)	This is constant Graphics.clWebMediumVioletRed.
clWebMidnightBlue (see page 14715)	This is constant Graphics.clWebMidnightBlue.
clWebMintcream (see page 14716)	This is constant Graphics.clWebMintcream.
clWebMistyRose (see page 14716)	This is constant Graphics.clWebMistyRose.
clWebMoccasin (see page 14716)	This is constant Graphics.clWebMoccasin.
clWebNavajoWhite (see page 14717)	This is constant Graphics.clWebNavajoWhite.
clWebNavy (see page 14717)	This is constant Graphics.clWebNavy.
clWebOldLace (see page 14717)	This is constant Graphics.clWebOldLace.
clWebOlive (see page 14718)	This is constant Graphics.clWebOlive.
clWebOliveDrab (see page 14718)	This is constant Graphics.clWebOliveDrab.
clWebOrange (see page 14718)	This is constant Graphics.clWebOrange.
clWebOrangeRed (see page 14719)	This is constant Graphics.clWebOrangeRed.
clWebOrchid (see page 14719)	This is constant Graphics.clWebOrchid.

clWebPaleGoldenrod (see page 14719)	This is constant Graphics.clWebPaleGoldenrod.
clWebPaleGreen (see page 14720)	This is constant Graphics.clWebPaleGreen.
clWebPaleTurquoise (see page 14720)	This is constant Graphics.clWebPaleTurquoise.
clWebPaleVioletRed (see page 14720)	This is constant Graphics.clWebPaleVioletRed.
clWebPapayaWhip (see page 14721)	This is constant Graphics.clWebPapayaWhip.
clWebPeachPuff (see page 14721)	This is constant Graphics.clWebPeachPuff.
clWebPeru (see page 14721)	This is constant Graphics.clWebPeru.
clWebPink (see page 14722)	This is constant Graphics.clWebPink.
clWebPlum (see page 14722)	This is constant Graphics.clWebPlum.
clWebPowderBlue (see page 14722)	This is constant Graphics.clWebPowderBlue.
clWebPurple (see page 14723)	This is constant Graphics.clWebPurple.
clWebRed (see page 14723)	This is constant Graphics.clWebRed.
clWebRosyBrown (see page 14723)	This is constant Graphics.clWebRosyBrown.
clWebRoyalBlue (see page 14724)	This is constant Graphics.clWebRoyalBlue.
clWebSaddleBrown (see page 14724)	This is constant Graphics.clWebSaddleBrown.
clWebSalmon (see page 14724)	This is constant Graphics.clWebSalmon.
clWebSandyBrown (see page 14725)	This is constant Graphics.clWebSandyBrown.
clWebSeaGreen (see page 14725)	This is constant Graphics.clWebSeaGreen.
clWebSeashell (see page 14725)	This is constant Graphics.clWebSeashell.
clWebSienna (see page 14726)	This is constant Graphics.clWebSienna.
clWebSilver (see page 14726)	This is constant Graphics.clWebSilver.
clWebSkyBlue (see page 14726)	This is constant Graphics.clWebSkyBlue.
clWebSlateBlue (see page 14727)	This is constant Graphics.clWebSlateBlue.
clWebSlateGray (see page 14727)	This is constant Graphics.clWebSlateGray.
clWebSnow (see page 14727)	This is constant Graphics.clWebSnow.
clWebSpringGreen (see page 14728)	This is constant Graphics.clWebSpringGreen.
clWebSteelBlue (see page 14728)	This is constant Graphics.clWebSteelBlue.
clWebTan (see page 14728)	This is constant Graphics.clWebTan.
clWebTeal (see page 14729)	This is constant Graphics.clWebTeal.
clWebThistle (see page 14729)	This is constant Graphics.clWebThistle.
clWebTomato (see page 14729)	This is constant Graphics.clWebTomato.
clWebTurquoise (see page 14730)	This is constant Graphics.clWebTurquoise.
clWebViolet (see page 14730)	This is constant Graphics.clWebViolet.
clWebWheat (see page 14730)	This is constant Graphics.clWebWheat.
clWebWhite (see page 14731)	This is constant Graphics.clWebWhite.
clWebWhiteSmoke (see page 14731)	This is constant Graphics.clWebWhiteSmoke.
clWebYellow (see page 14731)	This is constant Graphics.clWebYellow.
clWebYellowGreen (see page 14732)	This is constant Graphics.clWebYellowGreen.
clWhite (see page 14732)	Represents the color white.
clWindow (see page 14732)	Represents the default Window background color.
clWindowFrame (see page 14733)	Represents the default Window frame background color.
clWindowText (see page 14733)	Represents the default Window text color.
clYellow (see page 14734)	Represents the color yellow.
cmBlackness (see page 14734)	TCopyMode (see page 14650) value : fills the destination rectangle on the canvas with black.
cmDstInvert (see page 14735)	TCopyMode (see page 14650) value : inverts the image on the canvas and ignores the source.
cmMergeCopy (see page 14735)	TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean AND operator.
cmMergePaint (see page 14736)	TCopyMode (see page 14650) value : combines the inverted source bitmap with the image on the canvas by using the Boolean OR operator.
cmNotSrcCopy (see page 14736)	TCopyMode (see page 14650) value : copies the inverted source bitmap to the canvas.
cmNotSrcErase (see page 14737)	TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean OR operator, and inverts the result.
cmPatCopy (see page 14737)	TCopyMode (see page 14650) value : copies the source pattern to the canvas.

cmPatInvert (see page 14738)	TCopyMode (see page 14650) value : combines the source pattern with the image on the canvas using the Boolean XOR operator.
cmPatPaint (see page 14738)	TCopyMode (see page 14650) value : combines the inverted source bitmap with the source pattern by using the Boolean OR operator. Combines the result of this operation with the image on the canvas by using the Boolean OR operator.
cmSrcAnd (see page 14739)	TCopyMode (see page 14650) value : combines the image on the canvas and source bitmap by using the Boolean AND operator.
cmSrcCopy (see page 14739)	TCopyMode (see page 14650) value : copies the source bitmap to the canvas.
cmSrcErase (see page 14740)	TCopyMode (see page 14650) value : inverts the image on the canvas and combines the result with the source bitmap by using the Boolean AND operator.
cmSrcInvert (see page 14740)	TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean XOR operator.
cmSrcPaint (see page 14741)	TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean OR operator.
cmWhiteness (see page 14741)	TCopyMode (see page 14650) value : fills the destination rectangle on the canvas with white.
ExtendedColorsCount (see page 14742)	The total number of extended colors available
rc3_Cursor (see page 14743)	This is constant Graphics.rc3_Cursor.
rc3_Icon (see page 14743)	This is constant Graphics.rc3_Icon.
rc3_StockIcon (see page 14743)	This is constant Graphics.rc3_StockIcon.
StandardColorsCount (see page 14744)	The total number of standard colors available
WebColorsCount (see page 14745)	The total number of web colors available

73.7.1 Graphics.cl3DDkShadow Constant

Represents the dark shadow of 3D components.

Pascal

```
cl3DDkShadow = TColor(clSystemColor or COLOR_3DDKSHADOW);
```

C++

```
cl3DDkShadow = TColor(clSystemColor or COLOR_3DDKSHADOW);
```

File

Graphics

Description

For Windows 95 or NT 4.0 only, cl3DDkShadow represents the dark shadow for three-dimensional display elements.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.2 Graphics.cl3DLight Constant

Represents the light part of 3D components.

Pascal

```
cl3DLight = TColor(clSystemColor or COLOR_3DLIGHT);
```

C++

```
cl3DLight = TColor(clSystemColor or COLOR_3DLIGHT);
```

File

Graphics

Description

For Windows 95 or NT 4.0 only, cl3DLight represents the light color for three-dimensional display elements (for edges facing the light source).

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.3 Graphics.clActiveBorder Constant

Represents the default border color of an active window.

Pascal

```
clActiveBorder = TColor(clSystemColor or COLOR_ACTIVEBORDER);
```

C++

```
clActiveBorder = TColor(clSystemColor or COLOR_ACTIVEBORDER);
```

File

Graphics

Description

clActiveBorder is the default color used to paint the border of an active window. clActiveBorder is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.4 Graphics.clActiveCaption Constant

Represents the default color of the title bar of an active window.

Pascal

```
clActiveCaption = TColor(clSystemColor or COLOR_ACTIVECAPTION);
```

C++

```
clActiveCaption = TColor(clSystemColor or COLOR_ACTIVECAPTION);
```

File

Graphics

Description

clActiveCaption is the default color used to paint the border of an active window. clActiveCaption is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.5 Graphics.clAppWorkSpace Constant

Represents the default Application WorkSpace color.

Pascal

```
clAppWorkSpace = TColor(clSystemColor or COLOR_APPWORKSPACE);
```

C++

```
clAppWorkSpace = TColor(clSystemColor or COLOR_APPWORKSPACE);
```

File

Graphics

Description

clAppWorkSpace is the default Application WorkSpace color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.6 Graphics.clAqua Constant

Represents the color Aqua.

Pascal

```
clAqua = TColor($FFFF00);
```

C++

```
clAqua = TColor($FFFF00);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to Aqua. Aqua is the Delphi name for cyan - 100% blue and green with no red. Aqua is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.7 Graphics.clBackground Constant

Represents the default Windows background color.

Pascal

```
clBackground = TColor(clSystemColor or COLOR_BACKGROUND);
```

C++

```
clBackground = TColor(clSystemColor or COLOR_BACKGROUND);
```

File

Graphics

Description

clBackground is the default Windows background color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.8 Graphics.clBlack Constant

Represents the color black.

Pascal

```
clBlack = TColor($000000);
```

C++

```
clBlack = TColor($000000);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to black. Black is the complete absence of blue, green and red. Black is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.9 Graphics.clBlue Constant

Represents the color blue.

Pascal

```
clBlue = TColor($FF0000);
```

C++

```
clBlue = TColor($FF0000);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to blue. Blue is 100% blue with no green or red. Blue is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.10 Graphics.clBtnFace Constant

Represents the color of the face of a button.

Pascal

```
clBtnFace = TColor(clSystemColor or COLOR_BTNFACE);
```

C++

```
clBtnFace = TColor(clSystemColor or COLOR_BTNFACE);
```

File

Graphics

Description

clBtnFace is the color used to paint the face of a button.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.11 Graphics.clBtnHighlight Constant

Represents the color of the highlighting on a button.

Pascal

```
clBtnHighlight = TColor(clSystemColor or COLOR_BTNHIGHLIGHT);
```

C++

```
clBtnHighlight = TColor(clSystemColor or COLOR_BTNHIGHLIGHT);
```

File

Graphics

Description

clBtnHighlight is the color used to paint the highlighting on a button.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.12 Graphics.clBtnShadow Constant

Represents the color of the shadow cast by of a button.

Pascal

```
clBtnShadow = TColor(clSystemColor or COLOR_BTNSHADOW);
```

C++

```
clBtnShadow = TColor(clSystemColor or COLOR_BTNSHADOW);
```

File

Graphics

Description

clBtnShadow is the color used to paint the shadow cast by a button.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.13 Graphics.clBtnText Constant

Represents the default color of the text on a button.

Pascal

```
clBtnText = TColor(clSystemColor or COLOR_BTNTEXT);
```

C++

```
clBtnText = TColor(clSystemColor or COLOR_BTNTEXT);
```

File

Graphics

Description

clBtnText is the default color used to paint the text on a button.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.14 Graphics.clCaptionText Constant

Represents the default color of the text on the title bar of an active window.

Pascal

```
clCaptionText = TColor(clSystemColor or COLOR_CAPTIONTEXT);
```

C++

```
clCaptionText = TColor(clSystemColor or COLOR_CAPTIONTEXT);
```

File

Graphics

Description

clCaptionText is the default color used for the text on the title bar of an active window. clCaptionText is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.15 Graphics.clCream Constant

Represents the color cream.

Pascal

```
clCream = TColor($F0FBFF);
```

C++

```
clCream = TColor($F0FBFF);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to cream. Cream is an off white color. Cream is an extended color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.16 Graphics.clDefault Constant

Specifies the default color of a component.

Pascal

```
clDefault = TColor($20000000);
```

C++

```
clDefault = TColor($20000000);
```

File

Graphics

Description

clDefault is used to determine or set the default color of a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.17 Graphics.clDkGray Constant

Represents the color dark gray.

Pascal

```
clDkGray = TColor($808080);
```

C++

```
clDkGray = TColor($808080);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to dark gray. Dark gray comprises 50% intensity of each of blue, green and red - identical to clGray (see page 14672). Dark Gray is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.18 Graphics.clFuchsia Constant

Represents the color fuchsia.

Pascal

```
clFuchsia = TColor($FF00FF);
```

C++

```
clFuchsia = TColor($FF00FF);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to fuchsia. Fuchsia is 100% intensity red, 100% intensity blue and 0% green. Fuchsia is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.19 Graphics.clGradientActiveCaption Constant

Right side color in the color gradient of an active window's title bar.

Pascal

```
clGradientActiveCaption = TColor(clSystemColor or COLOR_GRADIENTACTIVECAPTION);
```

C++

```
clGradientActiveCaption = TColor(clSystemColor or COLOR_GRADIENTACTIVECAPTION);
```

File

Graphics

Description

For a Windows 98 and Windows 2000 color gradient in an active caption, clActiveCaption (see page 14664) defines the left side color, and clGradientActiveCaption defines the right side color. The left side color blends to the right side color.

See Also

clActiveCaption (see page 14664)

clInactiveCaption (see page 14675)

clGradientInactiveCaption (see page 14671)

Color (see page 14437)

TColor (see page 14648)

73.7.20 Graphics.clGradientInactiveCaption Constant

Right side color in the color gradient of an inactive window's title bar.

Pascal

```
clGradientInactiveCaption = TColor(clSystemColor or COLOR_GRADIENTINACTIVECAPTION);
```

C++

```
clGradientInactiveCaption = TColor(clSystemColor or COLOR_GRADIENTINACTIVECAPTION);
```

File

Graphics

Description

For a Windows 98 and Windows 2000 color gradient in an inactive caption, clInactiveCaption (see page 14675) defines the left side color, and clGradientInactiveCaption defines the right side color. The left side color blends to the right side color.

See Also

clActiveCaption (see page 14664)

clGradientActiveCaption (see page 14671)

clInactiveCaption (see page 14675)

Color (see page 14437)

TColor (see page 14648)

73.7.21 Graphics.clGray Constant

Represents the color gray.

Pascal

```
clGray = TColor($808080);
```

C++

```
clGray = TColor($808080);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to gray. Gray comprises 50% intensity of each of blue, green and red. Gray is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.22 Graphics.clGrayText Constant

Represents the color of text that is grayed out.

Pascal

```
clGrayText = TColor(clSystemColor or COLOR_GRAYTEXT);
```

C++

```
clGrayText = TColor(clSystemColor or COLOR_GRAYTEXT);
```

File

Graphics

Description

clGrayText is the color used to paint text that has been set inactive, such as in an inactive menu item. clGrayText is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.23 Graphics.clGreen Constant

Represents the color green.

Pascal

```
clGreen = TColor($008000);
```

C++

```
clGreen = TColor($008000);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to green. Green is 100% green with no blue or red. Green is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.24 Graphics.clHighlight Constant

Represents the color of the background of a block of selected text.

Pascal

```
clHighlight = TColor(clSystemColor or COLOR_HIGHLIGHT);
```

C++

```
clHighlight = TColor(clSystemColor or COLOR_HIGHLIGHT);
```

File

Graphics

Description

clHighlight is the default color used to paint the background of a selected block of text. clHighlight is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.25 Graphics.clHighlightText Constant

Represents the color of selected text.

Pascal

```
clHighlightText = TColor(clSystemColor or COLOR_HIGHLIGHTTEXT);
```

C++

```
clHighlightText = TColor(clSystemColor or COLOR_HIGHLIGHTTEXT);
```

File

Graphics

Description

clHighlightText is the default color used for a selected block of text. clHighlightText is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.26 Graphics.clHotLight Constant

Pascal

```
clHotLight = TColor(clSystemColor or COLOR_HOTLIGHT);
```

C++

```
clHotLight = TColor(clSystemColor or COLOR_HOTLIGHT);
```

File

Graphics

Description

This is constant Graphics.clHotLight.

73.7.27 Graphics.clInactiveBorder Constant

Represents the default border color of an inactive window.

Pascal

```
clInactiveBorder = TColor(clSystemColor or COLOR_INACTIVEBORDER);
```

C++

```
clInactiveBorder = TColor(clSystemColor or COLOR_INACTIVEBORDER);
```

File

Graphics

Description

clInactiveBorder is the default color used to paint the border of an inactive window. clInactiveBorder is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.28 Graphics.clInactiveCaption Constant

Represents the default color of the title bar of an inactive window.

Pascal

```
clInactiveCaption = TColor(clSystemColor or COLOR_INACTIVECAPTION);
```

C++

```
clInactiveCaption = TColor(clSystemColor or COLOR_INACTIVECAPTION);
```

File

Graphics

Description

clInactiveCaption is the default color used to paint the border of an inactive window. clInactiveCaption is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.29 Graphics.clInactiveCaptionText Constant

Represents the default color of the title text in an inactive window.

Pascal

```
clInactiveCaptionText = TColor(clSystemColor or COLOR_INACTIVECAPTIONTEXT);
```

C++

```
clInactiveCaptionText = TColor(clSystemColor or COLOR_INACTIVECAPTIONTEXT);
```

File

Graphics

Description

clInactiveCaptionText is the default color used for the title font an inactive window. clInactiveCaptionText is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.30 Graphics.clInfoBk Constant

Represents the color of the background of a tool tip.

Pascal

```
clInfoBk = TColor(clSystemColor or COLOR_INFOBK);
```

C++

```
clInfoBk = TColor(clSystemColor or COLOR_INFOBK);
```

File

Graphics

Description

clInfoBk is the default color used for the background of a tool tip. clInfoBk is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.31 Graphics.clInfoText Constant

Represents the color of tool tip text.

Pascal

```
clInfoText = TColor(clSystemColor or COLOR_INFOTEXT);
```

C++

```
clInfoText = TColor(clSystemColor or COLOR_INFOTEXT);
```

File

Graphics

Description

clInfoText is the default color used for tool tip text. clInfoText is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.32 Graphics.clLime Constant

Represents the color lime.

Pascal

```
clLime = TColor($00FF00);
```

C++

```
clLime = TColor($00FF00);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to lime. Lime is 100% green with no blue or red. It is identical to clGreen (see page 14673). Lime is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.33 Graphics.clLtGray Constant

Represents the color light gray.

Pascal

```
clLtGray = TColor($C0C0C0);
```

C++

```
clLtGray = TColor($C0C0C0);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to light gray. Light gray comprises 75% intensity of each of blue, green and red. It is identical to clSilver (see page 14683). Light Gray is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.34 Graphics.clMaroon Constant

Represents the color maroon.

Pascal

```
clMaroon = TColor($000080);
```

C++

```
clMaroon = TColor($000080);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to maroon. Maroon gray comprises 50% intensity red, with no blue or green. Maroon is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.35 Graphics.clMedGray Constant

Represents the color medium gray.

Pascal

```
clMedGray = TColor($A4A0A0);
```

C++

```
clMedGray = TColor($A4A0A0);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to medium gray. Medium gray lies between clGray (see page 14672) and clLtGray (see page 14677), but, unusually, with a blue tint. Medium Gray is an extended color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.36 Graphics.clMenu Constant

Represents the color of the background of an unselected menu sub item.

Pascal

```
clMenu = TColor(clSystemColor or COLOR_MENU);
```

C++

```
clMenu = TColor(clSystemColor or COLOR_MENU);
```

File

Graphics

Description

clMenu is the default color used for the background of a sub menu item. clMenuBar (see page 14679) defines the color used for the background of the main menu items. clMenu is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.37 Graphics.clMenuBar Constant

Represents the color of the background of an unselected main menu item.

Pascal

```
clMenuBar = TColor(clSystemColor or COLOR_MENUBAR);
```

C++

```
clMenuBar = TColor(clSystemColor or COLOR_MENUBAR);
```

File

Graphics

Description

clMenuBar is the default color used for the background of a main menu item. clMenu (see page 14679) defines the color used for the background of menu sub items. clMenuBar is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.38 Graphics.clMenuHighlight Constant

Represents the color of the background of a selected menu item.

Pascal

```
clMenuHighlight = TColor(clSystemColor or COLOR_MENUHILIGHT);
```

C++

```
clMenuHighlight = TColor(clSystemColor or COLOR_MENUHILIGHT);
```

File

Graphics

Description

clMenuHighlight is the default color used for the background of a selcetd main or sub menu item. clMenuHighlight is a System (see page 22079) color - used for painting a component.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.39 Graphics.clMenuText Constant

Represents the default menu text color.

Pascal

```
clMenuText = TColor(clSystemColor or COLOR_MENUTEXT);
```

C++

```
clMenuText = TColor(clSystemColor or COLOR_MENUTEXT);
```

File

Graphics

Description

clMenuText is the default color for menu text.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.40 Graphics.clMoneyGreen Constant

Represents the color money green.

Pascal

```
clMoneyGreen = TColor($C0DCC0);
```

C++

```
clMoneyGreen = TColor($C0DCC0);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to money green. Money green is a green tinted light gray. Money green is an extended color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.41 Graphics.clNavy Constant

Represents the color navy.

Pascal

```
clNavy = TColor($800000);
```

C++

```
clNavy = TColor($800000);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to navy. Navy gray comprises 50% intensity blue, with no red or green. Navy is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.42 Graphics.clNone Constant

Represents no selected color.

Pascal

```
clNone = TColor($1FFFFFFF);
```

C++

```
clNone = TColor($1FFFFFFF);
```

File

Graphics

Description

clNone represents no selected color.

Note: clNone is white on Windows 9.x systems, and black on Windows NT systems.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.43 Graphics.clOlive Constant

Represents the color olive.

Pascal

```
clOlive = TColor($008080);
```

C++

```
clOlive = TColor($008080);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to olive. Olive is 50% intensity green, 50% intensity red with no blue. Olive is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.44 Graphics.clPurple Constant

Represents the color purple.

Pascal

```
clPurple = TColor($800080);
```

C++

```
clPurple = TColor($800080);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to purple. Purple is 50% intensity red, 50% intensity blue and 0% green. Purple is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.45 Graphics.clRed Constant

Represents the color red.

Pascal

```
clRed = TColor($0000FF);
```

C++

```
clRed = TColor($0000FF);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to red. Red is 100% red with no green or blue. Red is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.46 Graphics.clScrollBar Constant

Pascal

```
clScrollBar = TColor(clSystemColor or COLOR_SCROLLBAR);
```

C++

```
clScrollBar = TColor(clSystemColor or COLOR_SCROLLBAR);
```

File

Graphics

Description

This is constant Graphics.clScrollBar.

73.7.47 Graphics.clSilver Constant

Represents the color silver.

Pascal

```
clSilver = TColor($C0C0C0);
```

C++

```
clSilver = TColor($C0C0C0);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to silver. Silver comprises 75% intensity of each of blue, green and red. It is identical to clLtGray (see page 14677). Silver is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.48 Graphics.clSkyBlue Constant

Represents the color sky blue.

Pascal

```
clSkyBlue = TColor($F0CAA6);
```

C++

```
clSkyBlue = TColor($F0CAA6);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to sky blue. Sky blue light blue that is similar to the sky color. Sky blue is an extended color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.49 Graphics.clSystemColor Constant

Is a mask used to identify the set of system colors.

Pascal

```
clSystemColor = $FF000000;
```

C++

```
clSystemColor = 0xFF000000;
```

File

Graphics

Description

clSystemColor has the 1st byte bits set on as ameans of identifying a system color.

For example, clActiveBorder (see page 14664) is system color, used as the default color to paint the active border of a component - it has the high order byte set to $FF. clRed (see page 14683) is not a system color, since the high order byte is 0.

See Also

clActiveBorder (see page 14664)

clRed (see page 14683)

Color (see page 14437)

TColor (see page 14648)

73.7.50 Graphics.clTeal Constant

Represents the color teal.

Pascal

```
clTeal = TColor($808000);
```

C++

```
clTeal = TColor($808000);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to teal. Teal is dark cyan : 50% blue, 50% green, 0% red. Teal is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.51 Graphics.clWebAliceBlue Constant

Pascal

```
clWebAliceBlue = $FFF8F0;
```

C++

```
clWebAliceBlue = 0xFFF8F0;
```

File

Graphics

Description

This is constant Graphics.clWebAliceBlue.

73.7.52 Graphics.clWebAntiqueWhite Constant

Pascal

```
clWebAntiqueWhite = $D7EBFA;
```

C++

```
clWebAntiqueWhite = 0xD7EBFA;
```

File

Graphics

Description

This is constant Graphics.clWebAntiqueWhite.

73.7.53 Graphics.clWebAqua Constant

Pascal

```
clWebAqua = $FFFF00;
```

C++

```
clWebAqua = 0xFFFF00;
```

File

Graphics

Description

This is constant Graphics.clWebAqua.

73.7.54 Graphics.clWebAquamarine Constant

Pascal

```
clWebAquamarine = $D4FF7F;
```

C++

```
clWebAquamarine = 0xD4FF7F;
```

File

Graphics

Description

This is constant Graphics.clWebAquamarine.

73.7.55 Graphics.clWebAzure Constant

Pascal

```
clWebAzure = $FFFFF0;
```

C++

```
clWebAzure = 0xFFFFF0;
```

File

Graphics

Description

This is constant Graphics.clWebAzure.

73.7.56 Graphics.clWebBeige Constant

Pascal

```
clWebBeige = $DCF5F5;
```

C++

```
clWebBeige = 0xDCF5F5;
```

File

Graphics

Description

This is constant Graphics.clWebBeige.

73.7.57 Graphics.clWebBisque Constant

Pascal

```
clWebBisque = $C4E4FF;
```

C++

```
clWebBisque = 0xC4E4FF;
```

File

Graphics

Description

This is constant Graphics.clWebBisque.

73.7.58 Graphics.clWebBlack Constant

Pascal

```
clWebBlack = $000000;
```

C++

```
clWebBlack = 0x000000;
```

File

Graphics

Description

This is constant Graphics.clWebBlack.

73.7.59 Graphics.clWebBlanchedAlmond Constant

Pascal

```
clWebBlanchedAlmond = $CDEBFF;
```

C++

```
clWebBlanchedAlmond = 0xCDEBFF;
```

File

Graphics

Description

This is constant Graphics.clWebBlanchedAlmond.

73.7.60 Graphics.clWebBlue Constant

Pascal

```
clWebBlue = $FF0000;
```

C++

```
clWebBlue = 0xFF0000;
```

File

Graphics

Description

This is constant Graphics.clWebBlue.

73.7.61 Graphics.clWebBlueViolet Constant

Pascal

```
clWebBlueViolet = $E22B8A;
```

C++

```
clWebBlueViolet = 0xE22B8A;
```

File

Graphics

Description

This is constant Graphics.clWebBlueViolet.

73.7.62 Graphics.clWebBrown Constant

Pascal

```
clWebBrown = $2A2AA5;
```

C++

```
clWebBrown = 0x2A2AA5;
```

File

Graphics

Description

This is constant Graphics.clWebBrown.

73.7.63 Graphics.clWebBurlywood Constant

Pascal

```
clWebBurlywood = $87B8DE;
```

C++

```
clWebBurlywood = 0x87B8DE;
```

File

Graphics

Description

This is constant Graphics.clWebBurlywood.

73.7.64 Graphics.clWebCadetBlue Constant

Pascal

```
clWebCadetBlue = $A09E5F;
```

C++

```
clWebCadetBlue = 0xA09E5F;
```

File

Graphics

Description

This is constant Graphics.clWebCadetBlue.

73.7.65 Graphics.clWebChartreuse Constant

Pascal

```
clWebChartreuse = $00FF7F;
```

C++

```
clWebChartreuse = 0x00FF7F;
```

File

Graphics

Description

This is constant Graphics.clWebChartreuse.

73.7.66 Graphics.clWebChocolate Constant

Pascal

```
clWebChocolate = $1E69D2;
```

C++

```
clWebChocolate = 0x1E69D2;
```

File

Graphics

Description

This is constant Graphics.clWebChocolate.

73.7.67 Graphics.clWebCoral Constant

Pascal

```
clWebCoral = $507FFF;
```

C++

```
clWebCoral = 0x507FFF;
```

File

Graphics

Description

This is constant Graphics.clWebCoral.

73.7.68 Graphics.clWebCornFlowerBlue Constant

Pascal

```
clWebCornFlowerBlue = $ED9564;
```

C++

```
clWebCornFlowerBlue = 0xED9564;
```

File

Graphics

Description

This is constant Graphics.clWebCornFlowerBlue.

73.7.69 Graphics.clWebCornSilk Constant

Pascal

```
clWebCornSilk = $DCF8FF;
```

C++

```
clWebCornSilk = 0xDCF8FF;
```

File

Graphics

Description

This is constant Graphics.clWebCornSilk.

73.7.70 Graphics.clWebCrimson Constant

Pascal

```
clWebCrimson = $3C14DC;
```

C++

```
clWebCrimson = 0x3C14DC;
```

File

Graphics

Description

This is constant Graphics.clWebCrimson.

73.7.71 Graphics.clWebCyan Constant

Pascal

```
clWebCyan = $FFFF00;
```

C++

```
clWebCyan = 0xFFFF00;
```

File

Graphics

Description

This is constant Graphics.clWebCyan.

73.7.72 Graphics.clWebDarkBlue Constant

Pascal

```
clWebDarkBlue = $8B0000;
```

C++

```
clWebDarkBlue = 0x8B0000;
```

File

Graphics

Description

This is constant Graphics.clWebDarkBlue.

73.7.73 Graphics.clWebDarkCyan Constant

Pascal

```
clWebDarkCyan = $8B8B00;
```

C++

```
clWebDarkCyan = 0x8B8B00;
```

File

Graphics

Description

This is constant Graphics.clWebDarkCyan.

73.7.74 Graphics.clWebDarkGoldenRod Constant

Pascal

```
clWebDarkGoldenRod = $0B86B8;
```

C++

```
clWebDarkGoldenRod = 0x0B86B8;
```

File

Graphics

Description

This is constant Graphics.clWebDarkGoldenRod.

73.7.75 Graphics.clWebDarkGray Constant

Pascal

```
clWebDarkGray = $A9A9A9;
```

C++

```
clWebDarkGray = 0xA9A9A9;
```

File

Graphics

Description

This is constant Graphics.clWebDarkGray.

73.7.76 Graphics.clWebDarkgreen Constant

Pascal

```
clWebDarkgreen = $006400;
```

C++

```
clWebDarkgreen = 0x006400;
```

File

Graphics

Description

This is constant Graphics.clWebDarkgreen.

73.7.77 Graphics.clWebDarkKhaki Constant

Pascal

```
clWebDarkKhaki = $6BB7BD;
```

C++

```
clWebDarkKhaki = 0x6BB7BD;
```

File

Graphics

Description

This is constant Graphics.clWebDarkKhaki.

73.7.78 Graphics.clWebDarkMagenta Constant

Pascal

```
clWebDarkMagenta = $8B008B;
```

C++

```
clWebDarkMagenta = 0x8B008B;
```

File

Graphics

Description

This is constant Graphics.clWebDarkMagenta.

73.7.79 Graphics.clWebDarkOliveGreen Constant

Pascal

```
clWebDarkOliveGreen = $2F6B55;
```

C++

```
clWebDarkOliveGreen = 0x2F6B55;
```

File

Graphics

Description

This is constant Graphics.clWebDarkOliveGreen.

73.7.80 Graphics.clWebDarkOrange Constant

Pascal

```
clWebDarkOrange = $008CFF;
```

C++

```
clWebDarkOrange = 0x008CFF;
```

File

Graphics

Description

This is constant Graphics.clWebDarkOrange.

73.7.81 Graphics.clWebDarkOrchid Constant

Pascal

```
clWebDarkOrchid = $CC3299;
```

C++

```
clWebDarkOrchid = 0xCC3299;
```

File

Graphics

Description

This is constant Graphics.clWebDarkOrchid.

73.7.82 Graphics.clWebDarkRed Constant

Pascal

```
clWebDarkRed = $00008B;
```

C++

```
clWebDarkRed = 0x00008B;
```

File

Graphics

Description

This is constant Graphics.clWebDarkRed.

73.7.83 Graphics.clWebDarkSalmon Constant

Pascal

```
clWebDarkSalmon = $7A96E9;
```

C++

```
clWebDarkSalmon = 0x7A96E9;
```

File

Graphics

Description

This is constant Graphics.clWebDarkSalmon.

73.7.84 Graphics.clWebDarkSeaGreen Constant

Pascal

```
clWebDarkSeaGreen = $8FBC8F;
```

C++

```
clWebDarkSeaGreen = 0x8FBC8F;
```

File

Graphics

Description

This is constant Graphics.clWebDarkSeaGreen.

73.7.85 Graphics.clWebDarkSlateBlue Constant

Pascal

```
clWebDarkSlateBlue = $8B3D48;
```

C++

```
clWebDarkSlateBlue = 0x8B3D48;
```

File

Graphics

Description

This is constant Graphics.clWebDarkSlateBlue.

73.7.86 Graphics.clWebDarkSlategray Constant

Pascal

```
clWebDarkSlategray = $4F4F2F;
```

C++

```
clWebDarkSlategray = 0x4F4F2F;
```

File

Graphics

Description

This is constant Graphics.clWebDarkSlategray.

73.7.87 Graphics.clWebDarkTurquoise Constant

Pascal

```
clWebDarkTurquoise = $D1CE00;
```

C++

```
clWebDarkTurquoise = 0xD1CE00;
```

File

Graphics

Description

This is constant Graphics.clWebDarkTurquoise.

73.7.88 Graphics.clWebDarkViolet Constant

Pascal

```
clWebDarkViolet = $D30094;
```

C++

```
clWebDarkViolet = 0xD30094;
```

File

Graphics

Description

This is constant Graphics.clWebDarkViolet.

73.7.89 Graphics.clWebDeepPink Constant

Pascal

```
clWebDeepPink = $9314FF;
```

C++

```
clWebDeepPink = 0x9314FF;
```

File

Graphics

Description

This is constant Graphics.clWebDeepPink.

73.7.90 Graphics.clWebDeepskyBlue Constant

Pascal

```
clWebDeepskyBlue = $FFBF00;
```

C++

```
clWebDeepskyBlue = 0xFFBF00;
```

File

Graphics

Description

This is constant Graphics.clWebDeepskyBlue.

73.7.91 Graphics.clWebDimGray Constant

Pascal

```
clWebDimGray = $696969;
```

C++

```
clWebDimGray = 0x696969;
```

File

Graphics

Description

This is constant Graphics.clWebDimGray.

73.7.92 Graphics.clWebDodgerBlue Constant

Pascal

```
clWebDodgerBlue = $FF901E;
```

C++

```
clWebDodgerBlue = 0xFF901E;
```

File

Graphics

Description

This is constant Graphics.clWebDodgerBlue.

73.7.93 Graphics.clWebFirebrick Constant

Pascal

```
clWebFirebrick = $2222B2;
```

C++

```
clWebFirebrick = 0x2222B2;
```

File

Graphics

Description

This is constant Graphics.clWebFirebrick.

73.7.94 Graphics.clWebFloralWhite Constant

Pascal

```
clWebFloralWhite = $F0FAFF;
```

C++

```
clWebFloralWhite = 0xF0FAFF;
```

File

Graphics

Description

This is constant Graphics.clWebFloralWhite.

73.7.95 Graphics.clWebForestGreen Constant

Pascal

```
clWebForestGreen = $228B22;
```

C++

```
clWebForestGreen = 0x228B22;
```

File

Graphics

Description

This is constant Graphics.clWebForestGreen.

73.7.96 Graphics.clWebFuchsia Constant

Pascal

```
clWebFuchsia = $FF00FF;
```

C++

```
clWebFuchsia = 0xFF00FF;
```

File

Graphics

Description

This is constant Graphics.clWebFuchsia.

73.7.97 Graphics.clWebGainsboro Constant

Pascal

```
clWebGainsboro = $DCDCDC;
```

C++

```
clWebGainsboro = 0xDCDCDC;
```

File

Graphics

Description

This is constant Graphics.clWebGainsboro.

73.7.98 Graphics.clWebGhostWhite Constant

Pascal

```
clWebGhostWhite = $FFF8F8;
```

C++

```
clWebGhostWhite = 0xFFF8F8;
```

File

Graphics

Description

This is constant Graphics.clWebGhostWhite.

73.7.99 Graphics.clWebGold Constant

Pascal

```
clWebGold = $00D7FF;
```

C++

```
clWebGold = 0x00D7FF;
```

File

Graphics

Description

This is constant Graphics.clWebGold.

73.7.100 Graphics.clWebGoldenRod Constant

Pascal

```
clWebGoldenRod = $20A5DA;
```

C++

```
clWebGoldenRod = 0x20A5DA;
```

File

Graphics

Description

This is constant Graphics.clWebGoldenRod.

73.7.101 Graphics.clWebGray Constant

Pascal

```
clWebGray = $808080;
```

C++

```
clWebGray = 0x808080;
```

File

Graphics

Description

This is constant Graphics.clWebGray.

73.7.102 Graphics.clWebGreen Constant

Pascal

```
clWebGreen = $008000;
```

C++

```
clWebGreen = 0x008000;
```

File

Graphics

Description

This is constant Graphics.clWebGreen.

73.7.103 Graphics.clWebGreenYellow Constant

Pascal

```
clWebGreenYellow = $2FFFAD;
```

C++

```
clWebGreenYellow = 0x2FFFAD;
```

File

Graphics

Description

This is constant Graphics.clWebGreenYellow.

73.7.104 Graphics.clWebHoneydew Constant

Pascal

```
clWebHoneydew = $F0FFF0;
```

C++

```
clWebHoneydew = 0xF0FFF0;
```

File

Graphics

Description

This is constant Graphics.clWebHoneydew.

73.7.105 Graphics.clWebHotPink Constant

Pascal

```
clWebHotPink = $B469FF;
```

C++

```
clWebHotPink = 0xB469FF;
```

File

Graphics

Description

This is constant Graphics.clWebHotPink.

73.7.106 Graphics.clWebIndianRed Constant

Pascal

```
clWebIndianRed = $5C5CCD;
```

C++

```
clWebIndianRed = 0x5C5CCD;
```

File

Graphics

Description

This is constant Graphics.clWebIndianRed.

73.7.107 Graphics.clWebIndigo Constant

Pascal

```
clWebIndigo = $82004B;
```

C++

```
clWebIndigo = 0x82004B;
```

File

Graphics

Description

This is constant Graphics.clWebIndigo.

73.7.108 Graphics.clWebIvory Constant

Pascal

```
clWebIvory = $F0FFFF;
```

C++

```
clWebIvory = 0xF0FFFF;
```

File

Graphics

Description

This is constant Graphics.clWebIvory.

73.7.109 Graphics.clWebKhaki Constant

Pascal

```
clWebKhaki = $8CE6F0;
```

C++

```
clWebKhaki = 0x8CE6F0;
```

File

Graphics

Description

This is constant Graphics.clWebKhaki.

73.7.110 Graphics.clWebLavender Constant

Pascal

```
clWebLavender = $FAE6E6;
```

C++

```
clWebLavender = 0xFAE6E6;
```

File

Graphics

Description

This is constant Graphics.clWebLavender.

73.7.111 Graphics.clWebLavenderBlush Constant

Pascal

```
clWebLavenderBlush = $F5F0FF;
```

C++

```
clWebLavenderBlush = 0xF5F0FF;
```

File

Graphics

Description

This is constant Graphics.clWebLavenderBlush.

73.7.112 Graphics.clWebLawnGreen Constant

Pascal

```
clWebLawnGreen = $00FC7C;
```

C++

```
clWebLawnGreen = 0x00FC7C;
```

File

Graphics

Description

This is constant Graphics.clWebLawnGreen.

73.7.113 Graphics.clWebLemonChiffon Constant

Pascal

```
clWebLemonChiffon = $CDFAFF;
```

C++

```
clWebLemonChiffon = 0xCDFAFF;
```

File

Graphics

Description

This is constant Graphics.clWebLemonChiffon.

73.7.114 Graphics.clWebLightBlue Constant

Pascal

```
clWebLightBlue = $E6D8AD;
```

C++

```
clWebLightBlue = 0xE6D8AD;
```

File

Graphics

Description

This is constant Graphics.clWebLightBlue.

73.7.115 Graphics.clWebLightCoral Constant

Pascal

```
clWebLightCoral = $8080F0;
```

C++

```
clWebLightCoral = 0x8080F0;
```

File

Graphics

Description

This is constant Graphics.clWebLightCoral.

73.7.116 Graphics.clWebLightCyan Constant

Pascal

```
clWebLightCyan = $FFFFE0;
```

C++

```
clWebLightCyan = 0xFFFFE0;
```

File

Graphics

Description

This is constant Graphics.clWebLightCyan.

73.7.117 Graphics.clWebLightGoldenrodYellow Constant

Pascal

```
clWebLightGoldenrodYellow = $D2FAFA;
```

C++

```
clWebLightGoldenrodYellow = 0xD2FAFA;
```

File

Graphics

Description

This is constant Graphics.clWebLightGoldenrodYellow.

73.7.118 Graphics.clWebLightGreen Constant

Pascal

```
clWebLightGreen = $90EE90;
```

C++

```
clWebLightGreen = 0x90EE90;
```

File

Graphics

Description

This is constant Graphics.clWebLightGreen.

73.7.119 Graphics.clWebLightgrey Constant

Pascal

```
clWebLightgrey = $D3D3D3;
```

C++

```
clWebLightgrey = 0xD3D3D3;
```

File

Graphics

Description

This is constant Graphics.clWebLightgrey.

73.7.120 Graphics.clWebLightPink Constant

Pascal

```
clWebLightPink = $C1B6FF;
```

C++

```
clWebLightPink = 0xC1B6FF;
```

File

Graphics

Description

This is constant Graphics.clWebLightPink.

73.7.121 Graphics.clWebLightSalmon Constant

Pascal

```
clWebLightSalmon = $7AA0FF;
```

C++

```
clWebLightSalmon = 0x7AA0FF;
```

File

Graphics

Description

This is constant Graphics.clWebLightSalmon.

73.7.122 Graphics.clWebLightSeaGreen Constant

Pascal

```
clWebLightSeaGreen = $AAB220;
```

C++

```
clWebLightSeaGreen = 0xAAB220;
```

File

Graphics

Description

This is constant Graphics.clWebLightSeaGreen.

73.7.123 Graphics.clWebLightSkyBlue Constant

Pascal

```
clWebLightSkyBlue = $FACE87;
```

C++

```
clWebLightSkyBlue = 0xFACE87;
```

File

Graphics

Description

This is constant Graphics.clWebLightSkyBlue.

73.7.124 Graphics.clWebLightSlateGray Constant

Pascal

```
clWebLightSlateGray = $998877;
```

C++

```
clWebLightSlateGray = 0x998877;
```

File

Graphics

Description

This is constant Graphics.clWebLightSlateGray.

73.7.125 Graphics.clWebLightSteelBlue Constant

Pascal

```
clWebLightSteelBlue = $DEC4B0;
```

C++

```
clWebLightSteelBlue = 0xDEC4B0;
```

File

Graphics

Description

This is constant Graphics.clWebLightSteelBlue.

73.7.126 Graphics.clWebLightYellow Constant

Pascal

```
clWebLightYellow = $E0FFFF;
```

C++

```
clWebLightYellow = 0xE0FFFF;
```

File

Graphics

Description

This is constant Graphics.clWebLightYellow.

73.7.127 Graphics.clWebLime Constant

Pascal

```
clWebLime = $00FF00;
```

C++

```
clWebLime = 0x00FF00;
```

File

Graphics

Description

This is constant Graphics.clWebLime.

73.7.128 Graphics.clWebLimeGreen Constant

Pascal

```
clWebLimeGreen = $32CD32;
```

C++

```
clWebLimeGreen = 0x32CD32;
```

File

Graphics

Description

This is constant Graphics.clWebLimeGreen.

73.7.129 Graphics.clWebLinen Constant

Pascal

```
clWebLinen = $E6F0FA;
```

C++

```
clWebLinen = 0xE6F0FA;
```

File

Graphics

Description

This is constant Graphics.clWebLinen.

73.7.130 Graphics.clWebMagenta Constant

Pascal

```
clWebMagenta = $FF00FF;
```

C++

```
clWebMagenta = 0xFF00FF;
```

File

Graphics

Description

This is constant Graphics.clWebMagenta.

73.7.131 Graphics.clWebMaroon Constant

Pascal

```
clWebMaroon = $000080;
```

C++

```
clWebMaroon = 0x000080;
```

File

Graphics

Description

This is constant Graphics.clWebMaroon.

73.7.132 Graphics.clWebMediumAquamarine Constant

Pascal

```
clWebMediumAquamarine = $AACD66;
```

C++

```
clWebMediumAquamarine = 0xAACD66;
```

File

Graphics

Description

This is constant Graphics.clWebMediumAquamarine.

73.7.133 Graphics.clWebMediumBlue Constant

Pascal

```
clWebMediumBlue = $CD0000;
```

C++

```
clWebMediumBlue = 0xCD0000;
```

File

Graphics

Description

This is constant Graphics.clWebMediumBlue.

73.7.134 Graphics.clWebMediumOrchid Constant

Pascal

```
clWebMediumOrchid = $D355BA;
```

C++

```
clWebMediumOrchid = 0xD355BA;
```

File

Graphics

Description

This is constant Graphics.clWebMediumOrchid.

73.7.135 Graphics.clWebMediumPurple Constant

Pascal

```
clWebMediumPurple = $DB7093;
```

C++

```
clWebMediumPurple = 0xDB7093;
```

File

Graphics

Description

This is constant Graphics.clWebMediumPurple.

73.7.136 Graphics.clWebMediumSeaGreen Constant

Pascal

```
clWebMediumSeaGreen = $71B33C;
```

C++

```
clWebMediumSeaGreen = 0x71B33C;
```

File

Graphics

Description

This is constant Graphics.clWebMediumSeaGreen.

73.7.137 Graphics.clWebMediumSlateBlue Constant

Pascal

```
clWebMediumSlateBlue = $EE687B;
```

C++

```
clWebMediumSlateBlue = 0xEE687B;
```

File

Graphics

Description

This is constant Graphics.clWebMediumSlateBlue.

73.7.138 Graphics.clWebMediumSpringGreen Constant

Pascal

```
clWebMediumSpringGreen = $9AFA00;
```

C++

```
clWebMediumSpringGreen = 0x9AFA00;
```

File

Graphics

Description

This is constant Graphics.clWebMediumSpringGreen.

73.7.139 Graphics.clWebMediumTurquoise Constant

Pascal

```
clWebMediumTurquoise = $CCD148;
```

C++

```
clWebMediumTurquoise = 0xCCD148;
```

File

Graphics

Description

This is constant Graphics.clWebMediumTurquoise.

73.7.140 Graphics.clWebMediumVioletRed Constant

Pascal

```
clWebMediumVioletRed = $8515C7;
```

C++

```
clWebMediumVioletRed = 0x8515C7;
```

File

Graphics

Description

This is constant Graphics.clWebMediumVioletRed.

73.7.141 Graphics.clWebMidnightBlue Constant

Pascal

```
clWebMidnightBlue = $701919;
```

C++

```
clWebMidnightBlue = 0x701919;
```

File

Graphics

Description

This is constant Graphics.clWebMidnightBlue.

73.7.142 Graphics.clWebMintcream Constant

Pascal

```
clWebMintcream = $FAFFF5;
```

C++

```
clWebMintcream = 0xFAFFF5;
```

File

Graphics

Description

This is constant Graphics.clWebMintcream.

73.7.143 Graphics.clWebMistyRose Constant

Pascal

```
clWebMistyRose = $E1E4FF;
```

C++

```
clWebMistyRose = 0xE1E4FF;
```

File

Graphics

Description

This is constant Graphics.clWebMistyRose.

73.7.144 Graphics.clWebMoccasin Constant

Pascal

```
clWebMoccasin = $B5E4FF;
```

C++

```
clWebMoccasin = 0xB5E4FF;
```

File

Graphics

Description

This is constant Graphics.clWebMoccasin.

73.7.145 Graphics.clWebNavajoWhite Constant

Pascal

```
clWebNavajoWhite = $ADDEFF;
```

C++

```
clWebNavajoWhite = 0xADDEFF;
```

File

Graphics

Description

This is constant Graphics.clWebNavajoWhite.

73.7.146 Graphics.clWebNavy Constant

Pascal

```
clWebNavy = $800000;
```

C++

```
clWebNavy = 0x800000;
```

File

Graphics

Description

This is constant Graphics.clWebNavy.

73.7.147 Graphics.clWebOldLace Constant

Pascal

```
clWebOldLace = $E6F5FD;
```

C++

```
clWebOldLace = 0xE6F5FD;
```

File

Graphics

Description

This is constant Graphics.clWebOldLace.

73.7.148 Graphics.clWebOlive Constant

Pascal

```
clWebOlive = $008080;
```

C++

```
clWebOlive = 0x008080;
```

File

Graphics

Description

This is constant Graphics.clWebOlive.

73.7.149 Graphics.clWebOliveDrab Constant

Pascal

```
clWebOliveDrab = $238E6B;
```

C++

```
clWebOliveDrab = 0x238E6B;
```

File

Graphics

Description

This is constant Graphics.clWebOliveDrab.

73.7.150 Graphics.clWebOrange Constant

Pascal

```
clWebOrange = $00A5FF;
```

C++

```
clWebOrange = 0x00A5FF;
```

File

Graphics

Description

This is constant Graphics.clWebOrange.

73.7.151 Graphics.clWebOrangeRed Constant

Pascal

```
clWebOrangeRed = $0045FF;
```

C++

```
clWebOrangeRed = 0x0045FF;
```

File

Graphics

Description

This is constant Graphics.clWebOrangeRed.

73.7.152 Graphics.clWebOrchid Constant

Pascal

```
clWebOrchid = $D670DA;
```

C++

```
clWebOrchid = 0xD670DA;
```

File

Graphics

Description

This is constant Graphics.clWebOrchid.

73.7.153 Graphics.clWebPaleGoldenrod Constant

Pascal

```
clWebPaleGoldenrod = $AAE8EE;
```

C++

```
clWebPaleGoldenrod = 0xAAE8EE;
```

File

Graphics

Description

This is constant Graphics.clWebPaleGoldenrod.

73.7.154 Graphics.clWebPaleGreen Constant

Pascal

```
clWebPaleGreen = $98FB98;
```

C++

```
clWebPaleGreen = 0x98FB98;
```

File

Graphics

Description

This is constant Graphics.clWebPaleGreen.

73.7.155 Graphics.clWebPaleTurquoise Constant

Pascal

```
clWebPaleTurquoise = $EEEEAF;
```

C++

```
clWebPaleTurquoise = 0xEEEEAF;
```

File

Graphics

Description

This is constant Graphics.clWebPaleTurquoise.

73.7.156 Graphics.clWebPaleVioletRed Constant

Pascal

```
clWebPaleVioletRed = $9370DB;
```

C++

```
clWebPaleVioletRed = 0x9370DB;
```

File

Graphics

Description

This is constant Graphics.clWebPaleVioletRed.

73.7.157 Graphics.clWebPapayaWhip Constant

Pascal

```
clWebPapayaWhip = $D5EFFF;
```

C++

```
clWebPapayaWhip = 0xD5EFFF;
```

File

Graphics

Description

This is constant Graphics.clWebPapayaWhip.

73.7.158 Graphics.clWebPeachPuff Constant

Pascal

```
clWebPeachPuff = $B9DAFF;
```

C++

```
clWebPeachPuff = 0xB9DAFF;
```

File

Graphics

Description

This is constant Graphics.clWebPeachPuff.

73.7.159 Graphics.clWebPeru Constant

Pascal

```
clWebPeru = $3F85CD;
```

C++

```
clWebPeru = 0x3F85CD;
```

File

Graphics

Description

This is constant Graphics.clWebPeru.

73.7.160 Graphics.clWebPink Constant

Pascal

```
clWebPink = $CBC0FF;
```

C++

```
clWebPink = 0xCBC0FF;
```

File

Graphics

Description

This is constant Graphics.clWebPink.

73.7.161 Graphics.clWebPlum Constant

Pascal

```
clWebPlum = $DDA0DD;
```

C++

```
clWebPlum = 0xDDA0DD;
```

File

Graphics

Description

This is constant Graphics.clWebPlum.

73.7.162 Graphics.clWebPowderBlue Constant

Pascal

```
clWebPowderBlue = $E6E0B0;
```

C++

```
clWebPowderBlue = 0xE6E0B0;
```

File

Graphics

Description

This is constant Graphics.clWebPowderBlue.

73.7.163 Graphics.clWebPurple Constant

Pascal

```
clWebPurple = $800080;
```

C++

```
clWebPurple = 0x800080;
```

File

Graphics

Description

This is constant Graphics.clWebPurple.

73.7.164 Graphics.clWebRed Constant

Pascal

```
clWebRed = $0000FF;
```

C++

```
clWebRed = 0x0000FF;
```

File

Graphics

Description

This is constant Graphics.clWebRed.

73.7.165 Graphics.clWebRosyBrown Constant

Pascal

```
clWebRosyBrown = $8F8FBC;
```

C++

```
clWebRosyBrown = 0x8F8FBC;
```

File

Graphics

Description

This is constant Graphics.clWebRosyBrown.

73.7.166 Graphics.clWebRoyalBlue Constant

Pascal

```
clWebRoyalBlue = $E16941;
```

C++

```
clWebRoyalBlue = 0xE16941;
```

File

Graphics

Description

This is constant Graphics.clWebRoyalBlue.

73.7.167 Graphics.clWebSaddleBrown Constant

Pascal

```
clWebSaddleBrown = $13458B;
```

C++

```
clWebSaddleBrown = 0x13458B;
```

File

Graphics

Description

This is constant Graphics.clWebSaddleBrown.

73.7.168 Graphics.clWebSalmon Constant

Pascal

```
clWebSalmon = $7280FA;
```

C++

```
clWebSalmon = 0x7280FA;
```

File

Graphics

Description

This is constant Graphics.clWebSalmon.

73.7.169 Graphics.clWebSandyBrown Constant

Pascal

```
clWebSandyBrown = $60A4F4;
```

C++

```
clWebSandyBrown = 0x60A4F4;
```

File

Graphics

Description

This is constant Graphics.clWebSandyBrown.

73.7.170 Graphics.clWebSeaGreen Constant

Pascal

```
clWebSeaGreen = $578B2E;
```

C++

```
clWebSeaGreen = 0x578B2E;
```

File

Graphics

Description

This is constant Graphics.clWebSeaGreen.

73.7.171 Graphics.clWebSeashell Constant

Pascal

```
clWebSeashell = $EEF5FF;
```

C++

```
clWebSeashell = 0xEEF5FF;
```

File

Graphics

Description

This is constant Graphics.clWebSeashell.

73.7.172 Graphics.clWebSienna Constant

Pascal

```
clWebSienna = $2D52A0;
```

C++

```
clWebSienna = 0x2D52A0;
```

File

Graphics

Description

This is constant Graphics.clWebSienna.

73.7.173 Graphics.clWebSilver Constant

Pascal

```
clWebSilver = $C0C0C0;
```

C++

```
clWebSilver = 0xC0C0C0;
```

File

Graphics

Description

This is constant Graphics.clWebSilver.

73.7.174 Graphics.clWebSkyBlue Constant

Pascal

```
clWebSkyBlue = $EBCE87;
```

C++

```
clWebSkyBlue = 0xEBCE87;
```

File

Graphics

Description

This is constant Graphics.clWebSkyBlue.

73.7.175 Graphics.clWebSlateBlue Constant

Pascal

```
clWebSlateBlue = $CD5A6A;
```

C++

```
clWebSlateBlue = 0xCD5A6A;
```

File

Graphics

Description

This is constant Graphics.clWebSlateBlue.

73.7.176 Graphics.clWebSlateGray Constant

Pascal

```
clWebSlateGray = $908070;
```

C++

```
clWebSlateGray = 0x908070;
```

File

Graphics

Description

This is constant Graphics.clWebSlateGray.

73.7.177 Graphics.clWebSnow Constant

Pascal

```
clWebSnow = $FAFAFF;
```

C++

```
clWebSnow = 0xFAFAFF;
```

File

Graphics

Description

This is constant Graphics.clWebSnow.

73.7.178 Graphics.clWebSpringGreen Constant

Pascal

```
clWebSpringGreen = $7FFF00;
```

C++

```
clWebSpringGreen = 0x7FFF00;
```

File

Graphics

Description

This is constant Graphics.clWebSpringGreen.

73.7.179 Graphics.clWebSteelBlue Constant

Pascal

```
clWebSteelBlue = $B48246;
```

C++

```
clWebSteelBlue = 0xB48246;
```

File

Graphics

Description

This is constant Graphics.clWebSteelBlue.

73.7.180 Graphics.clWebTan Constant

Pascal

```
clWebTan = $8CB4D2;
```

C++

```
clWebTan = 0x8CB4D2;
```

File

Graphics

Description

This is constant Graphics.clWebTan.

73.7.181 Graphics.clWebTeal Constant

Pascal

```
clWebTeal = $808000;
```

C++

```
clWebTeal = 0x808000;
```

File

Graphics

Description

This is constant Graphics.clWebTeal.

73.7.182 Graphics.clWebThistle Constant

Pascal

```
clWebThistle = $D8BFD8;
```

C++

```
clWebThistle = 0xD8BFD8;
```

File

Graphics

Description

This is constant Graphics.clWebThistle.

73.7.183 Graphics.clWebTomato Constant

Pascal

```
clWebTomato = $4763FF;
```

C++

```
clWebTomato = 0x4763FF;
```

File

Graphics

Description

This is constant Graphics.clWebTomato.

73.7.184 Graphics.clWebTurquoise Constant

Pascal

```
clWebTurquoise = $D0E040;
```

C++

```
clWebTurquoise = 0xD0E040;
```

File

Graphics

Description

This is constant Graphics.clWebTurquoise.

73.7.185 Graphics.clWebViolet Constant

Pascal

```
clWebViolet = $EE82EE;
```

C++

```
clWebViolet = 0xEE82EE;
```

File

Graphics

Description

This is constant Graphics.clWebViolet.

73.7.186 Graphics.clWebWheat Constant

Pascal

```
clWebWheat = $B3DEF5;
```

C++

```
clWebWheat = 0xB3DEF5;
```

File

Graphics

Description

This is constant Graphics.clWebWheat.

73.7.187 Graphics.clWebWhite Constant

Pascal

```
clWebWhite = $FFFFFF;
```

C++

```
clWebWhite = 0xFFFFFF;
```

File

Graphics

Description

This is constant Graphics.clWebWhite.

73.7.188 Graphics.clWebWhiteSmoke Constant

Pascal

```
clWebWhiteSmoke = $F5F5F5;
```

C++

```
clWebWhiteSmoke = 0xF5F5F5;
```

File

Graphics

Description

This is constant Graphics.clWebWhiteSmoke.

73.7.189 Graphics.clWebYellow Constant

Pascal

```
clWebYellow = $00FFFF;
```

C++

```
clWebYellow = 0x00FFFF;
```

File

Graphics

Description

This is constant Graphics.clWebYellow.

73.7.190 Graphics.clWebYellowGreen Constant

Pascal

```
clWebYellowGreen = $32CD9A;
```

C++

```
clWebYellowGreen = 0x32CD9A;
```

File

Graphics

Description

This is constant Graphics.clWebYellowGreen.

73.7.191 Graphics.clWhite Constant

Represents the color white.

Pascal

```
clWhite = TColor($FFFFFF);
```

C++

```
clWhite = TColor($FFFFFF);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to white. White is 100% intensity blue, green and red. White is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.192 Graphics.clWindow Constant

Represents the default Window background color.

Pascal

```
clWindow = TColor(clSystemColor or COLOR_WINDOW);
```

C++

```
clWindow = TColor(clSystemColor or COLOR_WINDOW);
```

File

Graphics

Description

clWindow is the default background color for a window.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.193 Graphics.clWindowFrame Constant

Represents the default Window frame background color.

Pascal

```
clWindowFrame = TColor(clSystemColor or COLOR_WINDOWFRAME);
```

C++

```
clWindowFrame = TColor(clSystemColor or COLOR_WINDOWFRAME);
```

File

Graphics

Description

clWindowFrame is the default background color for a window frame.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.194 Graphics.clWindowText Constant

Represents the default Window text color.

Pascal

```
clWindowText = TColor(clSystemColor or COLOR_WINDOWTEXT);
```

C++

```
clWindowText = TColor(clSystemColor or COLOR_WINDOWTEXT);
```

File

Graphics

Description

clWindowText is the default color for window text.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.195 Graphics.clYellow Constant

Represents the color yellow.

Pascal

```
clYellow = TColor($00FFFF);
```

C++

```
clYellow = TColor($00FFFF);
```

File

Graphics

Description

Use the Color property of a visual component to set its principle color to yellow. Yellow is 100% green, 100% red and 0% blue. Yellow is a standard color.

See Also

Color (see page 14437)

TColor (see page 14648)

73.7.196 Graphics.cmBlackness Constant

TCopyMode (see page 14650) value : fills the destination rectangle on the canvas with black.

Pascal

```
cmBlackness = BLACKNESS;
```

C++

```
cmBlackness = BLACKNESS;
```

File

Graphics

Description

cmBlackness is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

cmBlackness results in the destination rectangle on the canvas simply being filled with the clBlack (see page 14666) color.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.197 Graphics.cmDstInvert Constant

TCopyMode (see page 14650) value : inverts the image on the canvas and ignores the source.

Pascal

```
cmDstInvert = DSTINVERT;
```

C++

```
cmDstInvert = DSTINVERT;
```

File

Graphics

Description

cmDstInvert is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

cmDstInvert results in the the bits of each pixel in destination rectangle on the canvas simply being inverted. The source rectangle is ignored.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.198 Graphics.cmMergeCopy Constant

TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean AND operator.

Pascal

```
cmMergeCopy = MERGECOPY;
```

C++

```
cmMergeCopy = MERGECOPY;
```

File

Graphics

Description

cmMergeCopy is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

cmMergeCopy results in the pixels in the source and destination rectangles being logically ANDed. For example, a green pixel in the source will merge with a blue destination pixel to result in a cyan pixel.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.199 Graphics.cmMergePaint Constant

TCopyMode (see page 14650) value : combines the inverted source bitmap with the image on the canvas by using the Boolean OR operator.

Pascal

```
cmMergePaint = MERGEPAINT;
```

C++

```
cmMergePaint = MERGEPAINT;
```

File

Graphics

Description

cmMergePaint is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

With cmMergePaint, the source pixels are inverted before being logically ORed with the destination pixels.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.200 Graphics.cmNotSrcCopy Constant

TCopyMode (see page 14650) value : copies the inverted source bitmap to the canvas.

Pascal

```
cmNotSrcCopy = NOTSRCCOPY;
```

C++

```
cmNotSrcCopy = NOTSRCCOPY;
```

File

Graphics

Description

cmNotSrcCopy is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

With cmNotSrcCopy, the source pixels are inverted before being written to the target rectangle. The existing target rectangle contents are ignored and overwritten.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.201 Graphics.cmNotSrcErase Constant

TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean OR operator, and inverts the result.

Pascal

```
cmNotSrcErase = NOTSRCERASE;
```

C++

```
cmNotSrcErase = NOTSRCERASE;
```

File

Graphics

Description

cmNotSrcErase is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

With cmNotSrcErase, the source and destination pixels are ORed together and the result inverted and stored in the target rectangle.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.202 Graphics.cmPatCopy Constant

TCopyMode (see page 14650) value : copies the source pattern to the canvas.

Pascal

```
cmPatCopy = PATCOPY;
```

C++

```
cmPatCopy = PATCOPY;
```

File

Graphics

Description

cmPatCopy is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

With cmPatCopy, the source pattern is written to the target rectangle.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.203 Graphics.cmPatInvert Constant

TCopyMode (see page 14650) value : combines the source pattern with the image on the canvas using the Boolean XOR operator.

Pascal

```
cmPatInvert = PATINVERT;
```

C++

```
cmPatInvert = PATINVERT;
```

File

Graphics

Description

cmPatInvert is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

cmPatInvert, XORs each source pattern pixel with the target image pixels.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.204 Graphics.cmPatPaint Constant

TCopyMode (see page 14650) value : combines the inverted source bitmap with the source pattern by using the Boolean OR operator. Combines the result of this operation with the image on the canvas by using the Boolean OR operator.

Pascal

```
cmPatPaint = PATPAINT;
```

C++

```
cmPatPaint = PATPAINT;
```

File

Graphics

Description

cmPatPaint is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

With cmPatPaint, the source pattern and inverted bitmap pixels are ORed before ORing the resulting pixels with the target image pixels.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.205 Graphics.cmSrcAnd Constant

TCopyMode (see page 14650) value : combines the image on the canvas and source bitmap by using the Boolean AND operator.

Pascal

```
cmSrcAnd = SRCAND;
```

C++

```
cmSrcAnd = SRCAND;
```

File

Graphics

Description

cmSrcAnd is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

With cmSrcAnd, the source pixels are ANDed with the target target pixels.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.206 Graphics.cmSrcCopy Constant

TCopyMode (see page 14650) value : copies the source bitmap to the canvas.

Pascal

```
cmSrcCopy = SRCCOPY;
```

C++

```
cmSrcCopy = SRCCOPY;
```

File

Graphics

Description

cmSrcCopy is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

With cmSrcCopy, the source pixels are written unchanged to the target rectangle.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.207 Graphics.cmSrcErase Constant

TCopyMode (see page 14650) value : inverts the image on the canvas and combines the result with the source bitmap by using the Boolean AND operator.

Pascal

```
cmSrcErase = SRCERASE;
```

C++

```
cmSrcErase = SRCERASE;
```

File

Graphics

Description

cmSrcErase is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

With cmSrcErase, the source pixels are ANDed with the inverted target pixels.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.208 Graphics.cmSrcInvert Constant

TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean XOR operator.

Pascal

```
cmSrcInvert = SRCINVERT;
```

C++

```
cmSrcInvert = SRCINVERT;
```

File

Graphics

Description

cmSrcInvert is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

With cmSrcInvert, the source pixels are XORed with the target pixels.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.209 Graphics.cmSrcPaint Constant

TCopyMode (see page 14650) value : combines the image on the canvas and the source bitmap by using the Boolean OR operator.

Pascal

```
cmSrcPaint = SRCPAINT;
```

C++

```
cmSrcPaint = SRCPAINT;
```

File

Graphics

Description

cmSrcPaint is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

With cmSrcPaint, the source pixels are ORed with the target pixels.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.210 Graphics.cmWhiteness Constant

TCopyMode (see page 14650) value : fills the destination rectangle on the canvas with white.

Pascal

```
cmWhiteness = WHITENESS;
```

C++

```
cmWhiteness = WHITENESS;
```

File

Graphics

Description

cmWhiteness is a TCopyMode (see page 14650) value used in the TCanvas (see page 14441) CopyMode property.

The CopyMode property is used by the CopyRect routine when copying an image from another canvas onto the current canvas.

cmWhiteness results in the destination rectangle on the canvas simply being filled with the clWhite (see page 14732) color.

See Also

CopyMode (see page 14487)

CopyRect (see page 14452)

TCopyMode (see page 14650)

73.7.211 Graphics.ExtendedColorsCount Constant

The total number of extended colors available

Pascal

```
ExtendedColorsCount = 4;
```

C++

```
ExtendedColorsCount = 4;
```

File

Graphics

Description

TColor (see page 14648) can be assigned standard, extended, web and system color values. The system colors are default values for various visual component colors. Extended colors are :

Name	Meaning
clMoneyGreen (see page 14680)	Money Green.
clSkyBlue (see page 14684)	Sky blue.
clCream (see page 14669)	Cream.
clMedGray (see page 14678)	Medium Gray.

See Also

Color (see page 14437)

StandardColorsCount (see page 14744)

WebColorsCount (see page 14745)

TColor (see page 14648)

73.7.212 Graphics.rc3_Cursor Constant

Pascal

```
rc3_Cursor = 2;
```

C++

```
rc3_Cursor = 2;
```

File

Graphics

Description

This is constant Graphics.rc3_Cursor.

73.7.213 Graphics.rc3_Icon Constant

Pascal

```
rc3_Icon = 1;
```

C++

```
rc3_Icon = 1;
```

File

Graphics

Description

This is constant Graphics.rc3_Icon.

73.7.214 Graphics.rc3_StockIcon Constant

Pascal

```
rc3_StockIcon = 0;
```

C++

```
rc3_StockIcon = 0;
```

File

Graphics

Description

This is constant Graphics.rc3_StockIcon.

73.7.215 Graphics.StandardColorsCount Constant

The total number of standard colors available

Pascal

```
StandardColorsCount = 16;
```

C++

```
StandardColorsCount = 16;
```

File

Graphics

Description

TColor (see page 14648) can be assigned standard, extended, web and system color values. The system colors are default values for various visual component colors. Extended colors include clCream (see page 14669). The standard colors are :

Name	Meaning
clBlack (see page 14666)	Black.
clMaroon (see page 14678)	Maroon.
clOlive (see page 14682)	Olive.
clNavy (see page 14681)	Navy.
clPurple (see page 14682)	Purple.
clTeal (see page 14685)	Teal.
clGray (see page 14672)	Gray.
clSilver (see page 14683)	Silver.
clRed (see page 14683)	Red.
clLime (see page 14677)	Lime.
clYellow (see page 14734)	Yellow.
clBlue (see page 14666)	Blue.
clFuchsia (see page 14670)	Fuchsia.
clAqua (see page 14665)	Aqua (cyan).
clLtGray (see page 14677)	Light Gray.
clDkGray (see page 14670)	Dark Gray.
clWhite (see page 14732)	White.

See Also

Color (see page 14437)

ExtendedColorsCount (see page 14742)

WebColorsCount (see page 14745)

TColor (see page 14648)

73.7.216 Graphics.WebColorsCount Constant

The total number of web colors available

Pascal

```
WebColorsCount = 140;
```

C++

```
WebColorsCount = 140;
```

File

Graphics

Description

TColor (see page 14648) can be assigned standard, extended, web and system color values. The system colors are default values for various visual component colors. Web colors are those defined as uniformly displayable across the Internet - they represent the Internet standard colors.

See Also

Color (see page 14437)

ExtendedColorsCount (see page 14742)

StandardColorsCount (see page 14744)

TColor (see page 14648)

74 GraphUtil Namespace

This is namespace GraphUtil.

Topics

Name	Description
Functions (see page 14749)	The following table lists functions in this documentation.

Constants

Name	Description
WebNamedColors (see page 14760)	This is constant GraphUtil.WebNamedColors.
WebNamedColorsCount (see page 14762)	This is constant GraphUtil.WebNamedColorsCount.

Functions

	Name	Description
	ColorAdjustLuma (see page 14749)	This is function GraphUtil.ColorAdjustLuma.
	ColorHLSToRGB (see page 14749)	This is function GraphUtil.ColorHLSToRGB.
	ColorRGBToHLS (see page 14750)	This is function GraphUtil.ColorRGBToHLS.
	ColorToWebColorName (see page 14750)	This is function GraphUtil.ColorToWebColorName.
	ColorToWebColorStr (see page 14750)	This is function GraphUtil.ColorToWebColorStr.
	DrawArrow (see page 14751)	This is function GraphUtil.DrawArrow.
	DrawCheck (see page 14751)	This is function GraphUtil.DrawCheck.
	DrawChevron (see page 14751)	This is function GraphUtil.DrawChevron.
	GetHighLightColor (see page 14752)	This is function GraphUtil.GetHighLightColor.
	GetShadowColor (see page 14752)	This is function GraphUtil.GetShadowColor.
	GradientFillCanvas (see page 14752)	This is function GraphUtil.GradientFillCanvas.
	RGBToWebColorName (see page 14753)	This is function GraphUtil.RGBToWebColorName.
	RGBToWebColorStr (see page 14753)	This is function GraphUtil.RGBToWebColorStr.
	ScaleImage (see page 14753)	This is function GraphUtil.ScaleImage.
	SortColorArray (see page 14754)	This is function GraphUtil.SortColorArray.
	WebColorNameToColor (see page 14754)	This is function GraphUtil.WebColorNameToColor.
	WebColorStrToColor (see page 14754)	This is function GraphUtil.WebColorStrToColor.
	WebColorToRGB (see page 14755)	This is function GraphUtil.WebColorToRGB.

Structs, Records, Enums

	Name	Description
	TArrowType (see page 14756)	This is record GraphUtil.TArrowType.
	TColorArraySortType (see page 14756)	This is record GraphUtil.TColorArraySortType.
	TGradientDirection (see page 14757)	This is record GraphUtil.TGradientDirection.
	TScrollDirection (see page 14757)	This is record GraphUtil.TScrollDirection.

Types

Name	Description
TColorArray (see page 14759)	This is type GraphUtil.TColorArray.

74.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	ColorAdjustLuma (see page 14749)	This is function GraphUtil.ColorAdjustLuma.
	ColorHLSToRGB (see page 14749)	This is function GraphUtil.ColorHLSToRGB.
	ColorRGBToHLS (see page 14750)	This is function GraphUtil.ColorRGBToHLS.
	ColorToWebColorName (see page 14750)	This is function GraphUtil.ColorToWebColorName.
	ColorToWebColorStr (see page 14750)	This is function GraphUtil.ColorToWebColorStr.
	DrawArrow (see page 14751)	This is function GraphUtil.DrawArrow.
	DrawCheck (see page 14751)	This is function GraphUtil.DrawCheck.
	DrawChevron (see page 14751)	This is function GraphUtil.DrawChevron.
	GetHighLightColor (see page 14752)	This is function GraphUtil.GetHighLightColor.
	GetShadowColor (see page 14752)	This is function GraphUtil.GetShadowColor.
	GradientFillCanvas (see page 14752)	This is function GraphUtil.GradientFillCanvas.
	RGBToWebColorName (see page 14753)	This is function GraphUtil.RGBToWebColorName.
	RGBToWebColorStr (see page 14753)	This is function GraphUtil.RGBToWebColorStr.
	ScaleImage (see page 14753)	This is function GraphUtil.ScaleImage.
	SortColorArray (see page 14754)	This is function GraphUtil.SortColorArray.
	WebColorNameToColor (see page 14754)	This is function GraphUtil.WebColorNameToColor.
	WebColorStrToColor (see page 14754)	This is function GraphUtil.WebColorStrToColor.
	WebColorToRGB (see page 14755)	This is function GraphUtil.WebColorToRGB.

74.1.1 GraphUtil.ColorAdjustLuma Function

Pascal

```
function ColorAdjustLuma(clrRGB: TColor; n: Integer; fScale: BOOL): TColor;
```

C++

```
TColor ColorAdjustLuma(TColor clrRGB, int n, BOOL fScale);
```

File

GraphUtil

Description

This is function GraphUtil.ColorAdjustLuma.

74.1.2 GraphUtil.ColorHLSToRGB Function

Pascal

```
function ColorHLSToRGB(Hue: Word; Luminance: Word; Saturation: Word): TColorRef;
```

C++

```
TColorRef ColorHLSToRGB(Word Hue, Word Luminance, Word Saturation);
```

File

GraphUtil

Description

This is function GraphUtil.ColorHLSToRGB.

74.1.3 GraphUtil.ColorRGBToHLS Function

Pascal

```
procedure ColorRGBToHLS(clrRGB: TColorRef; var Hue: Word; var Luminance: Word; var Saturation:
Word);
```

C++

```
ColorRGBToHLS(TColorRef clrRGB, Word Hue, Word Luminance, Word Saturation);
```

File

GraphUtil

Description

This is function GraphUtil.ColorRGBToHLS.

74.1.4 GraphUtil.ColorToWebColorName Function

Pascal

```
function ColorToWebColorName(Color: TColor): string;
```

C++

```
AnsiString ColorToWebColorName(TColor Color);
```

File

GraphUtil

Description

This is function GraphUtil.ColorToWebColorName.

74.1.5 GraphUtil.ColorToWebColorStr Function

Pascal

```
function ColorToWebColorStr(Color: TColor): string;
```

C++

```
AnsiString ColorToWebColorStr(TColor Color);
```

File

GraphUtil

Description

This is function GraphUtil.ColorToWebColorStr.

74.1.6 GraphUtil.DrawArrow Function

Pascal

```
procedure DrawArrow(ACanvas: TCanvas; Direction: TScrollDirection; Location: TPoint; Size:
Integer);
```

C++

```
DrawArrow(TCanvas ACanvas, TScrollDirection Direction, TPoint Location, int Size);
```

File

GraphUtil

Description

This is function GraphUtil.DrawArrow.

74.1.7 GraphUtil.DrawCheck Function

Pascal

```
procedure DrawCheck(ACanvas: TCanvas; Location: TPoint; Size: Integer; Shadow: Boolean = True);
```

C++

```
DrawCheck(TCanvas ACanvas, TPoint Location, int Size, Boolean Shadow = True);
```

File

GraphUtil

Description

This is function GraphUtil.DrawCheck.

74.1.8 GraphUtil.DrawChevron Function

Pascal

```
procedure DrawChevron(ACanvas: TCanvas; Direction: TScrollDirection; Location: TPoint; Size:
Integer);
```

C++

```
DrawChevron(TCanvas ACanvas, TScrollDirection Direction, TPoint Location, int Size);
```

File

GraphUtil

Description

This is function GraphUtil.DrawChevron.

74.1.9 GraphUtil.GetHighLightColor Function

Pascal

```
function GetHighLightColor(const Color: TColor; Luminance: Integer = 19): TColor;
```

C++

```
TColor GetHighLightColor(const TColor Color, int Luminance = 19);
```

File

GraphUtil

Description

This is function GraphUtil.GetHighLightColor.

74.1.10 GraphUtil.GetShadowColor Function

Pascal

```
function GetShadowColor(const Color: TColor; Luminance: Integer = -50): TColor;
```

C++

```
TColor GetShadowColor(const TColor Color, int Luminance = -50);
```

File

GraphUtil

Description

This is function GraphUtil.GetShadowColor.

74.1.11 GraphUtil.GradientFillCanvas Function

Pascal

```
procedure GradientFillCanvas(const ACanvas: TCanvas; const AStartColor: TColor; const
AEndColor: TColor; const ARect: TRect; const Direction: TGradientDirection);
```

C++

```
GradientFillCanvas(const TCanvas ACanvas, const TColor AStartColor, const TColor AEndColor,
const TRect ARect, const TGradientDirection Direction);
```

File

GraphUtil

Description

This is function GraphUtil.GradientFillCanvas.

74.1.12 GraphUtil.RGBToWebColorName Function

Pascal

```
function RGBToWebColorName(RGB: Integer): string;
```

C++

```
AnsiString RGBToWebColorName(int RGB);
```

File

GraphUtil

Description

This is function GraphUtil.RGBToWebColorName.

74.1.13 GraphUtil.RGBToWebColorStr Function

Pascal

```
function RGBToWebColorStr(RGB: Integer): string;
```

C++

```
AnsiString RGBToWebColorStr(int RGB);
```

File

GraphUtil

Description

This is function GraphUtil.RGBToWebColorStr.

74.1.14 GraphUtil.ScaleImage Function

Pascal

```
procedure ScaleImage(const SourceBitmap: TBitmap; const ResizedBitmap: TBitmap; const
ScaleAmount: Double);
```

C++

```
ScaleImage(const TBitmap SourceBitmap, const TBitmap ResizedBitmap, const Double ScaleAmount);
```

File

GraphUtil

Description

This is function GraphUtil.ScaleImage.

74.1.15 GraphUtil.SortColorArray Function

Pascal

```
procedure SortColorArray(ColorArray: TColorArray; L: Integer; R: Integer; SortType:
TColorArraySortType; Reverse: Boolean = False);
```

C++

```
SortColorArray(TColorArray ColorArray, int L, int R, TColorArraySortType SortType, Boolean
Reverse = False);
```

File

GraphUtil

Description

This is function GraphUtil.SortColorArray.

74.1.16 GraphUtil.WebColorNameToColor Function

Pascal

```
function WebColorNameToColor(WebColorName: string): TColor;
```

C++

```
TColor WebColorNameToColor(AnsiString WebColorName);
```

File

GraphUtil

Description

This is function GraphUtil.WebColorNameToColor.

74.1.17 GraphUtil.WebColorStrToColor Function

Pascal

```
function WebColorStrToColor(WebColor: string): TColor;
```

C++

```
TColor WebColorStrToColor(AnsiString WebColor);
```

File

GraphUtil

Description

This is function GraphUtil.WebColorStrToColor.

74.1.18 GraphUtil.WebColorToRGB Function

Pascal

```
function WebColorToRGB(WebColor: Integer): Integer;
```

C++

```
int WebColorToRGB(int WebColor);
```

File

GraphUtil

Description

This is function GraphUtil.WebColorToRGB.

74.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TArrowType (see page 14756)	This is record GraphUtil.TArrowType.
	TColorArraySortType (see page 14756)	This is record GraphUtil.TColorArraySortType.
	TGradientDirection (see page 14757)	This is record GraphUtil.TGradientDirection.
	TScrollDirection (see page 14757)	This is record GraphUtil.TScrollDirection.

74.2.1 GraphUtil.TArrowType Enumeration

Pascal

```
TArrowType = (
  atSolid,
  atArrows
);
```

C++

```
enum TArrowType {
  atSolid,
  atArrows
};
```

File

GraphUtil

Description

This is record GraphUtil.TArrowType.

74.2.2 GraphUtil.TColorArraySortType Enumeration

Pascal

```
TColorArraySortType = (
  stHue,
  stSaturation,
  stLuminance,
  stRed,
  stGreen,
  stBlue,
  stCombo
);
```

C++

```
enum TColorArraySortType {
  stHue,
  stSaturation,
```

```
    stLuminance,
    stRed,
    stGreen,
    stBlue,
    stCombo
  };
```

File

GraphUtil

Description

This is record GraphUtil.TColorArraySortType.

74.2.3 GraphUtil.TGradientDirection Enumeration

Pascal

```
  TGradientDirection = (
    gdHorizontal,
    gdVertical
  );
```

C++

```
  enum TGradientDirection {
    gdHorizontal,
    gdVertical
  };
```

File

GraphUtil

Description

This is record GraphUtil.TGradientDirection.

74.2.4 GraphUtil.TScrollDirection Enumeration

Pascal

```
  TScrollDirection = (
    sdLeft,
    sdRight,
    sdUp,
    sdDown
  );
```

C++

```
  enum TScrollDirection {
    sdLeft,
    sdRight,
    sdUp,
    sdDown
  };
```

File

GraphUtil

Description

This is record GraphUtil.TScrollDirection.

74.3 Types

The following table lists types in this documentation.

Types

Name	Description
TColorArray (see page 14759)	This is type GraphUtil.TColorArray.

74.3.1 GraphUtil.TColorArray Type

Pascal

```
TColorArray = array of TIdentMapEntry;
```

C++

```
array of TIdentMapEntry TColorArray;
```

File

GraphUtil

Description

This is type GraphUtil.TColorArray.

74.4 Constants

The following table lists constants in this documentation.

Constants

Name	Description
WebNamedColors (see page 14760)	This is constant GraphUtil.WebNamedColors.
WebNamedColorsCount (see page 14762)	This is constant GraphUtil.WebNamedColorsCount.

74.4.1 GraphUtil.WebNamedColors Constant

Pascal

```
WebNamedColors: array[0..WebNamedColorsCount - 1] of TIdentMapEntry = ( (Value: clWebSnow;
Name: 'clWebSnow'), (Value: clWebFloralWhite; Name: 'clWebFloralWhite'), (Value:
clWebLavenderBlush; Name: 'clWebLavenderBlush'), (Value: clWebOldLace; Name: 'clWebOldLace'),
(Value: clWebIvory; Name: 'clWebIvory'), (Value: clWebCornSilk; Name: 'clWebCornSilk'),
(Value: clWebBeige; Name: 'clWebBeige'), (Value: clWebAntiqueWhite; Name:
'clWebAntiqueWhite'), (Value: clWebWheat; Name: 'clWebWheat'), (Value: clWebAliceBlue; Name:
'clWebAliceBlue'), (Value: clWebGhostWhite; Name: 'clWebGhostWhite'), (Value: clWebLavender;
Name: 'clWebLavender'), (Value: clWebSeashell; Name: 'clWebSeashell'), (Value:
clWebLightYellow; Name: 'clWebLightYellow'), (Value: clWebPapayaWhip; Name:
'clWebPapayaWhip'), (Value: clWebNavajoWhite; Name: 'clWebNavajoWhite'), (Value:
clWebMoccasin; Name: 'clWebMoccasin'), (Value: clWebBurlywood; Name: 'clWebBurlywood'),
(Value: clWebAzure; Name: 'clWebAzure'), (Value: clWebMintcream; Name: 'clWebMintcream'),
(Value: clWebHoneydew; Name: 'clWebHoneydew'), (Value: clWebLinen; Name: 'clWebLinen'),
(Value: clWebLemonChiffon; Name: 'clWebLemonChiffon'), (Value: clWebBlanchedAlmond; Name:
'clWebBlanchedAlmond'), (Value: clWebBisque; Name: 'clWebBisque'), (Value: clWebPeachPuff;
Name: 'clWebPeachPuff'), (Value: clWebTan; Name: 'clWebTan'), (Value: clWebYellow; Name:
'clWebYellow'), (Value: clWebDarkOrange; Name: 'clWebDarkOrange'), (Value: clWebRed; Name:
'clWebRed'), (Value: clWebDarkRed; Name: 'clWebDarkRed'), (Value: clWebMaroon; Name:
'clWebMaroon'), (Value: clWebIndianRed; Name: 'clWebIndianRed'), (Value: clWebSalmon; Name:
'clWebSalmon'), (Value: clWebCoral; Name: 'clWebCoral'), (Value: clWebGold; Name:
'clWebGold'), (Value: clWebTomato; Name: 'clWebTomato'), (Value: clWebCrimson; Name:
'clWebCrimson'), (Value: clWebBrown; Name: 'clWebBrown'), (Value: clWebChocolate; Name:
'clWebChocolate'), (Value: clWebSandyBrown; Name: 'clWebSandyBrown'), (Value:
clWebLightSalmon; Name: 'clWebLightSalmon'), (Value: clWebLightCoral; Name:
'clWebLightCoral'), (Value: clWebOrange; Name: 'clWebOrange'), (Value: clWebOrangeRed; Name:
'clWebOrangeRed'), (Value: clWebFirebrick; Name: 'clWebFirebrick'), (Value: clWebSaddleBrown;
Name: 'clWebSaddleBrown'), (Value: clWebSienna; Name: 'clWebSienna'), (Value: clWebPeru; Name:
'clWebPeru'), (Value: clWebDarkSalmon; Name: 'clWebDarkSalmon'), (Value: clWebRosyBrown; Name:
'clWebRosyBrown'), (Value: clWebPaleGoldenrod; Name: 'clWebPaleGoldenrod'), (Value:
clWebLightGoldenrodYellow; Name: 'clWebLightGoldenrodYellow'), (Value: clWebOlive; Name:
'clWebOlive'), (Value: clWebForestGreen; Name: 'clWebForestGreen'), (Value: clWebGreenYellow;
Name: 'clWebGreenYellow'), (Value: clWebChartreuse; Name: 'clWebChartreuse'), (Value:
clWebLightGreen; Name: 'clWebLightGreen'), (Value: clWebAquamarine; Name: 'clWebAquamarine'),
(Value: clWebSeaGreen; Name: 'clWebSeaGreen'), (Value: clWebGoldenRod; Name:
'clWebGoldenRod'), (Value: clWebKhaki; Name: 'clWebKhaki'), (Value: clWebOliveDrab; Name:
'clWebOliveDrab'), (Value: clWebGreen; Name: 'clWebGreen'), (Value: clWebYellowGreen; Name:
'clWebYellowGreen'), (Value: clWebLawnGreen; Name: 'clWebLawnGreen'), (Value: clWebPaleGreen;
Name: 'clWebPaleGreen'), (Value: clWebMediumAquamarine; Name: 'clWebMediumAquamarine'),
(Value: clWebMediumSeaGreen; Name: 'clWebMediumSeaGreen'), (Value: clWebDarkGoldenRod; Name:
'clWebDarkGoldenRod'), (Value: clWebDarkKhaki; Name: 'clWebDarkKhaki'), (Value:
clWebDarkOliveGreen; Name: 'clWebDarkOliveGreen'), (Value: clWebDarkgreen; Name:
'clWebDarkgreen'), (Value: clWebLimeGreen; Name: 'clWebLimeGreen'), (Value: clWebLime; Name:
'clWebLime'), (Value: clWebSpringGreen; Name: 'clWebSpringGreen'), (Value:
```

```
clWebMediumSpringGreen; Name: 'clWebMediumSpringGreen'), (Value: clWebDarkSeaGreen; Name:
'clWebDarkSeaGreen'), (Value: clWebLightSeaGreen; Name: 'clWebLightSeaGreen'), (Value:
clWebPaleTurquoise; Name: 'clWebPaleTurquoise'), (Value: clWebLightCyan; Name:
'clWebLightCyan'), (Value: clWebLightBlue; Name: 'clWebLightBlue'), (Value: clWebLightSkyBlue;
Name: 'clWebLightSkyBlue'), (Value: clWebCornFlowerBlue; Name: 'clWebCornFlowerBlue'), (Value:
clWebDarkBlue; Name: 'clWebDarkBlue'), (Value: clWebIndigo; Name: 'clWebIndigo'), (Value:
clWebMediumTurquoise; Name: 'clWebMediumTurquoise'), (Value: clWebTurquoise; Name:
'clWebTurquoise'), (Value: clWebCyan; Name: 'clWebCyan'), (Value: clWebPowderBlue; Name:
'clWebPowderBlue'), (Value: clWebSkyBlue; Name: 'clWebSkyBlue'), (Value: clWebRoyalBlue; Name:

File

GraphUtil

Description

This is constant GraphUtil.WebNamedColors.

74.4.2 GraphUtil.WebNamedColorsCount Constant

Pascal

```
WebNamedColorsCount = 138;
```

C++

```
WebNamedColorsCount = 138;
```

File

GraphUtil

Description

This is constant GraphUtil.WebNamedColorsCount.

75 Grids Namespace

This is namespace Grids.

Topics

Name	Description
Classes (see page 14767)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 14997)	The following table lists structs, records, enums in this documentation.
Types (see page 15003)	The following table lists types in this documentation.
Constants (see page 15009)	The following table lists constants in this documentation.

Classes

	Name	Description
	EInvalidGridOperation (see page 14767)	EInvalidGridOperation is the exception class for illegal grid operations.
	TCustomDrawGrid (see page 14768)	TCustomDrawGrid is the base class for grids that publish events for painting and manipulating the cells in the grid.
	TCustomGrid (see page 14800)	TCustomGrid is the base type for all components that present information in a two-dimensional grid.
	TDrawGrid (see page 14860)	TDrawGrid represents a grid control that displays information in column and row format.
	TInplaceEdit (see page 14938)	TInplaceEdit provides text editing capabilities for grid controls.
	TInplaceEditList (see page 14959)	This is class Grids.TInplaceEditList.
	TStringGrid (see page 14968)	TStringGrid represents a grid control designed to simplify the handling of strings and associated objects.
	TStringGridStrings (see page 14988)	TStringGridStrings maintains a list of the strings that appear in the cells of a string grid.

Constants

Name	Description
MaxCustomExtents (see page 15009)	This is constant Grids.MaxCustomExtents.
MaxShortInt (see page 15009)	This is constant Grids.MaxShortInt.

Structs, Records, Enums

	Name	Description
	TEditStyle (see page 14997)	TEditStyle indicates whether a cell in a grid contains a drop-down arrow or ellipsis button.
	TGridAxisDrawInfo (see page 14998)	TGridAxisDrawInfo and TGridDrawInfo (see page 14999) represent information that is useful when rendering a grid.
	TGridCoord (see page 14998)	TGridCoord specifies a cell in a grid control.

	TGridDrawInfo (see page 14999)	This is record Grids.TGridDrawInfo.
	TGridOption (see page 14999)	TGridOption and TGridOptions (see page 15005) customize the appearance and behavior of a grid control.
	TGridRect (see page 15001)	TGridRect specifies a set of cells that occupy a rectangular region in a grid control.
	TGridState (see page 15001)	TGridState indicates any user actions that are currently changing the layout of the grid.

Types

Name	Description
TDrawCellEvent (see page 15003)	Function type for OnDrawCell event.
TGetEditEvent (see page 15004)	TGetEditEvent is the type of the event handlers that provide strings for the inplace editor of a grid.
TGetExtentsFunc (see page 15004)	This is type Grids.TGetExtentsFunc.
TGridDrawState (see page 15004)	TGridDrawState represents information that is useful when rendering the cell of a grid.
TGridMovement (see page 15005)	This is type Grids.TGridMovement.
TGridOptions (see page 15005)	TGridOptions and TGridOption (see page 14999) customize the appearance and behavior of a grid control.
TGridScrollDirection (see page 15006)	TGridScrollDirection indicates the direction in which to scroll the cells of a grid control.
TMovedEvent (see page 15007)	This is type Grids.TMovedEvent.
TOnGetPickListItems (see page 15007)	This is type Grids.TOnGetPickListItems.
TSelectCellEvent (see page 15007)	This is type Grids.TSelectCellEvent.
TSetEditEvent (see page 15008)	TSetEditEvent is the type of the event handlers that assign strings to a cell in a grid.

75.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EInvalidGridOperation (see page 14767)	EInvalidGridOperation is the exception class for illegal grid operations.
	TCustomDrawGrid (see page 14768)	TCustomDrawGrid is the base class for grids that publish events for painting and manipulating the cells in the grid.
	TCustomGrid (see page 14800)	TCustomGrid is the base type for all components that present information in a two-dimensional grid.
	TDrawGrid (see page 14860)	TDrawGrid represents a grid control that displays information in column and row format.
	TInplaceEdit (see page 14938)	TInplaceEdit provides text editing capabilities for grid controls.
	TInplaceEditList (see page 14959)	This is class Grids.TInplaceEditList.
	TStringGrid (see page 14968)	TStringGrid represents a grid control designed to simplify the handling of strings and associated objects.
	TStringGridStrings (see page 14988)	TStringGridStrings maintains a list of the strings that appear in the cells of a string grid.

75.1.1 EInvalidGridOperation Class

EInvalidGridOperation is the exception class for illegal grid operations.

Class Hierarchy

Pascal

```
EInvalidGridOperation = class(Exception);
```

C++

```
class EInvalidGridOperation : public Exception;
```

File

Grids

Description

EInvalidGridOperation is raised when an application attempts an illegal operation on a grid. For example, EInvalidGridOperation is raised if an application tries to access a cell or column that does not exist within the grid.

See Also

TStringGrid (see page 14968)

TCustomGrid (see page 14800)

75.1.2 TCustomDrawGrid Class

TCustomDrawGrid is the base class for grids that publish events for painting and manipulating the cells in the grid.

Class Hierarchy

Pascal

```
TCustomDrawGrid = class(TCustomGrid);
```

C++

```
class TCustomDrawGrid : public TCustomGrid;
```

File

Grids

Description

Use TCustomDrawGrid as a base class when defining grid components that publish events for painting or manipulating the cells in the grid. TCustomDrawGrid introduces a number of events and methods that take advantage of the tabular organization of the grid in responding to user actions.

Do not create instances of TCustomDrawGrid. Instead, put a grid control in a form by instantiating a descendant of TCustomDrawGrid. Use TDrawGrid (see page 14860) to represent non-textual material in a tabular grid. For text, use a TStringGrid (see page 14968) object. If the text represents field values from a dataset, use TDBGrid. If you are displaying Name/Value pairs, use TValueListEditor.

See Also

TDrawGrid (see page 14860)

TStringGrid (see page 14968)

75.1.2.1 TCustomDrawGrid Members

The following tables list the members exposed by TCustomDrawGrid.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnColumnMoved (see page 14794)	Occurs immediately after the position of a column changes.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.

	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnDrawCell (see page 14795)	Occurs when a cell in the grid needs to be drawn.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetEditMask (see page 14796)	Occurs when the in-place editor requests an edit mask.
	OnGetEditText (see page 14797)	Occurs when the in-place editor requests the value of a cell.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnRowMoved (see page 14798)	Occurs immediately after the position of a row changes.
	OnSelectCell (see page 14798)	Occurs before a cell in the grid is selected.
	OnSetEditText (see page 14800)	Occurs when the user edits the value of a cell.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnTopLeftChanged (see page 14800)	Occurs immediately after the TopRow (see page 14793) property or the LeftCol (see page 14790) property changes.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	DesignOptionsBoost (see page 14814)	This is DesignOptionsBoost, a member of class TCustomGrid.
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FGridState (see page 14814)	This is FGridState, a member of class TCustomGrid.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.

	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.
	FSaveCellExtents (see page 14814)	This is FSaveCellExtents, a member of class TCustomGrid.
	VirtualView (see page 14814)	This is VirtualView, a member of class TCustomGrid.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AdjustSize (see page 14816)	Adds or deletes rows or columns from the grid.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	BeginColumnDrag (see page 14817)	Starts the dragging of a column in the grid.
	BeginRowDrag (see page 14817)	Starts the dragging of a row in the grid.
	BoxRect (see page 14818)	Returns the screen coordinates of a specified set of cells.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CalcDrawInfo (see page 14818)	Calculates the pixel locations of the grid boundaries.
	CalcFixedInfo (see page 14818)	Calculates the pixel locations of the fixed cells.
V	CalcSizingState (see page 14819)	Determines the appearance of the mouse cursor during resizing.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanEditAcceptKey (see page 14819)	Indicates whether the Key parameter can be entered into the current cell.
	CanEditModify (see page 14819)	Indicates whether the current cell in the grid can be edited.
V	CanEditShow (see page 14820)	Indicates whether the inplace edit control can be created to allow editing.
	CanGridAcceptKey (see page 14820)	Indicates whether the grid should respond to a given key combination.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeGridOrientation (see page 14821)	Prepares the grid's canvas for painting to reflect a right-to-left or left-to-right orientation.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	CheckColumnDrag (see page 14821)	CheckColumnDrag validates whether the column currently selected for dragging can be dropped at the current location.
	CheckRowDrag (see page 14822)	CheckRowDrag validates whether the row currently selected for dragging can be dropped at the current location.
	Click (see page 5743)	Respond to user click.
V	ColumnMoved (see page 14781)	Generates an OnColumnMoved (see page 14794) event.
	ColWidthsChanged (see page 14822)	Responds when the column widths change.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.

	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateEditor (see page 14823)	Creates the inplace editor control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
V	CreateParams (see page 14823)	Initializes the window-creation parameter record.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWnd (see page 6137)	Creates the underlying window.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
V	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
V	DefineProperties (see page 14824)	Adds the ColWidths (see page 14845) and RowHeights (see page 14855) properties to the values saved with the grid.
V	DeleteColumn (see page 14824)	Deletes a specified column from the grid.
V	DeleteRow (see page 14825)	Deletes a specified from the grid.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
V	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
V	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
V	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
V	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
V	DoExit (see page 14825)	Hides the inplace editor when selection moves to another control in a form.
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
V	DoMouseWheelDown (see page 14825)	Performs tasks when the mouse wheel is rotated downward.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
V	DoMouseWheelUp (see page 14826)	Performs tasks when the mouse wheel is rotated upward.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.

	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
V	DrawCell (see page 14782)	Generates an OnDrawCell (see page 14795) event.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EndColumnDrag (see page 14827)	Ends the dragging of a column in the grid.
	EndRowDrag (see page 14827)	Ends the dragging of a row in the grid.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	FocusCell (see page 14827)	Changes the current cell to a specified cell.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEditLimit (see page 14828)	Provides the interface for a method that limits the number of characters the user can type into cells.
V	GetEditMask (see page 14782)	Generates an OnGetEditMask (see page 14796) event.
	GetEditStyle (see page 14828)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
V	GetEditText (see page 14783)	Generates an OnGetEditText (see page 14797) event.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetGridHeight (see page 14829)	Returns the value of the GridHeight (see page 14850) property.
	GetGridWidth (see page 14830)	Returns the value of the GridWidth (see page 14851) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HideEdit (see page 14830)	Hides the inplace editor.
	HideEditor (see page 14830)	Hides the inplace editor when it is not in use.
	InvalidateCell (see page 14831)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.

	InvalidateCol (see page 14831)	Invalidates the region occupied by a column so that it will be repainted with the next Windows paint message.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	InvalidateEditor (see page 14832)	Causes the inplace editor to repaint itself, moving to a new location if necessary.
	InvalidateGrid (see page 14832)	Tells Windows to repaint the grid after other important Windows messages are handled.
	InvalidateRow (see page 14832)	Invalidates the region occupied by a row so that it will be repainted with the next Windows paint message.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
V	KeyDown (see page 14833)	Provides special processing when the user presses a key.
	KeyPress (see page 6163)	Respond to keyboard input.
V	KeyPress (see page 14833)	Provides special processing when the user presses a key.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
V	MouseDown (see page 14834)	Provides special processing when the user presses a mouse button.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
V	MouseMove (see page 14834)	Provides special processing when the user moves the mouse.
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	MouseUp (see page 14835)	Provides special processing when the user releases the mouse button.
	MoveColRow (see page 14835)	Selects the cell indicated by the ACol and ARow parameters.
	MoveColumn (see page 14836)	Moves a column to a new position.
	MoveRow (see page 14836)	Moves a row to a new position.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 5920)	Renders the image of a custom control.
V	Paint (see page 14836)	Draws the image of the grid control on the screen.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.

	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	RowHeightsChanged (see page 14837)	Responds when the row heights change.
V	RowMoved (see page 14783)	Generates an OnRowMoved (see page 14798) event.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	ScrollData (see page 14838)	Scrolls the visual image of the cells in the grid.
V	SelectCell (see page 14784)	Determines whether a particular cell in the grid can be selected.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEditText (see page 14784)	Generates an OnSetEditText (see page 14800) event.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	ShowEditor (see page 14839)	Displays the inplace editor when the grid enters edit mode.
	ShowEditorChar (see page 14839)	Displays the inplace editor, with its text set to the specified character.
	SizeChanged (see page 14840)	Responds to changes in the size of the grid.
	Sizing (see page 14840)	Indicates whether the indicated coordinates are on one of the resize hot zones of the graph.
	TimedScroll (see page 14840)	Extends a move, resize, or selection out of the scrollable region when the user drags the mouse in a direction where the grid is scrolled.
V	TopLeftChanged (see page 14784)	Generates an OnTopLeftChanged (see page 14800) event.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.

	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateDesigner (see page 14841)	Notifies the designer when rows and columns of the grid are moved or resized.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderStyle (see page 14843)	Determines whether a single line border is drawn around the grid.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	ColCount (see page 14844)	Specifies the number of columns in the grid.
	Color (see page 5812)	Specifies the background color of the control.
	Color (see page 14844)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultColWidth (see page 14846)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 14847)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 14847)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	FixedColor (see page 14848)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 14848)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	FixedRows (see page 14849)	Specifies the number of rows on the top of the grid that cannot be scrolled.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	GridLineWidth (see page 14850)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
R	HitTest (see page 14851)	Indicates the current position of the mouse cursor.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

R	InplaceEditor (see page 14852)	Designates the edit control the grid uses to allow users to edit the contents of the selected cell.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	Options (see page 14853)	Specifies various display and behavioral properties of the grid.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentColor (see page 14853)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	RowCount (see page 14854)	Specifies the number of rows in the grid.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	ScrollBars (see page 14856)	Specifies whether the grid includes horizontal and vertical scroll bars.
	Text (see page 5842)	Contains a text string associated with the control.
R	VisibleColCount (see page 14859)	Indicates the number of scrollable columns visible in the grid.
R	VisibleRowCount (see page 14859)	Indicates the number of scrollable rows visible in the grid.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	CellRect (see page 14781)	Returns the screen coordinates of a cell in the grid.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 5731)	Creates an instance of TControl (see page 5724).

	Create (see page 5918)	Creates an instance of TCustomControl (see page 5908).
	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
	Create (see page 14813)	Creates an instance of TCustomGrid (see page 14800).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
	Destroy (see page 5919)	Destroys an instance of TCustomControl (see page 5908).
	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
	Destroy (see page 14813)	Destroys an instance of TCustomGrid (see page 14800).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.

	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseCoord (see page 14834)	Returns the row and column indexes of the cell that contains a point specified in screen coordinates.
	MouseToCell (see page 14783)	Returns the column and row of the cell at the position with screen coordinates (X,Y).
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.

V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	Canvas (see page 14785)	Specifies the TCanvas object that presents a drawing surface for the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
	Col (see page 14787)	Specifies the index of the column that contains the selected cell.
	ColWidths (see page 14788)	Indicates the width (in pixels) of all the columns in the grid.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

	EditorMode (see page 14789)	Determines whether the current cell can be edited.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	GridHeight (see page 14789)	Specifies the height of the grid in pixels.
	GridWidth (see page 14789)	Specifies the width of the grid in pixels.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LeftCol (see page 14790)	Specifies the index of the first visible scrollable column in the grid.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	Row (see page 14790)	Specifies the index of the row that contains the selected cell.
	RowHeights (see page 14791)	Gives the height (in pixels) of all rows in the grid.
	Selection (see page 14791)	Indicates the boundaries of the current selection.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TabStops (see page 14793)	Indicates whether the user can tab to specified columns in the grid.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TopRow (see page 14793)	Specifies the index of the first visible scrollable row in the grid.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.

	Name (see page 2805)	Specifies the name of the component as referenced in code.
	TabStop (see page 14857)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

75.1.2.2 TCustomDrawGrid Methods

The methods of the TCustomDrawGrid class are listed here.

Protected Methods

	Name	Description
	ColumnMoved (see page 14781)	Generates an OnColumnMoved (see page 14794) event.
	DrawCell (see page 14782)	Generates an OnDrawCell (see page 14795) event.
	GetEditMask (see page 14782)	Generates an OnGetEditMask (see page 14796) event.
	GetEditText (see page 14783)	Generates an OnGetEditText (see page 14797) event.
	RowMoved (see page 14783)	Generates an OnRowMoved (see page 14798) event.
	SelectCell (see page 14784)	Determines whether a particular cell in the grid can be selected.
	SetEditText (see page 14784)	Generates an OnSetEditText (see page 14800) event.
	TopLeftChanged (see page 14784)	Generates an OnTopLeftChanged (see page 14800) event.

Public Methods

	Name	Description
	CellRect (see page 14781)	Returns the screen coordinates of a cell in the grid.
	MouseToCell (see page 14783)	Returns the column and row of the cell at the position with screen coordinates (X,Y).

75.1.2.2.1 TCustomDrawGrid.CellRect Method

Returns the screen coordinates of a cell in the grid.

Pascal

```
function CellRect(ACol: Longint; ARow: Longint): TRect;
```

C++

```
__fastcall TRect CellRect(Longint ACol, Longint ARow);
```

Description

Call CellRect to obtain the boundaries, in pixels, of the cell in the column and row indicated by the ACol and ARow parameters. The top left cell is specified when ACol and ARow are set to zero.

If the indicated cell is not visible, CellRect returns an empty rectangle.

See Also

MouseToCell (see page 14783)

75.1.2.2.2 TCustomDrawGrid.ColumnMoved Method

Generates an OnColumnMoved (see page 14794) event.

Pascal

```
procedure ColumnMoved(FromIndex: Longint; ToIndex: Longint); override;
```

C++

```
virtual __fastcall ColumnMoved(Longint FromIndex, Longint ToIndex);
```

Description

ColumnMoved is called immediately after a column in the grid has moved. It overrides the inherited method to generate an OnColumnMoved (see page 14794) event. Descendants of TCustomDrawGrid (see page 14768) can override this method to make internal adjustments or to block the OnColumnMoved (see page 14794) event.

See Also

OnColumnMoved (see page 14794)

75.1.2.2.3 TCustomDrawGrid.DrawCell Method

Generates an OnDrawCell (see page 14795) event.

Pascal

```
procedure DrawCell(ACol: Longint; ARow: Longint; ARect: TRect; AState: TGridDrawState);
override;
```

C++

```
virtual __fastcall DrawCell(Longint ACol, Longint ARow, TRect ARect, TGridDrawState AState);
```

Description

DrawCell is called automatically whenever a cell in the grid is drawn. If the DefaultDrawing (see page 14847) property is true, the background of the cell is painted before DrawCell is called, and the 3D effects of the fixed cells or the focus rectangle around the focused cell are drawn after DrawCell. Descendants of TCustomDrawGrid (see page 14768) can override this method to draw the contents of the cell or to block the OnDrawCell (see page 14795) event.

See Also

DefaultDrawing (see page 14847)

FixedCols (see page 14848)

FixedRows (see page 14849)

OnDrawCell (see page 14795)

75.1.2.2.4 TCustomDrawGrid.GetEditMask Method

Generates an OnGetEditMask (see page 14796) event.

Pascal

```
function GetEditMask(ACol: Longint; ARow: Longint): string; override;
```

C++

```
virtual __fastcall AnsiString GetEditMask(Longint ACol, Longint ARow);
```

Description

The inplace editor calls GetEditMask to obtain any input mask associated with the cell specified by the ACol and ARow parameters. GetEditMask returns the Value parameter set by the OnGetEditMask (see page 14796) event handler. If there is no OnGetEditMask (see page 14796) event handler, GetEditMask returns an empty string, indicating that there is no edit mask.

See Also

OnGetEditMask (see page 14796)

75.1.2.2.5 TCustomDrawGrid.GetEditText Method

Generates an OnGetEditText (see page 14797) event.

Pascal

```
function GetEditText(ACol: Longint; ARow: Longint): string; override;
```

C++

```
virtual __fastcall AnsiString GetEditText(Longint ACol, Longint ARow);
```

Description

The inplace editor calls GetEditText to obtain the text for the indicated cell. GetEditText returns the Value parameter set by the OnGetEditText (see page 14797) event handler. If there is no OnGetEditText (see page 14797) event handler, GetEditText returns an empty string.

See Also

OnGetEditText (see page 14797)

75.1.2.2.6 TCustomDrawGrid.MouseToCell Method

Returns the column and row of the cell at the position with screen coordinates (X,Y).

Pascal

```
procedure MouseToCell(X: Integer; Y: Integer; var ACol: Longint; var ARow: Longint);
```

C++

```
__fastcall MouseToCell(int X, int Y, Longint ACol, Longint ARow);
```

Description

Call MouseToCell to convert from grid-relative screen coordinates to row and column indexes. The X and Y parameters are the screen coordinates of the point to be converted. MouseToCell returns the ACol parameter as the number of the column over the point (X,Y), and the ARow parameter as the number of the row.

Usually the MouseToCell method is used in a mouse event handler, which supplies the mouse coordinates as the X and Y parameters of the method call.

See Also

CellRect (see page 14781)

75.1.2.2.7 TCustomDrawGrid.RowMoved Method

Generates an OnRowMoved (see page 14798) event.

Pascal

```
procedure RowMoved(FromIndex: Longint; ToIndex: Longint); override;
```

C++

```
virtual __fastcall RowMoved(Longint FromIndex, Longint ToIndex);
```

Description

RowMoved is called immediately after a row in the grid changes position. It overrides the inherited method to generate an OnRowMoved (see page 14798) event. Descendants of TCustomDrawGrid (see page 14768) can override this method to make internal adjustments or to block the OnRowMoved (see page 14798) event.

See Also

OnRowMoved (see page 14798)

75.1.2.2.8 TCustomDrawGrid.SelectCell Method

Determines whether a particular cell in the grid can be selected.

Pascal

```
function SelectCell(ACol: Longint; ARow: Longint): Boolean; override;
```

C++

```
virtual __fastcall Boolean SelectCell(Longint ACol, Longint ARow);
```

Description

Grid controls call SelectCell internally before attempting to move selection to a the cell identified by the ACol and ARow parameters. ACol and ARow are the column and row indexes for the cell, where the first column has index 0, and the top row has index 0.

SelectCell generates an OnSelectCell (see page 14798) event. This method then returns true, unless the OnSelectCell (see page 14798) event handler indicates that the cell should not be selected. Descendants of TCustomDrawGrid (see page 14768) can override this method to check the properties of the information displayed in the cell or block the OnSelectCell (see page 14798) event.

See Also

OnSelectCell (see page 14798)

75.1.2.2.9 TCustomDrawGrid.SetEditText Method

Generates an OnSetEditText (see page 14800) event.

Pascal

```
procedure SetEditText(ACol: Longint; ARow: Longint; const Value: string); override;
```

C++

```
virtual __fastcall SetEditText(Longint ACol, Longint ARow, const AnsiString Value);
```

Description

SetEditText is called by the inplace editor so that the grid can store the new value for the current cell. SetEditText overrides the inherited parent class's method to generate an OnSetEditText (see page 14800) event. Descendants of TCustomDrawGrid (see page 14768) can override this method to update an internal representation of the cell's value, or to block the OnSetEditText (see page 14800) event.

See Also

OnSetEditText (see page 14800)

75.1.2.2.10 TCustomDrawGrid.TopLeftChanged Method

Generates an OnTopLeftChanged (see page 14800) event.

Pascal

```
procedure TopLeftChanged; override;
```

C++

```
virtual __fastcall TopLeftChanged();
```

Description

Grid controls call TopLeftChanged internally, whenever the LeftCol (see page 14790) or TopRow (see page 14793) property changes. After calling the inherited parent class's method to update the position of the inplace editor, TopLeftChanged generates an OnTopLeftChanged (see page 14800) event.

See Also

LeftCol (see page 14852)

OnTopLeftChanged (see page 14800)

TopRow (see page 14858)

75.1.2.3 TCustomDrawGrid Properties

The properties of the TCustomDrawGrid class are listed here.

Public Properties

	Name	Description
	Canvas (see page 14785)	Specifies the TCanvas object that presents a drawing surface for the control.
	Col (see page 14787)	Specifies the index of the column that contains the selected cell.
	ColWidths (see page 14788)	Indicates the width (in pixels) of all the columns in the grid.
	EditorMode (see page 14789)	Determines whether the current cell can be edited.
	GridHeight (see page 14789)	Specifies the height of the grid in pixels.
	GridWidth (see page 14789)	Specifies the width of the grid in pixels.
	LeftCol (see page 14790)	Specifies the index of the first visible scrollable column in the grid.
	Row (see page 14790)	Specifies the index of the row that contains the selected cell.
	RowHeights (see page 14791)	Gives the height (in pixels) of all rows in the grid.
	Selection (see page 14791)	Indicates the boundaries of the current selection.
	TabStops (see page 14793)	Indicates whether the user can tab to specified columns in the grid.
	TopRow (see page 14793)	Specifies the index of the first visible scrollable row in the grid.

75.1.2.3.1 TCustomDrawGrid.Canvas Property

Specifies the TCanvas object that presents a drawing surface for the control.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control. Canvas encapsulates a Windows device context, providing all the tools and methods needed for drawing and painting.

Canvas is a protected property that is usually redeclared as public in descendants of TCustomControl.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
```

```
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  ImageList1->Draw(DrawGrid1->Canvas,Rect.Left,Rect.Top,index);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(index) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}
//---------------------------------------------------------------------------
void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TStringGrid *myStringGrid;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TStringGrid")
  {
    myStringGrid = (TStringGrid *)ListBox1->Items->Objects[Index];
    // make sure we are using the TControls canvas and not the from's!
    myStringGrid->Canvas->MoveTo(myStringGrid->ClientRect.Left, myStringGrid->ClientRect.Top);
    myStringGrid->Canvas->LineTo(myStringGrid->ClientRect.Right,
myStringGrid->ClientRect.Bottom);
    myStringGrid = NULL;
  }
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
```

```
    DrawGrid1.Canvas.Brush.Color := clWhite;
    DrawGrid1.Canvas.FillRect(Rect);
    if (gdFocused in State) then
    begin
      DrawGrid1.Canvas.DrawFocusRect(Rect);
      Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
    end;
    ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  end;

  procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
    var CanSelect: Boolean);
  begin
    CanSelect:= True;
  end;
  {
  The following code uses ClientRect to find and draw a line
  from the top left to the bottom right of the current
  control.  Select a TControl in the ListBox list.  This
  example assumes that the current object is a descendent of
  TControl and has a public Canvas property.
  }
    if (ListBox1.Items.Objects[Index] is TStringGrid) then
    begin
      myStringGrid:= (ListBox1.Items.Objects[Index] as TStringGrid);
      with myStringGrid.ClientRect do
      begin // make sure we are using the TControl's canvas and not the form's!
        myStringGrid.Canvas.MoveTo(Left, Top);
        myStringGrid.Canvas.LineTo(Right, Bottom);
      end;
    myStringGrid:= nil;
    end;
```

See Also

Paint (see page 5920)

75.1.2.3.2 TCustomDrawGrid.Col Property

Specifies the index of the column that contains the selected cell.

Pascal

```
property Col: Longint;
```

C++

```
__property Longint Col;
```

Description

Use Col at runtime to determine the current column in the grid. Setting Col moves focus to the cell in the current row that is in the new column. The first column has an index of 0, the second column an index of 1, and so on.

The selected cell in the grid can be located by reading the Col property and the Row property to obtain the indexes of its column and row. When focus moves to the grid, the selected cell gets input focus.

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It uses a draw grid with a label above it on a form. When
the user clicks a cell in the grid, the location of the
cursor is displayed in the label caption. This example
requires a populated image list, or can just display an
empty grid.
```

```
}
procedure TForm1.DrawGrid1Click(Sender: TObject);
begin
  Label1.Caption := 'From OnClick: The cursor is in column ' +
                    IntToStr(DrawGrid1.Col + 1) +
                    ', row ' +
                    IntToStr(DrawGrid1.Row + 1);
end;

procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clBackground;
  DrawGrid1.Canvas.FillRect(Rect);
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label2.Caption:= 'From OnDrawCell: Cell ' + InttoStr(index) + ' has the focus.';
  end;
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
```

See Also

Row (see page 14854)

75.1.2.3.3 TCustomDrawGrid.ColWidths Property

Indicates the width (in pixels) of all the columns in the grid.

Pascal

```
property ColWidths [Index: Longint]: Integer;
```

C++

```
__property int ColWidths[Longint Index];
```

Description

Read ColWidths to determine the width of the cells in the column specified by the Index parameter. An index of 0 refers to the first column. Set ColWidths at runtime to change the width of an individual column.

If the width of a column has not been set explicitly by resizing with the mouse, or by using the ColWidths property, its width is DefaultColWidth.

Use the ColCount property to determine the number of entries in the ColWidths array.

See Also

ColCount (see page 14844)

DefaultColWidth (see page 14846)

RowHeights (see page 14855)

75.1.2.3.4 TCustomDrawGrid.EditorMode Property

Determines whether the current cell can be edited.

Pascal

```
property EditorMode: Boolean;
```

C++

```
__property Boolean EditorMode;
```

Description

Set EditorMode to true, at runtime, to put the grid in edit mode. When EditorMode is true, the user can edit cells in the grid. When the user presses F2, EditorMode is set to true. When the user presses Enter, the value of EditorMode is toggled.

Note: EditorMode has no effect if the Options property does not include goEditing or if the Options property includes goAlwaysShowEditor.

See Also

HideEditor (see page 14830)

Options (see page 14853)

ShowEditor (see page 14839)

75.1.2.3.5 TCustomDrawGrid.GridHeight Property

Specifies the height of the grid in pixels.

Pascal

```
property GridHeight: Integer;
```

C++

```
__property int GridHeight;
```

Description

Read GridHeight to determine the size of the grid. If GridHeight is less than the value of ClientHeight, all of the rows of the grid appear in the control with an empty region below the grid. If the underlying grid is too tall to appear in the control, GridHeight is the same as ClientHeight, and the user must scroll to see the entire contents of the grid.

See Also

ClientHeight (see page 5808)

GridWidth (see page 14851)

75.1.2.3.6 TCustomDrawGrid.GridWidth Property

Specifies the width of the grid in pixels.

Pascal

```
property GridWidth: Integer;
```

C++

```
__property int GridWidth;
```

Description

Read GridWidth to determine the size of the grid. If GridWidth is less than the value of ClientWidth, all of the columns of the grid appear in the control with an empty region to the right of the grid. If the underlying grid is too wide to appear in the control, GridWidth is the same as ClientWidth, and the user must scroll to see the entire contents of the grid.

See Also

ClientWidth (see page 5811)

GridHeight (see page 14850)

75.1.2.3.7 TCustomDrawGrid.LeftCol Property

Specifies the index of the first visible scrollable column in the grid.

Pascal

```
property LeftCol: Longint;
```

C++

```
__property Longint LeftCol;
```

Description

Read LeftCol to determine the index of the first column in the scrollable region that is visible. Set LeftCol to scroll the columns in the grid so that the column with index LeftCol is the first column after the fixed columns.

See Also

FixedCols (see page 14848)

ScrollData (see page 14838)

VisibleColCount (see page 14859)

75.1.2.3.8 TCustomDrawGrid.Row Property

Specifies the index of the row that contains the selected cell.

Pascal

```
property Row: Longint;
```

C++

```
__property Longint Row;
```

Description

Use Row at runtime to determine the current row in the grid. Setting Row moves focus to the cell in the current column that is in the new row. The first row has an index of 0, the second row an index of 1, and so on.

The selected cell in the grid can be located by reading the Row property and the Col property to obtain the indexes of its row and column. When focus moves to the grid, the selected cell gets input focus.

Delphi Examples:

```
{
This example displays a string grid, a list box, and a
button on a form. When the application runs, strings are put
in the cells of row 1 of the string grid. When the user
clicks the button, The strings in the current row of the
grid are displayed in the list box.
Note that when the grid contains an empty cell, the list box
```

```
has a corresponding empty string.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ListBox1.Items := StringGrid1.Rows[StringGrid1.Row];
end;
procedure TForm1.FormCreate(Sender: TObject);
begin
  with StringGrid1 do
  begin
    Cells[1,0] := 'Column 1';
    Cells[2,0] := 'Column 2';
    Cells[3,0] := 'Column 3';
    Cells[4,0] := 'Column 4';
    Cells[0,1] := 'Row 1';
    Cells[1,1] := 'Object';
    Cells[2,1] := 'Pascal';
    Cells[3,1] := 'is';
    Cells[4,1] := 'excellent';
    Cells[0,2] := 'Row 2';
    Cells[1,2] := 'Delphi';
    Cells[2,2] := 'is';
    Cells[4,2] := 'RAD';
  end;
end;
```

See Also

Col (see page 14843)

75.1.2.3.9 TCustomDrawGrid.RowHeights Property

Gives the height (in pixels) of all rows in the grid.

Pascal

```
property RowHeights [Index: Longint]: Integer;
```

C++

```
__property int RowHeights[Longint Index];
```

Description

Read RowHeights to determine the height of the cells in the row specified by the Index parameter. An index of 0 refers to the first row. Set RowWidths at runtime to change the height of an individual row.

If the height of a row has not been set explicitly by resizing with the mouse, or by using the RowHeights property, it's height is DefaultRowHeight.

Use the RowCount property to determine the number of entries in the RowHeights array.

See Also

ColWidths (see page 14845)

DefaultRowHeight (see page 14847)

RowCount (see page 14854)

75.1.2.3.10 TCustomDrawGrid.Selection Property

Indicates the boundaries of the current selection.

Pascal

```
property Selection: TGridRect;
```

C++

```
__property TGridRect Selection;
```

Description

Set Selection to select a range of cells in the grid. Selection can either represent the first column, first row, last column and last row in the grid, or the row and column coordinates of the upper left and bottom right cells in the selected region.

Selection can only indicate more than one cell when Options includes goRangeSelect.

Delphi Examples:

```
{
The following code selects the rectangle containing rows 1
through 4, and columns 2 and 3.  goRangeSelect in the
DrawGrid Options parameter must be True to select a range of
cells.  This example requires a button, a DrawGrid and a
populated ImageList.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  myRect: TGridRect;
begin
  myRect.Left := 2;
  myRect.Top := 1;
  myRect.Right := 3;
  myRect.Bottom := 4;
  DrawGrid1.Selection := myRect;
  DrawGrid1.Repaint;
end;

procedure TForm1.DrawGrid1Click(Sender: TObject);
begin
  Label1.Caption := 'From OnClick: The cursor is in column ' +
                    IntToStr(DrawGrid1.Col + 1) +
                    ', row ' +
                    IntToStr(DrawGrid1.Row + 1);
end;

procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := (ARow * DrawGrid1.ColCount + ACol) mod (DrawGrid1.ColCount + 1);
  if (gdSelected in State) then
    DrawGrid1.Canvas.Brush.Color := clYellow
  else
    DrawGrid1.Canvas.Brush.Color := clBackground;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label2.Caption:= 'From OnDrawCell: Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
```

```
end;
```

See Also

Col (see page 14843)

Options (see page 14853)

Row (see page 14854)

75.1.2.3.11 TCustomDrawGrid.TabStops Property

Indicates whether the user can tab to specified columns in the grid.

Pascal

```
property TabStops [Index: Longint]: Boolean;
```

C++

```
__property Boolean TabStops[Longint Index];
```

Description

Set TabStops to false to remove the column identified by Index from the tab order. The first column in the grid is identified by an Index of 0.

Note: When the Options property does not include goTabs, the user can't tab to any column, even if TabStops is true.

See Also

Options (see page 14853)

75.1.2.3.12 TCustomDrawGrid.TopRow Property

Specifies the index of the first visible scrollable row in the grid.

Pascal

```
property TopRow: Longint;
```

C++

```
__property Longint TopRow;
```

Description

Read TopRow to determine the index of the first row in the scrollable region that is visible. Set TopRow to scroll the rows in the grid so that the row with index TopRow is the first row after the fixed rows.

Delphi Examples:

```
{
This code uses a draw grid and a button on a form. When
the user clicks the button, the last row of the draw
grid becomes the top row.  This example requires a
button, a DrawGrid and a populated ImageList.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  DrawGrid1.TopRow := DrawGrid1.RowCount - 1;
end;

procedure TForm1.DrawGrid1Click(Sender: TObject);
begin
  Label1.Caption := 'From OnClick: The cursor is in column ' +
                    IntToStr(DrawGrid1.Col + 1) +
```

```
                        ', row ' +
                        IntToStr(DrawGrid1.Row + 1);
  end;

  procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
    Rect: TRect; State: TGridDrawState);
  var
    index: Integer;
  begin
    index := (ARow * DrawGrid1.ColCount + ACol) mod (DrawGrid1.ColCount + 1);
    if (gdSelected in State) then
      DrawGrid1.Canvas.Brush.Color := clYellow
    else
      DrawGrid1.Canvas.Brush.Color := clBackground;
    DrawGrid1.Canvas.FillRect(Rect);
    if (gdFocused in State) then
    begin
      DrawGrid1.Canvas.DrawFocusRect(Rect);
      Label2.Caption:= 'From OnDrawCell: Cell ' + InttoStr(index) + ' has the focus.';
    end;
    ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  end;

  procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
    var CanSelect: Boolean);
  begin
    CanSelect:= True;
  end;
```

See Also

FixedRows (see page 14849)

ScrollData (see page 14838)

VisibleRowCount (see page 14859)

75.1.2.4 TCustomDrawGrid Events

The events of the TCustomDrawGrid class are listed here.

Protected Events

	Name	Description
	OnColumnMoved (see page 14794)	Occurs immediately after the position of a column changes.
	OnDrawCell (see page 14795)	Occurs when a cell in the grid needs to be drawn.
	OnGetEditMask (see page 14796)	Occurs when the in-place editor requests an edit mask.
	OnGetEditText (see page 14797)	Occurs when the in-place editor requests the value of a cell.
	OnRowMoved (see page 14798)	Occurs immediately after the position of a row changes.
	OnSelectCell (see page 14798)	Occurs before a cell in the grid is selected.
	OnSetEditText (see page 14800)	Occurs when the user edits the value of a cell.
	OnTopLeftChanged (see page 14800)	Occurs immediately after the TopRow (see page 14793) property or the LeftCol (see page 14790) property changes.

75.1.2.4.1 TCustomDrawGrid.OnColumnMoved Event

Occurs immediately after the position of a column changes.

Pascal

```
property OnColumnMoved: TMovedEvent;
```

C++

```
__property TMovedEvent OnColumnMoved;
```

Description

Use OnColumnMoved to perform special processing when the position of a grid column changes. Columns can be moved programmatically or by user manipulation. OnColumnMoved does not occur unless the Options (see page 14853) property includes goColMoving.

See Also

OnRowMoved (see page 14798)

Options (see page 14853)

75.1.2.4.2 TCustomDrawGrid.OnDrawCell Event

Occurs when a cell in the grid needs to be drawn.

Pascal

```
property OnDrawCell: TDrawCellEvent;
```

C++

```
__property TDrawCellEvent OnDrawCell;
```

Description

Write an OnDrawCell event handler to draw the contents of all the cells in the grid. Draw on the cell using the methods of the Canvas (see page 14785) property. The Rect parameter indicates the location of the cell on the canvas. The Col (see page 14787) and Row (see page 14790) parameters indicate the column and row indexes of the cell that should be drawn. The State parameter indicates whether the cell has input focus, whether the cell is selected, and whether the cell is a fixed (nonscrolling) cell.

If the OnDrawCell event handler is not assigned, all cells in the draw grid will appear empty. If the DefaultDrawing (see page 14847) property is true, the draw grid paints the background color of the cell before the OnDrawCell event, and draws a focus rectangle around the selected cell after the OnDrawCell event handler finishes drawing the contents of the cell. If the DefaultDrawing (see page 14847) property is false, the OnDrawCell event handler should paint the background of the cell and provide all visual indication of selection and focus.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  ImageList1->Draw(DrawGrid1->Canvas,Rect.Left,Rect.Top,index);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(index) + " has the focus.";
```

```
    }
    ImageList1->Draw(
      DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
  }
  //---------------------------------------------------------------------------
  void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
        bool &CanSelect)
  {
    CanSelect= True;
  }
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clWhite;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
```

DefaultDrawing (see page 14847)

75.1.2.4.3 TCustomDrawGrid.OnGetEditMask Event

Occurs when the in-place editor requests an edit mask.

Pascal

```
property OnGetEditMask: TGetEditEvent;
```

C++

```
__property TGetEditEvent OnGetEditMask;
```

Description

Write an OnGetEditMask event handler to provide the in-place editor with an edit mask that describes the valid input strings a user can type into a cell. Set the Value parameter to the string that describes the edit mask for the cell specified by the ACol and ARow parameters. If the cell does not have an edit mask, set the Value parameter to an empty string.

OnGetEditMask does not occur unless the Options (see page 14853) property includes goEditing.

Delphi Examples:

```
{
This example specifies an edit mask in a string grid to
limit the cells that contain telephone numbers, as indicated
by a label cell in the first row.  Include goEditing in the
TStringGrid Options property.  Set the title of one of the
columns to 'Phone Number'.  Set the DefaultColWidth large
enough to see a phone number.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  StringGrid1.Cells[2, 0]:= 'Phone Number';
end;

procedure TForm1.StringGrid1GetEditMask(Sender: TObject; ACol, ARow: Longint; var Value:
string);
begin
  if StringGrid1.Cells[ACol, 0] = 'Phone Number' then
    Value :=  '!\(999\)000-0000;1';
end;
```

See Also

Options (see page 14853)

EditMask (see page 15821)

75.1.2.4.4 TCustomDrawGrid.OnGetEditText Event

Occurs when the in-place editor requests the value of a cell.

Pascal

```
property OnGetEditText: TGetEditEvent;
```

C++

```
__property TGetEditEvent OnGetEditText;
```

Description

Write an OnGetEditText event handler to provide the in-place editor with a string representing the contents of the cell. Set the Value parameter to the string for the cell specified by the ACol and ARow parameters. When the cell enters edit mode, the contents of the cell are drawn as the Value string returned by the OnGetEditText event handler. This image need not match the appearance of the cell when it is not in edit mode, which is drawn using the OnDrawCell (see page 14795) event handler.

OnGetEditText does not occur unless the Options (see page 14853) property includes goEditing.

Delphi Examples:

```
{
The following code lowercases the text for a string grid
cell when the user begins to edit it.
}
procedure TForm1.StringGrid1GetEditText(Sender: TObject; ACol, ARow: Longint; var Value:
string);
begin
  Value := AnsiLowerCase(Value);
end;
```

See Also

OnDrawCell (see page 14795)

OnSetEditText (see page 14800)

75.1.2.4.5 TCustomDrawGrid.OnRowMoved Event

Occurs immediately after the position of a row changes.

Pascal

```
property OnRowMoved: TMovedEvent;
```

C++

```
__property TMovedEvent OnRowMoved;
```

Description

Write an OnRowMoved event handler to provide special processing whenever a row in the grid changes position. Rows can be moved programmatically or by user manipulation. OnRowMoved does not occur unless the Options (see page 14853) property includes goRowMoving.

Delphi Examples:

```
{
The following code displays the number of rows a row was
moved in a label.  To move rows in a TStringGrid, goRowMoving
must be included in the Options property.
}
procedure TForm1.StringGrid1RowMoved(Sender: TObject; FromIndex, ToIndex: Longint);
begin
  Label1.Caption := IntToStr(Abs(FromIndex-ToIndex));
end;
```

See Also

OnColumnMoved (see page 14794)

Options (see page 14853)

75.1.2.4.6 TCustomDrawGrid.OnSelectCell Event

Occurs before a cell in the grid is selected.

Pascal

```
property OnSelectCell: TSelectCellEvent;
```

C++

```
__property TSelectCellEvent OnSelectCell;
```

Description

Write an OnSelectCell event handler to specify whether any particular cell in the grid can be selected. The Col (see page 14787) and Row (see page 14790) parameters indicate the column and row indexes of the cell that is about to be selected. Set the CanSelect parameter to false to prevent the cell being selected.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
```

```
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  ImageList1->Draw(DrawGrid1->Canvas,Rect.Left,Rect.Top,index);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(index) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}
//---------------------------------------------------------------------------
void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clWhite;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
{
The following code ensures that the user cannot select a cell unless it is empty.
}
procedure TForm1.StringGrid1SelectCell(Sender: TObject; ACol, ARow: Longint; var CanSelect:
Boolean);
begin
  CanSelect := (StringGrid1.Cells[ACol, ARow]='')
end;
```

See Also

Col (see page 14843)

Row (see page 14854)

TabStops (see page 14858)

75.1.2.4.7 TCustomDrawGrid.OnSetEditText Event

Occurs when the user edits the value of a cell.

Pascal

```
property OnSetEditText: TSetEditEvent;
```

C++

```
__property TSetEditEvent OnSetEditText;
```

Description

Write an OnSetEditText event handler to perform any special processing of the text edited by the user in an in-place editor. For example, use the OnSetEditText event to retrieve and store the value of a cell so that it can be displayed in an OnDrawCell (see page 14795) event handler. OnSetEditText occurs every time the user changes the text.

The Value parameter is the new value for the cell specified by the ACol and ARow parameters.

OnSetEditText does not occur unless the Options (see page 14853) property includes goEditing.

See Also

OnDrawCell (see page 14795)

OnGetEditText (see page 14797)

Options (see page 14853)

75.1.2.4.8 TCustomDrawGrid.OnTopLeftChanged Event

Occurs immediately after the TopRow (see page 14793) property or the LeftCol (see page 14790) property changes.

Pascal

```
property OnTopLeftChanged: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnTopLeftChanged;
```

Description

Use OnTopLeftChanged to perform special processing when the non-fixed cells in the grid are scrolled.

See Also

LeftCol (see page 14852)

TopRow (see page 14858)

75.1.3 TCustomGrid Class

TCustomGrid is the base type for all components that present information in a two-dimensional grid.

Class Hierarchy

Pascal

```
TCustomGrid = class(TCustomControl);
```

C++

```
class TCustomGrid : public TCustomControl;
```

File

Grids

Description

Use TCustomGrid as a base class when defining components that represent information in a tabular format. TCustomGrid introduces properties and methods to control the appearance and behavior of the grid, including responses to mouse actions and user editing.

Do not create instances of TCustomGrid. Instead, put a grid control in a form by instantiating a descendant of TCustomGrid. Use TDrawGrid (see page 14860) to represent non-textual material in a tabular grid. For text, use a TStringGrid (see page 14968) object. If the text represents field values from a dataset, use TDBGrid.

See Also

TDBGrid (see page 9668)

TDrawGrid (see page 14860)

TStringGrid (see page 14968)

75.1.3.1 TCustomGrid Members

The following tables list the members exposed by TCustomGrid.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	DesignOptionsBoost (see page 14814)	This is DesignOptionsBoost, a member of class TCustomGrid.
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FGridState (see page 14814)	This is FGridState, a member of class TCustomGrid.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.
	FSaveCellExtents (see page 14814)	This is FSaveCellExtents, a member of class TCustomGrid.
	VirtualView (see page 14814)	This is VirtualView, a member of class TCustomGrid.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 14816)	Adds or deletes rows or columns from the grid.

	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	BeginColumnDrag (see page 14817)	Starts the dragging of a column in the grid.
	BeginRowDrag (see page 14817)	Starts the dragging of a row in the grid.
	BoxRect (see page 14818)	Returns the screen coordinates of a specified set of cells.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CalcDrawInfo (see page 14818)	Calculates the pixel locations of the grid boundaries.
	CalcFixedInfo (see page 14818)	Calculates the pixel locations of the fixed cells.
	CalcSizingState (see page 14819)	Determines the appearance of the mouse cursor during resizing.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanEditAcceptKey (see page 14819)	Indicates whether the Key parameter can be entered into the current cell.
	CanEditModify (see page 14819)	Indicates whether the current cell in the grid can be edited.
	CanEditShow (see page 14820)	Indicates whether the inplace edit control can be created to allow editing.
	CanGridAcceptKey (see page 14820)	Indicates whether the grid should respond to a given key combination.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	CellRect (see page 14821)	Returns the screen coordinates of a cell in the grid.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeGridOrientation (see page 14821)	Prepares the grid's canvas for painting to reflect a right-to-left or left-to-right orientation.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	CheckColumnDrag (see page 14821)	CheckColumnDrag validates whether the column currently selected for dragging can be dropped at the current location.
	CheckRowDrag (see page 14822)	CheckRowDrag validates whether the row currently selected for dragging can be dropped at the current location.
	Click (see page 5743)	Respond to user click.
	ColumnMoved (see page 14822)	Provides the interface for a method that responds when the position of a column changes.
	ColWidthsChanged (see page 14822)	Responds when the column widths change.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateEditor (see page 14823)	Creates the inplace editor control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 14823)	Initializes the window-creation parameter record.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 14824)	Adds the ColWidths (see page 14845) and RowHeights (see page 14855) properties to the values saved with the grid.
	DeleteColumn (see page 14824)	Deletes a specified column from the grid.

	DeleteRow (see page 14825)	Deletes a specified from the grid.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 14825)	Hides the inplace editor when selection moves to another control in a form.
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 14825)	Performs tasks when the mouse wheel is rotated downward.
	DoMouseWheelUp (see page 14826)	Performs tasks when the mouse wheel is rotated upward.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawCell (see page 14826)	Provides the prototype for a method that draws the contents of a cell in the grid.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EndColumnDrag (see page 14827)	Ends the dragging of a column in the grid.
	EndRowDrag (see page 14827)	Ends the dragging of a row in the grid.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	FocusCell (see page 14827)	Changes the current cell to a specified cell.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.

	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEditLimit (see page 14828)	Provides the interface for a method that limits the number of characters the user can type into cells.
	GetEditMask (see page 14828)	Provides the interface for a method that returns an input mask for the specified cell.
	GetEditStyle (see page 14828)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
	GetEditText (see page 14829)	Returns the value of the indicated cell formatted for editing.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetGridHeight (see page 14829)	Returns the value of the GridHeight (see page 14850) property.
	GetGridWidth (see page 14830)	Returns the value of the GridWidth (see page 14851) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HideEdit (see page 14830)	Hides the inplace editor.
	HideEditor (see page 14830)	Hides the inplace editor when it is not in use.
	InvalidateCell (see page 14831)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.
	InvalidateCol (see page 14831)	Invalidates the region occupied by a column so that it will be repainted with the next Windows paint message.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	InvalidateEditor (see page 14832)	Causes the inplace editor to repaint itself, moving to a new location if necessary.
	InvalidateGrid (see page 14832)	Tells Windows to repaint the grid after other important Windows messages are handled.
	InvalidateRow (see page 14832)	Invalidates the region occupied by a row so that it will be repainted with the next Windows paint message.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
V	KeyDown (see page 14833)	Provides special processing when the user presses a key.
V	KeyPress (see page 14833)	Provides special processing when the user presses a key.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
V	MouseDown (see page 14834)	Provides special processing when the user presses a mouse button.
V	MouseMove (see page 14834)	Provides special processing when the user moves the mouse.
V	MouseUp (see page 14835)	Provides special processing when the user releases the mouse button.
	MoveColRow (see page 14835)	Selects the cell indicated by the ACol and ARow parameters.
	MoveColumn (see page 14836)	Moves a column to a new position.

	MoveRow (see page 14836)	Moves a row to a new position.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 14836)	Draws the image of the grid control on the screen.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	RowHeightsChanged (see page 14837)	Responds when the row heights change.
	RowMoved (see page 14837)	Provides the interface for a method that responds when the position of a row changes.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	ScrollData (see page 14838)	Scrolls the visual image of the cells in the grid.
V	SelectCell (see page 14838)	Determines whether a particular cell in the grid can be selected.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEditText (see page 14839)	Provides the interface for a method that updates the text associated with a cell.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.

	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	ShowEditor (see page 14839)	Displays the inplace editor when the grid enters edit mode.
	ShowEditorChar (see page 14839)	Displays the inplace editor, with its text set to the specified character.
	SizeChanged (see page 14840)	Responds to changes in the size of the grid.
	Sizing (see page 14840)	Indicates whether the indicated coordinates are on one of the resize hot zones of the graph.
	TimedScroll (see page 14840)	Extends a move, resize, or selection out of the scrollable region when the user drags the mouse in a direction where the grid is scrolled.
	TopLeftChanged (see page 14841)	Updates the position of the inplace editor when the grid scrolls.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateDesigner (see page 14841)	Notifies the designer when rows and columns of the grid are moved or resized.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.

	BorderStyle (see page 14843)	Determines whether a single line border is drawn around the grid.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
R	Canvas (see page 5921)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Col (see page 14843)	Specifies the index of the column that contains the selected cell.
	ColCount (see page 14844)	Specifies the number of columns in the grid.
	Color (see page 14844)	Specifies the background color of the control.
	ColWidths (see page 14845)	Indicates the width (in pixels) of all the columns in the grid.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultColWidth (see page 14846)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 14847)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 14847)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	EditorMode (see page 14848)	Determines whether the current cell can be edited.
	FixedColor (see page 14848)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 14848)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	FixedRows (see page 14849)	Specifies the number of rows on the top of the grid that cannot be scrolled.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
R	GridHeight (see page 14850)	Specifies the height of the grid in pixels.
	GridLineWidth (see page 14850)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
R	GridWidth (see page 14851)	Specifies the width of the grid in pixels.
R	HitTest (see page 14851)	Indicates the current position of the mouse cursor.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
R	InplaceEditor (see page 14852)	Designates the edit control the grid uses to allow users to edit the contents of the selected cell.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	LeftCol (see page 14852)	Specifies the index of the first visible scrollable column in the grid.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	Options (see page 14853)	Specifies various display and behavioral properties of the grid.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 14853)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	Row (see page 14854)	Specifies the index of the row that contains the selected cell.
	RowCount (see page 14854)	Specifies the number of rows in the grid.
	RowHeights (see page 14855)	Gives the height (in pixels) of all rows in the grid.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	ScrollBars (see page 14856)	Specifies whether the grid includes horizontal and vertical scroll bars.
	Selection (see page 14856)	Indicates the boundaries of the current selection.
	TabStops (see page 14858)	Indicates whether the user can tab to specified columns in the grid.
	Text (see page 5842)	Contains a text string associated with the control.
	TopRow (see page 14858)	Specifies the index of the first visible scrollable row in the grid.

R	VisibleColCount (see page 14859)	Indicates the number of scrollable columns visible in the grid.
R	VisibleRowCount (see page 14859)	Indicates the number of scrollable rows visible in the grid.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 14813)	Creates an instance of TCustomGrid (see page 14800).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 14813)	Destroys an instance of TCustomGrid (see page 14800).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.

	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseCoord (see page 14834)	Returns the row and column indexes of the cell that contains a point specified in screen coordinates.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.

	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.

R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.

	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	TabStop (see page 14857)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

75.1.3.2 TCustomGrid.Create Constructor

Creates an instance of TCustomGrid (see page 14800).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TCustomGrid(TComponent * AOwner);
```

Description

Call Create to create a grid control at runtime. Grid controls placed on a form at design time are created automatically.

Owner is a component that is responsible for freeing the grid and for initiating the streaming process when it is saved to a form file.

See Also

Owner (see page 2807)

75.1.3.3 TCustomGrid.Destroy Destructor

Destroys an instance of TCustomGrid (see page 14800).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomGrid();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the grid reference is not nil, and only then calls Destroy.

See Also

Free (see page 22300)

75.1.3.4 TCustomGrid Fields

The fields of the TCustomGrid class are listed here.

Protected Fields

	Name	Description
	DesignOptionsBoost (see page 14814)	This is DesignOptionsBoost, a member of class TCustomGrid.
	FGridState (see page 14814)	This is FGridState, a member of class TCustomGrid.
	FSaveCellExtents (see page 14814)	This is FSaveCellExtents, a member of class TCustomGrid.
	VirtualView (see page 14814)	This is VirtualView, a member of class TCustomGrid.

75.1.3.4.1 TCustomGrid.DesignOptionsBoost Field

Pascal

```
DesignOptionsBoost: TGridOptions;
```

C++

```
TGridOptions DesignOptionsBoost;
```

Description

This is DesignOptionsBoost, a member of class TCustomGrid.

75.1.3.4.2 TCustomGrid.FGridState Field

Pascal

```
FGridState: TGridState;
```

C++

```
TGridState FGridState;
```

Description

This is FGridState, a member of class TCustomGrid.

75.1.3.4.3 TCustomGrid.FSaveCellExtents Field

Pascal

```
FSaveCellExtents: Boolean;
```

C++

```
Boolean FSaveCellExtents;
```

Description

This is FSaveCellExtents, a member of class TCustomGrid.

75.1.3.4.4 TCustomGrid.VirtualView Field

Pascal

```
VirtualView: Boolean;
```

C++

```
Boolean VirtualView;
```

Description

This is VirtualView, a member of class TCustomGrid.

75.1.3.5 TCustomGrid Methods

The methods of the TCustomGrid class are listed here.

Protected Methods

	Name	Description
	AdjustSize (see page 14816)	Adds or deletes rows or columns from the grid.
	BeginColumnDrag (see page 14817)	Starts the dragging of a column in the grid.
	BeginRowDrag (see page 14817)	Starts the dragging of a row in the grid.
	BoxRect (see page 14818)	Returns the screen coordinates of a specified set of cells.
	CalcDrawInfo (see page 14818)	Calculates the pixel locations of the grid boundaries.
	CalcFixedInfo (see page 14818)	Calculates the pixel locations of the fixed cells.
V	CalcSizingState (see page 14819)	Determines the appearance of the mouse cursor during resizing.
	CanEditAcceptKey (see page 14819)	Indicates whether the Key parameter can be entered into the current cell.
	CanEditModify (see page 14819)	Indicates whether the current cell in the grid can be edited.
V	CanEditShow (see page 14820)	Indicates whether the inplace edit control can be created to allow editing.
	CanGridAcceptKey (see page 14820)	Indicates whether the grid should respond to a given key combination.
	CellRect (see page 14821)	Returns the screen coordinates of a cell in the grid.
	ChangeGridOrientation (see page 14821)	Prepares the grid's canvas for painting to reflect a right-to-left or left-to-right orientation.
	CheckColumnDrag (see page 14821)	CheckColumnDrag validates whether the column currently selected for dragging can be dropped at the current location.
	CheckRowDrag (see page 14822)	CheckRowDrag validates whether the row currently selected for dragging can be dropped at the current location.
	ColumnMoved (see page 14822)	Provides the interface for a method that responds when the position of a column changes.
	ColWidthsChanged (see page 14822)	Responds when the column widths change.
V	CreateEditor (see page 14823)	Creates the inplace editor control.
V	CreateParams (see page 14823)	Initializes the window-creation parameter record.
V	DefineProperties (see page 14824)	Adds the ColWidths (see page 14845) and RowHeights (see page 14855) properties to the values saved with the grid.
V	DeleteColumn (see page 14824)	Deletes a specified column from the grid.
V	DeleteRow (see page 14825)	Deletes a specified from the grid.
V	DoExit (see page 14825)	Hides the inplace editor when selection moves to another control in a form.
V	DoMouseWheelDown (see page 14825)	Performs tasks when the mouse wheel is rotated downward.
V	DoMouseWheelUp (see page 14826)	Performs tasks when the mouse wheel is rotated upward.
A	DrawCell (see page 14826)	Provides the prototype for a method that draws the contents of a cell in the grid.
	EndColumnDrag (see page 14827)	Ends the dragging of a column in the grid.
	EndRowDrag (see page 14827)	Ends the dragging of a row in the grid.
	FocusCell (see page 14827)	Changes the current cell to a specified cell.
	GetEditLimit (see page 14828)	Provides the interface for a method that limits the number of characters the user can type into cells.
	GetEditMask (see page 14828)	Provides the interface for a method that returns an input mask for the specified cell.
	GetEditStyle (see page 14828)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
	GetEditText (see page 14829)	Returns the value of the indicated cell formatted for editing.
	GetGridHeight (see page 14829)	Returns the value of the GridHeight (see page 14850) property.
	GetGridWidth (see page 14830)	Returns the value of the GridWidth (see page 14851) property.
	HideEdit (see page 14830)	Hides the inplace editor.

	HideEditor (see page 14830)	Hides the inplace editor when it is not in use.
	InvalidateCell (see page 14831)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.
	InvalidateCol (see page 14831)	Invalidates the region occupied by a column so that it will be repainted with the next Windows paint message.
	InvalidateEditor (see page 14832)	Causes the inplace editor to repaint itself, moving to a new location if necessary.
	InvalidateGrid (see page 14832)	Tells Windows to repaint the grid after other important Windows messages are handled.
	InvalidateRow (see page 14832)	Invalidates the region occupied by a row so that it will be repainted with the next Windows paint message.
V	KeyDown (see page 14833)	Provides special processing when the user presses a key.
V	KeyPress (see page 14833)	Provides special processing when the user presses a key.
V	MouseDown (see page 14834)	Provides special processing when the user presses a mouse button.
V	MouseMove (see page 14834)	Provides special processing when the user moves the mouse.
V	MouseUp (see page 14835)	Provides special processing when the user releases the mouse button.
	MoveColRow (see page 14835)	Selects the cell indicated by the ACol and ARow parameters.
	MoveColumn (see page 14836)	Moves a column to a new position.
	MoveRow (see page 14836)	Moves a row to a new position.
V	Paint (see page 14836)	Draws the image of the grid control on the screen.
	RowHeightsChanged (see page 14837)	Responds when the row heights change.
	RowMoved (see page 14837)	Provides the interface for a method that responds when the position of a row changes.
	ScrollData (see page 14838)	Scrolls the visual image of the cells in the grid.
V	SelectCell (see page 14838)	Determines whether a particular cell in the grid can be selected.
	SetEditText (see page 14839)	Provides the interface for a method that updates the text associated with a cell.
	ShowEditor (see page 14839)	Displays the inplace editor when the grid enters edit mode.
	ShowEditorChar (see page 14839)	Displays the inplace editor, with its text set to the specified character.
	SizeChanged (see page 14840)	Responds to changes in the size of the grid.
	Sizing (see page 14840)	Indicates whether the indicated coordinates are on one of the resize hot zones of the graph.
	TimedScroll (see page 14840)	Extends a move, resize, or selection out of the scrollable region when the user drags the mouse in a direction where the grid is scrolled.
	TopLeftChanged (see page 14841)	Updates the position of the inplace editor when the grid scrolls.
	UpdateDesigner (see page 14841)	Notifies the designer when rows and columns of the grid are moved or resized.

Public Methods

	Name	Description
	MouseCoord (see page 14834)	Returns the row and column indexes of the cell that contains a point specified in screen coordinates.

75.1.3.5.1 TCustomGrid.AdjustSize Method

Adds or deletes rows or columns from the grid.

Pascal

```
procedure AdjustSize(Index: Longint; Amount: Longint; Rows: Boolean); dynamic; reintroduce;
```

C++

```
__fastcall AdjustSize(Longint Index, Longint Amount, Boolean Rows);
```

Description

Grid components call AdjustSize internally to fix up the number of rows or columns when the user resizes them using the mouse. Index is the index of the row or column where the insertion or deletion should begin. Amount is the number of rows or columns to insert (Amount > 0) or delete (Amount < 0). Rows is a boolean that indicates whether the rows or the columns are changing.

See Also

DefaultColWidth (see page 14846)

DefaultRowHeight (see page 14847)

75.1.3.5.2 TCustomGrid.BeginColumnDrag Method

Starts the dragging of a column in the grid.

Pascal

```
function BeginColumnDrag(var Origin: Integer; var Destination: Integer; const MousePt:
TPoint): Boolean; dynamic;
```

C++

```
__fastcall Boolean BeginColumnDrag(int Origin, int Destination, const TPoint MousePt);
```

Description

BeginColumnDrag is called automatically when the user clicks on a column to start dragging. It enables the grid to control whether the column can be repositioned and if so, which column.

Origin is the index of the column to be moved. When BeginColumnDrag is called, this is the index of the column in which the mouse was clicked. TCustomGrid (see page 14800) does not change this value. However, descendant classes can override this method to adjust which column can be moved.

Destination is the index of where the column should move. When BeginColumnDrag is called, this is the same as Origin. TCustomGrid (see page 14800) does not change this value because the mouse has not yet moved. Descendant classes can override this method to adjust the default destination of the column.

MousePt is the coordinates of the mouse button when the user clicked.

BeginColumnDrag returns true if the drag operation is permitted, false if the drag should be disallowed.

See Also

BeginRowDrag (see page 14817)

EndColumnDrag (see page 14827)

75.1.3.5.3 TCustomGrid.BeginRowDrag Method

Starts the dragging of a row in the grid.

Pascal

```
function BeginRowDrag(var Origin: Integer; var Destination: Integer; const MousePt: TPoint):
Boolean; dynamic;
```

C++

```
__fastcall Boolean BeginRowDrag(int Origin, int Destination, const TPoint MousePt);
```

Description

Call BeginRowDrag to start a drag operation. BeginRowDrag enables the grid to control where the row can be dropped. It is exposed as a protected method so that descendants of TCustomGrid (see page 14800) can customize row dragging in a grid.

See Also

BeginColumnDrag (see page 14817)

EndRowDrag (see page 14827)

75.1.3.5.4 TCustomGrid.BoxRect Method

Returns the screen coordinates of a specified set of cells.

Pascal

```
function BoxRect(ALeft: Longint; ATop: Longint; ARight: Longint; ABottom: Longint): TRect;
```

C++

```
__fastcall TRect BoxRect(Longint ALeft, Longint ATop, Longint ARight, Longint ABottom);
```

Description

Call BoxRect to obtain the screen coordinates, in pixels, of the cells that run from the column with index ALeft to the column with index ARight and the row with index ATop to the row with index ABottom. The coordinates of cells that are not visible onscreen are not included in the final rectangle.

See Also

BoundsRect (see page 5803)

CellRect (see page 14821)

75.1.3.5.5 TCustomGrid.CalcDrawInfo Method

Calculates the pixel locations of the grid boundaries.

Pascal

```
procedure CalcDrawInfo(var DrawInfo: TGridDrawInfo);
```

C++

```
__fastcall CalcDrawInfo(TGridDrawInfo DrawInfo);
```

Description

Use CalcDrawInfo to determine the pixel locations of the major grid boundaries in the X and Y directions, including things like the first visible column/row, the last visible column/row, the pixel extent of the fixed column/row, etc.

See Also

CalcFixedInfo (see page 14818)

75.1.3.5.6 TCustomGrid.CalcFixedInfo Method

Calculates the pixel locations of the fixed cells.

Pascal

```
procedure CalcFixedInfo(var DrawInfo: TGridDrawInfo);
```

C++

```
__fastcall CalcFixedInfo(TGridDrawInfo DrawInfo);
```

Description

Use CalcDrawInfo (see page 14818) to determine the pixel locations of the fixed cells in the X and Y directions.

See Also

CalcDrawInfo (see page 14818)

75.1.3.5.7 TCustomGrid.CalcSizingState Method

Determines the appearance of the mouse cursor during resizing.

Pascal

```
procedure CalcSizingState(X: Integer; Y: Integer; var State: TGridState; var Index: Longint;
var SizingPos: Integer; var SizingOfs: Integer; var FixedInfo: TGridDrawInfo); virtual;
```

C++

```
virtual __fastcall CalcSizingState(int X, int Y, TGridState State, Longint Index, int
SizingPos, int SizingOfs, TGridDrawInfo FixedInfo);
```

Description

Use CalcSizingState to determine if the mouse cursor should be changed to a resize or drag cursor based on where the mouse is in the grid. For example, cursor over a grid line, in the fixed cell region, and column resize is enabled = resize cursor.

See Also

CalcFixedInfo (see page 14818)

75.1.3.5.8 TCustomGrid.CanEditAcceptKey Method

Indicates whether the Key parameter can be entered into the current cell.

Pascal

```
function CanEditAcceptKey(Key: Char): Boolean; dynamic;
```

C++

```
__fastcall Boolean CanEditAcceptKey(Char Key);
```

Description

CanEditAcceptKey provides a simple screening of keyboard input while the user is editing the contents of a cell. The CanEditAcceptKey method for TCustomGrid (see page 14800) always returns true. Descendants of TCustomGrid (see page 14800) override this method to screen out illegal characters.

More refined validation can be obtained by using an edit mask.

See Also

CanGridAcceptKey (see page 14820)

GetEditMask (see page 14828)

KeyPress (see page 14833)

75.1.3.5.9 TCustomGrid.CanEditModify Method

Indicates whether the current cell in the grid can be edited.

Pascal

```
function CanEditModify: Boolean; dynamic;
```

C++

```
__fastcall Boolean CanEditModify();
```

Description

Grid components use CanEditModify internally to determine whether to allow the user to edit the current cell. CanEditModify

returns true unless the inplace editor has disallowed editing for the cell.

See Also

CanEditShow (see page 14820)

InplaceEditor (see page 14852)

75.1.3.5.10 TCustomGrid.CanEditShow Method

Indicates whether the inplace edit control can be created to allow editing.

Pascal

```
function CanEditShow: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean CanEditShow();
```

Description

Grid controls call CanEditShow internally before creating the editor for a cell. CanEditShow is called after the grid has determined that the field can be edited by calling CanEditModify (see page 14819).

CanEditShow returns false if the Options (see page 14853) property does not indicate that the grid allows editing, or if it indicates that the grid permits row selection. Otherwise, if the Options (see page 14853) property indicates that the grid is locked in edit mode, or if the grid has input focus, CanEditShow returns true. If the grid is not locked in edit mode and the grid does not have input focus, CanEditShow returns false.

See Also

CanEditModify (see page 14819)

InplaceEditor (see page 14852)

Options (see page 14853)

75.1.3.5.11 TCustomGrid.CanGridAcceptKey Method

Indicates whether the grid should respond to a given key combination.

Pascal

```
function CanGridAcceptKey(Key: Word; Shift: TShiftState): Boolean; dynamic;
```

C++

```
__fastcall Boolean CanGridAcceptKey(Word Key, TShiftState Shift);
```

Description

Grid controls call CanGridAcceptKey internally to screen key combinations when the user first presses a key. The CanGridAcceptKey method for TCustomGrid (see page 14800) always returns true. Descendants of TCustomGrid (see page 14800) override this method to screen out irrelevant key combinations, or key combinations that indicate actions that would violate the Options (see page 14853) or mode of the grid.

See Also

CanEditAcceptKey (see page 14819)

KeyDown (see page 14833)

Options (see page 14853)

75.1.3.5.12 TCustomGrid.CellRect Method

Returns the screen coordinates of a cell in the grid.

Pascal

```
function CellRect(ACol: Longint; ARow: Longint): TRect;
```

C++

```
__fastcall TRect CellRect(Longint ACol, Longint ARow);
```

Description

Call CellRect to obtain the boundaries, in pixels, of the cell in the column and row indicated by the ACol and ARow parameters. The top left cell is specified when ACol and ARow are set to zero.

If the indicated cell is not visible, CellRect returns an empty rectangle.

See Also

BoxRect (see page 14818)

75.1.3.5.13 TCustomGrid.ChangeGridOrientation Method

Prepares the grid's canvas for painting to reflect a right-to-left or left-to-right orientation.

Pascal

```
procedure ChangeGridOrientation(RightToLeftOrientation: Boolean);
```

C++

```
__fastcall ChangeGridOrientation(Boolean RightToLeftOrientation);
```

Description

TCustomGrid (see page 14800) uses ChangeGridOrientation internally when painting. ChangeGridOrientation sets the origin and dimensions of the grid's canvas so that painting occurs from right-to-left or from left-to-right based on the value of the RightToLeftOrientation parameter.

RightToLeftOrientation is true if the grid should prepare for painting from right to left. RightToLeftOrientation is false if the grid should restore the canvas to normal.

See Also

UseRightToLeftAlignment (see page 5790)

BiDiMode (see page 5803)

75.1.3.5.14 TCustomGrid.CheckColumnDrag Method

CheckColumnDrag validates whether the column currently selected for dragging can be dropped at the current location.

Pascal

```
function CheckColumnDrag(var Origin: Integer; var Destination: Integer; const MousePt:
TPoint): Boolean; dynamic;
```

C++

```
__fastcall Boolean CheckColumnDrag(int Origin, int Destination, const TPoint MousePt);
```

Description

Use CheckColumnDrag to validate that the column currently selected for dragging can be dropped at the current location.

CheckColumnDrag can change the Origin (the column being dragged) and/or the Destination (the drop target), as needed, to keep the grid's columns in order.

See Also

BeginColumnDrag (see page 14817)

EndColumnDrag (see page 14827)

75.1.3.5.15 TCustomGrid.CheckRowDrag Method

CheckRowDrag validates whether the row currently selected for dragging can be dropped at the current location.

Pascal

```
function CheckRowDrag(var Origin: Integer; var Destination: Integer; const MousePt: TPoint):
Boolean; dynamic;
```

C++

```
__fastcall Boolean CheckRowDrag(int Origin, int Destination, const TPoint MousePt);
```

Description

Use CheckRowDrag to validate that the row currently selected for dragging can be dropped at the current location. CheckRowDrag can change the Origin (the row being dragged) and/or the Destination (the drop target), as needed, to keep the grid's rows in order.

See Also

BeginRowDrag (see page 14817)

EndRowDrag (see page 14827)

75.1.3.5.16 TCustomGrid.ColumnMoved Method

Provides the interface for a method that responds when the position of a column changes.

Pascal

```
procedure ColumnMoved(FromIndex: Longint; ToIndex: Longint); dynamic;
```

C++

```
__fastcall ColumnMoved(Longint FromIndex, Longint ToIndex);
```

Description

ColumnMoved is called immediately after a column in the grid has moved. The FromIndex parameter is the old index of the column, and the ToIndex parameter is the new index. The ColumnMoved method of TCustomGrid (see page 14800) does nothing. Descendants of TCustomGrid (see page 14800) override this method to make internal adjustments or to generate an OnColumnMoved event.

See Also

MoveColumn (see page 14836)

75.1.3.5.17 TCustomGrid.ColWidthsChanged Method

Responds when the column widths change.

Pascal

```
procedure ColWidthsChanged; dynamic;
```

C++

```
__fastcall ColWidthsChanged();
```

Description

ColWidthsChanged is called immediately after the column widths change. The change can result from setting the ColWidths (see page 14845) property, from setting the DefaultColWidth (see page 14846) property, from moving one of the columns, or from resizing the columns with the mouse.

ColWidthsChanged adjusts the scroll bar and the position of the inplace editor to take into account the new column size and positions of the columns.

See Also

ColWidths (see page 14845)

DefaultColWidth (see page 14846)

InplaceEditor (see page 14852)

ScrollBars (see page 14856)

75.1.3.5.18 TCustomGrid.CreateEditor Method

Creates the inplace editor control.

Pascal

```
function CreateEditor: TInplaceEdit; virtual;
```

C++

```
virtual __fastcall TInplaceEdit CreateEditor();
```

Description

Grid controls call CreateEditor internally the first time the grid goes into edit mode. CreateEditor is exposed as a protected method so that descendants of TCustomGrid (see page 14800) can substitute a specialized descendant of TInplaceEdit (see page 14938) to handle cell editing.

See Also

EditorMode (see page 14848)

InplaceEditor (see page 14852)

ShowEditor (see page 14839)

75.1.3.5.19 TCustomGrid.CreateParams Method

Initializes the window-creation parameter record.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method is called internally to specify the properties of the window that implements this control. These properties are set in the window-creation parameter record passed as Params. The fields of this record become the parameters to a call to

the CreateWindowEx API function.

After calling the inherited method, CreateParams adjusts the value of Params to request that the grid receive double click messages, and to implement the values of the ScrollBars (see page 14856) and BorderStyle (see page 14843) properties.

See Also

BorderStyle (see page 14843)

ScrollBars (see page 14856)

CreateWnd (see page 6137)

75.1.3.5.20 TCustomGrid.DefineProperties Method

Adds the ColWidths (see page 14845) and RowHeights (see page 14855) properties to the values saved with the grid.

Pascal

```
procedure DefineProperties(Filer: TFiler); override;
```

C++

```
virtual __fastcall DefineProperties(TFiler Filer);
```

Description

DefineProperties overrides the inherited method to save the ColWidths (see page 14845) and RowHeights (see page 14855) properties with the grid when they contain values other than the default widths and heights.

See Also

ColWidths (see page 14845)

DefaultColWidth (see page 14846)

DefaultRowHeight (see page 14847)

RowHeights (see page 14855)

TFiler (see page 2834)

75.1.3.5.21 TCustomGrid.DeleteColumn Method

Deletes a specified column from the grid.

Pascal

```
procedure DeleteColumn(ACol: Longint); virtual;
```

C++

```
virtual __fastcall DeleteColumn(Longint ACol);
```

Description

Call DeleteColumn to remove a column from the middle of the grid. Provide the index of the column to remove as ACol. To remove the last column from the grid, set the ColCount (see page 14844) property instead.

See Also

ColCount (see page 14844)

75.1.3.5.22 TCustomGrid.DeleteRow Method

Deletes a specified from the grid.

Pascal

```
procedure DeleteRow(ARow: Longint); virtual;
```

C++

```
virtual __fastcall DeleteRow(Longint ARow);
```

Description

Call DeleteRow to remove a row from the middle of the grid. Provide the index of the row to remove as ARow. To remove the last row from the grid, set the RowCount (see page 14854) property instead.

See Also

RowCount (see page 14854)

75.1.3.5.23 TCustomGrid.DoExit Method

Hides the inplace editor when selection moves to another control in a form.

Pascal

```
procedure DoExit; override;
```

C++

```
virtual __fastcall DoExit();
```

Description

After calling the inherited method, which generates an OnExit event, DoExit hides the inplace editor unless the Options (see page 14853) property includes goAlwaysShowEditor.

See Also

HideEditor (see page 14830)

Options (see page 14853)

OnExit (see page 6221)

75.1.3.5.24 TCustomGrid.DoMouseWheelDown Method

Performs tasks when the mouse wheel is rotated downward.

Pascal

```
function DoMouseWheelDown(Shift: TShiftState; MousePos: TPoint): Boolean; override;
```

C++

```
virtual __fastcall Boolean DoMouseWheelDown(TShiftState Shift, TPoint MousePos);
```

Description

Override DoMouseWheelDown to perform tasks when the mouse wheel is rotated downward.

DoMouseWheelDown returns false if the control's parent should handle the message.

In TCustomGrid (see page 14800), DoMouseWheelDown increments the current row and returns true.

See Also

DoMouseWheelUp (see page 14826)

Row (see page 14854)

75.1.3.5.25 TCustomGrid.DoMouseWheelUp Method

Performs tasks when the mouse wheel is rotated upward.

Pascal

```
function DoMouseWheelUp(Shift: TShiftState; MousePos: TPoint): Boolean; override;
```

C++

```
virtual __fastcall Boolean DoMouseWheelUp(TShiftState Shift, TPoint MousePos);
```

Description

Override DoMouseWheelUp to perform tasks when the mouse wheel is rotated downward.

DoMouseWheelUp should return false if the control's parent should handle the message.

In TCustomGrid (see page 14800), DoMouseWheelUp decrements the current row and returns true.

See Also

DoMouseWheelDown (see page 14825)

Row (see page 14854)

75.1.3.5.26 TCustomGrid.DrawCell Method

Provides the prototype for a method that draws the contents of a cell in the grid.

Pascal

```
procedure DrawCell(ACol: Longint; ARow: Longint; ARect: TRect; AState: TGridDrawState);
virtual; abstract;
```

C++

```
virtual __fastcall DrawCell(Longint ACol, Longint ARow, TRect ARect, TGridDrawState AState) =
0;
```

Description

Descendants of TCustomGrid (see page 14800) implement the DrawCell method to draw the contents of the cell or to generate an OnDrawCell event. If the DefaultDrawing (see page 14847) property is true, the background of the cell is painted before DrawCell is called, and the 3D effects of the fixed cells or the focus rectangle around the focused cell are drawn after DrawCell.

The ACol and ARow parameters give the column and row indexes of the cell that should be drawn. The ARect parameter gives the boundaries of the cell in the coordinates of the canvas. The AState parameter indicates whether the cell is selected, whether the cell has input focus, and whether the cell is in the fixed, non-scrolling portion of the grid.

See Also

DefaultDrawing (see page 14847)

FixedCols (see page 14848)

FixedRows (see page 14849)

Options (see page 14853)

75.1.3.5.27 TCustomGrid.EndColumnDrag Method

Ends the dragging of a column in the grid.

Pascal

```
function EndColumnDrag(var Origin: Integer; var Destination: Integer; const MousePt: TPoint):
Boolean; dynamic;
```

C++

```
__fastcall Boolean EndColumnDrag(int Origin, int Destination, const TPoint MousePt);
```

Description

Call EndColumnDrag to end a drag operation. EndColumnDrag enables the grid to control where the column can be dropped. It is exposed as a protected method so that descendants of TCustomGrid (see page 14800) can customize column dragging in a grid.

See Also

BeginColumnDrag (see page 14817)

75.1.3.5.28 TCustomGrid.EndRowDrag Method

Ends the dragging of a row in the grid.

Pascal

```
function EndRowDrag(var Origin: Integer; var Destination: Integer; const MousePt: TPoint):
Boolean; dynamic;
```

C++

```
__fastcall Boolean EndRowDrag(int Origin, int Destination, const TPoint MousePt);
```

Description

Call EndRowDrag to end a drag operation. EndRowDrag enables the grid to control where the row can be dropped. It is exposed as a protected method so that descendants of TCustomGrid (see page 14800) can customize row dragging in a grid.

See Also

BeginRowDrag (see page 14817)

75.1.3.5.29 TCustomGrid.FocusCell Method

Changes the current cell to a specified cell.

Pascal

```
procedure FocusCell(ACol: Longint; ARow: Longint; MoveAnchor: Boolean);
```

C++

```
__fastcall FocusCell(Longint ACol, Longint ARow, Boolean MoveAnchor);
```

Description

TCustomGrid (see page 14800) calls FocusCell internally to change the currently selected cell. FocusCell changes the current cell and updates the selection appropriately.

ACol is the column of the cell to select.

ARow is the row of the cell to select.

MoveAnchor determines how the selection changes. If the grid does not allow multiple cells to be selected (Options (see page 14853) does not include goRangeSelect), MoveAnchor is ignored and the specified cell becomes the selected cell. If the grid allows multiple cells to be selected, MoveAnchor determines whether the new cell becomes the starting cell (anchor) of a new selection, or whether the current selection is updated to range from the current anchor to the specified cell.

See Also

Col (see page 14843)

Row (see page 14854)

Selection (see page 14856)

Options (see page 14853)

75.1.3.5.30 TCustomGrid.GetEditLimit Method

Provides the interface for a method that limits the number of characters the user can type into cells.

Pascal

```
function GetEditLimit: Integer; dynamic;
```

C++

```
__fastcall int GetEditLimit();
```

Description

The inplace editor calls GetEditLimit to determine if a limit should be placed on the number of characters a user can type into a cell. GetEditLimit sets no limits. Descendants of TCustomGrid (see page 14800) override this method to limit the text for certain cells.

See Also

InplaceEditor (see page 14852)

75.1.3.5.31 TCustomGrid.GetEditMask Method

Provides the interface for a method that returns an input mask for the specified cell.

Pascal

```
function GetEditMask(ACol: Longint; ARow: Longint): string; dynamic;
```

C++

```
__fastcall AnsiString GetEditMask(Longint ACol, Longint ARow);
```

Description

The inplace editor calls GetEditMask to obtain any input mask associated with the cell specified by the ACol and ARow parameters. GetEditMask returns an empty string, indicating that the cell has no input mask. Descendants of TCustomGrid (see page 14800) override this method to provide an input mask or generate an OnGetEditMask event.

See Also

InplaceEditor (see page 14852)

EditMask (see page 15821)

75.1.3.5.32 TCustomGrid.GetEditStyle Method

Indicates whether a specified cell has an ellipsis button or drop-down arrow.

Pascal

```
function GetEditStyle(ACol: Longint; ARow: Longint): TEditStyle; dynamic;
```

C++

```
__fastcall TEditStyle GetEditStyle(Longint ACol, Longint ARow);
```

Description

GetEditStyle indicates whether the specified cell can only be edited directly (esSimple), whether it has an ellipsis button that users can click to launch an editor for modifying field values (esEllipsis), or whether it has a drop-down arrow that users can click to display a pick list of possible values (esPickList).

ACol is the column that contains the cell. ARow is the row that contains the cell.

In TCustomGrid (see page 14800), GetEditStyle always returns esSimple, indicating that there is no ellipsis button or drop-down arrow. Descendant classes can override this methods if they provide a way to add pick lists or ellipsis buttons to cells.

75.1.3.5.33 TCustomGrid.GetEditText Method

Returns the value of the indicated cell formatted for editing.

Pascal

```
function GetEditText(ACol: Longint; ARow: Longint): string; dynamic;
```

C++

```
__fastcall AnsiString GetEditText(Longint ACol, Longint ARow);
```

Description

The inplace editor calls GetEditText to obtain the text for the indicated cell. GetEditText returns an empty string. Descendants of TCustomGrid (see page 14800) override the GetEditText method to return a string that represents the contents of the cell indicated by the ACol and ARow parameters.

See Also

InplaceEditor (see page 14852)

75.1.3.5.34 TCustomGrid.GetGridHeight Method

Returns the value of the GridHeight (see page 14850) property.

Pascal

```
function GetGridHeight: Integer;
```

C++

```
__fastcall int GetGridHeight();
```

Description

GetGridHeight is the protected property access method for the GridHeight (see page 14850) property. It computes the value of the GridHeight (see page 14850) property based on the row heights, separator width, and the size of the control.

See Also

ClientHeight (see page 5808)

GetGridWidth (see page 14830)

GridHeight (see page 14850)

GridLineWidth (see page 14850)

RowHeights (see page 14855)

75.1.3.5.35 TCustomGrid.GetGridWidth Method

Returns the value of the GridWidth (see page 14851) property.

Pascal

```
function GetGridWidth: Integer;
```

C++

```
__fastcall int GetGridWidth();
```

Description

GetGridWidth is the protected property access method for the GridWidth (see page 14851) property. It computes the value of the GridWidth (see page 14851) property based on the column widths, separator width, and the size of the control.

See Also

ClientWidth (see page 5811)

ColWidths (see page 14845)

GetGridHeight (see page 14829)

GridWidth (see page 14851)

GridLineWidth (see page 14850)

75.1.3.5.36 TCustomGrid.HideEdit Method

Hides the inplace editor.

Pascal

```
procedure HideEdit;
```

C++

```
__fastcall HideEdit();
```

Description

The HideEditor (see page 14830) method calls the protected HideEdit method to hide the editor. This method hides the editor window after updating the text to reflect the text in the editor.

See Also

HideEditor (see page 14830)

InplaceEditor (see page 14852)

75.1.3.5.37 TCustomGrid.HideEditor Method

Hides the inplace editor when it is not in use.

Pascal

```
procedure HideEditor;
```

C++

```
__fastcall HideEditor();
```

Description

Grid controls call HideEditor when the grid goes out of edit mode. HideEditor hides the window of the inplace editor.

See Also

EditorMode (see page 14848)

InplaceEditor (see page 14852)

ShowEditor (see page 14839)

75.1.3.5.38 TCustomGrid.InvalidateCell Method

Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.

Pascal

```
procedure InvalidateCell(ACol: Longint; ARow: Longint);
```

C++

```
__fastcall InvalidateCell(Longint ACol, Longint ARow);
```

Description

Call InvalidateCell when the contents of a cell change so that the cell will need to be repainted. The ACol parameter is the column index of the cell, and the ARow parameter is the row index.

See Also

CellRect (see page 14821)

InvalidateCol (see page 14831)

InvalidateEditor (see page 14832)

InvalidateRow (see page 14832)

75.1.3.5.39 TCustomGrid.InvalidateCol Method

Invalidates the region occupied by a column so that it will be repainted with the next Windows paint message.

Pascal

```
procedure InvalidateCol(ACol: Longint);
```

C++

```
__fastcall InvalidateCol(Longint ACol);
```

Description

Call InvalidateCol when a column changes so that the area it occupies will need to be repainted. The ACol parameter is the column index.

See Also

BoxRect (see page 14818)

InvalidateCell (see page 14831)

InvalidateRow (see page 14832)

75.1.3.5.40 TCustomGrid.InvalidateEditor Method

Causes the inplace editor to repaint itself, moving to a new location if necessary.

Pascal

```
procedure InvalidateEditor;
```

C++

```
__fastcall InvalidateEditor();
```

Description

InvalidateEditor is called when the selected cell changes while the grid is in edit mode.

See Also

EditorMode (see page 14848)

HideEditor (see page 14830)

InplaceEditor (see page 14852)

InvalidateCell (see page 14831)

ShowEditor (see page 14839)

75.1.3.5.41 TCustomGrid.InvalidateGrid Method

Tells Windows to repaint the grid after other important Windows messages are handled.

Pascal

```
procedure InvalidateGrid;
```

C++

```
__fastcall InvalidateGrid();
```

Description

InvalidateGrid is used internally to ensure that the grid is repainted when its properties change. It calls the Invalidate method to indicate that the grid needs repainting.

See Also

Invalidate (see page 6161)

75.1.3.5.42 TCustomGrid.InvalidateRow Method

Invalidates the region occupied by a row so that it will be repainted with the next Windows paint message.

Pascal

```
procedure InvalidateRow(ARow: Longint);
```

C++

```
__fastcall InvalidateRow(Longint ARow);
```

Description

Call InvalidateRow when a row changes so that the area it occupies will need to be repainted. The ARow parameter is the row index.

See Also

BoxRect (see page 14818)

InvalidateCell (see page 14831)

InvalidateCol (see page 14831)

75.1.3.5.43 TCustomGrid.KeyDown Method

Provides special processing when the user presses a key.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

After generating an OnKeyDown event, KeyDown calls CanGridAcceptKey (see page 14820) to screen out problematic key combinations. KeyDown moves to the appropriate cell in response to navigational key combinations, or sets the EditorMode (see page 14848) property to true when the user presses F2.

See Also

CanGridAcceptKey (see page 14820)

EditorMode (see page 14848)

KeyPress (see page 14833)

OnKeyDown (see page 6225)

75.1.3.5.44 TCustomGrid.KeyPress Method

Provides special processing when the user presses a key.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress is called automatically after the KeyDown (see page 14833) method, but before the user releases the key.

After generating an OnKeyPress event, KeyPress toggles the EditorMode (see page 14848) property when the user presses the Enter key.

See Also

EditorMode (see page 14848)

KeyDown (see page 14833)

OnKeyPress (see page 6227)

75.1.3.5.45 TCustomGrid.MouseCoord Method

Returns the row and column indexes of the cell that contains a point specified in screen coordinates.

Pascal

```
function MouseCoord(X: Integer; Y: Integer): TGridCoord;
```

C++

```
__fastcall TGridCoord MouseCoord(int X, int Y);
```

Description

Call MouseCoord to locate the column and row of the cell which contains a given screen coordinate. Usually, MouseCoord is used to locate the cell that is under the mouse.

See Also

CellRect (see page 14821)

MouseDown (see page 14834)

MouseMove (see page 14834)

MouseUp (see page 14835)

75.1.3.5.46 TCustomGrid.MouseDown Method

Provides special processing when the user presses a mouse button.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

MouseDown hides the editor window so that it can move selection to the cell that receives the mouse click. If the mouse lands in the hot region for beginning a move or resize of a row or column, MouseDown starts the move or resize, and provides visual feedback by changing the cursor. If the editor window was hidden, it is brought back up in its new location. Finally, MouseDown generates an OnMouseDown event.

See Also

HideEditor (see page 14830)

InplaceEditor (see page 14852)

MouseMove (see page 14834)

MouseUp (see page 14835)

ShowEditor (see page 14839)

OnMouseDown (see page 5862)

75.1.3.5.47 TCustomGrid.MouseMove Method

Provides special processing when the user moves the mouse.

Pascal

```
procedure MouseMove(Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseMove(TShiftState Shift, int X, int Y);
```

Description

If the grid is in the middle of moving or resizing a row or column, or in the middle of selecting a range of cells using the mouse, MouseMove calculates the changes implied by the mouse move and provides visual feedback to the user. Finally, MouseMove generates an OnMouseMove event.

See Also

MouseDown (see page 14834)

MouseUp (see page 14835)

OnMouseMove (see page 5865)

75.1.3.5.48 TCustomGrid.MouseUp Method

Provides special processing when the user releases the mouse button.

Pascal

```
procedure MouseUp(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseUp(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

MouseUp finishes a move or resize operation on a row or column, or if the user is selecting a range of cells using the mouse, MouseUp finishes the select operation. Finally, MouseUp generates an OnMouseUp event.

See Also

MouseDown (see page 14834)

MouseMove (see page 14834)

MoveColumn (see page 14836)

MoveRow (see page 14836)

OnMouseUp (see page 5867)

75.1.3.5.49 TCustomGrid.MoveColRow Method

Selects the cell indicated by the ACol and ARow parameters.

Pascal

```
procedure MoveColRow(ACol: Longint; ARow: Longint; MoveAnchor: Boolean; Show: Boolean);
```

C++

```
__fastcall MoveColRow(Longint ACol, Longint ARow, Boolean MoveAnchor, Boolean Show);
```

Description

Grid controls call MoveColRow internally when changing the selected cell or cells. MoveColRow selects the indicated cell, but does not take care of removing any previous selection.

The ACol and ARow parameters are the column index and the row index of the cell to be selected. The MoveAnchor parameter indicates whether the new cell becomes the upper left corner of the selected region. MoveAnchor is true unless MoveColRow is called when extending a multicell selected region. The Show parameter indicates whether MoveColRow should ensure that the newly selected cell is visible.

See Also

Col (see page 14843)

Row (see page 14854)

SelectCell (see page 14838)

Selection (see page 14856)

75.1.3.5.50 TCustomGrid.MoveColumn Method

Moves a column to a new position.

Pascal

```
procedure MoveColumn(FromIndex: Longint; ToIndex: Longint);
```

C++

```
__fastcall MoveColumn(Longint FromIndex, Longint ToIndex);
```

Description

Call MoveColumn to move the column identified by the FromIndex parameter to the position specified by the ToIndex parameter.

See Also

ColumnMoved (see page 14822)

ColWidthsChanged (see page 14822)

75.1.3.5.51 TCustomGrid.MoveRow Method

Moves a row to a new position.

Pascal

```
procedure MoveRow(FromIndex: Longint; ToIndex: Longint);
```

C++

```
__fastcall MoveRow(Longint FromIndex, Longint ToIndex);
```

Description

Call MoveRow to move the row identified by the FromIndex parameter to the position specified by the ToIndex parameter.

See Also

RowHeightsChanged (see page 14837)

RowMoved (see page 14837)

75.1.3.5.52 TCustomGrid.Paint Method

Draws the image of the grid control on the screen.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

Paint is called when the grid receives a paint message. Paint draws the grid, calling the DrawCell (see page 14826) method when it is time to paint the contents of each cell. If DefaultDrawing (see page 14847) is false, Paint does not draw the background of the cells, provide the raised 3D effects on the fixed cells, or draw the focus rectangle around the selected cell when it has focus.

See Also

DefaultDrawing (see page 14847)

DrawCell (see page 14826)

InvalidateCell (see page 14831)

InvalidateCol (see page 14831)

InvalidateRow (see page 14832)

75.1.3.5.53 TCustomGrid.RowHeightsChanged Method

Responds when the row heights change.

Pascal

```
procedure RowHeightsChanged; dynamic;
```

C++

```
__fastcall RowHeightsChanged();
```

Description

RowHeightsChanged is called immediately after the row heights change. The change can result from setting the RowHeights (see page 14855) property, from setting the DefaultRowHeight (see page 14847) property, from moving one of the rows, or from resizing the rows with the mouse.

RowHeightsChanged adjusts the scroll bar and the position of the inplace editor to take into account the new row size and positions of the rows.

See Also

DefaultRowHeight (see page 14847)

InplaceEditor (see page 14852)

RowHeights (see page 14855)

ScrollBars (see page 14856)

75.1.3.5.54 TCustomGrid.RowMoved Method

Provides the interface for a method that responds when the position of a row changes.

Pascal

```
procedure RowMoved(FromIndex: Longint; ToIndex: Longint); dynamic;
```

C++

```
__fastcall RowMoved(Longint FromIndex, Longint ToIndex);
```

Description

RowMoved is called immediately after a row in the grid changes position. The FromIndex parameter is the old index of the row, and the ToIndex parameter is the new index. The RowMoved method of TCustomGrid (see page 14800) does nothing. Descendants of TCustomGrid (see page 14800) override this method to make internal adjustments or to generate an OnRowMoved event.

See Also

MoveRow (see page 14836)

75.1.3.5.55 TCustomGrid.ScrollData Method

Scrolls the visual image of the cells in the grid.

Pascal

```
procedure ScrollData(DX: Integer; DY: Integer);
```

C++

```
__fastcall ScrollData(int DX, int DY);
```

Description

Grid controls call ScrollData internally when the nonfixed rows or columns scroll. ScrollData updates the image of the grid.

See Also

LeftCol (see page 14852)

TopRow (see page 14858)

75.1.3.5.56 TCustomGrid.SelectCell Method

Determines whether a particular cell in the grid can be selected.

Pascal

```
function SelectCell(ACol: Longint; ARow: Longint): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean SelectCell(Longint ACol, Longint ARow);
```

Description

Grid controls call SelectCell internally before attempting to move selection to a the cell identified by the ACol and ARow parameters. ACol and ARow are the column and row indexes for the cell, where the first column has index 0, and the top row has index 0.

The SelectCell method for TCustomGrid (see page 14800) always returns true, allowing the cell to be selected. Descendants of TCustomGrid (see page 14800) override this method to check the properties of the information displayed in the cell or generating an OnSelectCell event.

See Also

MoveColRow (see page 14835)

TabStops (see page 14858)

75.1.3.5.57 TCustomGrid.SetEditText Method

Provides the interface for a method that updates the text associated with a cell.

Pascal

```
procedure SetEditText(ACol: Longint; ARow: Longint; const Value: string); dynamic;
```

C++

```
__fastcall SetEditText(Longint ACol, Longint ARow, const AnsiString Value);
```

Description

SetEditText is called by the inplace editor so that the grid can store the new value for the current cell. The SetEditText method for TCustomGrid (see page 14800) does nothing. Descendants of TCustomGrid (see page 14800) override this method to update an internal representation of the cell's value, or to generate an OnSetEditText event.

See Also

GetEditText (see page 14829)

75.1.3.5.58 TCustomGrid.ShowEditor Method

Displays the inplace editor when the grid enters edit mode.

Pascal

```
procedure ShowEditor;
```

C++

```
__fastcall ShowEditor();
```

Description

Grid controls call ShowEditor when the grid enters edit mode. ShowEditor displays the window of the inplace editor over the currently selected cell. If the inplace editor does not yet exist, ShowEditor creates it.

See Also

CreateEditor (see page 14823)

EditorMode (see page 14848)

HideEditor (see page 14830)

InplaceEditor (see page 14852)

75.1.3.5.59 TCustomGrid.ShowEditorChar Method

Displays the inplace editor, with its text set to the specified character.

Pascal

```
procedure ShowEditorChar(Ch: Char);
```

C++

```
__fastcall ShowEditorChar(Char Ch);
```

Description

Grid controls call ShowEditorChar when the user types a character into a cell and the editor is not already showing. ShowEditorChar displays the window of the inplace editor over the currently selected cell, and sets its text property to the

character Ch. If the inplace editor does not yet exist, ShowEditorChar creates it.

See Also

CreateEditor (see page 14823)

EditorMode (see page 14848)

HideEditor (see page 14830)

InplaceEditor (see page 14852)

ShowEditor (see page 14839)

75.1.3.5.60 TCustomGrid.SizeChanged Method

Responds to changes in the size of the grid.

Pascal

```
procedure SizeChanged(OldColCount: Longint; OldRowCount: Longint); dynamic;
```

C++

```
__fastcall SizeChanged(Longint OldColCount, Longint OldRowCount);
```

Description

SizeChanged provides the interface for a method that responds to changes in the number of rows or columns in the grid. The SizeChanged method of TCustomGrid (see page 14800) does nothing. Descendants of TCustomGrid (see page 14800) override this method to make internal adjustments or generate events.

See Also

ColCount (see page 14844)

RowCount (see page 14854)

75.1.3.5.61 TCustomGrid.Sizing Method

Indicates whether the indicated coordinates are on one of the resize hot zones of the graph.

Pascal

```
function Sizing(X: Integer; Y: Integer): Boolean;
```

C++

```
__fastcall Boolean Sizing(int X, int Y);
```

Description

Grid controls call Sizing internally with the coordinates of a mouse click to determine whether the user is about to resize a row or column.

See Also

MouseDown (see page 14834)

75.1.3.5.62 TCustomGrid.TimedScroll Method

Extends a move, resize, or selection out of the scrollable region when the user drags the mouse in a direction where the grid is scrolled.

Pascal

```
procedure TimedScroll(Direction: TGridScrollDirection); dynamic;
```

C++

```
__fastcall TimedScroll(TGridScrollDirection Direction);
```

Description

TimedScroll is called periodically as the user continues to drag with the mouse outside of the scrollable cells in the grid. TimedScroll does nothing unless the user is moving a row or column, resizing a row or column, or selecting a multiple cell region using the mouse. TimedScroll scrolls the cells in the grid to allow the operation to continue into the portion of the grid that was hidden due to scrolling.

See Also

LeftCol (see page 14852)

MouseMove (see page 14834)

TopRow (see page 14858)

VisibleColCount (see page 14859)

VisibleRowCount (see page 14859)

75.1.3.5.63 TCustomGrid.TopLeftChanged Method

Updates the position of the inplace editor when the grid scrolls.

Pascal

```
procedure TopLeftChanged; dynamic;
```

C++

```
__fastcall TopLeftChanged();
```

Description

Grid controls call TopLeftChanged internally, whenever the LeftCol (see page 14852) or TopRow (see page 14858) property changes.

Descendants of TCustomGrid (see page 14800) override this method to make additional adjustments or to generate an OnTopLeftChanged event.

See Also

InplaceEditor (see page 14852)

LeftCol (see page 14852)

TopRow (see page 14858)

75.1.3.5.64 TCustomGrid.UpdateDesigner Method

Notifies the designer when rows and columns of the grid are moved or resized.

Pascal

```
procedure UpdateDesigner;
```

C++

```
__fastcall UpdateDesigner();
```

Description

At design time, the designer automatically keeps track of property changes so that it can prompt the user to save any changes. Moving or resizing the rows and columns of the grid using the mouse bypasses this system. When such changes occur, UpdateDesigner notifies the designer that the properties of the grid have changed and that the changes should be saved.

See Also

MouseUp (see page 14835)

75.1.3.6 TCustomGrid Properties

The properties of the TCustomGrid class are listed here.

Protected Properties

	Name	Description
	BorderStyle (see page 14843)	Determines whether a single line border is drawn around the grid.
	Col (see page 14843)	Specifies the index of the column that contains the selected cell.
	ColCount (see page 14844)	Specifies the number of columns in the grid.
	Color (see page 14844)	Specifies the background color of the control.
	ColWidths (see page 14845)	Indicates the width (in pixels) of all the columns in the grid.
	DefaultColWidth (see page 14846)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 14847)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 14847)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	EditorMode (see page 14848)	Determines whether the current cell can be edited.
	FixedColor (see page 14848)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 14848)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	FixedRows (see page 14849)	Specifies the number of rows on the top of the grid that cannot be scrolled.
R	GridHeight (see page 14850)	Specifies the height of the grid in pixels.
	GridLineWidth (see page 14850)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
R	GridWidth (see page 14851)	Specifies the width of the grid in pixels.
R	HitTest (see page 14851)	Indicates the current position of the mouse cursor.
R	InplaceEditor (see page 14852)	Designates the edit control the grid uses to allow users to edit the contents of the selected cell.
	LeftCol (see page 14852)	Specifies the index of the first visible scrollable column in the grid.
	Options (see page 14853)	Specifies various display and behavioral properties of the grid.
	ParentColor (see page 14853)	Determines where a control looks for its color information.
	Row (see page 14854)	Specifies the index of the row that contains the selected cell.
	RowCount (see page 14854)	Specifies the number of rows in the grid.
	RowHeights (see page 14855)	Gives the height (in pixels) of all rows in the grid.
	ScrollBars (see page 14856)	Specifies whether the grid includes horizontal and vertical scroll bars.
	Selection (see page 14856)	Indicates the boundaries of the current selection.
	TabStops (see page 14858)	Indicates whether the user can tab to specified columns in the grid.
	TopRow (see page 14858)	Specifies the index of the first visible scrollable row in the grid.
R	VisibleColCount (see page 14859)	Indicates the number of scrollable columns visible in the grid.
R	VisibleRowCount (see page 14859)	Indicates the number of scrollable rows visible in the grid.

Published Properties

	Name	Description
	TabStop (see page 14857)	Determines if the user can tab to a control.

75.1.3.6.1 TCustomGrid.BorderStyle Property

Determines whether a single line border is drawn around the grid.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Set BorderStyle to bsSingle to add a single line border around the grid's image. Set BorderStyle to bsNone to omit the border.

75.1.3.6.2 TCustomGrid.Col Property

Specifies the index of the column that contains the selected cell.

Pascal

```
property Col: Longint;
```

C++

```
__property Longint Col;
```

Description

Use Col at runtime to determine the current column in the grid. Setting Col moves focus to the cell in the current row that is in the new column. The first column has an index of 0, the second column an index of 1, and so on.

The selected cell in the grid can be located by reading the Col property and the Row (see page 14854) property to obtain the indexes of its column and row. When focus moves to the grid, the selected cell gets input focus.

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It uses a draw grid with a label above it on a form. When
the user clicks a cell in the grid, the location of the
cursor is displayed in the label caption. This example
requires a populated image list, or can just display an
empty grid.
}
procedure TForm1.DrawGrid1Click(Sender: TObject);
begin
  Label1.Caption := 'From OnClick: The cursor is in column ' +
                    IntToStr(DrawGrid1.Col + 1) +
                    ', row ' +
                    IntToStr(DrawGrid1.Row + 1);
end;

procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clBackground;
  DrawGrid1.Canvas.FillRect(Rect);
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  if (gdFocused in State) then
  begin
```

```
      DrawGrid1.Canvas.DrawFocusRect(Rect);
      Label2.Caption:= 'From OnDrawCell: Cell ' + InttoStr(index) + ' has the focus.';
    end;
  end;

  procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
    var CanSelect: Boolean);
  begin
    CanSelect:= True;
  end;
```

See Also

Row (see page 14854)

75.1.3.6.3 TCustomGrid.ColCount Property

Specifies the number of columns in the grid.

Pascal

```
property ColCount: Longint;
```

C++

```
__property Longint ColCount;
```

Description

Read ColCount to determine the number entries in the ColWidths (see page 14845) array. Set ColCount to add or delete columns at the righthand side of the grid. The value of ColCount includes any fixed columns at the left of the grid as well as the scrollable columns in the body of the grid.

Delphi Examples:

```
{
This code fills each cell with a number. The numbers are
arranged in consecutive order by rows.  Notice that even
cells in the fixed rows and columns are altered.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I, J, K : Integer;
begin
  K := 0;
  with StringGrid1 do
    for I := 0 to ColCount - 1 do
      for J:= 0 to RowCount - 1 do
        begin
          K := K + 1;
          Cells[I,J] := IntToStr(K);
        end;
end;
```

See Also

ColWidths (see page 14845)

RowCount (see page 14854)

VisibleColCount (see page 14859)

75.1.3.6.4 TCustomGrid.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

75.1.3.6.5 TCustomGrid.ColWidths Property

Indicates the width (in pixels) of all the columns in the grid.

Pascal

```
property ColWidths [Index: Longint]: Integer;
```

C++

```
__property int ColWidths[Longint Index];
```

Description

Read ColWidths to determine the width of the cells in the column specified by the Index parameter. An index of 0 refers to the first column. Set ColWidths at runtime to change the width of an individual column.

If the width of a column has not been set explicitly by resizing with the mouse, or by using the ColWidths property, its width is DefaultColWidth (see page 14846).

Use the ColCount (see page 14844) property to determine the number of entries in the ColWidths array.

See Also

ColCount (see page 14844)

DefaultColWidth (see page 14846)

RowHeights (see page 14855)

75.1.3.6.6 TCustomGrid.DefaultColWidth Property

Determines the width (in pixels) of all columns that have not been explicitly resized.

Pascal

```
property DefaultColWidth: Integer;
```

C++

```
__property int DefaultColWidth;
```

Description

Set DefaultColWidth to change the size of all columns in the grid. When DefaultColWidth is set, columns that have been resized using the mouse or by setting the ColWidths (see page 14845) property are given the DefaultColWidth as well.

When new columns are added to the grid using the ColCount (see page 14844) property, they are created with a width of DefaultColWidth.

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
This example includes a draw grid on a form. When the
application runs and the form is created, the width of the
lines on the draw grid changes if the default column width of
the grid is over 90 pixels wide.  This example requires a
populated image list, or can just display an empty grid.
Set the drawgrid DefaultColWidth and GridLineWidth statically
to values the cause the button click to do something.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if DrawGrid1.DefaultColWidth > 90 then
    DrawGrid1.GridLineWidth := 2
  else
    DrawGrid1.GridLineWidth := 1;
end;

procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clBackground;
  DrawGrid1.Canvas.FillRect(Rect);
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
```

```
  end;
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
```

See Also

ColCount (see page 14844)

ColWidths (see page 14845)

DefaultRowHeight (see page 14847)

75.1.3.6.7 TCustomGrid.DefaultDrawing Property

Determines whether the Cells are painted when the grid is drawn.

Pascal

```
property DefaultDrawing: Boolean;
```

C++

```
__property Boolean DefaultDrawing;
```

Description

Set DefaultDrawing to true to have the grid automatically paint the cells in the grid, including adding the background color, the 3-D effects on the fixed cells, and the focus rectangle around the selected cell. Set DefaultDrawing to false to skip the painting of the cells when the grid is drawn.

When DefaultDrawing is false, the cells should be painted using the DrawCell (see page 14826) method. For TCustomGrid (see page 14800), DrawCell (see page 14826) is an abstract method. Descendants of TCustomGrid (see page 14800) use DrawCell (see page 14826) to provide their own customized drawing code, or to generate an OnDrawCell event.

See Also

DrawCell (see page 14826)

OnDrawCell (see page 14914)

75.1.3.6.8 TCustomGrid.DefaultRowHeight Property

Specifies the height (in pixels) of all rows that have not been explicitly resized.

Pascal

```
property DefaultRowHeight: Integer;
```

C++

```
__property int DefaultRowHeight;
```

Description

Set DefaultRowHeight to change the size of all rows in the grid. When DefaultRowHeight is set, rows that have been resized using the mouse or by setting the RowHeights (see page 14855) property are given the DefaultRowHeight as well.

When new rows are added to the grid using the RowCount (see page 14854) property, they are created with a height of DefaultRowHeight.

See Also

DefaultColWidth (see page 14846)

RowCount (see page 14854)

RowHeights (see page 14855)

75.1.3.6.9 TCustomGrid.EditorMode Property

Determines whether the current cell can be edited.

Pascal

```
property EditorMode: Boolean;
```

C++

```
__property Boolean EditorMode;
```

Description

Set EditorMode to true, at runtime, to put the grid in edit mode. When EditorMode is true, the user can edit cells in the grid. When the user presses F2, EditorMode is set to true. When the user presses Enter, the value of EditorMode is toggled.

Note: EditorMode has no effect if the Options (see page 14853) property does not include goEditing or if the Options (see page 14853) property includes goAlwaysShowEditor.

See Also

HideEditor (see page 14830)

Options (see page 14853)

ShowEditor (see page 14839)

75.1.3.6.10 TCustomGrid.FixedColor Property

Specifies the background color of the fixed rows and columns in the grid.

Pascal

```
property FixedColor: TColor;
```

C++

```
__property TColor FixedColor;
```

Description

Set FixedColor to specify the color for the nonscrolling cells in the grid. The scrolling region of the grid is drawn using the Color (see page 14844) property.

See Also

Color (see page 5812)

FixedCols (see page 14848)

FixedRows (see page 14849)

75.1.3.6.11 TCustomGrid.FixedCols Property

Specifies the number of columns on the left of the grid that cannot be scrolled.

Pascal

```
property FixedCols: Integer;
```

C++

```
__property int FixedCols;
```

Description

Set FixedCols to create or get rid of nonscrolling columns. Nonscrolling columns appear at the left of the grid, and are always visible, even when the user scrolls the other columns in the grid. Use nonscrolling columns for displaying row titles or row numbers, or to implement a scroll lock that the user can set.

Nonscrolling columns are visually distinct from the scrollable columns in the grid. They are painted with a separate background color, and their cells have a raised, 3-D look.

Note: Grids (see page 14765) must include at least one scrolling column. Do not set FixedCols to a value greater than ColCount (see page 14844) - 1.

See Also

ColCount (see page 14844)

DefaultDrawing (see page 14847)

FixedColor (see page 14848)

FixedRows (see page 14849)

75.1.3.6.12 TCustomGrid.FixedRows Property

Specifies the number of rows on the top of the grid that cannot be scrolled.

Pascal

```
property FixedRows: Integer;
```

C++

```
__property int FixedRows;
```

Description

Set FixedRows to create or get rid of nonscrolling rows. Nonscrolling rows appear at the top of the grid, and are always visible, even when the user scrolls the other rows in the grid. Use nonscrolling rows for displaying column titles or column numbers.

Nonscrolling rows are visually distinct from the scrollable rows in the grid. They are painted with a separate background color, and their cells have a raised, 3-D look.

Note: Grids (see page 14765) must include at least one scrolling row. Do not set FixedRows to a value greater than RowCount (see page 14854) - 1.

See Also

DefaultDrawing (see page 14847)

FixedColor (see page 14848)

FixedCols (see page 14848)

RowCount (see page 14854)

75.1.3.6.13 TCustomGrid.GridHeight Property

Specifies the height of the grid in pixels.

Pascal

```
property GridHeight: Integer;
```

C++

```
__property int GridHeight;
```

Description

Read GridHeight to determine the size of the grid. If GridHeight is less than the value of ClientHeight, all of the rows of the grid appear in the control with an empty region below the grid. If the underlying grid is too tall to appear in the control, GridHeight is the same as ClientHeight, and the user must scroll to see the entire contents of the grid.

See Also

ClientHeight (see page 5808)

GridWidth (see page 14851)

75.1.3.6.14 TCustomGrid.GridLineWidth Property

Specifies the width (in pixels) of the lines that separate the cells of the grid.

Pascal

```
property GridLineWidth: Integer;
```

C++

```
__property int GridLineWidth;
```

Description

Set GridLineWidth to make the lines that separate the cells in the grid heavier or lighter. When GridLineWidth is zero, no separators are drawn between the cells of the grid.

GridLineWidth will have no effect if the Options (see page 14853) property does not include goFixedHorzLine, goFixedVertLine, goHorzLine, or goVertLine.

Note: Values greater than 3 pixels are not recommended for applications that run on Windows 9x or Windows ME because of distortions that can appear.

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
This example includes a draw grid on a form. When the
application runs and the form is created, the width of the
lines on the draw grid changes if the default column width of
the grid is over 90 pixels wide.  This example requires a
populated image list, or can just display an empty grid.
Set the drawgrid DefaultColWidth and GridLineWidth statically
to values the cause the button click to do something.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if DrawGrid1.DefaultColWidth > 90 then
```

```
    DrawGrid1.GridLineWidth := 2
  else
    DrawGrid1.GridLineWidth := 1;
end;

procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clBackground;
  DrawGrid1.Canvas.FillRect(Rect);
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
  end;
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
```

See Also

FixedCols (see page 14848)

FixedRows (see page 14849)

Options (see page 14853)

75.1.3.6.15 TCustomGrid.GridWidth Property

Specifies the width of the grid in pixels.

Pascal

```
property GridWidth: Integer;
```

C++

```
__property int GridWidth;
```

Description

Read GridWidth to determine the size of the grid. If GridWidth is less than the value of ClientWidth, all of the columns of the grid appear in the control with an empty region to the right of the grid. If the underlying grid is too wide to appear in the control, GridWidth is the same as ClientWidth, and the user must scroll to see the entire contents of the grid.

See Also

ClientWidth (see page 5811)

GridHeight (see page 14850)

75.1.3.6.16 TCustomGrid.HitTest Property

Indicates the current position of the mouse cursor.

Pascal

```
property HitTest: TPoint;
```

C++

```
__property TPoint HitTest;
```

Description

Read HitTest to determine the position of the mouse when it is over the grid or when the grid has captured the mouse. HitTest may represent a position that is not within the client area of the grid control if the user is moving or resizing the rows or columns, or if the user is selecting a range of cells using the mouse. HitTest is the position of the mouse cursor in the coordinate system where (0,0) is the upper left corner of the grid control's client area.

See Also

ClientOrigin

MouseCoord (see page 14834)

75.1.3.6.17 TCustomGrid.InplaceEditor Property

Designates the edit control the grid uses to allow users to edit the contents of the selected cell.

Pascal

```
property InplaceEditor: TInplaceEdit;
```

C++

```
__property TInplaceEdit InplaceEditor;
```

Description

Read InplaceEditor to gain direct access to the edit control that sits on top of the selected cell when the grid is in edit mode. The inplace editor is created the first time the grid is put in edit mode. It is not destroyed until the grid is destroyed. The grid moves the editor when the selected cell changes. The grid hides the editor's window when the grid goes out of edit mode.

See Also

CreateEditor (see page 14823)

EditorMode (see page 14848)

HideEditor (see page 14830)

ShowEditor (see page 14839)

75.1.3.6.18 TCustomGrid.LeftCol Property

Specifies the index of the first visible scrollable column in the grid.

Pascal

```
property LeftCol: Longint;
```

C++

```
__property Longint LeftCol;
```

Description

Read LeftCol to determine the index of the first column in the scrollable region that is visible. Set LeftCol to scroll the columns in the grid so that the column with index LeftCol is the first column after the fixed columns.

See Also

FixedCols (see page 14848)

ScrollData (see page 14838)

VisibleColCount (see page 14859)

75.1.3.6.19 TCustomGrid.Options Property

Specifies various display and behavioral properties of the grid.

Pascal

```
property Options: TGridOptions;
```

C++

```
__property TGridOptions Options;
```

Description

Set Options to include the desired properties for the grid. See the type Grids.TGridOptions for definitions of these properties.

See Also

ColWidths (see page 14788)

EditorMode (see page 14848)

GridLineWidth (see page 14850)

RowHeights (see page 14855)

Selection (see page 14856)

TabStops (see page 14858)

75.1.3.6.20 TCustomGrid.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

75.1.3.6.21 TCustomGrid.Row Property

Specifies the index of the row that contains the selected cell.

Pascal

```
property Row: Longint;
```

C++

```
__property Longint Row;
```

Description

Use Row at runtime to determine the current row in the grid. Setting Row moves focus to the cell in the current column that is in the new row. The first row has an index of 0, the second row an index of 1, and so on.

The selected cell in the grid can be located by reading the Row property and the Col (see page 14843) property to obtain the indexes of its row and column. When focus moves to the grid, the selected cell gets input focus.

Delphi Examples:

```
{
This example displays a string grid, a list box, and a
button on a form. When the application runs, strings are put
in the cells of row 1 of the string grid. When the user
clicks the button, The strings in the current row of the
grid are displayed in the list box.
Note that when the grid contains an empty cell, the list box
has a corresponding empty string.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ListBox1.Items := StringGrid1.Rows[StringGrid1.Row];
end;
procedure TForm1.FormCreate(Sender: TObject);
begin
  with StringGrid1 do
  begin
    Cells[1,0] := 'Column 1';
    Cells[2,0] := 'Column 2';
    Cells[3,0] := 'Column 3';
    Cells[4,0] := 'Column 4';
    Cells[0,1] := 'Row 1';
    Cells[1,1] := 'Object';
    Cells[2,1] := 'Pascal';
    Cells[3,1] := 'is';
    Cells[4,1] := 'excellent';
    Cells[0,2] := 'Row 2';
    Cells[1,2] := 'Delphi';
    Cells[2,2] := 'is';
    Cells[4,2] := 'RAD';
  end;
end;
```

See Also

Col (see page 14843)

75.1.3.6.22 TCustomGrid.RowCount Property

Specifies the number of rows in the grid.

Pascal

```
property RowCount: Longint;
```

C++

```
__property Longint RowCount;
```

Description

Read RowCount to determine the number entries in the RowHeights (see page 14855) array. Set RowCount to add or delete rows at the bottom of the grid. The value of RowCount includes any fixed rows at the top of the grid as well as the scrollable rows in the body of the grid.

Delphi Examples:

```
{
This code fills each cell with a number. The numbers are
arranged in consecutive order by rows.  Notice that even
cells in the fixed rows and columns are altered.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I, J, K : Integer;
begin
  K := 0;
  with StringGrid1 do
    for I := 0 to ColCount - 1 do
      for J:= 0 to RowCount - 1 do
        begin
          K := K + 1;
          Cells[I,J] := IntToStr(K);
        end;
end;
```

See Also

ColCount (see page 14844)

RowHeights (see page 14855)

VisibleRowCount (see page 14859)

75.1.3.6.23 TCustomGrid.RowHeights Property

Gives the height (in pixels) of all rows in the grid.

Pascal

```
property RowHeights [Index: Longint]: Integer;
```

C++

```
__property int RowHeights[Longint Index];
```

Description

Read RowHeights to determine the height of the cells in the row specified by the Index parameter. An index of 0 refers to the first row. Set RowWidths at runtime to change the height of an individual row.

If the height of a row has not been set explicitly by resizing with the mouse, or by using the RowHeights property, it's height is DefaultRowHeight (see page 14847).

Use the RowCount (see page 14854) property to determine the number of entries in the RowHeights array.

See Also

ColWidths (see page 14845)

DefaultRowHeight (see page 14847)

RowCount (see page 14854)

75.1.3.6.24 TCustomGrid.ScrollBars Property

Specifies whether the grid includes horizontal and vertical scroll bars.

Pascal

```
property ScrollBars: TScrollStyle;
```

C++

```
__property TScrollStyle ScrollBars;
```

Description

Use ScrollBars to give the grid horizontal or vertical scroll bars.

Note: If all the cells in the grid fit in the ClientWidth, no horizontal scroll bar appears, even if ScrollBars is ssHorizontal or ssBoth. If all the cells fit in the ClientHeight, no vertical scroll bar appears, even if ScrollBars is ssVertical or ssBoth.

See Also

ClientHeight (see page 5808)

ClientWidth (see page 5811)

75.1.3.6.25 TCustomGrid.Selection Property

Indicates the boundaries of the current selection.

Pascal

```
property Selection: TGridRect;
```

C++

```
__property TGridRect Selection;
```

Description

Set Selection to select a range of cells in the grid. Selection can either represent the first column, first row, last column and last row in the grid, or the row and column coordinates of the upper left and bottom right cells in the selected region.

Selection can only indicate more than one cell when Options (see page 14853) includes goRangeSelect.

Delphi Examples:

```
{
The following code selects the rectangle containing rows 1
through 4, and columns 2 and 3.  goRangeSelect in the
DrawGrid Options parameter must be True to select a range of
cells.  This example requires a button, a DrawGrid and a
populated ImageList.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  myRect: TGridRect;
begin
  myRect.Left := 2;
```

```
    myRect.Top := 1;
    myRect.Right := 3;
    myRect.Bottom := 4;
    DrawGrid1.Selection := myRect;
    DrawGrid1.Repaint;
  end;

  procedure TForm1.DrawGrid1Click(Sender: TObject);
  begin
    Label1.Caption := 'From OnClick: The cursor is in column ' +
                      IntToStr(DrawGrid1.Col + 1) +
                      ', row ' +
                      IntToStr(DrawGrid1.Row + 1);
  end;

  procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
    Rect: TRect; State: TGridDrawState);
  var
    index: Integer;
  begin
    index := (ARow * DrawGrid1.ColCount + ACol) mod (DrawGrid1.ColCount + 1);
    if (gdSelected in State) then
      DrawGrid1.Canvas.Brush.Color := clYellow
    else
      DrawGrid1.Canvas.Brush.Color := clBackground;
    DrawGrid1.Canvas.FillRect(Rect);
    if (gdFocused in State) then
    begin
      DrawGrid1.Canvas.DrawFocusRect(Rect);
      Label2.Caption:= 'From OnDrawCell: Cell ' + InttoStr(index) + ' has the focus.';
    end;
    ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  end;

  procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
    var CanSelect: Boolean);
  begin
    CanSelect:= True;
  end;
```

See Also

Col (see page 14843)

Options (see page 14853)

Row (see page 14854)

75.1.3.6.26 TCustomGrid.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

75.1.3.6.27 TCustomGrid.TabStops Property

Indicates whether the user can tab to specified columns in the grid.

Pascal

```
property TabStops [Index: Longint]: Boolean;
```

C++

```
__property Boolean TabStops[Longint Index];
```

Description

Set TabStops to false to remove the column identified by Index from the tab order. The first column in the grid is identified by an Index of 0.

Note: When the Options (see page 14853) property does not include goTabs, the user can't tab to any column, even if TabStops is true.

See Also

Options (see page 14853)

75.1.3.6.28 TCustomGrid.TopRow Property

Specifies the index of the first visible scrollable row in the grid.

Pascal

```
property TopRow: Longint;
```

C++

```
__property Longint TopRow;
```

Description

Read TopRow to determine the index of the first row in the scrollable region that is visible. Set TopRow to scroll the rows in the grid so that the row with index TopRow is the first row after the fixed rows.

Delphi Examples:

```
{
This code uses a draw grid and a button on a form. When
the user clicks the button, the last row of the draw
grid becomes the top row.  This example requires a
button, a DrawGrid and a populated ImageList.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  DrawGrid1.TopRow := DrawGrid1.RowCount - 1;
end;

procedure TForm1.DrawGrid1Click(Sender: TObject);
begin
  Label1.Caption := 'From OnClick: The cursor is in column ' +
                    IntToStr(DrawGrid1.Col + 1) +
                    ', row ' +
                    IntToStr(DrawGrid1.Row + 1);
```

```
end;

procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := (ARow * DrawGrid1.ColCount + ACol) mod (DrawGrid1.ColCount + 1);
  if (gdSelected in State) then
    DrawGrid1.Canvas.Brush.Color := clYellow
  else
    DrawGrid1.Canvas.Brush.Color := clBackground;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label2.Caption:= 'From OnDrawCell: Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
```

See Also

FixedRows (see page 14849)

ScrollData (see page 14838)

VisibleRowCount (see page 14859)

75.1.3.6.29 TCustomGrid.VisibleColCount Property

Indicates the number of scrollable columns visible in the grid.

Pascal

```
property VisibleColCount: Integer;
```

C++

```
__property int VisibleColCount;
```

Description

Use VisibleColCount to determine the number of scrollable columns fully visible in the grid. VisibleColCount does not include the fixed columns counted by the FixedCols (see page 14848) property. It does not include any partially visible columns on the right edge of the grid.

See Also

ColCount (see page 14844)

FixedCols (see page 14848)

VisibleRowCount (see page 14859)

75.1.3.6.30 TCustomGrid.VisibleRowCount Property

Indicates the number of scrollable rows visible in the grid.

Pascal

```
property VisibleRowCount: Integer;
```

C++

```
__property int VisibleRowCount;
```

Description

Use VisibleRowCount to determine the number of scrollable rows fully visible in the grid. VisibleRowCount does not include the fixed rows counted by the FixedRows (see page 14849) property. It does not include any partially visible rows on the bottom of the grid.

See Also

FixedRows (see page 14849)

RowCount (see page 14854)

VisibleColCount (see page 14859)

75.1.4 TDrawGrid Class

TDrawGrid represents a grid control that displays information in column and row format.

Class Hierarchy

Pascal

```
TDrawGrid = class(TCustomDrawGrid);
```

C++

```
class TDrawGrid : public TCustomDrawGrid;
```

File

Grids

Description

Add a TDrawGrid object to a form to present arbitrary information in a tabular format. TDrawGrid provides many properties to control the appearance of the grid, as well as events and methods that take advantage of the tabular organization of the grid in responding to user actions.

TDrawGrid introduces several events and methods to allow applications to customize the appearance and behavior of the grid.

If the cells of the grid contain text strings that represent objects, consider using a TStringGrid (see page 14968) object instead. If the grid displays field values from the records in a dataset, use TDBGrid instead.

See Also

TDBGrid (see page 9668)

TStringGrid (see page 14968)

Draw Grids

Grids

TGridOption (see page 14999)

75.1.4.1 TDrawGrid Members

The following tables list the members exposed by TDrawGrid.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	DesignOptionsBoost (see page 14814)	This is DesignOptionsBoost, a member of class TCustomGrid.
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FGridState (see page 14814)	This is FGridState, a member of class TCustomGrid.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.
	FSaveCellExtents (see page 14814)	This is FSaveCellExtents, a member of class TCustomGrid.
	VirtualView (see page 14814)	This is VirtualView, a member of class TCustomGrid.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AdjustSize (see page 14816)	Adds or deletes rows or columns from the grid.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.

	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	BeginColumnDrag (see page 14817)	Starts the dragging of a column in the grid.
	BeginRowDrag (see page 14817)	Starts the dragging of a row in the grid.
	BoxRect (see page 14818)	Returns the screen coordinates of a specified set of cells.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CalcDrawInfo (see page 14818)	Calculates the pixel locations of the grid boundaries.
	CalcFixedInfo (see page 14818)	Calculates the pixel locations of the fixed cells.
	CalcSizingState (see page 14819)	Determines the appearance of the mouse cursor during resizing.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanEditAcceptKey (see page 14819)	Indicates whether the Key parameter can be entered into the current cell.
	CanEditModify (see page 14819)	Indicates whether the current cell in the grid can be edited.
	CanEditShow (see page 14820)	Indicates whether the inplace edit control can be created to allow editing.
	CanGridAcceptKey (see page 14820)	Indicates whether the grid should respond to a given key combination.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	CellRect (see page 14821)	Returns the screen coordinates of a cell in the grid.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeGridOrientation (see page 14821)	Prepares the grid's canvas for painting to reflect a right-to-left or left-to-right orientation.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	CheckColumnDrag (see page 14821)	CheckColumnDrag validates whether the column currently selected for dragging can be dropped at the current location.
	CheckRowDrag (see page 14822)	CheckRowDrag validates whether the row currently selected for dragging can be dropped at the current location.
	Click (see page 5743)	Respond to user click.
	ColumnMoved (see page 14781)	Generates an OnColumnMoved (see page 14794) event.
	ColumnMoved (see page 14822)	Provides the interface for a method that responds when the position of a column changes.
	ColWidthsChanged (see page 14822)	Responds when the column widths change.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateEditor (see page 14823)	Creates the inplace editor control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 14823)	Initializes the window-creation parameter record.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.

V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
V	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
V	DefineProperties (see page 14824)	Adds the ColWidths (see page 14845) and RowHeights (see page 14855) properties to the values saved with the grid.
V	DeleteColumn (see page 14824)	Deletes a specified column from the grid.
V	DeleteRow (see page 14825)	Deletes a specified from the grid.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
V	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
V	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
V	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
V	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
V	DoExit (see page 14825)	Hides the inplace editor when selection moves to another control in a form.
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
V	DoMouseWheelDown (see page 14825)	Performs tasks when the mouse wheel is rotated downward.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
V	DoMouseWheelUp (see page 14826)	Performs tasks when the mouse wheel is rotated upward.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
V	DrawCell (see page 14782)	Generates an OnDrawCell (see page 14795) event.
A	DrawCell (see page 14826)	Provides the prototype for a method that draws the contents of a cell in the grid.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EndColumnDrag (see page 14827)	Ends the dragging of a column in the grid.
	EndRowDrag (see page 14827)	Ends the dragging of a row in the grid.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	FocusCell (see page 14827)	Changes the current cell to a specified cell.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.

	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEditLimit (see page 14828)	Provides the interface for a method that limits the number of characters the user can type into cells.
V	GetEditMask (see page 14782)	Generates an OnGetEditMask (see page 14796) event.
	GetEditMask (see page 14828)	Provides the interface for a method that returns an input mask for the specified cell.
	GetEditStyle (see page 14828)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
V	GetEditText (see page 14783)	Generates an OnGetEditText (see page 14797) event.
	GetEditText (see page 14829)	Returns the value of the indicated cell formatted for editing.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetGridHeight (see page 14829)	Returns the value of the GridHeight (see page 14850) property.
	GetGridWidth (see page 14830)	Returns the value of the GridWidth (see page 14851) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HideEdit (see page 14830)	Hides the inplace editor.
	HideEditor (see page 14830)	Hides the inplace editor when it is not in use.
	InvalidateCell (see page 14831)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.
	InvalidateCol (see page 14831)	Invalidates the region occupied by a column so that it will be repainted with the next Windows paint message.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	InvalidateEditor (see page 14832)	Causes the inplace editor to repaint itself, moving to a new location if necessary.
	InvalidateGrid (see page 14832)	Tells Windows to repaint the grid after other important Windows messages are handled.
	InvalidateRow (see page 14832)	Invalidates the region occupied by a row so that it will be repainted with the next Windows paint message.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.

	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
V	KeyDown (see page 14833)	Provides special processing when the user presses a key.
	KeyPress (see page 6163)	Respond to keyboard input.
V	KeyPress (see page 14833)	Provides special processing when the user presses a key.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
V	MouseDown (see page 14834)	Provides special processing when the user presses a mouse button.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
V	MouseMove (see page 14834)	Provides special processing when the user moves the mouse.
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	MouseUp (see page 14835)	Provides special processing when the user releases the mouse button.
	MoveColRow (see page 14835)	Selects the cell indicated by the ACol and ARow parameters.
	MoveColumn (see page 14836)	Moves a column to a new position.
	MoveRow (see page 14836)	Moves a row to a new position.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 5920)	Renders the image of a custom control.
V	Paint (see page 14836)	Draws the image of the grid control on the screen.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	RowHeightsChanged (see page 14837)	Responds when the row heights change.
V	RowMoved (see page 14783)	Generates an OnRowMoved (see page 14798) event.
	RowMoved (see page 14837)	Provides the interface for a method that responds when the position of a row changes.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	ScrollData (see page 14838)	Scrolls the visual image of the cells in the grid.

	SelectCell (see page 14784)	Determines whether a particular cell in the grid can be selected.
	SelectCell (see page 14838)	Determines whether a particular cell in the grid can be selected.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEditText (see page 14784)	Generates an OnSetEditText (see page 14800) event.
	SetEditText (see page 14839)	Provides the interface for a method that updates the text associated with a cell.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	ShowEditor (see page 14839)	Displays the inplace editor when the grid enters edit mode.
	ShowEditorChar (see page 14839)	Displays the inplace editor, with its text set to the specified character.
	SizeChanged (see page 14840)	Responds to changes in the size of the grid.
	Sizing (see page 14840)	Indicates whether the indicated coordinates are on one of the resize hot zones of the graph.
	TimedScroll (see page 14840)	Extends a move, resize, or selection out of the scrollable region when the user drags the mouse in a direction where the grid is scrolled.
	TopLeftChanged (see page 14784)	Generates an OnTopLeftChanged (see page 14800) event.
	TopLeftChanged (see page 14841)	Updates the position of the inplace editor when the grid scrolls.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateDesigner (see page 14841)	Notifies the designer when rows and columns of the grid are moved or resized.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.

V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
R	Canvas (see page 5921)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Col (see page 14843)	Specifies the index of the column that contains the selected cell.
	ColWidths (see page 14845)	Indicates the width (in pixels) of all the columns in the grid.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	EditorMode (see page 14848)	Determines whether the current cell can be edited.
R	GridHeight (see page 14850)	Specifies the height of the grid in pixels.
R	GridWidth (see page 14851)	Specifies the width of the grid in pixels.
R	HitTest (see page 14851)	Indicates the current position of the mouse cursor.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
R	InplaceEditor (see page 14852)	Designates the edit control the grid uses to allow users to edit the contents of the selected cell.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	LeftCol (see page 14852)	Specifies the index of the first visible scrollable column in the grid.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	Row (see page 14854)	Specifies the index of the row that contains the selected cell.
	RowHeights (see page 14855)	Gives the height (in pixels) of all rows in the grid.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Selection (see page 14856)	Indicates the boundaries of the current selection.
	TabStops (see page 14858)	Indicates whether the user can tab to specified columns in the grid.
	Text (see page 5842)	Contains a text string associated with the control.
	TopRow (see page 14858)	Specifies the index of the first visible scrollable row in the grid.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	CellRect (see page 14781)	Returns the screen coordinates of a cell in the grid.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 5731)	Creates an instance of TControl (see page 5724).
V	Create (see page 5918)	Creates an instance of TCustomControl (see page 5908).
V	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
V	Create (see page 14813)	Creates an instance of TCustomGrid (see page 14800).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 5919)	Destroys an instance of TCustomControl (see page 5908).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 14813)	Destroys an instance of TCustomGrid (see page 14800).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.

	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseCoord (see page 14834)	Returns the row and column indexes of the cell that contains a point specified in screen coordinates.

	MouseToCell (see page 14783)	Returns the column and row of the cell at the position with screen coordinates (X,Y).
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	Canvas (see page 14785)	Specifies the TCanvas object that presents a drawing surface for the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.

R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
	Col (see page 14787)	Specifies the index of the column that contains the selected cell.
	ColWidths (see page 14788)	Indicates the width (in pixels) of all the columns in the grid.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	EditorMode (see page 14789)	Determines whether the current cell can be edited.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	GridHeight (see page 14789)	Specifies the height of the grid in pixels.
	GridWidth (see page 14789)	Specifies the width of the grid in pixels.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LeftCol (see page 14790)	Specifies the index of the first visible scrollable column in the grid.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	Row (see page 14790)	Specifies the index of the row that contains the selected cell.
	RowHeights (see page 14791)	Gives the height (in pixels) of all rows in the grid.
	Selection (see page 14791)	Indicates the boundaries of the current selection.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TabStops (see page 14793)	Indicates whether the user can tab to specified columns in the grid.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TopRow (see page 14793)	Specifies the index of the first visible scrollable row in the grid.

	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnClick (see page 14906)	Occurs when the user clicks the control.
	OnColumnMoved (see page 14908)	Occurs immediately after the position of a column changes.
	OnContextPopup (see page 14908)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 14909)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 14909)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14911)	Occurs when the user drags an object over a control.
	OnDrawCell (see page 14914)	Occurs when a cell in the grid needs to be drawn.
	OnEndDock (see page 14914)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 14915)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 14916)	Occurs when a control receives the input focus.
	OnExit (see page 14918)	Occurs when the input focus shifts away from one control to another.
	OnGetEditMask (see page 14920)	Occurs when the in-place editor requests an edit mask.
	OnGetEditText (see page 14920)	Occurs when the in-place editor requests the value of a cell.
	OnKeyDown (see page 14920)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 14923)	Occurs when a key is pressed.
	OnKeyUp (see page 14924)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 14926)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14927)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14929)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14929)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14930)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14932)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheelDown (see page 14934)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14935)	Occurs when the mouse wheel is rotated upward.
	OnRowMoved (see page 14935)	Occurs immediately after the position of a row changes.
	OnSelectCell (see page 14935)	Occurs before a cell in the grid is selected.
	OnSetEditText (see page 14936)	Occurs when the user edits the value of a cell.
	OnStartDock (see page 14936)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 14937)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnTopLeftChanged (see page 14937)	Occurs immediately after the TopRow (see page 14793) property or the LeftCol (see page 14790) property changes.

Published Properties

	Name	Description
	Align (see page 14874)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 14878)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 14879)	Specifies which edges of the control are beveled.
	BevelInner (see page 14879)	Specifies the cut of the inner bevel.
	BevelKind (see page 14879)	Specifies the control's bevel style.

	BevelOuter (see page 14880)	Specifies the cut of the outer bevel.
	BevelWidth (see page 14880)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 14881)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 14881)	Determines whether a single line border is drawn around the grid.
	ColCount (see page 14881)	Specifies the number of columns in the grid.
	Color (see page 14882)	Specifies the background color of the control.
	Constraints (see page 14883)	Specifies the size constraints for the control.
	Ctl3D (see page 14884)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DefaultColWidth (see page 14884)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 14885)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 14885)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DragCursor (see page 14886)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 14886)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14887)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14888)	Controls whether the control responds to mouse, keyboard, and timer events.
	FixedColor (see page 14889)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 14889)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	FixedRows (see page 14889)	Specifies the number of rows on the top of the grid that cannot be scrolled.
	Font (see page 14890)	Controls the attributes of text written on or in the control.
	GridLineWidth (see page 14891)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Options (see page 14892)	Specifies various display and behavioral properties of the grid.
	ParentBiDiMode (see page 14893)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 14893)	Determines where a control looks for its color information.
	ParentCtl3D (see page 14893)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 14894)	Determines where a control looks for its font information.
	ParentShowHint (see page 14894)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 14895)	Identifies the pop-up menu associated with the control.
	RowCount (see page 14899)	Specifies the number of rows in the grid.
	ScrollBars (see page 14900)	Specifies whether the grid includes horizontal and vertical scroll bars.
	ShowHint (see page 14901)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 14902)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 14857)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 14903)	Determines whether the component appears onscreen.
	VisibleColCount (see page 14904)	Indicates the number of scrollable columns visible in the grid.
	VisibleRowCount (see page 14905)	Indicates the number of scrollable rows visible in the grid.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

75.1.4.2 TDrawGrid Properties

The properties of the TDrawGrid class are listed here.

Published Properties

	Name	Description
	Align (see page 14874)	Determines how the control aligns within its container (parent control).
	Anchors (see page 14878)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 14879)	Specifies which edges of the control are beveled.
	BevelInner (see page 14879)	Specifies the cut of the inner bevel.
	BevelKind (see page 14879)	Specifies the control's bevel style.
	BevelOuter (see page 14880)	Specifies the cut of the outer bevel.
	BevelWidth (see page 14880)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 14881)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 14881)	Determines whether a single line border is drawn around the grid.
	ColCount (see page 14881)	Specifies the number of columns in the grid.
	Color (see page 14882)	Specifies the background color of the control.
	Constraints (see page 14883)	Specifies the size constraints for the control.
	Ctl3D (see page 14884)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultColWidth (see page 14884)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 14885)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 14885)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DragCursor (see page 14886)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 14886)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14887)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14888)	Controls whether the control responds to mouse, keyboard, and timer events.
	FixedColor (see page 14889)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 14889)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	FixedRows (see page 14889)	Specifies the number of rows on the top of the grid that cannot be scrolled.
	Font (see page 14890)	Controls the attributes of text written on or in the control.
	GridLineWidth (see page 14891)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
	Options (see page 14892)	Specifies various display and behavioral properties of the grid.
	ParentBiDiMode (see page 14893)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 14893)	Determines where a control looks for its color information.
	ParentCtl3D (see page 14893)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 14894)	Determines where a control looks for its font information.
	ParentShowHint (see page 14894)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 14895)	Identifies the pop-up menu associated with the control.
	RowCount (see page 14899)	Specifies the number of rows in the grid.
	ScrollBars (see page 14900)	Specifies whether the grid includes horizontal and vertical scroll bars.
	ShowHint (see page 14901)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 14902)	Indicates the position of the control in its parent's tab order.
	Visible (see page 14903)	Determines whether the component appears onscreen.
	VisibleColCount (see page 14904)	Indicates the number of scrollable columns visible in the grid.
	VisibleRowCount (see page 14905)	Indicates the number of scrollable rows visible in the grid.

75.1.4.2.1 TDrawGrid.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;
```

```
  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);

        Caption := TabTitles[i];
        Brush.Color := colorPalette[i];
     end;
    end;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
    i: Integer;
  begin
    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i].Free;
    end;
    PageControl1.Free;
  end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

75.1.4.2.2 TDrawGrid.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

75.1.4.2.3 TDrawGrid.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

75.1.4.2.4 TDrawGrid.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

75.1.4.2.5 TDrawGrid.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

75.1.4.2.6 TDrawGrid.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelWidth (see page 6194)

75.1.4.2.7 TDrawGrid.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth: TBevelWidth;
```

C++

```
__property TBevelWidth BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelOuter (see page 6194)

75.1.4.2.8 TDrawGrid.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

75.1.4.2.9 TDrawGrid.BorderStyle Property

Determines whether a single line border is drawn around the grid.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Set BorderStyle to bsSingle to add a single line border around the grid's image. Set BorderStyle to bsNone to omit the border.

75.1.4.2.10 TDrawGrid.ColCount Property

Specifies the number of columns in the grid.

Pascal

```
property ColCount: Longint;
```

C++

```
__property Longint ColCount;
```

Description

Read ColCount to determine the number entries in the ColWidths array. Set ColCount to add or delete columns at the righthand side of the grid. The value of ColCount includes any fixed columns at the left of the grid as well as the scrollable columns in the body of the grid.

Delphi Examples:

```
{
This code fills each cell with a number. The numbers are
arranged in consecutive order by rows.  Notice that even
cells in the fixed rows and columns are altered.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I, J, K : Integer;
begin
  K := 0;
  with StringGrid1 do
    for I := 0 to ColCount - 1 do
      for J:= 0 to RowCount - 1 do
        begin
          K := K + 1;
          Cells[I,J] := IntToStr(K);
        end;
end;
```

See Also

ColWidths (see page 14845)

RowCount (see page 14854)

VisibleColCount (see page 14859)

75.1.4.2.11 TDrawGrid.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

75.1.4.2.12 TDrawGrid.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

75.1.4.2.13 TDrawGrid.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

75.1.4.2.14 TDrawGrid.DefaultColWidth Property

Determines the width (in pixels) of all columns that have not been explicitly resized.

Pascal

```
property DefaultColWidth: Integer;
```

C++

```
__property int DefaultColWidth;
```

Description

Set DefaultColWidth to change the size of all columns in the grid. When DefaultColWidth is set, columns that have been resized using the mouse or by setting the ColWidths property are given the DefaultColWidth as well.

When new columns are added to the grid using the ColCount property, they are created with a width of DefaultColWidth.

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
This example includes a draw grid on a form. When the
application runs and the form is created, the width of the
lines on the draw grid changes if the default column width of
the grid is over 90 pixels wide.  This example requires a
populated image list, or can just display an empty grid.
Set the drawgrid DefaultColWidth and GridLineWidth statically
to values the cause the button click to do something.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if DrawGrid1.DefaultColWidth > 90 then
    DrawGrid1.GridLineWidth := 2
```

```
    else
      DrawGrid1.GridLineWidth := 1;
  end;

  procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
    Rect: TRect; State: TGridDrawState);
  var
    index: Integer;
  begin
    index := ARow * DrawGrid1.ColCount + ACol;
    DrawGrid1.Canvas.Brush.Color := clBackground;
    DrawGrid1.Canvas.FillRect(Rect);
    ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
    if (gdFocused in State) then
    begin
      DrawGrid1.Canvas.DrawFocusRect(Rect);
    end;
  end;

  procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
    var CanSelect: Boolean);
  begin
    CanSelect:= True;
  end;
```

See Also

ColCount (see page 14844)

ColWidths (see page 14845)

DefaultRowHeight (see page 14847)

75.1.4.2.15 TDrawGrid.DefaultDrawing Property

Determines whether the Cells are painted when the grid is drawn.

Pascal

```
property DefaultDrawing: Boolean;
```

C++

```
__property Boolean DefaultDrawing;
```

Description

Set DefaultDrawing to true to have the grid automatically paint the cells in the grid, including adding the background color, the 3-D effects on the fixed cells, and the focus rectangle around the selected cell. Set DefaultDrawing to false to skip the painting of the cells when the grid is drawn.

When DefaultDrawing is false, the cells should be painted using the DrawCell method. For TCustomGrid, DrawCell is an abstract method. Descendants of TCustomGrid use DrawCell to provide their own customized drawing code, or to generate an OnDrawCell event.

See Also

DrawCell (see page 14826)

OnDrawCell (see page 14914)

75.1.4.2.16 TDrawGrid.DefaultRowHeight Property

Specifies the height (in pixels) of all rows that have not been explicitly resized.

Pascal

```
property DefaultRowHeight: Integer;
```

C++

```
__property int DefaultRowHeight;
```

Description

Set DefaultRowHeight to change the size of all rows in the grid. When DefaultRowHeight is set, rows that have been resized using the mouse or by setting the RowHeights property are given the DefaultRowHeight as well.

When new rows are added to the grid using the RowCount property, they are created with a height of DefaultRowHeight.

See Also

DefaultColWidth (see page 14846)

RowCount (see page 14854)

RowHeights (see page 14855)

75.1.4.2.17 TDrawGrid.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

75.1.4.2.18 TDrawGrid.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

75.1.4.2.19 TDrawGrid.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
```

```
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TTreeView;
  end;
```

Arranging the Order of Persistent Columns

75.1.4.2.20 TDrawGrid.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

75.1.4.2.21 TDrawGrid.FixedColor Property

Specifies the background color of the fixed rows and columns in the grid.

Pascal

```
property FixedColor: TColor;
```

C++

```
__property TColor FixedColor;
```

Description

Set FixedColor to specify the color for the nonscrolling cells in the grid. The scrolling region of the grid is drawn using the Color property.

See Also

Color (see page 5812)

FixedCols (see page 14848)

FixedRows (see page 14849)

75.1.4.2.22 TDrawGrid.FixedCols Property

Specifies the number of columns on the left of the grid that cannot be scrolled.

Pascal

```
property FixedCols: Integer;
```

C++

```
__property int FixedCols;
```

Description

Set FixedCols to create or get rid of nonscrolling columns. Nonscrolling columns appear at the left of the grid, and are always visible, even when the user scrolls the other columns in the grid. Use nonscrolling columns for displaying row titles or row numbers, or to implement a scroll lock that the user can set.

Nonscrolling columns are visually distinct from the scrollable columns in the grid. They are painted with a separate background color, and their cells have a raised, 3-D look.

Note: Grids must include at least one scrolling column. Do not set FixedCols to a value greater than ColCount - 1.

See Also

ColCount (see page 14844)

DefaultDrawing (see page 14847)

FixedColor (see page 14848)

FixedRows (see page 14849)

75.1.4.2.23 TDrawGrid.FixedRows Property

Specifies the number of rows on the top of the grid that cannot be scrolled.

Pascal

```
property FixedRows: Integer;
```

C++

```
__property int FixedRows;
```

Description

Set FixedRows to create or get rid of nonscrolling rows. Nonscrolling rows appear at the top of the grid, and are always visible, even when the user scrolls the other rows in the grid. Use nonscrolling rows for displaying column titles or column numbers.

Nonscrolling rows are visually distinct from the scrollable rows in the grid. They are painted with a separate background color, and their cells have a raised, 3-D look.

Note: Grids must include at least one scrolling row. Do not set FixedRows to a value greater than RowCount - 1.

FixedCols (see page 14848)

RowCount (see page 14854)

75.1.4.2.24 TDrawGrid.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

DesktopFont (see page 5818)

ParentFont (see page 5834)

Displaying and Editing Text in a Memo Control

75.1.4.2.25 TDrawGrid.GridLineWidth Property

Specifies the width (in pixels) of the lines that separate the cells of the grid.

Pascal

```
property GridLineWidth: Integer;
```

C++

```
__property int GridLineWidth;
```

Description

Set GridLineWidth to make the lines that separate the cells in the grid heavier or lighter. When GridLineWidth is zero, no separators are drawn between the cells of the grid.

GridLineWidth will have no effect if the Options property does not include goFixedHorzLine, goFixedVertLine, goHorzLine, or goVertLine.

Note: Values greater than 3 pixels are not recommended for applications that run on Windows 9x or Windows ME because of distortions that can appear.

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
This example includes a draw grid on a form. When the
application runs and the form is created, the width of the
lines on the draw grid changes if the default column width of
the grid is over 90 pixels wide.  This example requires a
populated image list, or can just display an empty grid.
Set the drawgrid DefaultColWidth and GridLineWidth statically
to values the cause the button click to do something.
```

```
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if DrawGrid1.DefaultColWidth > 90 then
    DrawGrid1.GridLineWidth := 2
  else
    DrawGrid1.GridLineWidth := 1;
end;

procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clBackground;
  DrawGrid1.Canvas.FillRect(Rect);
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
  end;
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
```

See Also

FixedCols (see page 14848)

FixedRows (see page 14849)

Options (see page 14853)

75.1.4.2.26 TDrawGrid.Options Property

Specifies various display and behavioral properties of the grid.

Pascal

```
property Options: TGridOptions;
```

C++

```
__property TGridOptions Options;
```

Description

Set Options to include the desired properties for the grid. See the type Grids.TGridOptions for definitions of these properties.

See Also

ColWidths (see page 14788)

EditorMode (see page 14848)

GridLineWidth (see page 14850)

RowHeights (see page 14855)

Selection (see page 14856)

TabStops (see page 14858)

75.1.4.2.27 TDrawGrid.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

75.1.4.2.28 TDrawGrid.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

75.1.4.2.29 TDrawGrid.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

75.1.4.2.30 TDrawGrid.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

75.1.4.2.31 TDrawGrid.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

75.1.4.2.32 TDrawGrid.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
```

```
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }

  void __fastcall TForm1::Cut1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;
    if (pComponent)
    {
      if (pComponent->ClassNameIs("TEdit"))
        ((TEdit *)pComponent)->CutToClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }

  void __fastcall TForm1::Paste1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;
    if (pComponent)
    {
      if (pComponent->ClassNameIs("TEdit"))
        ((TEdit *)pComponent)->PasteFromClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }
  /*
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  */
  void __fastcall TForm1::AddButtonClick(TObject *Sender)
  {
      const int num_items = 4;
      for (int index = 0; index < num_items; ++index)
      {
          TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
          PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
          NewItem->Caption = "Menu Item " + IntToStr(index);
          NewItem->Tag = index;
          NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
          TNotifyEvent();
      }
  }

  void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
  {
      TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
      if (ClickedItem)
      {
          switch (ClickedItem->Tag)
          {
```

```
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
```

```
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

75.1.4.2.33 TDrawGrid.RowCount Property

Specifies the number of rows in the grid.

Pascal

```
property RowCount: Longint;
```

C++

```
__property Longint RowCount;
```

Description

Read RowCount to determine the number entries in the RowHeights array. Set RowCount to add or delete rows at the bottom of the grid. The value of RowCount includes any fixed rows at the top of the grid as well as the scrollable rows in the body of the grid.

Delphi Examples:

```
{
This code fills each cell with a number. The numbers are
arranged in consecutive order by rows.  Notice that even
cells in the fixed rows and columns are altered.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I, J, K : Integer;
begin
  K := 0;
  with StringGrid1 do
    for I := 0 to ColCount - 1 do
      for J:= 0 to RowCount - 1 do
        begin
          K := K + 1;
          Cells[I,J] := IntToStr(K);
        end;
end;
```

See Also

ColCount (see page 14844)

RowHeights (see page 14855)

VisibleRowCount (see page 14859)

75.1.4.2.34 TDrawGrid.ScrollBars Property

Specifies whether the grid includes horizontal and vertical scroll bars.

Pascal

```
property ScrollBars: TScrollStyle;
```

C++

```
__property TScrollStyle ScrollBars;
```

Description

Use ScrollBars to give the grid horizontal or vertical scroll bars.

Note: If all the cells in the grid fit in the ClientWidth, no horizontal scroll bar appears, even if ScrollBars is ssHorizontal or ssBoth. If all the cells fit in the ClientHeight, no vertical scroll bar appears, even if ScrollBars is ssVertical or ssBoth.

See Also

ClientHeight (see page 5808)

ClientWidth (see page 5811)

75.1.4.2.35 TDrawGrid.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
```

```
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

75.1.4.2.36 TDrawGrid.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

FindNextControl (see page 6149)

TabStop (see page 6211)

75.1.4.2.37 TDrawGrid.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
```

```
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

75.1.4.2.38 TDrawGrid.VisibleColCount Property

Indicates the number of scrollable columns visible in the grid.

Pascal

```
property VisibleColCount: Integer;
```

C++

```
__property int VisibleColCount;
```

Description

Use VisibleColCount to determine the number of scrollable columns fully visible in the grid. VisibleColCount does not include the fixed columns counted by the FixedCols property. It does not include any partially visible columns on the right edge of the grid.

See Also

ColCount (see page 14844)

FixedCols (see page 14848)

VisibleRowCount (see page 14859)

75.1.4.2.39 TDrawGrid.VisibleRowCount Property

Indicates the number of scrollable rows visible in the grid.

Pascal

```
property VisibleRowCount: Integer;
```

C++

```
__property int VisibleRowCount;
```

Description

Use VisibleRowCount to determine the number of scrollable rows fully visible in the grid. VisibleRowCount does not include the fixed rows counted by the FixedRows property. It does not include any partially visible rows on the bottom of the grid.

See Also

FixedRows (see page 14849)

RowCount (see page 14854)

75.1.4.3 TDrawGrid Events

The events of the TDrawGrid class are listed here.

Published Events

	Name	Description
	OnClick (see page 14906)	Occurs when the user clicks the control.
	OnColumnMoved (see page 14908)	Occurs immediately after the position of a column changes.
	OnContextPopup (see page 14908)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 14909)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 14909)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14911)	Occurs when the user drags an object over a control.
	OnDrawCell (see page 14914)	Occurs when a cell in the grid needs to be drawn.
	OnEndDock (see page 14914)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 14915)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 14916)	Occurs when a control receives the input focus.
	OnExit (see page 14918)	Occurs when the input focus shifts away from one control to another.
	OnGetEditMask (see page 14920)	Occurs when the in-place editor requests an edit mask.
	OnGetEditText (see page 14920)	Occurs when the in-place editor requests the value of a cell.
	OnKeyDown (see page 14920)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 14923)	Occurs when a key is pressed.
	OnKeyUp (see page 14924)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 14926)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14927)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14929)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14929)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14930)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

	OnMouseUp (see page 14932)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheelDown (see page 14934)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14935)	Occurs when the mouse wheel is rotated upward.
	OnRowMoved (see page 14935)	Occurs immediately after the position of a row changes.
	OnSelectCell (see page 14935)	Occurs before a cell in the grid is selected.
	OnSetEditText (see page 14936)	Occurs when the user edits the value of a cell.
	OnStartDock (see page 14936)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 14937)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnTopLeftChanged (see page 14937)	Occurs immediately after the TopRow (see page 14793) property or the LeftCol (see page 14790) property changes.

75.1.4.3.1 TDrawGrid.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}
```

```
void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

75.1.4.3.2 TDrawGrid.OnColumnMoved Event

Occurs immediately after the position of a column changes.

Pascal

```
property OnColumnMoved: TMovedEvent;
```

C++

```
__property TMovedEvent OnColumnMoved;
```

Description

Use OnColumnMoved to perform special processing when the position of a grid column changes. Columns can be moved programmatically or by user manipulation. The FromIndex parameter is the old index of the column, and the ToIndex parameter is the new index. OnColumnMoved does not occur unless the Options (see page 14892) property includes goColMoving.

See Also

OnRowMoved (see page 14935)

Options (see page 14853)

75.1.4.3.3 TDrawGrid.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

PopupMenu (see page 5835)

AutoPopup (see page 16178)

75.1.4.3.4 TDrawGrid.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

75.1.4.3.5 TDrawGrid.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}
```

```
/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
```

```
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

75.1.4.3.6 TDrawGrid.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;
```

```
procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

75.1.4.3.7 TDrawGrid.OnDrawCell Event

Occurs when a cell in the grid needs to be drawn.

Pascal

```
property OnDrawCell: TDrawCellEvent;
```

C++

```
__property TDrawCellEvent OnDrawCell;
```

Description

Write an OnDrawCell event handler to draw the contents of all the cells in the grid. Draw on the cell using the methods of the Canvas (see page 14785) property.

If the OnDrawCell event handler is not assigned, all cells in the draw grid will appear empty. If the DefaultDrawing (see page 14885) property is true, the draw grid paints the background color of the cell before the OnDrawCell event, and draws a focus rectangle around the selected cell after the OnDrawCell event handler finishes drawing the contents of the cell. If the DefaultDrawing (see page 14885) property is false, the OnDrawCell event handler should paint the background of the cell and provide all visual indication of selection and focus.

75.1.4.3.8 TDrawGrid.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

OnStartDock (see page 5871)

75.1.4.3.9 TDrawGrid.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

75.1.4.3.10 TDrawGrid.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
```

```
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
```

```
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

75.1.4.3.11 TDrawGrid.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

75.1.4.3.12 TDrawGrid.OnGetEditMask Event

Occurs when the in-place editor requests an edit mask.

Pascal

```
property OnGetEditMask: TGetEditEvent;
```

C++

```
__property TGetEditEvent OnGetEditMask;
```

Description

Write an OnGetEditMask event handler to provide the in-place editor with an edit mask that describes the valid input strings a user can type into a cell. Set the Value parameter to the string that describes the edit mask for the specified cell. If the cell does not have an edit mask, set the Value parameter to an empty string.

OnGetEditMask does not occur unless the Options (see page 14892) property includes goEditing.

See Also

Options (see page 14853)

EditMask (see page 15821)

75.1.4.3.13 TDrawGrid.OnGetEditText Event

Occurs when the in-place editor requests the value of a cell.

Pascal

```
property OnGetEditText: TGetEditEvent;
```

C++

```
__property TGetEditEvent OnGetEditText;
```

Description

Write an OnGetEditText event handler to provide the in-place editor with a string representing the contents of the cell. Set the Value parameter to the string for the specified cell. When the cell enters edit mode, the contents of the cell are drawn as the Value string returned by the OnGetEditText event handler. This image need not match the appearance of the cell when it is not in edit mode, which is drawn using the OnDrawCell (see page 14914) event handler.

OnGetEditText does not occur unless the Options (see page 14892) property includes goEditing.

See Also

OnDrawCell (see page 14914)

OnSetEditText (see page 14936)

75.1.4.3.14 TDrawGrid.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;
{
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
}

uses Printers;

procedure TForm1.Button1Click(Sender: TObject);
var
  I, X, Y: Integer;
  Memo1 : TMemo;

75.1.4.3.15 TDrawGrid.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys

that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

75.1.4.3.16 TDrawGrid.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}

75.1.4.3.17 TDrawGrid.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the

OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

75.1.4.3.18 TDrawGrid.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
```

```
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}

75.1.4.3.19 TDrawGrid.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

75.1.4.3.20 TDrawGrid.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

75.1.4.3.21 TDrawGrid.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

75.1.4.3.22 TDrawGrid.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

Responding to a Mouse-up Action

75.1.4.3.23 TDrawGrid.OnMouseWheelDown Event

Occurs when the mouse wheel is rotated downward.

Pascal

```
property OnMouseWheelDown: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelDown;
```

Description

Write code in the OnMouseWheelDown event handler to perform actions when the mouse wheel is rotated downward. OnMouseWheelDown occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheel (see page 5869)

OnMouseWheelUp (see page 5870)

75.1.4.3.24 TDrawGrid.OnMouseWheelUp Event

Occurs when the mouse wheel is rotated upward.

Pascal

```
property OnMouseWheelUp: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelUp;
```

Description

Write code in the OnMouseWheelUp event handler to perform actions when the mouse wheel is rotated upward. OnMouseWheelUp occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheel (see page 5869)

75.1.4.3.25 TDrawGrid.OnRowMoved Event

Occurs immediately after the position of a row changes.

Pascal

```
property OnRowMoved: TMovedEvent;
```

C++

```
__property TMovedEvent OnRowMoved;
```

Description

Write an OnRowMoved event handler to provide special processing whenever a row in the grid changes position. Rows can be moved programmatically or by user manipulation. The FromIndex parameter is the old index of the row, and the ToIndex parameter is the new index. OnRowMoved does not occur unless the Options (see page 14892) property includes goRowMoving.

See Also

OnColumnMoved (see page 14908)

Options (see page 14853)

75.1.4.3.26 TDrawGrid.OnSelectCell Event

Occurs before a cell in the grid is selected.

Pascal

```
property OnSelectCell: TSelectCellEvent;
```

C++

```
__property TSelectCellEvent OnSelectCell;
```

Description

Write an OnSelectCell event handler to specify whether any particular cell in the grid can be selected.

See Also

Col (see page 14843)

Row (see page 14854)

TabStops (see page 14858)

75.1.4.3.27 TDrawGrid.OnSetEditText Event

Occurs when the user edits the value of a cell.

Pascal

```
property OnSetEditText: TSetEditEvent;
```

C++

```
__property TSetEditEvent OnSetEditText;
```

Description

Write an OnSetEditText event handler to perform any special processing of the text edited by the user in an in-place editor. For example, use the OnSetEditText event to retrieve and store the value of a cell so that it can be displayed in an OnDrawCell (see page 14914) event handler. OnSetEditText occurs every time the user changes the text.

OnSetEditText does not occur unless the Options (see page 14892) property includes goEditing.

See Also

OnDrawCell (see page 14914)

OnGetEditText (see page 14920)

Options (see page 14853)

75.1.4.3.28 TDrawGrid.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

See Also

OnEndDock (see page 5859)

TDragDockObjectEx (see page 6018)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

75.1.4.3.29 TDrawGrid.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

See Also

OnEndDrag (see page 5860)

TDragControlObjectEx (see page 6007)

DragKind (see page 5819)

OnDragOver (see page 5857)

75.1.4.3.30 TDrawGrid.OnTopLeftChanged Event

Occurs immediately after the TopRow (see page 14793) property or the LeftCol (see page 14790) property changes.

Pascal

```
property OnTopLeftChanged: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnTopLeftChanged;
```

Description

Use OnTopLeftChanged to perform special processing when the non-fixed cells in the grid are scrolled.

See Also

LeftCol (see page 14852)

TopRow (see page 14858)

75.1.5 TInplaceEdit Class

TInplaceEdit provides text editing capabilities for grid controls.

Class Hierarchy

Pascal

```
TInplaceEdit = class(TCustomMaskEdit);
```

C++

```
class TInplaceEdit : public TCustomMaskEdit;
```

File

Grids

Description

TInplaceEdit is a helper object tailored to work with grid controls. It provides a multiline editing window that appears in the appropriate cell of a grid control. TInplaceEdit provides services so that the grid can influence the response of the control to user actions, and can move or resize the editing window as cells are moved or resized.

The TInplaceEdit window has no border, so it does not stand out as a separate control. TInplaceEdit is not a data-aware control, but can work with a data-aware grid such as TDBGrid, allowing the grid to fetch or post the text, and allowing the grid to impose a mask to limit the text of the edit control to data that is valid.

See Also

TCustomGrid (see page 14800)

TDBEdit (see page 8735)

TDBGrid (see page 9668)

75.1.5.1 TInplaceEdit Members

The following tables list the members exposed by TInplaceEdit.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnChange (see page 21275)	Occurs when the text for the edit control may have changed.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.

	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
V	BoundsChanged (see page 14951)	Indents the text area of the window slightly after the grid repositions the edit control.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Change (see page 21245)	Generates an OnChange (see page 21275) event.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	CheckCursor (see page 15811)	Moves the cursor to the closest editable character and selects it if nothing is currently selected.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 14952)	Initializes a window-creation parameter record passed in the Params parameter.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWindowHandle (see page 21248)	Creates a Windows control to represent the control.
V	CreateWnd (see page 6137)	Creates the underlying window.
V	CreateWnd (see page 21248)	Creates a Windows control corresponding to the edit control.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
V	DblClick (see page 14952)	Informs the grid when the user double-clicks in the edit window.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.

	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DestroyWnd (see page 21251)	Destroys the Windows control that corresponds to the edit control.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 14953)	Delegates mouse wheel messages to the associated grid.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoSetMaxLength (see page 21251)	Sets the MaxLength (see page 21263) property.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EditCanModify (see page 14953)	Determines whether the user can edit the Text.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.

	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFirstEditChar (see page 15813)	Returns the index in the EditMask (see page 15821) of the first nonliteral character.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetLastEditChar (see page 15813)	Returns the index in the EditMask (see page 15821) of the last nonliteral character.
	GetMaxChars (see page 15814)	Returns the length of the EditText (see page 15821).
	GetNextEditChar (see page 15814)	Returns the first index of a nonliteral character equal to or greater than an offset.
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetPriorEditChar (see page 15815)	Returns the first index of a nonliteral character equal to or less than an offset.
	GetSel (see page 15815)	Returns the endpoints of the current selection in the EditText (see page 15821).
	GetSelLength (see page 21252)	Returns the SelLength (see page 21265) property.
	GetSelStart (see page 21252)	Returns the SelStart (see page 21269) property.
	GetSelText (see page 21252)	Returns the SelText (see page 21272) property.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 14954)	Responds when the user presses a key.
	KeyPress (see page 14955)	Responds when the user types a key.
	KeyUp (see page 14955)	Responds when the user releases a key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.

	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReformatText (see page 15817)	Applies the mask NewMask to the underlying text, and updates the internal representation of the mask.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
V	Reset (see page 15818)	Returns the EditText (see page 15821) to its value at the time when the edit control last lost focus.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetAutoSize (see page 21257)	Sets the AutoSize (see page 21260) property.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetCursor (see page 15818)	Moves the cursor to the first editable character at or before Pos, and selects that character.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.

	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetSel (see page 15819)	Selects character range.
	SetSelLength (see page 21257)	Sets the SelLength (see page 21265) property.
	SetSelStart (see page 21257)	Sets the SelStart (see page 21269) property.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateContents (see page 14957)	Sets the EditMask and Text properties to values specified by the grid.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	Validate (see page 15819)	Validates a specified string against the current mask.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateError (see page 15820)	Beeps and raises an EDBEditError (see page 15798) exception.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 14958)	Supplements the inherited method to add special processing to some Windows messages.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSelect (see page 21260)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	AutoSize (see page 21260)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderStyle (see page 21261)	Determines whether the edit control has a single line border around the client area.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	CharCase (see page 21262)	Determines the case of the text within the edit control.
	Color (see page 5812)	Specifies the background color of the control.

	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	EditMask (see page 15821)	Specifies the mask that represents what text is valid for the masked edit control.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
R	Grid (see page 14958)	Specifies the grid object that owns and controls this TInplaceEdit (see page 14938).
	HideSelection (see page 21262)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MaskState (see page 15822)	Indicates state information about how the mask is being applied.
	MaxLength (see page 15822)	Specifies the maximum number of characters that can appear in the edit control.
	MaxLength (see page 21263)	Specifies the maximum number of characters the user can enter into the edit control.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	OEMConvert (see page 21264)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentColor (see page 21264)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PasswordChar (see page 21265)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.

	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 15812)	Sets the Text (see page 15823) property to an empty string.
V	Clear (see page 21245)	Deletes all text from the edit control.
	ClearSelection (see page 21245)	Removes the selected text from the edit control.
	ClearUndo (see page 21246)	Clears the undo buffer so that no changes to the text can be backed out.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
	CopyToClipboard (see page 21246)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
V	Create (see page 14950)	Creates an instance of TInplaceEdit (see page 14938).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	CutToClipboard (see page 21249)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 21250)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Deselect (see page 14952)	Removes the selection from the edit window.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.

	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
V	GetSelTextBuf (see page 21253)	Copies the selected text into a buffer and returns the number of characters copied.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	GetTextLen (see page 15816)	Returns the length of the underlying text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 14953)	Hides the edit control window and moves input focus to the grid.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 14954)	Invalidates the edit window and the corresponding portion of the grid window.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	Move (see page 14956)	Changes the position of the edit window and repaints the contents.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	PasteFromClipboard (see page 21254)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PosEqual (see page 14956)	Indicates whether the edit window has the size and position indicated by Rect.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.

	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SelectAll (see page 21255)	Selects all text in the edit control.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
	SetFocus (see page 14956)	Gives the editor window input focus if it is visible.
	SetSelTextBuf (see page 21258)	Replaces the selected text with a null-terminated string.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Undo (see page 21259)	Backs out all changes in the undo buffer.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UpdateLoc (see page 14957)	Changes the position of the edit window but does not repaint the contents.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.
V	ValidateEdit (see page 15819)	Validates the EditText (see page 15821) against the current mask.
	Visible (see page 14958)	This is Visible, a member of class TInplaceEdit.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	CanUndo (see page 21262)	Indicates whether the edit control contains changes that can be backed out.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.

R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	EditText (see page 15821)	Specifies the text that appears in the window of the masked edit control.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
R	IsMasked (see page 15822)	Indicates whether a mask exists for the edit control.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
	Modified (see page 21263)	Indicates whether the user edited the text of the edit control.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ReadOnly (see page 21265)	Determines whether the user can change the text of the edit control.
	SelLength (see page 21265)	Specifies the number of characters (bytes) that are selected.
	SelStart (see page 21269)	Specifies the position of the first selected character in the text.
	SelText (see page 21272)	Specifies the selected portion of the edit control's text.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.

	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	Text (see page 15823)	Denotes the underlying text for the masked edit control before the mask has been applied.
	Text (see page 21273)	Contains a text string associated with the control.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	TabStop (see page 21273)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

75.1.5.2 TInplaceEdit.Create Constructor

Creates an instance of TInplaceEdit (see page 14938).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TInplaceEdit(TComponent * AOwner);
```

Description

Do not create instances of TInplaceEdit (see page 14938). These are created automatically by the grid that uses the editor.

AOwner specifies the Owner for the editor. This is the component that is responsible for freeing the TInplaceEdit (see page 14938) instance.

Create overrides the default constructor to make sure that the control has no border to provide a visual indication that the control exists.

See Also

Hide (see page 14953)

BoundsChanged (see page 14951)

Owner (see page 2807)

75.1.5.3 TInplaceEdit Methods

The methods of the TInplaceEdit class are listed here.

Protected Methods

	Name	Description
	BoundsChanged (see page 14951)	Indents the text area of the window slightly after the grid repositions the edit control.
	CreateParams (see page 14952)	Initializes a window-creation parameter record passed in the Params parameter.
	DblClick (see page 14952)	Informs the grid when the user double-clicks in the edit window.
	DoMouseWheel (see page 14953)	Delegates mouse wheel messages to the associated grid.
	EditCanModify (see page 14953)	Determines whether the user can edit the Text.
	KeyDown (see page 14954)	Responds when the user presses a key.
	KeyPress (see page 14955)	Responds when the user types a key.
	KeyUp (see page 14955)	Responds when the user releases a key.
	UpdateContents (see page 14957)	Sets the EditMask and Text properties to values specified by the grid.
	WndProc (see page 14958)	Supplements the inherited method to add special processing to some Windows messages.

Public Methods

	Name	Description
	Deselect (see page 14952)	Removes the selection from the edit window.
	Hide (see page 14953)	Hides the edit control window and moves input focus to the grid.
	Invalidate (see page 14954)	Invalidates the edit window and the corresponding portion of the grid window.
	Move (see page 14956)	Changes the position of the edit window and repaints the contents.
	PosEqual (see page 14956)	Indicates whether the edit window has the size and position indicated by Rect.
	SetFocus (see page 14956)	Gives the editor window input focus if it is visible.
	UpdateLoc (see page 14957)	Changes the position of the edit window but does not repaint the contents.
	Visible (see page 14958)	This is Visible, a member of class TInplaceEdit.

75.1.5.3.1 TInplaceEdit.BoundsChanged Method

Indents the text area of the window slightly after the grid repositions the edit control.

Pascal

```
procedure BoundsChanged; virtual;
```

C++

```
virtual __fastcall BoundsChanged();
```

Description

BoundsChanged reinitializes the editing window after the control has been moved or resized. It creates a slight indentation in the text formatting area so that the contents of the editor do not appear to crowd the edges of the cell.

BoundsChanged is exposed as a protected method so that derived objects can add further enhancements when the editing window changes size or location.

See Also

Move (see page 14956)

UpdateLoc (see page 14957)

PosEqual (see page 14956)

75.1.5.3.2 TInplaceEdit.CreateParams Method

Initializes a window-creation parameter record passed in the Params parameter.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. TInplaceEdit (see page 14938) overrides the inherited method to specify a multiline edit control.

See Also

CreateWnd (see page 21248)

CreateWindowHandle (see page 6137)

75.1.5.3.3 TInplaceEdit.DblClick Method

Informs the grid when the user double-clicks in the edit window.

Pascal

```
procedure DblClick; override;
```

C++

```
virtual __fastcall DblClick();
```

Description

DblClick is called when the user double-clicks in the edit window. DblClick simply passes the event on to the grid. The grid must interpret and respond to the double-click. If the edit window needs to respond to the double-click, the grid must trigger the response by calling a method or setting a property of the TInplaceEdit (see page 14938).

See Also

Grid (see page 14958)

75.1.5.3.4 TInplaceEdit.Deselect Method

Removes the selection from the edit window.

Pascal

```
procedure Deselect;
```

C++

```
__fastcall Deselect();
```

Description

Use Deselect to cause all text in the edit window to be unselected. Deselect simply changes the selection, it does not change the actual text.

See Also

ClearSelection (see page 21245)

SelectAll (see page 21255)

KeyPress (see page 14955)

75.1.5.3.5 TInplaceEdit.DoMouseWheel Method

Delegates mouse wheel messages to the associated grid.

Pascal

```
function DoMouseWheel(Shift: TShiftState; WheelDelta: Integer; MousePos: TPoint): Boolean;
override;
```

C++

```
virtual __fastcall Boolean DoMouseWheel(TShiftState Shift, int WheelDelta, TPoint MousePos);
```

Description

TInplaceEdit (see page 14938) overrides the inherited DoMouseWheel method so that it can pass any mouse wheel messages on to the grid specified by the Grid (see page 14958) property. This causes the grid's OnMouseWheel event handler to execute even though the inplace edit control has focus.

See Also

OnMouseWheel (see page 5869)

Grid (see page 14958)

75.1.5.3.6 TInplaceEdit.EditCanModify Method

Determines whether the user can edit the Text.

Pascal

```
function EditCanModify: Boolean; override;
```

C++

```
virtual __fastcall Boolean EditCanModify();
```

Description

EditCanModify is called automatically when the user tries to edit the value of Text. EditCanModify calls the CanEditModify method of the grid to determine whether the current cell of the grid should be edited. When EditCanModify returns true, the user is permitted to edit the text. When EditCanModify returns false, the user is prevented from editing the text.

See Also

Grid (see page 14958)

CanEditModify (see page 14819)

Text (see page 5842)

75.1.5.3.7 TInplaceEdit.Hide Method

Hides the edit control window and moves input focus to the grid.

Pascal

```
procedure Hide;
```

C++

```
__fastcall Hide();
```

Description

Hide makes the edit control window invisible without destroying it. Hide also moves the input focus from the editor window to the grid, so that the invisible window does not swallow keyboard events.

The grid calls Hide to hide the edit window when changing out of edit mode. It also calls Hide when scrolling the cell that is being edited out of the grid window.

See Also

Grid (see page 14958)

75.1.5.3.8 TInplaceEdit.Invalidate Method

Invalidates the edit window and the corresponding portion of the grid window.

Pascal

```
procedure Invalidate; reintroduce;
```

C++

```
__fastcall Invalidate();
```

Description

Invalidate ensures that the portion of the grid window under the edit control is invalidated at the same time as the edit window. This is important when the edit window is hidden or destroyed so that the grid window can repaint the cell that was covered by the edit window.

See Also

Grid (see page 14958)

Hide (see page 14953)

75.1.5.3.9 TInplaceEdit.KeyDown Method

Responds when the user presses a key.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

When the user presses a key, KeyDown checks whether the edit control or grid should process the KeyDown event. The Enter key is always passed on to the grid. The F2 key calls Deselect (see page 14952) to remove the current selection. Navigation keystrokes are passed on to the grid when the movement cannot be accommodated within the text window. For example, if the user types Left when the cursor is already at the left edge of the edit window, the keystroke is passed to the grid which moves focus to the previous cell. If the cursor is in the middle of a line, the keystroke is processed by the edit window, which moves left a single character.

KeyDown calls the OnKeyDown event handler for the grid, if there is one, before calling the inherited KeyDown for the edit control.

See Also

Grid (see page 14958)

KeyPress (see page 14955)

KeyUp (see page 14955)

KeyDown (see page 15816)

75.1.5.3.10 TInplaceEdit.KeyPress Method

Responds when the user types a key.

Pascal

```
procedure KeyPress(var Key: Char); override;
```

C++

```
virtual __fastcall KeyPress(Char Key);
```

Description

KeyPress allows the grid to handle the keystroke, and only processes keystrokes that the grid does not fully handle. If the grid is not in edit mode after handling the keystroke, KeyPress throws away the keystroke. Keystroke processes the Return Key and calls the inherited method to handle all other unprocessed keystrokes.

Pressing the Return key causes KeyPress to select all the text, unless it is already selected, in which case it causes KeyPress to deselect all the text.

See Also

Grid (see page 14958)

SelectAll (see page 21255)

Deselect (see page 14952)

KeyPress (see page 15816)

KeyDown (see page 14954)

KeyUp (see page 14955)

75.1.5.3.11 TInplaceEdit.KeyUp Method

Responds when the user releases a key.

Pascal

```
procedure KeyUp(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyUp(Word Key, TShiftState Shift);
```

Description

The inplace edit control does not process the KeyUp event at all. It simply passes this event on to the grid, which may or may not process the event.

See Also

Grid (see page 14958)

KeyDown (see page 14954)

KeyPress (see page 14955)

75.1.5.3.12 TInplaceEdit.Move Method

Changes the position of the edit window and repaints the contents.

Pascal

```
procedure Move(const Loc: TRect);
```

C++

```
__fastcall Move(const TRect Loc);
```

Description

The grid calls Move to move the edit window to the indicated rectangle when the corresponding cell moves or resizes. The position of Loc is relative to the grid's client area.

See Also

Grid (see page 14958)

UpdateLoc (see page 14957)

75.1.5.3.13 TInplaceEdit.PosEqual Method

Indicates whether the edit window has the size and position indicated by Rect.

Pascal

```
function PosEqual(const Rect: TRect): Boolean;
```

C++

```
__fastcall Boolean PosEqual(const TRect Rect);
```

Description

Use PosEqual to determine if the edit window occupies a particular rectangle, where Rect is given in global coordinates. PosEqual can be used to determine whether the inplace edit control represents a particular cell in the grid, by checking the bounding rectangle of the cell.

See Also

BoundsRect (see page 5803)

TCustomGrid (see page 14800)

75.1.5.3.14 TInplaceEdit.SetFocus Method

Gives the editor window input focus if it is visible.

Pascal

```
procedure SetFocus; reintroduce;
```

C++

```
__fastcall SetFocus();
```

Description

Use SetFocus to cause keyboard events to go to the editor window. Focus will not move to the window if it is hidden by a call to

the Hide (see page 14953) method.

See Also

KeyPress (see page 14955)

KeyDown (see page 14954)

KeyUp (see page 14955)

Hide (see page 14953)

75.1.5.3.15 TInplaceEdit.UpdateContents Method

Sets the EditMask and Text properties to values specified by the grid.

Pascal

```
procedure UpdateContents; virtual;
```

C++

```
virtual __fastcall UpdateContents();
```

Description

UpdateContents calls the GetEditMask and GetEditText methods of the grid, and sets the EditMask and Text properties accordingly. UpdateContents allows the grid to bring up the inplace edit control with the contents of a particular cell, and to impose a mask to restrict the editor to valid input for the particular cell.

See Also

Grid (see page 14958)

EditMask (see page 15821)

Text (see page 5842)

GetEditMask (see page 14828)

GetEditText (see page 14829)

75.1.5.3.16 TInplaceEdit.UpdateLoc Method

Changes the position of the edit window but does not repaint the contents.

Pascal

```
procedure UpdateLoc(const Loc: TRect);
```

C++

```
__fastcall UpdateLoc(const TRect Loc);
```

Description

The grid calls UpdateLoc to move the edit window when the grid is moved. Unlike the Move (see page 14956) method, UpdateLoc does not invalidate the edit window to cause a repaint.

See Also

Grid (see page 14958)

Move (see page 14956)

Invalidate (see page 14954)

75.1.5.3.17 TInplaceEdit.Visible Method

Pascal

```
function Visible: Boolean;
```

C++

```
__fastcall Boolean Visible();
```

Description

This is Visible, a member of class TInplaceEdit.

75.1.5.3.18 TInplaceEdit.WndProc Method

Supplements the inherited method to add special processing to some Windows messages.

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

WndProc is the first method of a control that receives Windows messages.

WndProc for TInplaceEdit (see page 14938) passes focus events on to the grid. It calls the inherited method for all other Windows messages. WndProc converts mouse clicks to double clicks when the grid receives the first click within the double-click time period.

See Also

Grid (see page 14958)

WndProc (see page 6187)

75.1.5.4 TInplaceEdit Properties

The properties of the TInplaceEdit class are listed here.

Protected Properties

	Name	Description
R	Grid (see page 14958)	Specifies the grid object that owns and controls this TInplaceEdit (see page 14938).

75.1.5.4.1 TInplaceEdit.Grid Property

Specifies the grid object that owns and controls this TInplaceEdit (see page 14938).

Pascal

```
property Grid: TCustomGrid;
```

C++

```
__property TCustomGrid Grid;
```

Description

Read Grid to obtain the grid object for which TInplaceEdit (see page 14938) provides editing services. TInplaceEdit (see page 14938) uses the Grid property so that it can receive information about the text to be edited and so that it can pass on relevant events.

See Also

UpdateContents (see page 14957)

UpdateLoc (see page 14957)

75.1.6 TInplaceEditList Class

Class Hierarchy

Pascal

```
TInplaceEditList = class(TInPlaceEdit);
```

C++

```
class TInplaceEditList : public TInPlaceEdit;
```

File

Grids

Description

This is class Grids.TInplaceEditList.

75.1.6.1 TInplaceEditList Members

The following tables list the members exposed by TInplaceEditList.

Protected Methods

	Name	Description
	BoundsChanged (see page 14961)	This is BoundsChanged, a member of class TInplaceEditList.
	ButtonRect (see page 14961)	This is ButtonRect, a member of class TInplaceEditList.
	CloseUp (see page 14961)	This is CloseUp, a member of class TInplaceEditList.
	DblClick (see page 14961)	This is DblClick, a member of class TInplaceEditList.
	DoDropDownKeys (see page 14962)	This is DoDropDownKeys, a member of class TInplaceEditList.
	DoEditButtonClick (see page 14962)	This is DoEditButtonClick, a member of class TInplaceEditList.
	DoGetPickListItems (see page 14962)	This is DoGetPickListItems, a member of class TInplaceEditList.
	DropDown (see page 14962)	This is DropDown, a member of class TInplaceEditList.
	KeyDown (see page 14963)	This is KeyDown, a member of class TInplaceEditList.
	ListMouseUp (see page 14963)	This is ListMouseUp, a member of class TInplaceEditList.
	MouseDown (see page 14963)	This is MouseDown, a member of class TInplaceEditList.
	MouseMove (see page 14963)	This is MouseMove, a member of class TInplaceEditList.
	MouseUp (see page 14963)	This is MouseUp, a member of class TInplaceEditList.
	OverButton (see page 14964)	This is OverButton, a member of class TInplaceEditList.
	PaintWindow (see page 14964)	This is PaintWindow, a member of class TInplaceEditList.
	StopTracking (see page 14964)	This is StopTracking, a member of class TInplaceEditList.

	TrackButton (see page 14965)	This is TrackButton, a member of class TInplaceEditList.
V	UpdateContents (see page 14965)	This is UpdateContents, a member of class TInplaceEditList.
V	WndProc (see page 14965)	This is WndProc, a member of class TInplaceEditList.

Public Events

	Name	Description
	OnEditButtonClick (see page 14967)	This is OnEditButtonClick, a member of class TInplaceEditList.
	OnGetPickListitems (see page 14968)	This is OnGetPickListitems, a member of class TInplaceEditList.

Public Methods

	Name	Description
V	Create (see page 14960)	This is Create, a member of class TInplaceEditList.
	RestoreContents (see page 14964)	This is RestoreContents, a member of class TInplaceEditList.

Public Properties

	Name	Description
	ActiveList (see page 14966)	This is ActiveList, a member of class TInplaceEditList.
	ButtonWidth (see page 14966)	This is ButtonWidth, a member of class TInplaceEditList.
	DropDownRows (see page 14966)	This is DropDownRows, a member of class TInplaceEditList.
R	EditStyle (see page 14966)	This is EditStyle, a member of class TInplaceEditList.
	ListVisible (see page 14966)	This is ListVisible, a member of class TInplaceEditList.
R	PickList (see page 14967)	This is PickList, a member of class TInplaceEditList.
	PickListLoaded (see page 14967)	This is PickListLoaded, a member of class TInplaceEditList.
R	Pressed (see page 14967)	This is Pressed, a member of class TInplaceEditList.

75.1.6.2 TInplaceEditList.Create Constructor

Pascal

```
constructor Create(Owner: TComponent); override;
```

C++

```
virtual __fastcall TInplaceEditList(TComponent * Owner);
```

Description

This is Create, a member of class TInplaceEditList.

75.1.6.3 TInplaceEditList Methods

The methods of the TInplaceEditList class are listed here.

Protected Methods

	Name	Description
V	BoundsChanged (see page 14961)	This is BoundsChanged, a member of class TInplaceEditList.
	ButtonRect (see page 14961)	This is ButtonRect, a member of class TInplaceEditList.
	CloseUp (see page 14961)	This is CloseUp, a member of class TInplaceEditList.
V	DblClick (see page 14961)	This is DblClick, a member of class TInplaceEditList.
V	DoDropDownKeys (see page 14962)	This is DoDropDownKeys, a member of class TInplaceEditList.
V	DoEditButtonClick (see page 14962)	This is DoEditButtonClick, a member of class TInplaceEditList.
	DoGetPickListItems (see page 14962)	This is DoGetPickListItems, a member of class TInplaceEditList.
	DropDown (see page 14962)	This is DropDown, a member of class TInplaceEditList.
V	KeyDown (see page 14963)	This is KeyDown, a member of class TInplaceEditList.
	ListMouseUp (see page 14963)	This is ListMouseUp, a member of class TInplaceEditList.

	MouseDown (see page 14963)	This is MouseDown, a member of class TInplaceEditList.
	MouseMove (see page 14963)	This is MouseMove, a member of class TInplaceEditList.
	MouseUp (see page 14963)	This is MouseUp, a member of class TInplaceEditList.
	OverButton (see page 14964)	This is OverButton, a member of class TInplaceEditList.
	PaintWindow (see page 14964)	This is PaintWindow, a member of class TInplaceEditList.
	StopTracking (see page 14964)	This is StopTracking, a member of class TInplaceEditList.
	TrackButton (see page 14965)	This is TrackButton, a member of class TInplaceEditList.
	UpdateContents (see page 14965)	This is UpdateContents, a member of class TInplaceEditList.
	WndProc (see page 14965)	This is WndProc, a member of class TInplaceEditList.

Public Methods

	Name	Description
	RestoreContents (see page 14964)	This is RestoreContents, a member of class TInplaceEditList.

75.1.6.3.1 TInplaceEditList.BoundsChanged Method

Pascal

```
procedure BoundsChanged; override;
```

C++

```
virtual __fastcall BoundsChanged();
```

Description

This is BoundsChanged, a member of class TInplaceEditList.

75.1.6.3.2 TInplaceEditList.ButtonRect Method

Pascal

```
function ButtonRect: TRect;
```

C++

```
__fastcall TRect ButtonRect();
```

Description

This is ButtonRect, a member of class TInplaceEditList.

75.1.6.3.3 TInplaceEditList.CloseUp Method

Pascal

```
procedure CloseUp(Accept: Boolean); dynamic;
```

C++

```
__fastcall CloseUp(Boolean Accept);
```

Description

This is CloseUp, a member of class TInplaceEditList.

75.1.6.3.4 TInplaceEditList.DblClick Method

Pascal

```
procedure DblClick; override;
```

C++

```
virtual __fastcall DblClick();
```

Description

This is DblClick, a member of class TInplaceEditList.

75.1.6.3.5 TInplaceEditList.DoDropDownKeys Method

Pascal

```
procedure DoDropDownKeys(var Key: Word; Shift: TShiftState); virtual;
```

C++

```
virtual __fastcall DoDropDownKeys(Word Key, TShiftState Shift);
```

Description

This is DoDropDownKeys, a member of class TInplaceEditList.

75.1.6.3.6 TInplaceEditList.DoEditButtonClick Method

Pascal

```
procedure DoEditButtonClick; virtual;
```

C++

```
virtual __fastcall DoEditButtonClick();
```

Description

This is DoEditButtonClick, a member of class TInplaceEditList.

75.1.6.3.7 TInplaceEditList.DoGetPickListItems Method

Pascal

```
procedure DoGetPickListItems; dynamic;
```

C++

```
__fastcall DoGetPickListItems();
```

Description

This is DoGetPickListItems, a member of class TInplaceEditList.

75.1.6.3.8 TInplaceEditList.DropDown Method

Pascal

```
procedure DropDown; dynamic;
```

C++

```
__fastcall DropDown();
```

Description

This is DropDown, a member of class TInplaceEditList.

75.1.6.3.9 TInplaceEditList.KeyDown Method

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

This is KeyDown, a member of class TInplaceEditList.

75.1.6.3.10 TInplaceEditList.ListMouseUp Method

Pascal

```
procedure ListMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X: Integer;
Y: Integer);
```

C++

```
__fastcall ListMouseUp(TObject * Sender, TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

This is ListMouseUp, a member of class TInplaceEditList.

75.1.6.3.11 TInplaceEditList.MouseDown Method

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

This is MouseDown, a member of class TInplaceEditList.

75.1.6.3.12 TInplaceEditList.MouseMove Method

Pascal

```
procedure MouseMove(Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseMove(TShiftState Shift, int X, int Y);
```

Description

This is MouseMove, a member of class TInplaceEditList.

75.1.6.3.13 TInplaceEditList.MouseUp Method

Pascal

```
procedure MouseUp(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer); override;
```

C++

```
virtual __fastcall MouseUp(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

This is MouseUp, a member of class TInplaceEditList.

75.1.6.3.14 TInplaceEditList.OverButton Method

Pascal

```
function OverButton(const P: TPoint): Boolean;
```

C++

```
__fastcall Boolean OverButton(const TPoint P);
```

Description

This is OverButton, a member of class TInplaceEditList.

75.1.6.3.15 TInplaceEditList.PaintWindow Method

Pascal

```
procedure PaintWindow(DC: HDC); override;
```

C++

```
virtual __fastcall PaintWindow(HDC DC);
```

Description

This is PaintWindow, a member of class TInplaceEditList.

75.1.6.3.16 TInplaceEditList.RestoreContents Method

Pascal

```
procedure RestoreContents;
```

C++

```
__fastcall RestoreContents();
```

Description

This is RestoreContents, a member of class TInplaceEditList.

75.1.6.3.17 TInplaceEditList.StopTracking Method

Pascal

```
procedure StopTracking;
```

C++

```
__fastcall StopTracking();
```

Description

This is StopTracking, a member of class TInplaceEditList.

75.1.6.3.18 TInplaceEditList.TrackButton Method

Pascal

```
procedure TrackButton(X: Integer; Y: Integer);
```

C++

```
__fastcall TrackButton(int X, int Y);
```

Description

This is TrackButton, a member of class TInplaceEditList.

75.1.6.3.19 TInplaceEditList.UpdateContents Method

Pascal

```
procedure UpdateContents; override;
```

C++

```
virtual __fastcall UpdateContents();
```

Description

This is UpdateContents, a member of class TInplaceEditList.

75.1.6.3.20 TInplaceEditList.WndProc Method

Pascal

```
procedure WndProc(var Message: TMessage); override;
```

C++

```
virtual __fastcall WndProc(TMessage Message);
```

Description

This is WndProc, a member of class TInplaceEditList.

75.1.6.4 TInplaceEditList Properties

The properties of the TInplaceEditList class are listed here.

Public Properties

	Name	Description
	ActiveList (see page 14966)	This is ActiveList, a member of class TInplaceEditList.
	ButtonWidth (see page 14966)	This is ButtonWidth, a member of class TInplaceEditList.
	DropDownRows (see page 14966)	This is DropDownRows, a member of class TInplaceEditList.
R	EditStyle (see page 14966)	This is EditStyle, a member of class TInplaceEditList.
	ListVisible (see page 14966)	This is ListVisible, a member of class TInplaceEditList.
R	PickList (see page 14967)	This is PickList, a member of class TInplaceEditList.
	PickListLoaded (see page 14967)	This is PickListLoaded, a member of class TInplaceEditList.
R	Pressed (see page 14967)	This is Pressed, a member of class TInplaceEditList.

75.1.6.4.1 TInplaceEditList.ActiveList Property

Pascal

```
property ActiveList: TWinControl;
```

C++

```
__property TWinControl * ActiveList;
```

Description

This is ActiveList, a member of class TInplaceEditList.

75.1.6.4.2 TInplaceEditList.ButtonWidth Property

Pascal

```
property ButtonWidth: Integer;
```

C++

```
__property int ButtonWidth;
```

Description

This is ButtonWidth, a member of class TInplaceEditList.

75.1.6.4.3 TInplaceEditList.DropDownRows Property

Pascal

```
property DropDownRows: Integer;
```

C++

```
__property int DropDownRows;
```

Description

This is DropDownRows, a member of class TInplaceEditList.

75.1.6.4.4 TInplaceEditList.EditStyle Property

Pascal

```
property EditStyle: TEditStyle;
```

C++

```
__property TEditStyle EditStyle;
```

Description

This is EditStyle, a member of class TInplaceEditList.

75.1.6.4.5 TInplaceEditList.ListVisible Property

Pascal

```
property ListVisible: Boolean;
```

C++

```
__property Boolean ListVisible;
```

Description

This is ListVisible, a member of class TInplaceEditList.

75.1.6.4.6 TInplaceEditList.PickList Property

Pascal

```
property PickList: TCustomListbox;
```

C++

```
__property TCustomListbox PickList;
```

Description

This is PickList, a member of class TInplaceEditList.

75.1.6.4.7 TInplaceEditList.PickListLoaded Property

Pascal

```
property PickListLoaded: Boolean;
```

C++

```
__property Boolean PickListLoaded;
```

Description

This is PickListLoaded, a member of class TInplaceEditList.

75.1.6.4.8 TInplaceEditList.Pressed Property

Pascal

```
property Pressed: Boolean;
```

C++

```
__property Boolean Pressed;
```

Description

This is Pressed, a member of class TInplaceEditList.

75.1.6.5 TInplaceEditList Events

The events of the TInplaceEditList class are listed here.

Public Events

	Name	Description
	OnEditButtonClick (see page 14967)	This is OnEditButtonClick, a member of class TInplaceEditList.
	OnGetPickListitems (see page 14968)	This is OnGetPickListitems, a member of class TInplaceEditList.

75.1.6.5.1 TInplaceEditList.OnEditButtonClick Event

Pascal

```
property OnEditButtonClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEditButtonClick;
```

Description

This is OnEditButtonClick, a member of class TInplaceEditList.

75.1.6.5.2 TInplaceEditList.OnGetPickListitems Event

Pascal

```
property OnGetPickListitems: TOnGetPickListItems;
```

C++

```
__property TOnGetPickListItems OnGetPickListitems;
```

Description

This is OnGetPickListitems, a member of class TInplaceEditList.

75.1.7 TStringGrid Class

TStringGrid represents a grid control designed to simplify the handling of strings and associated objects.

Class Hierarchy

Pascal

```
TStringGrid = class(TDrawGrid);
```

C++

```
class TStringGrid : public TDrawGrid;
```

File

Grids

Description

Add a TStringGrid object to a form to present textual data in a tabular format. TStringGrid provides many properties to control the appearance of the grid, as well as events and methods that take advantage of the tabular organization of the grid in responding to user actions.

TStringGrid introduces the ability to associate an object with each string in the grid. These objects can encapsulate any information or behavior represented by the strings that are presented to the user.

If the strings to be presented in a grid represent field values from the records in a dataset, use TDBGrid instead.

See Also

TDBGrid (see page 9668)

TValueListEditor (see page 23401)

String Grids

Grids

75.1.7.1 TStringGrid Members

The following tables list the members exposed by TStringGrid.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnColumnMoved (see page 14794)	Occurs immediately after the position of a column changes.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnDrawCell (see page 14795)	Occurs when a cell in the grid needs to be drawn.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetEditMask (see page 14796)	Occurs when the in-place editor requests an edit mask.
	OnGetEditText (see page 14797)	Occurs when the in-place editor requests the value of a cell.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnRowMoved (see page 14798)	Occurs immediately after the position of a row changes.
	OnSelectCell (see page 14798)	Occurs before a cell in the grid is selected.
	OnSetEditText (see page 14800)	Occurs when the user edits the value of a cell.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

	OnTopLeftChanged (see page 14800)	Occurs immediately after the TopRow (see page 14793) property or the LeftCol (see page 14790) property changes.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	DesignOptionsBoost (see page 14814)	This is DesignOptionsBoost, a member of class TCustomGrid.
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FGridState (see page 14814)	This is FGridState, a member of class TCustomGrid.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.
	FSaveCellExtents (see page 14814)	This is FSaveCellExtents, a member of class TCustomGrid.
	VirtualView (see page 14814)	This is VirtualView, a member of class TCustomGrid.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AdjustSize (see page 14816)	Adds or deletes rows or columns from the grid.
	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	BeginColumnDrag (see page 14817)	Starts the dragging of a column in the grid.
	BeginRowDrag (see page 14817)	Starts the dragging of a row in the grid.
	BoxRect (see page 14818)	Returns the screen coordinates of a specified set of cells.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CalcDrawInfo (see page 14818)	Calculates the pixel locations of the grid boundaries.
	CalcFixedInfo (see page 14818)	Calculates the pixel locations of the fixed cells.
	CalcSizingState (see page 14819)	Determines the appearance of the mouse cursor during resizing.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanEditAcceptKey (see page 14819)	Indicates whether the Key parameter can be entered into the current cell.
	CanEditModify (see page 14819)	Indicates whether the current cell in the grid can be edited.

	CanEditShow (see page 14820)	Indicates whether the inplace edit control can be created to allow editing.
	CanGridAcceptKey (see page 14820)	Indicates whether the grid should respond to a given key combination.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	CellRect (see page 14821)	Returns the screen coordinates of a cell in the grid.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeGridOrientation (see page 14821)	Prepares the grid's canvas for painting to reflect a right-to-left or left-to-right orientation.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	CheckColumnDrag (see page 14821)	CheckColumnDrag validates whether the column currently selected for dragging can be dropped at the current location.
	CheckRowDrag (see page 14822)	CheckRowDrag validates whether the row currently selected for dragging can be dropped at the current location.
	Click (see page 5743)	Respond to user click.
	ColumnMoved (see page 14984)	Generates an OnColumnMoved event.
	ColWidthsChanged (see page 14822)	Responds when the column widths change.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateEditor (see page 14823)	Creates the inplace editor control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 14823)	Initializes the window-creation parameter record.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DefineProperties (see page 14824)	Adds the ColWidths (see page 14845) and RowHeights (see page 14855) properties to the values saved with the grid.
	DeleteColumn (see page 14824)	Deletes a specified column from the grid.
	DeleteRow (see page 14825)	Deletes a specified from the grid.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.

	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
V	DoExit (see page 14825)	Hides the inplace editor when selection moves to another control in a form.
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
V	DoMouseWheelDown (see page 14825)	Performs tasks when the mouse wheel is rotated downward.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
V	DoMouseWheelUp (see page 14826)	Performs tasks when the mouse wheel is rotated upward.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
V	DrawCell (see page 14984)	Generates an OnDrawCell event.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EndColumnDrag (see page 14827)	Ends the dragging of a column in the grid.
	EndRowDrag (see page 14827)	Ends the dragging of a row in the grid.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	FocusCell (see page 14827)	Changes the current cell to a specified cell.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEditLimit (see page 14828)	Provides the interface for a method that limits the number of characters the user can type into cells.
V	GetEditMask (see page 14782)	Generates an OnGetEditMask (see page 14796) event.
	GetEditMask (see page 14828)	Provides the interface for a method that returns an input mask for the specified cell.
	GetEditStyle (see page 14828)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.

	GetEditText (see page 14985)	Generates an OnGetEditText event.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetGridHeight (see page 14829)	Returns the value of the GridHeight (see page 14850) property.
	GetGridWidth (see page 14830)	Returns the value of the GridWidth (see page 14851) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HideEdit (see page 14830)	Hides the inplace editor.
	HideEditor (see page 14830)	Hides the inplace editor when it is not in use.
	InvalidateCell (see page 14831)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.
	InvalidateCol (see page 14831)	Invalidates the region occupied by a column so that it will be repainted with the next Windows paint message.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	InvalidateEditor (see page 14832)	Causes the inplace editor to repaint itself, moving to a new location if necessary.
	InvalidateGrid (see page 14832)	Tells Windows to repaint the grid after other important Windows messages are handled.
	InvalidateRow (see page 14832)	Invalidates the region occupied by a row so that it will be repainted with the next Windows paint message.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyDown (see page 14833)	Provides special processing when the user presses a key.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyPress (see page 14833)	Provides special processing when the user presses a key.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseDown (see page 14834)	Provides special processing when the user presses a mouse button.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseMove (see page 14834)	Provides special processing when the user moves the mouse.
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	MouseUp (see page 14835)	Provides special processing when the user releases the mouse button.
	MoveColRow (see page 14835)	Selects the cell indicated by the ACol and ARow parameters.
	MoveColumn (see page 14836)	Moves a column to a new position.
	MoveRow (see page 14836)	Moves a row to a new position.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.

	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	Paint (see page 5920)	Renders the image of a custom control.
	Paint (see page 14836)	Draws the image of the grid control on the screen.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	RowHeightsChanged (see page 14837)	Responds when the row heights change.
	RowMoved (see page 14985)	Generates an OnRowMoved event.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	ScrollData (see page 14838)	Scrolls the visual image of the cells in the grid.
	SelectCell (see page 14784)	Determines whether a particular cell in the grid can be selected.
	SelectCell (see page 14838)	Determines whether a particular cell in the grid can be selected.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEditText (see page 14985)	Generates an OnSetEditText event.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.

	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	ShowEditor (see page 14839)	Displays the inplace editor when the grid enters edit mode.
	ShowEditorChar (see page 14839)	Displays the inplace editor, with its text set to the specified character.
	SizeChanged (see page 14840)	Responds to changes in the size of the grid.
	Sizing (see page 14840)	Indicates whether the indicated coordinates are on one of the resize hot zones of the graph.
	TimedScroll (see page 14840)	Extends a move, resize, or selection out of the scrollable region when the user drags the mouse in a direction where the grid is scrolled.
	TopLeftChanged (see page 14784)	Generates an OnTopLeftChanged (see page 14800) event.
	TopLeftChanged (see page 14841)	Updates the position of the inplace editor when the grid scrolls.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateDesigner (see page 14841)	Notifies the designer when rows and columns of the grid are moved or resized.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderStyle (see page 14843)	Determines whether a single line border is drawn around the grid.

	BorderWidth (see page 6195)	Specifies the width of the control's border.
R	Canvas (see page 5921)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Col (see page 14843)	Specifies the index of the column that contains the selected cell.
	ColCount (see page 14844)	Specifies the number of columns in the grid.
	Color (see page 5812)	Specifies the background color of the control.
	Color (see page 14844)	Specifies the background color of the control.
	ColWidths (see page 14845)	Indicates the width (in pixels) of all the columns in the grid.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultColWidth (see page 14846)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 14847)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 14847)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	EditorMode (see page 14848)	Determines whether the current cell can be edited.
	FixedColor (see page 14848)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 14848)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	FixedRows (see page 14849)	Specifies the number of rows on the top of the grid that cannot be scrolled.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
R	GridHeight (see page 14850)	Specifies the height of the grid in pixels.
	GridLineWidth (see page 14850)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
R	GridWidth (see page 14851)	Specifies the width of the grid in pixels.
R	HitTest (see page 14851)	Indicates the current position of the mouse cursor.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
R	InplaceEditor (see page 14852)	Designates the edit control the grid uses to allow users to edit the contents of the selected cell.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	LeftCol (see page 14852)	Specifies the index of the first visible scrollable column in the grid.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	Options (see page 14853)	Specifies various display and behavioral properties of the grid.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentColor (see page 14853)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	Row (see page 14854)	Specifies the index of the row that contains the selected cell.
	RowCount (see page 14854)	Specifies the number of rows in the grid.
	RowHeights (see page 14855)	Gives the height (in pixels) of all rows in the grid.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	ScrollBars (see page 14856)	Specifies whether the grid includes horizontal and vertical scroll bars.
	Selection (see page 14856)	Indicates the boundaries of the current selection.
	TabStops (see page 14858)	Indicates whether the user can tab to specified columns in the grid.
	Text (see page 5842)	Contains a text string associated with the control.

	TopRow (see page 14858)	Specifies the index of the first visible scrollable row in the grid.
R	VisibleColCount (see page 14859)	Indicates the number of scrollable columns visible in the grid.
R	VisibleRowCount (see page 14859)	Indicates the number of scrollable rows visible in the grid.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	CellRect (see page 14781)	Returns the screen coordinates of a cell in the grid.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 14983)	Creates an instance of TStringGrid (see page 14968).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 14983)	Destroys an instance of TStringGrid (see page 14968).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.

	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseCoord (see page 14834)	Returns the row and column indexes of the cell that contains a point specified in screen coordinates.
	MouseToCell (see page 14783)	Returns the column and row of the cell at the position with screen coordinates (X,Y).

	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	Canvas (see page 14785)	Specifies the TCanvas object that presents a drawing surface for the control.
	Cells (see page 14986)	Lists the strings for each cell in the grid.

	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
	Col (see page 14787)	Specifies the index of the column that contains the selected cell.
	Cols (see page 14987)	Lists strings with their associated objects for each column.
	ColWidths (see page 14788)	Indicates the width (in pixels) of all the columns in the grid.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	EditorMode (see page 14789)	Determines whether the current cell can be edited.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	GridHeight (see page 14789)	Specifies the height of the grid in pixels.
	GridWidth (see page 14789)	Specifies the width of the grid in pixels.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LeftCol (see page 14790)	Specifies the index of the first visible scrollable column in the grid.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	Objects (see page 14987)	Lists the objects for each cell in the grid.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	Row (see page 14790)	Specifies the index of the row that contains the selected cell.
	RowHeights (see page 14791)	Gives the height (in pixels) of all rows in the grid.

	Rows (see page 14987)	Lists the strings and their associated objects for each row.
	Selection (see page 14791)	Indicates the boundaries of the current selection.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TabStops (see page 14793)	Indicates whether the user can tab to specified columns in the grid.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TopRow (see page 14793)	Specifies the index of the first visible scrollable row in the grid.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnClick (see page 14906)	Occurs when the user clicks the control.
	OnColumnMoved (see page 14908)	Occurs immediately after the position of a column changes.
	OnContextPopup (see page 14908)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 14909)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 14909)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 14911)	Occurs when the user drags an object over a control.
	OnDrawCell (see page 14914)	Occurs when a cell in the grid needs to be drawn.
	OnEndDock (see page 14914)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 14915)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 14916)	Occurs when a control receives the input focus.
	OnExit (see page 14918)	Occurs when the input focus shifts away from one control to another.
	OnGetEditMask (see page 14920)	Occurs when the in-place editor requests an edit mask.
	OnGetEditText (see page 14920)	Occurs when the in-place editor requests the value of a cell.
	OnKeyDown (see page 14920)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 14923)	Occurs when a key is pressed.
	OnKeyUp (see page 14924)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 14926)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 14927)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 14929)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 14929)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 14930)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 14932)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheelDown (see page 14934)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 14935)	Occurs when the mouse wheel is rotated upward.
	OnRowMoved (see page 14935)	Occurs immediately after the position of a row changes.
	OnSelectCell (see page 14935)	Occurs before a cell in the grid is selected.
	OnSetEditText (see page 14936)	Occurs when the user edits the value of a cell.
	OnStartDock (see page 14936)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 14937)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

	OnTopLeftChanged (see page 14937)	Occurs immediately after the TopRow (see page 14793) property or the LeftCol (see page 14790) property changes.

Published Properties

	Name	Description
	Align (see page 14874)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 14878)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 14879)	Specifies which edges of the control are beveled.
	BevelInner (see page 14879)	Specifies the cut of the inner bevel.
	BevelKind (see page 14879)	Specifies the control's bevel style.
	BevelOuter (see page 14880)	Specifies the cut of the outer bevel.
	BevelWidth (see page 14880)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 14881)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 14881)	Determines whether a single line border is drawn around the grid.
	ColCount (see page 14881)	Specifies the number of columns in the grid.
	Color (see page 14882)	Specifies the background color of the control.
	Constraints (see page 14883)	Specifies the size constraints for the control.
	Ctl3D (see page 14884)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DefaultColWidth (see page 14884)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 14885)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 14885)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DragCursor (see page 14886)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 14886)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 14887)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 14888)	Controls whether the control responds to mouse, keyboard, and timer events.
	FixedColor (see page 14889)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 14889)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	FixedRows (see page 14889)	Specifies the number of rows on the top of the grid that cannot be scrolled.
	Font (see page 14890)	Controls the attributes of text written on or in the control.
	GridLineWidth (see page 14891)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Options (see page 14892)	Specifies various display and behavioral properties of the grid.
	ParentBiDiMode (see page 14893)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 14893)	Determines where a control looks for its color information.
	ParentCtl3D (see page 14893)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 14894)	Determines where a control looks for its font information.
	ParentShowHint (see page 14894)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 14895)	Identifies the pop-up menu associated with the control.
	RowCount (see page 14899)	Specifies the number of rows in the grid.
	ScrollBars (see page 14900)	Specifies whether the grid includes horizontal and vertical scroll bars.

	ShowHint (see page 14901)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 14902)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 14857)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 14903)	Determines whether the component appears onscreen.
	VisibleColCount (see page 14904)	Indicates the number of scrollable columns visible in the grid.
	VisibleRowCount (see page 14905)	Indicates the number of scrollable rows visible in the grid.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

75.1.7.2 TStringGrid.Create Constructor

Creates an instance of TStringGrid (see page 14968).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TStringGrid(TComponent * AOwner);
```

Description

Call Create to create an instance of TStringGrid (see page 14968) at runtime. For string grids placed on forms at design time, Create is called automatically.

AOwner is another component, typically a form, that becomes the grid's Owner. The Owner is responsible for freeing the grid.

See Also

Create (see page 14813)

75.1.7.3 TStringGrid.Destroy Destructor

Destroys an instance of TStringGrid (see page 14968).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TStringGrid();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the string grid is not nil, and only then calls Destroy.

Destroy frees the helper objects used to manage the array of strings and their associated objects.

See Also

Free (see page 22300)

75.1.7.4 TStringGrid Methods

The methods of the TStringGrid class are listed here.

Protected Methods

	Name	Description
	ColumnMoved (see page 14984)	Generates an OnColumnMoved event.
	DrawCell (see page 14984)	Generates an OnDrawCell event.
	GetEditText (see page 14985)	Generates an OnGetEditText event.
	RowMoved (see page 14985)	Generates an OnRowMoved event.
	SetEditText (see page 14985)	Generates an OnSetEditText event.

75.1.7.4.1 TStringGrid.ColumnMoved Method

Generates an OnColumnMoved event.

Pascal

```
procedure ColumnMoved(FromIndex: Longint; ToIndex: Longint); override;
```

C++

```
virtual __fastcall ColumnMoved(Longint FromIndex, Longint ToIndex);
```

Description

ColumnMoved is called immediately after a column in the grid has moved. It overrides the inherited method to generate an OnColumnMoved event. Descendants of TCustomDrawGrid can override this method to make internal adjustments or to block the OnColumnMoved event.

See Also

OnColumnMoved (see page 14794)

75.1.7.4.2 TStringGrid.DrawCell Method

Generates an OnDrawCell event.

Pascal

```
procedure DrawCell(ACol: Longint; ARow: Longint; ARect: TRect; AState: TGridDrawState);
override;
```

C++

```
virtual __fastcall DrawCell(Longint ACol, Longint ARow, TRect ARect, TGridDrawState AState);
```

Description

DrawCell is called automatically whenever a cell in the grid is drawn. If the DefaultDrawing property is true, the background of the cell is painted before DrawCell is called, and the 3D effects of the fixed cells or the focus rectangle around the focused cell are drawn after DrawCell. Descendants of TCustomDrawGrid can override this method to draw the contents of the cell or to block the OnDrawCell event.

See Also

DefaultDrawing (see page 14847)

FixedCols (see page 14848)

FixedRows (see page 14849)

OnDrawCell (see page 14795)

75.1.7.4.3 TStringGrid.GetEditText Method

Generates an OnGetEditText event.

Pascal

```
function GetEditText(ACol: Longint; ARow: Longint): string; override;
```

C++

```
virtual __fastcall AnsiString GetEditText(Longint ACol, Longint ARow);
```

Description

The inplace editor calls GetEditText to obtain the text for the indicated cell. GetEditText returns the Value parameter set by the OnGetEditText event handler. If there is no OnGetEditText event handler, GetEditText returns an empty string.

See Also

OnGetEditText (see page 14797)

75.1.7.4.4 TStringGrid.RowMoved Method

Generates an OnRowMoved event.

Pascal

```
procedure RowMoved(FromIndex: Longint; ToIndex: Longint); override;
```

C++

```
virtual __fastcall RowMoved(Longint FromIndex, Longint ToIndex);
```

Description

RowMoved is called immediately after a row in the grid changes position. It overrides the inherited method to generate an OnRowMoved event. Descendants of TCustomDrawGrid can override this method to make internal adjustments or to block the OnRowMoved event.

See Also

OnRowMoved (see page 14798)

75.1.7.4.5 TStringGrid.SetEditText Method

Generates an OnSetEditText event.

Pascal

```
procedure SetEditText(ACol: Longint; ARow: Longint; const Value: string); override;
```

C++

```
virtual __fastcall SetEditText(Longint ACol, Longint ARow, const AnsiString Value);
```

Description

SetEditText is called by the inplace editor so that the grid can store the new value for the current cell. SetEditText overrides the inherited parent class's method to generate an OnSetEditText event. Descendants of TCustomDrawGrid can override this method to update an internal representation of the cell's value, or to block the OnSetEditText event.

See Also

OnSetEditText (see page 14800)

75.1.7.5 TStringGrid Properties

The properties of the TStringGrid class are listed here.

Public Properties

	Name	Description
	Cells (see page 14986)	Lists the strings for each cell in the grid.
	Cols (see page 14987)	Lists strings with their associated objects for each column.
	Objects (see page 14987)	Lists the objects for each cell in the grid.
	Rows (see page 14987)	Lists the strings and their associated objects for each row.

75.1.7.5.1 TStringGrid.Cells Property

Lists the strings for each cell in the grid.

Pascal

```
property Cells [ACol, ARow: Integer]: string;
```

C++

```
__property AnsiString Cells[int ACol, ARow];
```

Description

Use Cells to access the string within a particular cell. ACol is the column coordinate of the cell, and ARow is the row coordinate of the cell. The first row is row zero, and the first column is column zero.

The ColCount (see page 14881) and RowCount (see page 14899) property values define the size of the array of strings.

To access the objects associated with the strings in the Cells array, use the Objects (see page 14987) property.

Delphi Examples:

```
{
This code fills each cell with a number. The numbers are
arranged in consecutive order by rows.  Notice that even
cells in the fixed rows and columns are altered.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I, J, K : Integer;
begin
  K := 0;
  with StringGrid1 do
    for I := 0 to ColCount - 1 do
      for J:= 0 to RowCount - 1 do
        begin
          K := K + 1;
          Cells[I,J] := IntToStr(K);
        end;
end;
```

See Also

ColCount (see page 14844)

Objects (see page 14987)

RowCount (see page 14854)

75.1.7.5.2 TStringGrid.Cols Property

Lists strings with their associated objects for each column.

Pascal

```
property Cols [Index: Integer]: TStrings;
```

C++

```
__property TStrings Cols[int Index];
```

Description

Use Cols to access all the strings for a single column, along with their associated objects. The number of strings and associated objects is always equal to the value of the ColCount (see page 14881) property, the number of columns in the grid. The Index parameter is the number of the column, where the value of the first column in the grid is zero.

To get all the strings and objects for a row, rather than for a column, use the Rows (see page 14987) property.

See Also

ColCount (see page 14844)

Objects (see page 14987)

Rows (see page 14987)

75.1.7.5.3 TStringGrid.Objects Property

Lists the objects for each cell in the grid.

Pascal

```
property Objects [ACol, ARow: Integer]: TObject;
```

C++

```
__property TObject * Objects[int ACol, ARow];
```

Description

Use the Objects property to access the object associated with a particular cell. The ColCount (see page 14881) and RowCount (see page 14899) values define the size of the array of objects. ACol is the column coordinate of the cell, and ARow is the row coordinate of the cell, where the first column is column 0, and the first row is row 0.

Note: The string grid does not own the objects in the Objects array. Objects added to the Objects array still exist even if the string grid is destroyed. They must be explicitly destroyed by the application.

See Also

Cells (see page 14986)

ColCount (see page 14844)

RowCount (see page 14854)

75.1.7.5.4 TStringGrid.Rows Property

Lists the strings and their associated objects for each row.

Pascal

```
property Rows [Index: Integer]: TStrings;
```

C++

```
__property TStrings Rows[int Index];
```

Description

Use Rows to access all the strings for a single row, along with their associated objects. The number of strings and associated objects is always equal to the value of the RowCount (see page 14899) property, the number of rows in the grid. The Index parameter is the number of the row, where the value of the first row in the grid is zero.

To get all the strings and objects for a column, rather than for a row, use the Cols (see page 14987) property.

Delphi Examples:

```
{
This example displays a string grid, a list box, and a
button on a form. When the application runs, strings are put
in the cells of row 1 of the string grid. When the user
clicks the button, The strings in the current row of the
grid are displayed in the list box.
Note that when the grid contains an empty cell, the list box
has a corresponding empty string.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ListBox1.Items := StringGrid1.Rows[StringGrid1.Row];
end;
procedure TForm1.FormCreate(Sender: TObject);
begin
  with StringGrid1 do
  begin
    Cells[1,0] := 'Column 1';
    Cells[2,0] := 'Column 2';
    Cells[3,0] := 'Column 3';
    Cells[4,0] := 'Column 4';
    Cells[0,1] := 'Row 1';
    Cells[1,1] := 'Object';
    Cells[2,1] := 'Pascal';
    Cells[3,1] := 'is';
    Cells[4,1] := 'excellent';
    Cells[0,2] := 'Row 2';
    Cells[1,2] := 'Delphi';
    Cells[2,2] := 'is';
    Cells[4,2] := 'RAD';
  end;
end;
```

See Also

ColCount (see page 14844)

Cols (see page 14987)

Objects (see page 14987)

75.1.8 TStringGridStrings Class

TStringGridStrings maintains a list of the strings that appear in the cells of a string grid.

Class Hierarchy

Pascal

```
TStringGridStrings = class(TStrings);
```

C++

```
class TStringGridStrings : public TStrings;
```

File

Grids

Description

Do not use TStringGridStrings directly in an application. It is tailored to work with a TStringGrid (see page 14968) object, and is created by the string grid to represent the strings (and associated objects) in a row or column of the grid.

See Also

TStringGrid (see page 14968)

TStringList (see page 3006)

75.1.8.1 TStringGridStrings Members

The following tables list the members exposed by TStringGridStrings.

Protected Methods

	Name	Description
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	CompareStrings (see page 3048)	Compares two strings.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 3049)	Reads and writes the Strings (see page 3080) property as if it were published.
	Error (see page 3052)	This is the overview for the Error method overload.
	ExtractName (see page 3053)	Returns the name portion of a string that is a name value pair.
V	Get (see page 14994)	Returns a string given its index.
V	GetCapacity (see page 3054)	Returns the currently allocated size of the list of strings.
V	GetCount (see page 14994)	Returns the number of strings in the list
V	GetObject (see page 14994)	Returns the object associated with the string at a specified index.
	GetOwner (see page 2932)	Returns the owner of an object.
V	GetTextStr (see page 3056)	Returns the value of the Text (see page 3084) property.
V	Put (see page 14995)	Changes the value of the string with a specified index.
V	PutObject (see page 14996)	Changes the object associated with the string at a specified index.
V	SetCapacity (see page 3068)	Changes the amount of memory allocated to hold strings in the list.
V	SetTextStr (see page 3069)	Sets the Text (see page 3084) property.
V	SetUpdateState (see page 14996)	Performs internal adjustments before or after a series of updates.

Protected Properties

	Name	Description
R	UpdateCount (see page 3085)	Indicates the number of calls to BeginUpdate (see page 3045) that have not been matched by a call to EndUpdate (see page 3050).

Public Methods

	Name	Description
V	Add (see page 14992)	Replaces the first empty string with a specified string.
V	AddObject (see page 3036)	Adds a string to the list, and associates an object with the string.
V	AddStrings (see page 3039)	Adds a group of strings to the list.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.

	Append (see page 3041)	Adds a string to the list.
V	Assign (see page 14992)	Copies the list of strings and objects from another TStrings object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginUpdate (see page 3045)	Enables the TStrings (see page 3029) object to track when the list of strings is changing.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Clear (see page 14993)	Replaces all strings in the list with empty strings.
	Create (see page 14991)	Creates an instance of TStringGridStrings (see page 14988).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Delete (see page 14993)	Prevents strings from being deleted.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 3032)	Destroys the TPersistent instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndUpdate (see page 3050)	Enables the TStrings (see page 3029) object to keep track of when the list of strings has finished changing.
	Equals (see page 3051)	Compares the list of strings to the list from another TStrings (see page 3029) object and returns true if the two lists match.
V	Exchange (see page 3053)	Swaps the position of two strings in the list.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 3054)	Returns a TStrings (see page 3029) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
V	GetText (see page 3055)	Allocates a text buffer and fills it with the value of the Text (see page 3084) property.
V	IndexOf (see page 3056)	Returns the position of a string in the list.
V	IndexOfName (see page 3057)	Returns the position of the first name-value pair with the specified name.
V	IndexOfObject (see page 3059)	Returns the index of the first string in the list associated with a given object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
V	Insert (see page 14995)	Prevents strings from being inserted.
V	InsertObject (see page 3060)	Inserts a string into the list at the specified position, and associates it with an object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	LoadFromFile (see page 3061)	Fills the list with the lines of text in a specified file.
V	LoadFromStream (see page 3062)	Fills the list with lines of text read from a stream.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	Move (see page 3063)	Changes the position of a string in the list.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	SaveToFile (see page 3065)	Saves the strings in the list to the specified file.

V	SaveToStream (see page 3067)	Writes the value of the Text (see page 3084) property to a stream object.
V	SetText (see page 3068)	Sets the Text (see page 3084) property.

Public Properties

	Name	Description
	Capacity (see page 3070)	Indicates the number of strings the TStrings (see page 3029) object can hold.
	CommaText (see page 3070)	Lists the strings in the TStrings (see page 3029) object in system data format (SDF).
R	Count (see page 3071)	Introduces an abstract property to represent the number of strings in the list.
	DelimitedText (see page 3074)	Represents all the strings in the TStrings (see page 3029) object as a single delimited string.
	Delimiter (see page 3074)	Specifies the delimiter used by the DelimitedText (see page 3074) property.
	LineBreak (see page 3075)	Defines the line break character(s).
R	Names (see page 3075)	Indicates the name part of strings that are name-value pairs.
	NameValueSeparator (see page 3077)	Indicates the character used to separate names from values.
	Objects (see page 3077)	Represents a set of objects that are associated one with each of the strings in the Strings (see page 3080) property.
	QuoteChar (see page 3080)	Specifies the quote character used by the DelimitedText (see page 3074) property.
	StrictDelimiter (see page 3080)	Determines how the Delimiter (see page 3074) property is used.
	Strings (see page 3080)	References the strings in the list by their positions.
	StringsAdapter (see page 3084)	Implements an IStringsAdapter (see page 3208) interface for the TStrings (see page 3029) object.
	Text (see page 3084)	Lists the strings in the TStrings (see page 3029) object as a single string with the individual strings delimited by carriage returns and line feeds.
	ValueFromIndex (see page 3085)	Represents the value part of a string with a given index, on strings that are name-value pairs.
	Values (see page 3086)	Represents the value part of a string associated with a given name, on strings that are name-value pairs.

75.1.8.2 TStringGridStrings.Create Constructor

Creates an instance of TStringGridStrings (see page 14988).

Pascal

```
constructor Create(AGrid: TStringGrid; AIndex: Longint);
```

C++

```
__fastcall TStringGridStrings(TStringGrid AGrid, Longint AIndex);
```

Description

Do not create instances of TStringGridStrings (see page 14988). String grids create TStringGridStrings (see page 14988) objects for every row and column, to allow quick access of the strings and objects associated with the cells in the grid.

The AGrid parameter specifies the string grid that will use the TStringGridStrings (see page 14988) object. The AIndex parameter specifies the index of the row or column associated with the TStringGridStrings (see page 14988) object. If AIndex is greater than 0, the TStringGridStrings (see page 14988) object represents the row indexed by AIndex. If AIndex is less than 0, the TStringGridStrings (see page 14988) object represents the column indexed by the absolute value of AIndex. If AIndex is 0, the TStringGridStrings (see page 14988) object represents an empty row or column.

See Also

TStringGrid (see page 14968)

75.1.8.3 TStringGridStrings Methods

The methods of the TStringGridStrings class are listed here.

Protected Methods

	Name	Description
	Get (see page 14994)	Returns a string given its index.
	GetCount (see page 14994)	Returns the number of strings in the list
	GetObject (see page 14994)	Returns the object associated with the string at a specified index.
	Put (see page 14995)	Changes the value of the string with a specified index.
	PutObject (see page 14996)	Changes the object associated with the string at a specified index.
	SetUpdateState (see page 14996)	Performs internal adjustments before or after a series of updates.

Public Methods

	Name	Description
	Add (see page 14992)	Replaces the first empty string with a specified string.
	Assign (see page 14992)	Copies the list of strings and objects from another TStrings object.
	Clear (see page 14993)	Replaces all strings in the list with empty strings.
	Delete (see page 14993)	Prevents strings from being deleted.
	Insert (see page 14995)	Prevents strings from being inserted.

75.1.8.3.1 TStringGridStrings.Add Method

Replaces the first empty string with a specified string.

Pascal

```
function Add(const S: string): Integer; override;
```

C++

```
virtual __fastcall int Add(const AnsiString S);
```

Description

Call Add to add a string to the list. Add searches the list for an empty string and replaces it with S. It then returns the index where it added S to the list. If there are no empty strings in the list, Add does not add S to the list and returns –1.

See Also

AddStrings (see page 3039)

Append (see page 3041)

Count

IndexOf (see page 3056)

Insert (see page 14995)

75.1.8.3.2 TStringGridStrings.Assign Method

Copies the list of strings and objects from another TStrings object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Call Assign to copy the strings and objects from a source object of type TStrings. If the source object has more strings than the number of cells in the row or column represented by the TStringGridStrings (see page 14988) object, Assign only copies the first Count strings and objects.

If the Source parameter is not a TStrings object, Assign calls the inherited method.

See Also

Count

Objects

Strings

75.1.8.3.3 TStringGridStrings.Clear Method

Replaces all strings in the list with empty strings.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Call Clear to remove all strings from the list, including any references to associated objects. Clear replaces every string with an empty string and every object reference with nil (Delphi) or NULL (C++).

Note that Clear does not free the objects that are associated with strings in the list.

See Also

Delete (see page 14993)

Objects

Strings

75.1.8.3.4 TStringGridStrings.Delete Method

Prevents strings from being deleted.

Pascal

```
procedure Delete(Index: Integer); override;
```

C++

```
virtual __fastcall Delete(int Index);
```

Description

Because TStringGridStrings (see page 14988) objects represent the rows or columns of a string grid, the number of entries in the list must correspond exactly to the number of cells in the corresponding row or column. Rather than allow entries to be deleted, destroying this correspondence, Delete raises an EInvalidGridOperation (see page 14767) exception.

See Also

EInvalidGridOperation (see page 14767)

Clear (see page 14993)

75.1.8.3.5 TStringGridStrings.Get Method

Returns a string given its index.

Pascal

```
function Get(Index: Integer): string; override;
```

C++

```
virtual __fastcall AnsiString Get(int Index);
```

Description

Get is the protected read implementation of the Strings property.

In TStrings Get is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to return the string with the specified index.

See Also

Strings (see page 3080)

75.1.8.3.6 TStringGridStrings.GetCount Method

Returns the number of strings in the list

Pascal

```
function GetCount: Integer; override;
```

C++

```
virtual __fastcall int GetCount();
```

Description

GetCount is the protected read implementation of the Count property.

In TStrings GetCount is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to return the number of strings that have been added to the list.

See Also

Count (see page 3071)

75.1.8.3.7 TStringGridStrings.GetObject Method

Returns the object associated with the string at a specified index.

Pascal

```
function GetObject(Index: Integer): TObject; override;
```

C++

```
virtual __fastcall TObject * GetObject(int Index);
```

Description

GetObject is the protected read implementation of the Objects property.

Index is the index of the string with which the object is associated.

In TStrings, GetObject always returns nil (Delphi) or NULL (C++). This provides a default implementation for descendants that do not support associating objects with the strings in the list. Descendants that support this feature override GetObject to return the specified object.

See Also

Objects (see page 3077)

75.1.8.3.8 TStringGridStrings.Insert Method

Prevents strings from being inserted.

Pascal

```
procedure Insert(Index: Integer; const S: string); override;
```

C++

```
virtual __fastcall Insert(int Index, const AnsiString S);
```

Description

Because TStringGridStrings (see page 14988) objects represent the rows or columns of a string grid, the number of entries in the list must correspond exactly to the number of cells in the corresponding row or column. Rather than allow entries to be inserted, destroying this correspondence, Insert raises an EInvalidGridOperation (see page 14767) exception.

See Also

EInvalidGridOperation (see page 14767)

Add (see page 14992)

75.1.8.3.9 TStringGridStrings.Put Method

Changes the value of the string with a specified index.

Pascal

```
procedure Put(Index: Integer; const S: string); override;
```

C++

```
virtual __fastcall Put(int Index, const AnsiString S);
```

Description

Put is the protected write implementation of the Strings property.

Put changes the value of the string with the index specified by Index to S. Put does not change the object at the specified position. That is, any object associated with the previous string becomes associated with the new string.

See Also

Strings (see page 3080)

Objects (see page 3077)

75.1.8.3.10 TStringGridStrings.PutObject Method

Changes the object associated with the string at a specified index.

Pascal

```
procedure PutObject(Index: Integer; AObject: TObject); override;
```

C++

```
virtual __fastcall PutObject(int Index, TObject * AObject);
```

Description

PutObject is the protected write implementation of the Objects property.

As implemented in TStrings, PutObject does nothing. This provides a default implementation for descendants that do not support associating objects with the strings in the list. Descendants that support this feature override PutObject to change the specified object.

See Also

Objects (see page 3077)

75.1.8.3.11 TStringGridStrings.SetUpdateState Method

Performs internal adjustments before or after a series of updates.

Pascal

```
procedure SetUpdateState(Updating: Boolean); override;
```

C++

```
virtual __fastcall SetUpdateState(Boolean Updating);
```

Description

SetUpdateState is called at the beginning or end of a series of updates. When the BeginUpdate method is first called and the TStrings object is not already in the middle of an update, TStrings calls SetUpdateState internally, with Updating set to true. When the EndUpdate method is called and it cancels out the last unmatched call to BeginUpdate, TStrings calls SetUpdateState internally, with Updating set to false.

As implemented in TStrings, SetUpdateState does nothing. Descendant classes can override this method to optimize the response to updates.

See Also

BeginUpdate (see page 3045)

EndUpdate (see page 3050)

75.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TEditStyle (see page 14997)	TEditStyle indicates whether a cell in a grid contains a drop-down arrow or ellipsis button.
	TGridOption (see page 14999)	TGridOption and TGridOptions (see page 15005) customize the appearance and behavior of a grid control.
	TGridState (see page 15001)	TGridState indicates any user actions that are currently changing the layout of the grid.

Records

	Name	Description
	TGridAxisDrawInfo (see page 14998)	TGridAxisDrawInfo and TGridDrawInfo (see page 14999) represent information that is useful when rendering a grid.
	TGridCoord (see page 14998)	TGridCoord specifies a cell in a grid control.
	TGridDrawInfo (see page 14999)	This is record Grids.TGridDrawInfo.
	TGridRect (see page 15001)	TGridRect specifies a set of cells that occupy a rectangular region in a grid control.

75.2.1 Grids.TEditStyle Enumeration

TEditStyle indicates whether a cell in a grid contains a drop-down arrow or ellipsis button.

Pascal

```
TEditStyle = (
  esSimple,
  esEllipsis,
  esPickList
);
```

C++

```
enum TEditStyle {
  esSimple,
  esEllipsis,
  esPickList
};
```

File

Grids

Description

TEditStyle describes the buttons, if any, that can appear in the cell of a grid. It can be any of the following values:

Value	Meaning
esSimple	The cell acts as a simple edit control where users can type a new value.
esEllipsis	The cell contains an ellipsis button that users can click to launch a dialog.
esPickList	The cell contains a drop-down arrow button that users can click to display a pick list of possible values.

75.2.2 Grids.TGridAxisDrawInfo Record

TGridAxisDrawInfo and TGridDrawInfo (see page 14999) represent information that is useful when rendering a grid.

Pascal

```
TGridAxisDrawInfo = record
  EffectiveLineWidth: Integer;
  FixedBoundary: Integer;
  GridBoundary: Integer;
  GridExtent: Integer;
  LastFullVisibleCell: Longint;
  FullVisBoundary: Integer;
  FixedCellCount: Integer;
  FirstGridCell: Integer;
  GridCellCount: Integer;
  GetExtent: TGetExtentsFunc;
end;
```

C++

```
struct TGridAxisDrawInfo {
  int EffectiveLineWidth;
  int FixedBoundary;
  int GridBoundary;
  int GridExtent;
  Longint LastFullVisibleCell;
  int FullVisBoundary;
  int FixedCellCount;
  int FirstGridCell;
  int GridCellCount;
  TGetExtentsFunc GetExtent;
};
```

File

Grids

Description

TGridDrawInfo (see page 14999) encapsulates information that reflects the layout of the grid axes. Each axis is described by a TGridAxisDrawInfo value, which encodes information about the size of the axis and the type and number of cells along that axis.

75.2.3 Grids.TGridCoord Record

TGridCoord specifies a cell in a grid control.

Pascal

```
TGridCoord = record
  X: Longint;
  Y: Longint;
end;
```

C++

```
struct TGridCoord {
  Longint X;
  Longint Y;
};
```

File

Grids

Description

TGridCoord indicates a specific cell in a grid.

X indicates the column of the grid, where 0 specifies the first column, 1 specifies the second column, and so on.

Y indicates the row of the grid, where 0 specifies the first row, 1 specifies the second row, and so on.

75.2.4 Grids.TGridDrawInfo Record

Pascal

```
TGridDrawInfo = record
  Horz: TGridAxisDrawInfo;
  Vert: TGridAxisDrawInfo;
end;
```

C++

```
struct TGridDrawInfo {
  TGridAxisDrawInfo Horz;
  TGridAxisDrawInfo Vert;
};
```

File

Grids

Description

This is record Grids.TGridDrawInfo.

75.2.5 Grids.TGridOption Enumeration

TGridOption and TGridOptions (see page 15005) customize the appearance and behavior of a grid control.

Pascal

```
TGridOption = (
  goFixedVertLine,
  goFixedHorzLine,
  goVertLine,
  goHorzLine,
  goRangeSelect,
  goDrawFocusSelected,
  goRowSizing,
  goColSizing,
  goRowMoving,
  goColMoving,
  goEditing,
  goTabs,
  goRowSelect,
  goAlwaysShowEditor,
  goThumbTracking
);
```

C++

```
enum TGridOption {
  goFixedVertLine,
  goFixedHorzLine,
  goVertLine,
  goHorzLine,
  goRangeSelect,
  goDrawFocusSelected,
  goRowSizing,
  goColSizing,
  goRowMoving,
  goColMoving,
  goEditing,
  goTabs,
  goRowSelect,
  goAlwaysShowEditor,
  goThumbTracking
};
```

File

Grids

Description

TGridOptions (see page 15005) is a set of TGridOption values. The following table lists the possible TGridOption values:

Value	Meaning
goFixedVertLine	Vertical lines are drawn to separate the fixed (nonscrolling) columns in the grid.
goFixedHorzLine	Horizontal lines are drawn to separate the fixed (nonscrolling) rows in the grid.
goVertLine	Vertical lines are drawn to separate the scrollable columns in the grid.
goHorzLine	Horizontal lines are drawn to separate the scrollable rows in the grid.
goRangeSelect	Users can select ranges of cells at one time. goRangeSelect is ignored if Options includes goEditing.
goDrawFocusSelected	Cells with input focus are drawn with a special highlight color, just like selected cells without input focus. If goDrawFocusSelected is not included, the cell with input focus is distinguished by a focus rectangle, not by a special background color.
goRowSizing	Scrollable rows can be individually resized.
goColSizing	Scrollable columns can be individually resized.
goRowMoving	Scrollable rows can be moved using the mouse.
goColMoving	Scrollable columns can be moved using the mouse.
goEditing	Users can edit the contents of cells. When goEditing is included in Options, goRangeSelect has no effect.
goTabs	Users can navigate through the cells in the grid using Tab and Shift+Tab.
goRowSelect	Entire rows are selected rather than individual cells. If goRowSelect is included in Options, goAlwaysShowEditor has no effect.
goAlwaysShowEditor	The grid is locked into edit mode. The user does not need to use Enter or F2 to turn on EditorMode. If Options does not include goEditing, goAlwaysShowEditor has no effect. If Options includes goRowSelect, goAlwaysShowEditor has no effect.
goThumbTracking	The grid image updates while the user is dragging the thumb of the scroll bar. If goThumbTracking is not included, the image does not update until the user releases the thumb in a new position.

75.2.6 Grids.TGridRect Record

TGridRect specifies a set of cells that occupy a rectangular region in a grid control.

Pascal

```
TGridRect = record
  case Integer of
    0: (Bottom: Longint;
        Left: Longint;
        Right: Longint;
        Top: Longint;);
    1: (BottomRight: TGridCoord;
        TopLeft: TGridCoord;);
end;
```

C++

```
struct TGridRect {
  Longint Bottom;
  Longint Left;
  Longint Right;
  Longint Top;
  TGridCoord BottomRight;
  TGridCoord TopLeft;
};
```

File

Grids

Description

TGridRect indicates a rectangular set of cells from the grid in one of two ways:

Using the first method, TopLeft indicates the coordinates of the top-left cell in the set and BottomRight indicates the coordinates of the bottom-right cell.

Using the second method, Left indicates the first column in the set and Right the last column in the set, where 0 is the first column of the grid, 1 is the second column, and so on. Top indicates the first row in the set and Bottom the last row, where 0 is the first row of the grid, 1 the second column, and so on.

75.2.7 Grids.TGridState Enumeration

TGridState indicates any user actions that are currently changing the layout of the grid.

Pascal

```
TGridState = (
  gsNormal,
  gsSelecting,
  gsRowSizing,
  gsColSizing,
  gsRowMoving,
  gsColMoving
);
```

C++

```
enum TGridState {
```

```
    gsNormal,
    gsSelecting,
    gsRowSizing,
    gsColSizing,
    gsRowMoving,
    gsColMoving
  };
```

File

Grids

Description

TGridState represents state information about how the grid layout is changing. The following table lists the possible values:

Value	Meaning
gsNormal	The grid layout is not changing.
gsSelecting	The user is selecting a cell or row.
gsRowSizing	The user is changing the height of a row.
gsColSizing	The user is changing the width of a column.
gsRowMoving	The user is dragging a row to a new position.
gsColMoving	The user is dragging a column to a new position.

75.3 Types

The following table lists types in this documentation.

Types

Name	Description
TDrawCellEvent (see page 15003)	Function type for OnDrawCell event.
TGetEditEvent (see page 15004)	TGetEditEvent is the type of the event handlers that provide strings for the inplace editor of a grid.
TGetExtentsFunc (see page 15004)	This is type Grids.TGetExtentsFunc.
TGridDrawState (see page 15004)	TGridDrawState represents information that is useful when rendering the cell of a grid.
TGridMovement (see page 15005)	This is type Grids.TGridMovement.
TGridOptions (see page 15005)	TGridOptions and TGridOption (see page 14999) customize the appearance and behavior of a grid control.
TGridScrollDirection (see page 15006)	TGridScrollDirection indicates the direction in which to scroll the cells of a grid control.
TMovedEvent (see page 15007)	This is type Grids.TMovedEvent.
TOnGetPickListItems (see page 15007)	This is type Grids.TOnGetPickListItems.
TSelectCellEvent (see page 15007)	This is type Grids.TSelectCellEvent.
TSetEditEvent (see page 15008)	TSetEditEvent is the type of the event handlers that assign strings to a cell in a grid.

75.3.1 Grids.TDrawCellEvent Type

Function type for OnDrawCell event.

Pascal

```
TDrawCellEvent = procedure (Sender: TObject; ACol, ARow: Longint; Rect: TRect; State:
TGridDrawState) of object;
```

C++

```
(Sender: TObject; ACol, ARow: Longint; Rect: TRect; State: TGridDrawState) ( TDrawCellEvent)();
```

File

Grids

Description

TDrawCellEvent is the function type for a OnDrawCell event. Its parameters are described in this table.

Parameter	Meaning
Sender	Grid in which cell is being drawn.
ACol, ARow	Column and row indexes of the cell being drawn.
Rect	Location of cell on canvas.
State	TGridDrawState (see page 15004) that indicates whether the cell has input focus, whether the cell is selected, and whether the cell is a fixed (nonscrolling) cell.

See Also

OnDrawCell (see page 14795)

TGridDrawState (see page 15004)

75.3.2 Grids.TGetEditEvent Type

TGetEditEvent is the type of the event handlers that provide strings for the inplace editor of a grid.

Pascal

```
TGetEditEvent = procedure (Sender: TObject; ACol, ARow: Longint; var Value: string) of object;
```

C++

```
(Sender: TObject; ACol, ARow: Longint; var Value: string) ( TGetEditEvent)();
```

File

Grids

Description

Sender is the grid whose cell is being edited.

ACol and ARow indicate the column and row indexes of the cell that is being edited.

Value is the string requested by the inplace editor for that cell. The event handler supplies this string.

75.3.3 Grids.TGetExtentsFunc Type

Pascal

```
TGetExtentsFunc = function (Index: Longint): Integer of object;
```

C++

```
(Index: Longint): Integer ( TGetExtentsFunc)();
```

File

Grids

Description

This is type Grids.TGetExtentsFunc.

75.3.4 Grids.TGridDrawState Type

TGridDrawState represents information that is useful when rendering the cell of a grid.

Pascal

```
TGridDrawState = set of (gdSelected, gdFocused, gdFixed);
```

C++

```
(gdSelected, gdFocused, gdFixed) TGridDrawState;
```

File

Grids

Description

TGridDrawState represents state information about the cell of a grid that is being rendered. It is a set that includes 0 or more of the following:

Value	Meaning
gdSelected	The cell is currently selected.
gdFocused	The cell has input focus.
gdFixed	The cell is in the fixed region of the grid.

75.3.5 Grids.TGridMovement Type

Pascal

```
TGridMovement = gsRowMoving..gsColMoving;
```

C++

```
gsRowMoving..gsColMoving TGridMovement;
```

File

Grids

Description

This is type Grids.TGridMovement.

75.3.6 Grids.TGridOptions Type

TGridOptions and TGridOption (see page 14999) customize the appearance and behavior of a grid control.

Pascal

```
TGridOptions = set of TGridOption;
```

C++

```
TGridOption TGridOptions;
```

File

Grids

Description

TGridOptions is a set of TGridOption (see page 14999) values. The following table lists the possible TGridOption (see page 14999) values:

Value	Meaning
goFixedVertLine	Vertical lines are drawn to separate the fixed (nonscrolling) columns in the grid.
goFixedHorzLine	Horizontal lines are drawn to separate the fixed (nonscrolling) rows in the grid.
goVertLine	Vertical lines are drawn to separate the scrollable columns in the grid.
goHorzLine	Horizontal lines are drawn to separate the scrollable rows in the grid.
goRangeSelect	Users can select ranges of cells at one time. goRangeSelect is ignored if Options includes goEditing.
goDrawFocusSelected	Cells with input focus are drawn with a special highlight color, just like selected cells without input focus. If goDrawFocusSelected is not included, the cell with input focus is distinguished by a focus rectangle, not by a special background color.
goRowSizing	Scrollable rows can be individually resized.
goColSizing	Scrollable columns can be individually resized.
goRowMoving	Scrollable rows can be moved using the mouse.
goColMoving	Scrollable columns can be moved using the mouse.
goEditing	Users can edit the contents of cells. When goEditing is included in Options, goRangeSelect has no effect.
goTabs	Users can navigate through the cells in the grid using Tab and Shift+Tab.
goRowSelect	Entire rows are selected rather than individual cells. If goRowSelect is included in Options, goAlwaysShowEditor has no effect.
goAlwaysShowEditor	The grid is locked into edit mode. The user does not need to use Enter or F2 to turn on EditorMode. If Options does not include goEditing, goAlwaysShowEditor has no effect. If Options includes goRowSelect, goAlwaysShowEditor has no effect.
goThumbTracking	The grid image updates while the user is dragging the thumb of the scroll bar. If goThumbTracking is not included, the image does not update until the user releases the thumb in a new position.

75.3.7 Grids.TGridScrollDirection Type

TGridScrollDirection indicates the direction in which to scroll the cells of a grid control.

Pascal

```
TGridScrollDirection = set of (sdLeft, sdRight, sdUp, sdDown);
```

C++

```
(sdLeft, sdRight, sdUp, sdDown) TGridScrollDirection;
```

File

Grids

Description

TGridScrollDirection is a set of one or two values that indicate the direction in which to scroll a grid. The set contains at least one value and at most one horizontal and one vertical value. The following table lists the possible values:

Value	Meaning
sdLeft	Scroll cells horizontally to the left.
sdRight	Scroll cells horizontally to the right.

sdUp	Scroll cells vertically up.
sdDown	Scroll cells vertically down.

See Also

TCustomGrid

75.3.8 Grids.TMovedEvent Type

Pascal

```
TMovedEvent = procedure (Sender: TObject; FromIndex, ToIndex: Longint) of object;
```

C++

```
(Sender: TObject; FromIndex, ToIndex: Longint) ( TMovedEvent)();
```

File

Grids

Description

This is type Grids.TMovedEvent.

75.3.9 Grids.TOnGetPickListItems Type

Pascal

```
TOnGetPickListItems = procedure (ACol, ARow: Integer; Items: TStrings) of object;
```

C++

```
(ACol, ARow: Integer; Items: TStrings) ( TOnGetPickListItems)();
```

File

Grids

Description

This is type Grids.TOnGetPickListItems.

75.3.10 Grids.TSelectCellEvent Type

Pascal

```
TSelectCellEvent = procedure (Sender: TObject; ACol, ARow: Longint; var CanSelect: Boolean) of
object;
```

C++

```
(Sender: TObject; ACol, ARow: Longint; var CanSelect: Boolean) ( TSelectCellEvent)();
```

File

Grids

Description

This is type Grids.TSelectCellEvent.

75.3.11 Grids.TSetEditEvent Type

TSetEditEvent is the type of the event handlers that assign strings to a cell in a grid.

Pascal

```
TSetEditEvent = procedure (Sender: TObject; ACol, ARow: Longint; const Value: string) of
object;
```

C++

```
(Sender: TObject; ACol, ARow: Longint; const Value: string) ( TSetEditEvent)();
```

File

Grids

Description

Sender is the grid whose cell was just edited.

ACol and ARow indicate the column and row indexes of the cell that was edited.

Value is the string to assign to the cell.

75.4 Constants

The following table lists constants in this documentation.

Constants

Name	Description
MaxCustomExtents (see page 15009)	This is constant Grids.MaxCustomExtents.
MaxShortInt (see page 15009)	This is constant Grids.MaxShortInt.

75.4.1 Grids.MaxCustomExtents Constant

Pascal

```
MaxCustomExtents = MaxListSize;
```

C++

```
MaxCustomExtents = MaxListSize;
```

File

Grids

Description

This is constant Grids.MaxCustomExtents.

75.4.2 Grids.MaxShortInt Constant

Pascal

```
MaxShortInt = High(ShortInt);
```

C++

```
MaxShortInt = High(ShortInt);
```

File

Grids

Description

This is constant Grids.MaxShortInt.

76 HelpIntfs Namespace

This is namespace HelpIntfs.

Topics

Name	Description
Classes (see page 15012)	The following table lists classes in this documentation.
Interfaces (see page 15013)	The following table lists interfaces in this documentation.
Functions (see page 15033)	The following table lists functions in this documentation.

Classes

	Name	Description
	EHelpSystemException (see page 15012)	EHelpSystemException is the class for errors raised by the RTL Help System (see page 22079).

Functions

	Name	Description
	GetHelpSystem (see page 15033)	Returns Help System (see page 22079) object.
	GetHelpSystem (see page 15033)	Returns Help System (see page 22079) object.
	RegisterViewer (see page 15033)	Register Help Viewer to receive requests.

Interfaces

	Name	Description
	ICustomHelpViewer (see page 15013)	Help Viewer access for Help System (see page 22079)..
	IExtendedHelpViewer (see page 15017)	Help Viewer with context help support.
	IHelpManager (see page 15020)	IHelpManager provides access to the Help System (see page 22079) for a Help Viewer.
	IHelpSelector (see page 15022)	Interface for Help Selector object.
	IHelpSelector2 (see page 15024)	This is class HelpIntfs.IHelpSelector2.
	IHelpSystem (see page 15025)	Application Help System (see page 22079) that supports multiple Help Viewers.
	IHelpSystem2 (see page 15028)	This is class HelpIntfs.IHelpSystem2.
	IHelpSystemFlags (see page 15029)	This is class HelpIntfs.IHelpSystemFlags.
	ISpecialWinHelpViewer (see page 15031)	Help Viewer that supports special Windows Help requests.

76.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EHelpSystemException (see page 15012)	EHelpSystemException is the class for errors raised by the RTL Help System (see page 22079).

76.1.1 EHelpSystemException Class

EHelpSystemException is the class for errors raised by the RTL Help System (see page 22079).

Class Hierarchy

System::TObject → SysUtils.Exception → HelpIntfs.EHelpSystemException

Pascal

```
EHelpSystemException = class(Exception);
```

C++

```
class EHelpSystemException : public Exception;
```

File

HelpIntfs

Description

The Run-Time Library Help System (see page 22079) raises EHelpSystemException when an error occurs while registering or invoking a help viewer.

76.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	ICustomHelpViewer (see page 15013)	Help Viewer access for Help System (see page 22079)..
	IExtendedHelpViewer (see page 15017)	Help Viewer with context help support.
	IHelpManager (see page 15020)	IHelpManager provides access to the Help System (see page 22079) for a Help Viewer.
	IHelpSelector (see page 15022)	Interface for Help Selector object.
	IHelpSelector2 (see page 15024)	This is class HelpIntfs.IHelpSelector2.
	IHelpSystem (see page 15025)	Application Help System (see page 22079) that supports multiple Help Viewers.
	IHelpSystem2 (see page 15028)	This is class HelpIntfs.IHelpSystem2.
	IHelpSystemFlags (see page 15029)	This is class HelpIntfs.IHelpSystemFlags.
	ISpecialWinHelpViewer (see page 15031)	Help Viewer that supports special Windows Help requests.

76.2.1 ICustomHelpViewer Interface

Help Viewer access for Help System (see page 22079)..

Class Hierarchy

Pascal

```
ICustomHelpViewer = interface(IInterface);
```

C++

```
__interface ICustomHelpViewer : public IInterface;
```

File

HelpIntfs

Description

A Help Viewer is an object which handles application Help requests passed to it by the Help System (see page 22079) on behalf of an application. A Help Viewer is typically a wrapper for an external application, such as a help engine or web browser.

The Help Viewer class must implement the ICustomHelpViewer interface, or one of its descendant interfaces, IExtendedHelpViewer (see page 15017) and ISpecialWinHelpViewer (see page 15031). The Help System (see page 22079) uses methods from these interfaces to pass Help requests to the Help Viewer.

To use a Help Viewer, an application must call the global RegisterViewer (see page 15033) function.

Note: ISpecialWinHelpViewer (see page 15031) is only provided with Windows products. Do not use this type in cross-platform applications.

Help System Interfaces

Implementing ICustomHelpViewer

76.2.1.1 ICustomHelpViewer Members

The following tables list the members exposed by ICustomHelpViewer.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	CanShowTableOfContents (see page 15014)	Query support for Table of Contents.
	GetHelpStrings (see page 15015)	Return Help Strings that match a keyword.
	GetViewerName (see page 15015)	Return string identifying Help Viewer.
	NotifyID (see page 15016)	Save Viewer's numeric ID.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ShowHelp (see page 15016)	Show a specific Help topic.
	ShowTableOfContents (see page 15016)	Show a Table of Contents.
	ShutDown (see page 15017)	Permanent Viewer shut down.
	SoftShutDown (see page 15017)	This is SoftShutDown, a member of class ICustomHelpViewer.
	UnderstandsKeyword (see page 15017)	Would respond to a keyword-based Help request.

76.2.1.2 ICustomHelpViewer Methods

The methods of the ICustomHelpViewer class are listed here.

Public Methods

	Name	Description
	CanShowTableOfContents (see page 15014)	Query support for Table of Contents.
	GetHelpStrings (see page 15015)	Return Help Strings that match a keyword.
	GetViewerName (see page 15015)	Return string identifying Help Viewer.
	NotifyID (see page 15016)	Save Viewer's numeric ID.
	ShowHelp (see page 15016)	Show a specific Help topic.
	ShowTableOfContents (see page 15016)	Show a Table of Contents.
	ShutDown (see page 15017)	Permanent Viewer shut down.
	SoftShutDown (see page 15017)	This is SoftShutDown, a member of class ICustomHelpViewer.
	UnderstandsKeyword (see page 15017)	Would respond to a keyword-based Help request.

76.2.1.2.1 ICustomHelpViewer.CanShowTableOfContents Method

Query support for Table of Contents.

Pascal

```
function CanShowTableOfContents: Boolean;
```

C++

```
__fastcall Boolean CanShowTableOfContents();
```

Description

The Help System (see page 22079) uses CanShowTableOfContents to determine which Help Viewers know how to display a

Table of Contents. CanShowTableOfContents should return true if the Viewer is ready for a subsequent call to ShowTableOfContents (see page 15016). The Help System (see page 22079) should not call ShowTableOfContents (see page 15016) for a Viewer after CanShowTableOfContents returns false; if this occurs, the Viewer should raise an EHelpSystemException (see page 15012).

See Also

ShowTableOfContents (see page 15027)

ShowTableOfContents (see page 15016)

EHelpSystemException (see page 15012)

76.2.1.2.2 ICustomHelpViewer.GetHelpStrings Method

Return Help Strings that match a keyword.

Pascal

```
function GetHelpStrings(const HelpString: string): TStringList;
```

C++

```
__fastcall TStringList GetHelpStrings(const AnsiString HelpString);
```

Description

The Help System (see page 22079) calls GetHelpStrings to obtain a list of Help Strings for topics that match a keyword-based Help request. GetHelpStrings should expect the keyword in the parameter and return the Help Strings in a TStringList object.

A Help String is an identifying string associated with a specific topic. The Help System (see page 22079) requires that each of the topics provided by a given Viewer have a different Help String. The Help System (see page 22079) does not require that two Viewers never use the same Help String, but an application should still avoid doing this. One strategy is to include the Viewer Name in the Help String.

The Help System (see page 22079) uses Help Strings to provide the Help Selector with a merged list of Help topics that match a request. Typically, Help Strings are human-readable topic descriptions, and the Help Selector simply displays them to the user so the user can choose which topic will be displayed.

See Also

ShowHelp (see page 15027)

UnderstandsKeyword (see page 15017)

ShowHelp (see page 15016)

GetViewerName (see page 15015)

76.2.1.2.3 ICustomHelpViewer.GetViewerName Method

Return string identifying Help Viewer.

Pascal

```
function GetViewerName: string;
```

C++

```
__fastcall AnsiString GetViewerName();
```

Description

The Help System (see page 22079) calls GetViewerName to obtain a string identifying the Help Viewer. Every Help Viewer

within an application must return a unique Viewer Name.

76.2.1.2.4 ICustomHelpViewer.NotifyID Method

Save Viewer's numeric ID.

Pascal

```
procedure NotifyID(const ViewerID: Integer);
```

C++

```
__fastcall NotifyID(const int ViewerID);
```

Description

The Help System (see page 22079) calls NotifyID to pass the application a unique numeric ID associated with a Viewer. The application uses this ID to identify a specific viewer in calls to Release (IHelpManager (see page 15020)).

See Also

Release (see page 15021)

76.2.1.2.5 ICustomHelpViewer.ShowHelp Method

Show a specific Help topic.

Pascal

```
procedure ShowHelp(const HelpString: string);
```

C++

```
__fastcall ShowHelp(const AnsiString HelpString);
```

Description

The Help System (see page 22079) calls ShowHelp when it needs the Help Viewer to display the Help Topic identified by HelpString. The HelpString parameter is a value previously provided by the Help Viewer in response to a GetHelpStrings (see page 15015) call.

76.2.1.2.6 ICustomHelpViewer.ShowTableOfContents Method

Show a Table of Contents.

Pascal

```
procedure ShowTableOfContents;
```

C++

```
__fastcall ShowTableOfContents();
```

Description

The Help System (see page 22079) calls ShowTableOfContents when it needs the Help Viewer to display a Table of Contents. The Help System (see page 22079) does not call ShowTableOfContents for a Viewer unless that Viewer has previously returned true for a call to CanShowTableOfContents (see page 15014).

See Also

CanShowTableOfContents (see page 15014)

76.2.1.2.7 ICustomHelpViewer.ShutDown Method

Permanent Viewer shut down.

Pascal

```
procedure ShutDown;
```

C++

```
__fastcall ShutDown();
```

Description

The Help System (see page 22079) calls ShutDown when it is notified that the application is shutting down. A Viewer should respond to this call by terminating any external applications used to display Help topics. After a call to ShutDown, a Viewer can assume that no more Help requests will arrive.

76.2.1.2.8 ICustomHelpViewer.SoftShutDown Method

Pascal

```
procedure SoftShutDown;
```

C++

```
__fastcall SoftShutDown();
```

Description

This is SoftShutDown, a member of class ICustomHelpViewer.

76.2.1.2.9 ICustomHelpViewer.UnderstandsKeyword Method

Would respond to a keyword-based Help request.

Pascal

```
function UnderstandsKeyword(const HelpString: string): Integer;
```

C++

```
__fastcall int UnderstandsKeyword(const AnsiString HelpString);
```

Description

The Help System (see page 22079) calls UnderstandsKeyword to determine to determine if the Help Viewer can provide topics for a keyword-based Help request based on HelpString. UnderstandsKeyword should return the number of Help topics that would match such a request.

76.2.2 IExtendedHelpViewer Interface

Help Viewer with context help support.

Class Hierarchy

Pascal

```
IExtendedHelpViewer = interface(ICustomHelpViewer);
```

C++

```
__interface IExtendedHelpViewer : public ICustomHelpViewer;
```

File

HelpIntfs

Description

IExtendedHelpViewer extends ICustomHelpViewer (see page 15013) by adding support for Topic IDs and Context IDs.

A topic ID is a short string that uniquely identifies each topic provided by a Help Viewer. A topic ID provides a simple way for an application to display a specific Help topic without searching for it.

A context ID is an integer value that uniquely identifies each Help topic. Context IDs support context-sensitive Help by providing a value that associates forms and controls with their help topics. A form or control can be associated a topic simply by setting its HelpContext property.

RegisterViewer (see page 15033)

tcontrol

Help System Interfaces

76.2.2.1 IExtendedHelpViewer Members

The following tables list the members exposed by IExtendedHelpViewer.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	CanShowTableOfContents (see page 15014)	Query support for Table of Contents.
	DisplayHelpByContext (see page 15019)	Use Context ID to display topic.
	DisplayTopic (see page 15019)	Use Topic ID to display topic.
	GetHelpStrings (see page 15015)	Return Help Strings that match a keyword.
	GetViewerName (see page 15015)	Return string identifying Help Viewer.
	NotifyID (see page 15016)	Save Viewer's numeric ID.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ShowHelp (see page 15016)	Show a specific Help topic.
	ShowTableOfContents (see page 15016)	Show a Table of Contents.
	ShutDown (see page 15017)	Permanent Viewer shut down.
	SoftShutDown (see page 15017)	This is SoftShutDown, a member of class ICustomHelpViewer.
	UnderstandsContext (see page 15019)	Can Help Viewer respond to Context-based. Help request?
	UnderstandsKeyword (see page 15017)	Would respond to a keyword-based Help request.
	UnderstandsTopic (see page 15020)	Can Help Viewer respond to Topic-based. Help request?

76.2.2.2 IExtendedHelpViewer Methods

The methods of the IExtendedHelpViewer class are listed here.

Public Methods

	Name	Description
	DisplayHelpByContext (see page 15019)	Use Context ID to display topic.

	DisplayTopic (see page 15019)	Use Topic ID to display topic.
	UnderstandsContext (see page 15019)	Can Help Viewer respond to Context-based. Help request?
	UnderstandsTopic (see page 15020)	Can Help Viewer respond to Topic-based. Help request?

76.2.2.2.1 IExtendedHelpViewer.DisplayHelpByContext Method

Use Context ID to display topic.

Pascal

```
procedure DisplayHelpByContext(const ContextID: Integer; const HelpFileName: string);
```

C++

```
__fastcall DisplayHelpByContext(const int ContextID, const AnsiString HelpFileName);
```

Description

The RTL Help System (see page 22079) calls DisplayHelpByContext to have the Viewer handle a context-based Help request. ContextID is the topic's Context ID. HelpFileName is the name of the file containing the topic. Note that some Help engines require the file name to be fully qualified.

See Also

UnderstandsTopic (see page 15020)

76.2.2.2.2 IExtendedHelpViewer.DisplayTopic Method

Use Topic ID to display topic.

Pascal

```
procedure DisplayTopic(const Topic: string);
```

C++

```
__fastcall DisplayTopic(const AnsiString Topic);
```

Description

The RTL Help System (see page 22079) calls DisplayTopic to have the Viewer handle a topic-based Help request. Topic is the Topic ID, a short string that must be unique for all the topics maintained by a particular Viewer.

See Also

UnderstandsTopic (see page 15020)

76.2.2.2.3 IExtendedHelpViewer.UnderstandsContext Method

Can Help Viewer respond to Context-based. Help request?

Pascal

```
function UnderstandsContext(const ContextID: Integer; const HelpFileName: string): Boolean;
```

C++

```
__fastcall Boolean UnderstandsContext(const int ContextID, const AnsiString HelpFileName);
```

Description

UnderstandsContext should return true if the Viewer is able to display the topic identified by ContextID in the file HelpFileName. When the RTL Help System (see page 22079) receives a Context-based Help request, it calls UnderstandsContext for each Viewer that implements it until the method returns true. (Viewers are polled in the order they were registered.) The Help System (see page 22079) than calls that Viewer's DisplayHelpByContext (see page 15019) method.

See Also

DisplayHelpByContext (see page 15019)

76.2.2.2.4 IExtendedHelpViewer.UnderstandsTopic Method

Can Help Viewer respond to Topic-based. Help request?

Pascal

```
function UnderstandsTopic(const Topic: string): Boolean;
```

C++

```
__fastcall Boolean UnderstandsTopic(const AnsiString Topic);
```

Description

UnderstandsTopic should return true if the Viewer is able to display the topic identified by the Topic parameter. When the RTL Help System (see page 22079) receives a Topic-based Help request, it calls UnderstandsTopic for each Viewer that implements it until the method returns true. (Viewers are polled in the order they were registered.) The Help System (see page 22079) than calls that Viewer's DisplayTopic (see page 15019) method.

See Also

DisplayTopic (see page 15019)

76.2.3 IHelpManager Interface

IHelpManager provides access to the Help System (see page 22079) for a Help Viewer.

Class Hierarchy

HelpIntfs.IHelpManager

Pascal

```
IHelpManager = interface;
```

C++

```
__interface IHelpManager;
```

File

HelpIntfs

Description

IHelpManager defines methods that a Help Viewer uses to interact with the Help System (see page 22079). A Viewer accesses these methods using the object that the global RegisterViewer (see page 15033) function returns.

See Also

RegisterViewer (see page 15033)

Help System Interfaces

76.2.3.1 IHelpManager Members

The following tables list the members exposed by IHelpManager.

Public Methods

	Name	Description
	GetHandle (see page 15021)	Get application window handle.
	GetHelpFile (see page 15021)	Get Help File name.
	Release (see page 15021)	Notify Help System (see page 22079) of Help Viewer shutdown.

76.2.3.2 IHelpManager Methods

The methods of the IHelpManager class are listed here.

Public Methods

	Name	Description
	GetHandle (see page 15021)	Get application window handle.
	GetHelpFile (see page 15021)	Get Help File name.
	Release (see page 15021)	Notify Help System (see page 22079) of Help Viewer shutdown.

76.2.3.2.1 IHelpManager.GetHandle Method

Get application window handle.

Pascal

```
function GetHandle: LongInt;
```

C++

```
__fastcall LongInt GetHandle();
```

Description

GetHandle returns the main window handle of the application responsible for the current Help request.

76.2.3.2.2 IHelpManager.GetHelpFile Method

Get Help File name.

Pascal

```
function GetHelpFile: string;
```

C++

```
__fastcall AnsiString GetHelpFile();
```

Description

GetHelpFile returns the name of the Help File associated with the current Help request.

76.2.3.2.3 IHelpManager.Release Method

Notify Help System (see page 22079) of Help Viewer shutdown.

Pascal

```
procedure Release(const ViewerID: Integer);
```

C++

```
__fastcall Release(const int ViewerID);
```

Description

Release disconnects the Help Viewer from the RTL Help System (see page 22079). The ViewerID parameter is the value the Help System (see page 22079) previously passed to the Viewer by calling NotifyID.

A Help Viewer should call Release when it is about to shut down, unless the Viewer is shutting down in response to a call to ShutDown.

See Also

NotifyID (see page 15016)

ShutDown (see page 15017)

76.2.4 IHelpSelector Interface

Interface for Help Selector object.

Class Hierarchy

Pascal

```
IHelpSelector = interface(IInterface);
```

C++

```
__interface IHelpSelector : public IInterface;
```

File

HelpIntfs

Description

When an application uses more than one Help Viewer, there may be multiple responses to a Help request. By default, the Help System (see page 22079) polls the Viewers in the order they were registered, and gives the request to the first viewer that claims to be able to handle it.

An application can optionally provide a Help Selector, which determines the Viewer for keyword-based Help requests and for requests to display a Table of Contents. To define a Help Selector, create an object that implements IHelpSelector and pass it to the Help System (see page 22079), using AssignHelpSelector.

The Help Selector cannot affect context-based or topic-based Help requests, which always go to the first Viewer that claims to be able to handle the request.

See Also

RegisterViewer (see page 15033)

IHelpSystem (see page 15025)

Help System Interfaces

76.2.4.1 IHelpSelector Members

The following tables list the members exposed by IHelpSelector.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	SelectKeyword (see page 15023)	Keyword-based Help support for multiple Viewers.
	TableOfContents (see page 15024)	Choose Viewer to display Table of Contents.

76.2.4.2 IHelpSelector Methods

The methods of the IHelpSelector class are listed here.

Public Methods

	Name	Description
	SelectKeyword (see page 15023)	Keyword-based Help support for multiple Viewers.
	TableOfContents (see page 15024)	Choose Viewer to display Table of Contents.

76.2.4.2.1 IHelpSelector.SelectKeyword Method

Keyword-based Help support for multiple Viewers.

Pascal

```
function SelectKeyword(Keywords: TStrings): Integer;
```

C++

```
__fastcall int SelectKeyword(TStrings Keywords);
```

Description

The Help System (see page 22079) calls SelectKeyword when more than one Help Viewer has topics that match a keyword-based Help request. The Keywords parameter contains a merged list of Help Strings, obtained by calling GetHelpStrings for each Viewer. SelectKeyword indicates a specific topic by returning the index of a specific Help String. The Help System (see page 22079) then passes this Help String to the ShowHelp method of the appropriate Viewer. If the return value is negative, the Help System (see page 22079) assumes that the Help request has been aborted and does nothing.

Typically, SelectKeyword displays a dialog box so the user can choose one of the Help Strings, and returns the index of the user's choice, or a negative value if the user cancels the dialog. This duplicates a feature of most Viewers, but allows the user to see all matching topics in a single list.

Note: SelectKeyword must not modify or rearrange the Help Strings list.

See Also

UnderstandsKeyword (see page 15017)

GetHelpStrings (see page 15015)

ShowHelp (see page 15016)

76.2.4.2.2 IHelpSelector.TableOfContents Method

Choose Viewer to display Table of Contents.

Pascal

```
function TableOfContents(Contents: TStrings): Integer;
```

C++

```
__fastcall int TableOfContents(TStrings Contents);
```

Description

The Help System (see page 22079) calls TableOfContents when more than one Help Viewer responds to a request to show a Help Table of Contents. The Help System (see page 22079) passes a list of Viewer names in the Contents parameter. TableOfContents should return the index of the chosen Viewer's name.

Note: TableOfContents must not modify or rearrange the Viewer names list.

See Also

CanShowTableOfContents (see page 15014)

76.2.5 IHelpSelector2 Interface

Class Hierarchy

Pascal

```
IHelpSelector2 = interface(IHelpSelector);
```

C++

```
__interface IHelpSelector2 : public IHelpSelector;
```

File

HelpIntfs

Description

This is class HelpIntfs.IHelpSelector2.

76.2.5.1 IHelpSelector2 Members

The following tables list the members exposed by IHelpSelector2.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	SelectContext (see page 15025)	This is SelectContext, a member of class IHelpSelector2.
	SelectKeyword (see page 15023)	Keyword-based Help support for multiple Viewers.
	TableOfContents (see page 15024)	Choose Viewer to display Table of Contents.

76.2.5.2 IHelpSelector2 Methods

The methods of the IHelpSelector2 class are listed here.

Public Methods

	Name	Description
	SelectContext (see page 15025)	This is SelectContext, a member of class IHelpSelector2.

76.2.5.2.1 IHelpSelector2.SelectContext Method

Pascal

```
function SelectContext(Viewers: TStrings): Integer;
```

C++

```
__fastcall int SelectContext(TStrings Viewers);
```

Description

This is SelectContext, a member of class IHelpSelector2.

76.2.6 IHelpSystem Interface

Application Help System (see page 22079) that supports multiple Help Viewers.

Class Hierarchy

Pascal

```
IHelpSystem = interface(IInterface);
```

C++

```
__interface IHelpSystem : public IInterface;
```

File

HelpIntfs

Description

The Run-Time Library Help System (see page 22079) allows an application to access one or more Help Viewers through a uniform interface, IHelpSystem. To obtain an object that implements IHelpSystem, use the HelpSystem property of the Application global variable, or call the global GetHelpSystem (see page 15033) function.

See Also

Help System Interfaces

76.2.6.1 IHelpSystem Members

The following tables list the members exposed by IHelpSystem.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AssignHelpSelector (see page 15026)	Assign a Help Selector object.
	Hook (see page 15026)	Do a WinHelp-style Help request.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ShowContextHelp (see page 15027)	Do Context-based Help request.
	ShowHelp (see page 15027)	Do Keyword-based Help request.
	ShowTableOfContents (see page 15027)	Show Table of Contents.
	ShowTopicHelp (see page 15028)	Show Help topic.

76.2.6.2 IHelpSystem Methods

The methods of the IHelpSystem class are listed here.

Public Methods

	Name	Description
	AssignHelpSelector (see page 15026)	Assign a Help Selector object.
	Hook (see page 15026)	Do a WinHelp-style Help request.
	ShowContextHelp (see page 15027)	Do Context-based Help request.
	ShowHelp (see page 15027)	Do Keyword-based Help request.
	ShowTableOfContents (see page 15027)	Show Table of Contents.
	ShowTopicHelp (see page 15028)	Show Help topic.

76.2.6.2.1 IHelpSystem.AssignHelpSelector Method

Assign a Help Selector object.

Pascal

```
procedure AssignHelpSelector(Selector: IHelpSelector);
```

C++

```
__fastcall AssignHelpSelector(IHelpSelector Selector);
```

Description

Call AssignHelpSelector to provide a Help Selector object. Use of a Help Selector allows an application to define the way a Help Viewer is chosen to handle keyword-based Help requests and requests to display a Table of Contents.

76.2.6.2.2 IHelpSystem.Hook Method

Do a WinHelp-style Help request.

Pascal

```
function Hook(Handle: Longint; HelpFile: string; Comand: Word; Data: Longint): Boolean;
```

C++

```
__fastcall Boolean Hook(Longint Handle, AnsiString HelpFile, Word Comand, Longint Data);
```

Description

Hook accepts Help requests that uses the same conventions as the Microsoft Windows WinHelp API. Hook should only be called for requests that cannot be translated into calls to ShowContextHelp (see page 15027), ShowHelp (see page 15027),

ShowTableOfContents (see page 15027), or ShowTopicHelp (see page 15028).

Note: If the Help System (see page 22079) is unable to decipher the Help request, it looks for a Viewer that implements ISpecialWinHelpViewer (see page 15031). If the application has registered such a viewer, the request succeeds if the Viewer is able to handle it. Otherwise the request fails.

76.2.6.2.3 IHelpSystem.ShowContextHelp Method

Do Context-based Help request.

Pascal

```
procedure ShowContextHelp(const ContextID: Longint; const HelpFileName: string);
```

C++

```
__fastcall ShowContextHelp(const Longint ContextID, const AnsiString HelpFileName);
```

Description

Call ShowContextHelp to display a single Help topic, identified by ContextID and HelpFileName. For context-based Help requests to work, the application must have previously registered at least one Help Viewer that implements IExtendedHelpViewer (see page 15017). If no such Viewer is found, an EHelpSystemException (see page 15012) is raised.

76.2.6.2.4 IHelpSystem.ShowHelp Method

Do Keyword-based Help request.

Pascal

```
procedure ShowHelp(const HelpKeyword: string; const HelpFileName: string);
```

C++

```
__fastcall ShowHelp(const AnsiString HelpKeyword, const AnsiString HelpFileName);
```

Description

Call ShowHelp to submit a keyword-based Help request. By default, the RTL Help System (see page 22079) gives the request to the first Help Viewer that claims to be able to handle it. Typically, the Viewer passes the Help request to an external Help engine, which displays a list of matching topics (if more than one topic matches) or goes directly to a specific topic (if a single topic matches).

To support keyword-based Help requests using multiple Help Viewers, assign a Help Selector, using the AssignHelpSelector (see page 15026) method.

76.2.6.2.5 IHelpSystem.ShowTableOfContents Method

Show Table of Contents.

Pascal

```
procedure ShowTableOfContents;
```

C++

```
__fastcall ShowTableOfContents();
```

Description

Call ShowTableOfContents to request that the Help System (see page 22079) display a Table of Contents.

Note: Tapplication.HelpShowTableOfContents is the preferred method of opening the Table of Contents.

76.2.6.2.6 IHelpSystem.ShowTopicHelp Method

Show Help topic.

Pascal

```
procedure ShowTopicHelp(const Topic: string; const HelpFileName: string);
```

C++

```
__fastcall ShowTopicHelp(const AnsiString Topic, const AnsiString HelpFileName);
```

Description

Call ShowTopicHelp to request that the Help System (see page 22079) display a specific Help topic.

The Topic parameter is a short string identifying the specific topic.

The HelpFileName parameter is the name of the file containing the topic. If this parameter is a zero-length string, the HelpFile property of the global Application variable is used.

76.2.7 IHelpSystem2 Interface

Class Hierarchy

Pascal

```
IHelpSystem2 = interface(IHelpSystem);
```

C++

```
__interface IHelpSystem2 : public IHelpSystem;
```

File

HelpIntfs

Description

This is class HelpIntfs.IHelpSystem2.

76.2.7.1 IHelpSystem2 Members

The following tables list the members exposed by IHelpSystem2.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AssignHelpSelector (see page 15026)	Assign a Help Selector object.
	Hook (see page 15026)	Do a WinHelp-style Help request.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ShowContextHelp (see page 15027)	Do Context-based Help request.
	ShowHelp (see page 15027)	Do Keyword-based Help request.
	ShowTableOfContents (see page 15027)	Show Table of Contents.
	ShowTopicHelp (see page 15028)	Show Help topic.

	UnderstandsKeyword (see page 15029)	This is UnderstandsKeyword, a member of class IHelpSystem2.

76.2.7.2 IHelpSystem2 Methods

The methods of the IHelpSystem2 class are listed here.

Public Methods

	Name	Description
	UnderstandsKeyword (see page 15029)	This is UnderstandsKeyword, a member of class IHelpSystem2.

76.2.7.2.1 IHelpSystem2.UnderstandsKeyword Method

Pascal

```
function UnderstandsKeyword(const HelpKeyword: string; const HelpFileName: string): Boolean;
```

C++

```
__fastcall Boolean UnderstandsKeyword(const AnsiString HelpKeyword, const AnsiString
HelpFileName);
```

Description

This is UnderstandsKeyword, a member of class IHelpSystem2.

76.2.8 IHelpSystemFlags Interface

Class Hierarchy

Pascal

```
IHelpSystemFlags = interface(IExtendedHelpViewer);
```

C++

```
__interface IHelpSystemFlags : public IExtendedHelpViewer;
```

File

HelpIntfs

Description

This is class HelpIntfs.IHelpSystemFlags.

76.2.8.1 IHelpSystemFlags Members

The following tables list the members exposed by IHelpSystemFlags.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	CanShowTableOfContents (see page 15014)	Query support for Table of Contents.

	DisplayHelpByContext (see page 15019)	Use Context ID to display topic.
	DisplayTopic (see page 15019)	Use Topic ID to display topic.
	GetHelpStrings (see page 15015)	Return Help Strings that match a keyword.
	GetUseDefaultTopic (see page 15030)	This is GetUseDefaultTopic, a member of class IHelpSystemFlags.
	GetViewerName (see page 15015)	Return string identifying Help Viewer.
	NotifyID (see page 15016)	Save Viewer's numeric ID.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	SetUseDefaultTopic (see page 15030)	This is SetUseDefaultTopic, a member of class IHelpSystemFlags.
	ShowHelp (see page 15016)	Show a specific Help topic.
	ShowTableOfContents (see page 15016)	Show a Table of Contents.
	ShutDown (see page 15017)	Permanent Viewer shut down.
	SoftShutDown (see page 15017)	This is SoftShutDown, a member of class ICustomHelpViewer.
	UnderstandsContext (see page 15019)	Can Help Viewer respond to Context-based. Help request?
	UnderstandsKeyword (see page 15017)	Would respond to a keyword-based Help request.
	UnderstandsTopic (see page 15020)	Can Help Viewer respond to Topic-based. Help request?

76.2.8.2 IHelpSystemFlags Methods

The methods of the IHelpSystemFlags class are listed here.

Public Methods

	Name	Description
	GetUseDefaultTopic (see page 15030)	This is GetUseDefaultTopic, a member of class IHelpSystemFlags.
	SetUseDefaultTopic (see page 15030)	This is SetUseDefaultTopic, a member of class IHelpSystemFlags.

76.2.8.2.1 IHelpSystemFlags.GetUseDefaultTopic Method

Pascal

```
function GetUseDefaultTopic: Boolean;
```

C++

```
__fastcall Boolean GetUseDefaultTopic();
```

Description

This is GetUseDefaultTopic, a member of class IHelpSystemFlags.

76.2.8.2.2 IHelpSystemFlags.SetUseDefaultTopic Method

Pascal

```
procedure SetUseDefaultTopic(AValue: Boolean);
```

C++

```
__fastcall SetUseDefaultTopic(Boolean AValue);
```

Description

This is SetUseDefaultTopic, a member of class IHelpSystemFlags.

76.2.9 ISpecialWinHelpViewer Interface

Help Viewer that supports special Windows Help requests.

Class Hierarchy

Pascal

```
ISpecialWinHelpViewer = interface(IExtendedHelpViewer);
```

C++

```
__interface ISpecialWinHelpViewer : public IExtendedHelpViewer;
```

File

HelpIntfs

Description

ISpecialWinHelpViewer supports Help requests that cannot be easily generalized, and should only be handled by the Microsoft Windows Help engine or a closely compatible application.

ISpecialWinHelpViewer consists of a single method, CallWinHelp (see page 15032), which should pass the Help request to the Help engine with as little manipulation as possible. An application needs to provide only one Viewer that implements ISpecialWinHelpViewer. If more than one Viewer is registered that implements ISpecialWinHelpViewer, only the first Viewer ever receives calls to CallWinHelp (see page 15032).

Help System Interfaces

76.2.9.1 ISpecialWinHelpViewer Members

The following tables list the members exposed by ISpecialWinHelpViewer.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	CallWinHelp (see page 15032)	Pass Help request directly to engine.
	CanShowTableOfContents (see page 15014)	Query support for Table of Contents.
	DisplayHelpByContext (see page 15019)	Use Context ID to display topic.
	DisplayTopic (see page 15019)	Use Topic ID to display topic.
	GetHelpStrings (see page 15015)	Return Help Strings that match a keyword.
	GetViewerName (see page 15015)	Return string identifying Help Viewer.
	NotifyID (see page 15016)	Save Viewer's numeric ID.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.

	ShowHelp (see page 15016)	Show a specific Help topic.
	ShowTableOfContents (see page 15016)	Show a Table of Contents.
	ShutDown (see page 15017)	Permanent Viewer shut down.
	SoftShutDown (see page 15017)	This is SoftShutDown, a member of class ICustomHelpViewer.
	UnderstandsContext (see page 15019)	Can Help Viewer respond to Context-based. Help request?
	UnderstandsKeyword (see page 15017)	Would respond to a keyword-based Help request.
	UnderstandsTopic (see page 15020)	Can Help Viewer respond to Topic-based. Help request?

76.2.9.2 ISpecialWinHelpViewer Methods

The methods of the ISpecialWinHelpViewer class are listed here.

Public Methods

	Name	Description
	CallWinHelp (see page 15032)	Pass Help request directly to engine.

76.2.9.2.1 ISpecialWinHelpViewer.CallWinHelp Method

Pass Help request directly to engine.

Pascal

```
function CallWinHelp(Handle: LongInt; const HelpFile: string; Command: Word; Data: LongInt):
Boolean;
```

C++

```
__fastcall Boolean CallWinHelp(LongInt Handle, const AnsiString HelpFile, Word Command,
LongInt Data);
```

Description

The RTL Help System (see page 22079) calls CallWinHelp when it receives a Windows-style Help request that cannot be generalized as a Topic-based or Context-based request. CallWinHelp should pass the request directly to the Windows winhelp() API or to a functional equivalent.

CallWinHelp should return true if it was able to handle the request.

76.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	GetHelpSystem (see page 15033)	Returns Help System (see page 22079) object.
	GetHelpSystem (see page 15033)	Returns Help System (see page 22079) object.
	RegisterViewer (see page 15033)	Register Help Viewer to receive requests.

76.3.1 HelpIntfs.GetHelpSystem Function

Returns Help System (see page 22079) object.

Pascal

```
function GetHelpSystem(out System: IHelpSystem): Boolean; overload;
function GetHelpSystem(out System: IHelpSystem2): Boolean; overload;
```

C++

```
Boolean GetHelpSystem(IHelpSystem System);
Boolean GetHelpSystem(IHelpSystem2 System);
```

File

HelpIntfs

Description

GetHelpSystem returns an object that implements IHelpSystem (see page 15025). An application calls IHelpSystem (see page 15025) methods to interact with the Help System (see page 22079).

GetHelpSystem returns 1 if the Help System (see page 22079) object was successfully obtained, 0 otherwise.

See Also

TApplication

76.3.2 HelpIntfs.RegisterViewer Function

Register Help Viewer to receive requests.

Pascal

```
function RegisterViewer(const newViewer: ICustomHelpViewer; out Manager: IHelpManager):
Integer;
```

C++

```
int RegisterViewer(const ICustomHelpViewer newViewer, IHelpManager Manager);
```

File

HelpIntfs

Description

Call RegisterViewer to register a Help Viewer with the Help System (see page 22079). An application can register any number of Viewers. The order in which Help Viewers are registered is significant, because each Help request causes the RTL Help System (see page 22079) to poll the Viewers in the order they were registered, and give the Help request to the first viewer that claims to be able to handle it. An application can override this behavior for keyword-based Help requests and for requests to display a Table of Contents by providing a Help Selector object.

Pass the Viewer object in the newViewer parameter.

RegisterViewer returns a Help Manager object in the Manager parameter; the Viewer uses this object to interact with the Help System (see page 22079).

The return value of RegisterViewer is 1 is the Viewer was successfully registered, 0 otherwise.

77 HTTPApp Namespace

This is namespace HTTPApp.

Topics

Name	Description
Classes (see page 15038)	The following table lists classes in this documentation.
Interfaces (see page 15219)	The following table lists interfaces in this documentation.
Functions (see page 15239)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 15246)	The following table lists structs, records, enums in this documentation.
Types (see page 15248)	The following table lists types in this documentation.
Constants (see page 15250)	The following table lists constants in this documentation.

Classes

	Name	Description
	EWebBrokerException (see page 15038)	EWebBrokerException is an exception raised by WebBroker (see page 24617) objects.
	TAbstractContentParser (see page 15039)	TAbstractContentParser is the base class for objects that parse the content of an HTTP request.
	TAbstractWebModuleFactory (see page 15043)	TAbstractWebModuleFactory is the base class for all Web module factory objects.
	TAbstractWebModuleList (see page 15051)	TAbstractWebModuleList lists the WebModules in a WebSnap application and provides access to their factory objects.
	TAbstractWebPageInfo (see page 15060)	TAbstractWebPageInfo represents the attributes of a Web page module.
	TAbstractWebPageModuleFactory (see page 15070)	TAbstractWebPageModuleFactory is the base class for Web module factory objects whose generated Web modules create Web pages.
	TAbstractWebRequestFile (see page 15073)	TAbstractWebRequestFile describes an uploaded file from an HTTP request.
	TAbstractWebRequestFiles (see page 15078)	TAbstractWebRequestFiles is a collection of TAbstractWebRequestFile (see page 15073) objects.
	TAbstractWebSession (see page 15082)	TAbstractWebSession is the base class for objects that represent a session in a WebSnap application.
	TContentParser (see page 15088)	TContentParser is the default parser for extracting named value strings and uploaded files from an HTTP request.
	TCookie (see page 15092)	TCookie represents a Cookie header in an HTTP response message.
	TCookieCollection (see page 15098)	TCookieCollection is a collection of TCookie (see page 15092) objects.
	TCustomContentProducer (see page 15102)	TCustomContentProducer is the base class for all objects that produce the string that is sent as the contents of an HTTP response message.
	TCustomWebDispatcher (see page 15110)	TCustomWebDispatcher is the abstract base class for Web dispatcher objects.
	TDefaultWebAppServices (see page 15125)	This is class HTTPApp.TDefaultWebAppServices.

	TWebActionItem (see page 15130)	TWebActionItem allows a Web server application to create and send responses to HTTP request messages.
	TWebActionItems (see page 15140)	TWebActionItems is a collection of TWebActionItem (see page 15130) objects.
	TWebDispatcher (see page 15147)	TWebDispatcher passes HTTP request messages on to the appropriate action items that assemble a response.
	TWebModule (see page 15154)	TWebModule is the automatically generated Web module for a Web server application.
	TWebRequest (see page 15161)	TWebRequest is the base class for all objects that represent client request information that is passed to a Web server application.
	TWebResponse (see page 15191)	TWebResponse is the base class for all objects that represent HTTP messages sent in response to an HTTP request message.

Constants

Name	Description
MAX_DATETIMES (see page 15250)	This is constant HTTPApp.MAX_DATETIMES.
MAX_INTEGERS (see page 15250)	This is constant HTTPApp.MAX_INTEGERS.
MAX_STRINGS (see page 15251)	This is constant HTTPApp.MAX_STRINGS.
sDateFormat (see page 15251)	This is constant HTTPApp.sDateFormat.

Functions

	Name	Description
	DayOfWeekStr (see page 15239)	Converts a TDateTime into a string representing the day of the week.
	DosPathToUnixPath (see page 15240)	Converts a DOS-compatible path specification to a Unix-compatible path specification.
	ExtractHeaderFields (see page 15240)	Parses a multi-valued string into its constituent fields.
	ExtractHTTPFields (see page 15241)	Parses a multi-valued string into its constituent fields.
	HTMLDecode (see page 15241)	This is function HTTPApp.HTMLDecode.
	HTMLEncode (see page 15242)	This is function HTTPApp.HTMLEncode.
	HTTPDecode (see page 15242)	Decodes a string that includes HTTP escape characters.
	HTTPEncode (see page 15243)	Converts a string into a form that contains no values that are illegal in an HTTP message header.
	MonthStr (see page 15243)	Converts a TDateTime into a string representing the month.
	ParseDate (see page 15244)	Converts a date value from an HTTP message header into a TDateTime.
	RegisterContentParser (see page 15244)	This is function HTTPApp.RegisterContentParser.
	StatusString (see page 15244)	Returns the explanatory string associated with one of the predefined HTTP response status codes.
	UnixPathToDosPath (see page 15245)	Converts a Unix-compatible path specification to a Dos-compatible path specification.

Interfaces

	Name	Description
	IGetAppDispatcher (see page 15219)	This is class HTTPApp.IGetAppDispatcher.
	IGetWebAppServices (see page 15220)	This is class HTTPApp.IGetWebAppServices.
	IGetWebRequestHandler (see page 15221)	This is class HTTPApp.IGetWebRequestHandler.
	IMultiModuleSupport (see page 15222)	This is class HTTPApp.IMultiModuleSupport.
	IProduceContent (see page 15223)	IProduceContent is the interface for generating the content of a Web page.
	IProduceContentFrom (see page 15225)	This is class HTTPApp.IProduceContentFrom.
	ISetAppDispatcher (see page 15226)	This is class HTTPApp.ISetAppDispatcher.
	IWebAppServices (see page 15227)	IWebAppServices is the interface for setting up and finishing the processing of HTTP request messages.
	IWebDispatch (see page 15230)	
	IWebDispatchActions (see page 15233)	IWebDispatchActions is the interface for components that dispatch HTTP request messages using action items.
	IWebDispatcherAccess (see page 15234)	IWebDispatcherAccess provides access to the current HTTP request and response object.
	IWebExceptionHandler (see page 15236)	This is class HTTPApp.IWebExceptionHandler.
	IWebRequestHandler (see page 15237)	IWebRequestHandler is the interface for objects that dispatch HTTP request messages.

Structs, Records, Enums

	Name	Description
	TMethodType (see page 15246)	This is record HTTPApp.TMethodType.
	TWebModuleCacheMode (see page 15246)	This is record HTTPApp.TWebModuleCacheMode.
	TWebModuleCreateMode (see page 15247)	This is record HTTPApp.TWebModuleCreateMode.

Types

Name	Description
TContentParserClass (see page 15248)	This is type HTTPApp.TContentParserClass.
THTTPMethodEvent (see page 15248)	This is type HTTPApp.THTTPMethodEvent.
TModuleAddedProc (see page 15249)	This is type HTTPApp.TModuleAddedProc.
TWebExceptionEvent (see page 15249)	This is type HTTPApp.TWebExceptionEvent.
TWebModuleContext (see page 15249)	This is type HTTPApp.TWebModuleContext.

77.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EWebBrokerException (see page 15038)	EWebBrokerException is an exception raised by WebBroker (see page 24617) objects.
	TAbstractContentParser (see page 15039)	TAbstractContentParser is the base class for objects that parse the content of an HTTP request.
	TAbstractWebModuleFactory (see page 15043)	TAbstractWebModuleFactory is the base class for all Web module factory objects.
	TAbstractWebModuleList (see page 15051)	TAbstractWebModuleList lists the WebModules in a WebSnap application and provides access to their factory objects.
	TAbstractWebPageInfo (see page 15060)	TAbstractWebPageInfo represents the attributes of a Web page module.
	TAbstractWebPageModuleFactory (see page 15070)	TAbstractWebPageModuleFactory is the base class for Web module factory objects whose generated Web modules create Web pages.
	TAbstractWebRequestFile (see page 15073)	TAbstractWebRequestFile describes an uploaded file from an HTTP request.
	TAbstractWebRequestFiles (see page 15078)	TAbstractWebRequestFiles is a collection of TAbstractWebRequestFile (see page 15073) objects.
	TAbstractWebSession (see page 15082)	TAbstractWebSession is the base class for objects that represent a session in a WebSnap application.
	TContentParser (see page 15088)	TContentParser is the default parser for extracting named value strings and uploaded files from an HTTP request.
	TCookie (see page 15092)	TCookie represents a Cookie header in an HTTP response message.
	TCookieCollection (see page 15098)	TCookieCollection is a collection of TCookie (see page 15092) objects.
	TCustomContentProducer (see page 15102)	TCustomContentProducer is the base class for all objects that produce the string that is sent as the contents of an HTTP response message.
	TCustomWebDispatcher (see page 15110)	TCustomWebDispatcher is the abstract base class for Web dispatcher objects.
	TDefaultWebAppServices (see page 15125)	This is class HTTPApp.TDefaultWebAppServices.
	TWebActionItem (see page 15130)	TWebActionItem allows a Web server application to create and send responses to HTTP request messages.
	TWebActionItems (see page 15140)	TWebActionItems is a collection of TWebActionItem (see page 15130) objects.
	TWebDispatcher (see page 15147)	TWebDispatcher passes HTTP request messages on to the appropriate action items that assemble a response.
	TWebModule (see page 15154)	TWebModule is the automatically generated Web module for a Web server application.
	TWebRequest (see page 15161)	TWebRequest is the base class for all objects that represent client request information that is passed to a Web server application.
	TWebResponse (see page 15191)	TWebResponse is the base class for all objects that represent HTTP messages sent in response to an HTTP request message.

77.1.1 EWebBrokerException Class

EWebBrokerException is an exception raised by WebBroker (see page 24617) objects.

Class Hierarchy

Pascal

```
EWebBrokerException = class(Exception);
```

C++

```
class EWebBrokerException : public Exception;
```

File

HTTPApp

Description

EWebBrokerException is raised when a WebBroker (see page 24617) object encounters a problem. It functions identically to its parent class, TException.

See Also

Exception (see page 22750)

77.1.2 TAbstractContentParser Class

TAbstractContentParser is the base class for objects that parse the content of an HTTP request.

Class Hierarchy

Pascal

```
TAbstractContentParser = class(TObject);
```

C++

```
class TAbstractContentParser : public TObject;
```

File

HTTPApp

Description

Web request objects use a descendant of TAbstractContentParser to retrieve information about the named values in the content of the HTTP request they represent. TAbstractContentParser defines two protected methods, GetContentFields (see page 15042) and GetFiles (see page 15042), which the Web request uses to obtain values for its ContentFields and Files properties, respectively.

TAbstractContentParser should not be instantiated. The GetContentFields (see page 15042) and GetFiles (see page 15042) methods are abstract or, in C++ terminology, pure virtual, which means that TAbstractContentParser does not supply an implementation. Each TAbstractContentParser descendant overrides these methods to support its own method of extracting named value strings and uploaded files from an HTTP request. The TAbstractContentParser descendant also overrides the public CanParse (see page 15041) method to check whether the request message contains information encoded in a way that the content parser understands.

Each TAbstractContentParser descendant registers itself with the Web server application. Then, when a Web request object needs to parse its content to set the ContentFields and Files properties, it searches through the registered content parsers to locate the most recently registered parser that can parse the current content.

See Also

TWebRequest (see page 15161)

TWebRequest (see page 15161)

TWebRequest (see page 15161)

TContentParser (see page 15088)

TMultipartContentParser (see page 18710)

77.1.2.1 TAbstractContentParser Members

The following tables list the members exposed by TAbstractContentParser.

Protected Methods

	Name	Description
	GetContentFields (see page 15042)	Returns the named value strings that are included in the content of the current Web request.
	GetFiles (see page 15042)	Returns a set of uploaded files that the parser extracts from the current Web request.

Protected Properties

	Name	Description
	WebRequest (see page 15043)	Indicates the Web request object that uses this parser to parse its content.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	CanParse (see page 15041)	Indicates whether a specified request message contains information encoded in a way that this parser understands.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 15041)	Creates and initializes a new TAbstractContentParser (see page 15039) object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

77.1.2.2 TAbstractContentParser.Create Constructor

Creates and initializes a new TAbstractContentParser (see page 15039) object.

Pascal

```
constructor Create(AWebRequest: TWebRequest); virtual;
```

C++

```
virtual __fastcall TAbstractContentParser(TWebRequest AWebRequest);
```

Description

Do not create instances of TAbstractContentParser (see page 15039). This class and its descendants are intended only as helper objects to the Web request. The Web request creates its own instance of a TAbstractContentParser (see page 15039) descendant that can parse its content.

AWebRequest is the Web request object that creates this content parser to extract information from its content. This becomes the value of the WebRequest (see page 15043) property.

See Also

WebRequest (see page 15043)

77.1.2.3 TAbstractContentParser Methods

The methods of the TAbstractContentParser class are listed here.

Protected Methods

	Name	Description
	GetContentFields (see page 15042)	Returns the named value strings that are included in the content of the current Web request.
	GetFiles (see page 15042)	Returns a set of uploaded files that the parser extracts from the current Web request.

Public Methods

	Name	Description
	CanParse (see page 15041)	Indicates whether a specified request message contains information encoded in a way that this parser understands.

77.1.2.3.1 TAbstractContentParser.CanParse Method

Indicates whether a specified request message contains information encoded in a way that this parser understands.

Pascal

```
class function CanParse(AWebRequest: TWebRequest): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean CanParse(TWebRequest AWebRequest);
```

Description

CanParse indicates whether a content parser class can handle parsing a specified request message. CanParse is a class method (Delphi) or static method (C++), which means the Web request does not need an instantiated object to call this method. The Web request object calls the CanParse method of every registered TAbstractContentParser (see page 15039) descendant until it finds one that can parse its content.

AWebRequest is the current HTTP request message.

CanParse returns true if this class can parse AWebRequest, false if AWebRequest does not indicate an encoding that this class understands.

In TAbstractContentParser (see page 15039), CanParse always returns false. Descendant classes that implement the GetContentFields (see page 15042) and GetFiles (see page 15042) methods override CanParse to indicate when a Web request has a format they can parse.

See Also

GetContentFields (see page 15042)

GetFiles (see page 15042)

77.1.2.3.2 TAbstractContentParser.GetContentFields Method

Returns the named value strings that are included in the content of the current Web request.

Pascal

```
function GetContentFields: TStrings; virtual; abstract;
```

C++

```
virtual __fastcall TStrings GetContentFields() = 0;
```

Description

GetContentFields returns a list of strings with the form "Name=Value" that represent any name/value pairs that the parser identifies in the content of the current Web request.

In TAbstractContentParser (see page 15039), GetContentFields is abstract or, in C++ terminology, pure virtual, meaning that this class does not supply an implementation. Descendant classes override this method to extract name/value pairs from the current request and add them to the returned string list.

Note: The content parser owns the string list it returns. The caller should not free the string list.

See Also

ContentFields (see page 15177)

WebRequest (see page 15043)

ExtractContentFields (see page 15166)

77.1.2.3.3 TAbstractContentParser.GetFiles Method

Returns a set of uploaded files that the parser extracts from the current Web request.

Pascal

```
function GetFiles: TAbstractWebRequestFiles; virtual; abstract;
```

C++

```
virtual __fastcall TAbstractWebRequestFiles GetFiles() = 0;
```

Description

GetFiles returns a list of Web request file objects, each of which represents an uploaded file from the current Web request. Each Web request file object has properties to describe an uploaded file, including a stream object from which to read the content of the uploaded file.

In TAbstractContentParser (see page 15039), GetFiles is abstract or, in C++ terminology, pure virtual, meaning that this class

does not supply an implementation. Descendant classes override this method to extract uploaded files from the current request and add them to the Web request files object.

Note: The content parser owns the list it returns. The caller should not free this list.

See Also

Files (see page 15182)

WebRequest (see page 15043)

TAbstractWebRequestFile (see page 15073)

77.1.2.4 TAbstractContentParser Properties

The properties of the TAbstractContentParser class are listed here.

Protected Properties

	Name	Description
	WebRequest (see page 15043)	Indicates the Web request object that uses this parser to parse its content.

77.1.2.4.1 TAbstractContentParser.WebRequest Property

Indicates the Web request object that uses this parser to parse its content.

Pascal

```
property WebRequest: TWebRequest;
```

C++

```
__property TWebRequest WebRequest;
```

Description

Content parsers use the protected WebRequest property internally to access the content they parse. The value of WebRequest is a Web request object whose properties represent the headers and content of the current HTTP request message.

See Also

Content (see page 15176)

77.1.3 TAbstractWebModuleFactory Class

TAbstractWebModuleFactory is the base class for all Web module factory objects.

Class Hierarchy

HTTPApp.TAbstractWebModuleFactory

Pascal

```
TAbstractWebModuleFactory = class;
```

C++

```
class TAbstractWebModuleFactory;
```

File

HTTPApp

Description

All WebSnap modules are registered with the WebSnap application using a factory object. In Delphi, the factory object is typically created in the initialization section of the module source file. The factory object is responsible for creating Web module instance. Applications can set flags for each factory object to indicate when it should create instances of its Web module and whether it can cache Web module instance for reuse with subsequent request messages.

Do not create instances of TAbstractWebModuleFactory. Most of its methods are abstract or, in C++ terminology, pure virtual, meaning they have no implementation. Instead, create instances of a TAbstractWebModuleFactory descendant such as TWebDataModuleFactory, TWebAppDataModuleFactory, TWebPageModuleFactory, or TWebAppPageModuleFactory. Each of these classes includes an implementation of the abstract or pure virtual methods, and represents group of Web module factories. These groups are based on whether the Web module factory generates the single application Web module (which contains the components to dispatch HTTP request messages), and it generates a Web module that creates a Web page.

See Also

TWebAppPageModuleFactory (see page 25012)

TWebAppDataModuleFactory (see page 25009)

TWebPageModuleFactory (see page 25019)

TWebRequestHandler (see page 25448)

TWebDataModuleFactory (see page 25014)

77.1.3.1 TAbstractWebModuleFactory Members

The following tables list the members exposed by TAbstractWebModuleFactory.

Protected Methods

	Name	Description
A	GetCacheMode (see page 15045)	Returns the value of the CacheMode (see page 15048) property.
A	GetComponentClass (see page 15045)	Returns the value of the ComponentClass (see page 15049) property.
A	GetCreateMode (see page 15046)	Returns the value of the CreateMode (see page 15049) property.
A	GetIsAppModule (see page 15046)	Returns the value of the IsAppModule (see page 15050) property.
A	GetModuleName (see page 15047)	Returns the value of the ModuleName (see page 15050) property.
V	GetWebPageInfo (see page 15047)	Returns the value of the WebPageInfo (see page 15050) property.

Public Methods

	Name	Description
A	GetModule (see page 15046)	Creates an instance of the associated Web module.
A	PreventDestruction (see page 15048)	Prevents the WebSnap application from freeing the Web module instance.

Public Properties

	Name	Description
R	CacheMode (see page 15048)	Indicates whether the factory can cache Web modules for reuse.
R	ComponentClass (see page 15049)	Specifies the class type of the Web module that this factory creates.
R	CreateMode (see page 15049)	Indicates when the factory creates instances of its Web module.
R	IsAppModule (see page 15050)	Indicates whether the corresponding Web module is the main Web application module.
R	ModuleName (see page 15050)	Specifies the name of the Web module class that this factory instantiates.
R	WebPageInfo (see page 15050)	Describes the attributes of the Web page that the corresponding Web module generates, if any.

77.1.3.2 TAbstractWebModuleFactory Methods

The methods of the TAbstractWebModuleFactory class are listed here.

Protected Methods

	Name	Description
	GetCacheMode (see page 15045)	Returns the value of the CacheMode (see page 15048) property.
	GetComponentClass (see page 15045)	Returns the value of the ComponentClass (see page 15049) property.
	GetCreateMode (see page 15046)	Returns the value of the CreateMode (see page 15049) property.
	GetIsAppModule (see page 15046)	Returns the value of the IsAppModule (see page 15050) property.
	GetModuleName (see page 15047)	Returns the value of the ModuleName (see page 15050) property.
	GetWebPageInfo (see page 15047)	Returns the value of the WebPageInfo (see page 15050) property.

Public Methods

	Name	Description
	GetModule (see page 15046)	Creates an instance of the associated Web module.
	PreventDestruction (see page 15048)	Prevents the WebSnap application from freeing the Web module instance.

77.1.3.2.1 TAbstractWebModuleFactory.GetCacheMode Method

Returns the value of the CacheMode (see page 15048) property.

Pascal

```
function GetCacheMode: TWebModuleCacheMode; virtual; abstract;
```

C++

```
virtual __fastcall TWebModuleCacheMode GetCacheMode() = 0;
```

Description

GetCacheMode is the protected read implementation of the CacheMode (see page 15048) property.

In TAbstractWebModuleFactory (see page 15043), GetCacheMode is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the CacheMode (see page 15048) property.

See Also

CacheMode (see page 15048)

77.1.3.2.2 TAbstractWebModuleFactory.GetComponentClass Method

Returns the value of the ComponentClass (see page 15049) property.

Pascal

```
function GetComponentClass: TComponentClass; virtual; abstract;
```

C++

```
virtual __fastcall TComponentClass GetComponentClass() = 0;
```

Description

GetComponentClass is the protected read implementation of the ComponentClass (see page 15049) property.

In TAbstractWebModuleFactory (see page 15043), GetComponentClass is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the

ComponentClass (see page 15049) property.

See Also

ComponentClass (see page 15049)

77.1.3.2.3 TAbstractWebModuleFactory.GetCreateMode Method

Returns the value of the CreateMode (see page 15049) property.

Pascal

```
function GetCreateMode: TWebModuleCreateMode; virtual; abstract;
```

C++

```
virtual __fastcall TWebModuleCreateMode GetCreateMode() = 0;
```

Description

GetCreateMode is the protected read implementation of the CreateMode (see page 15049) property.

In TAbstractWebModuleFactory (see page 15043), GetCreateMode is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the CreateMode (see page 15049) property.

See Also

CreateMode (see page 15049)

77.1.3.2.4 TAbstractWebModuleFactory.GetIsAppModule Method

Returns the value of the IsAppModule (see page 15050) property.

Pascal

```
function GetIsAppModule: Boolean; virtual; abstract;
```

C++

```
virtual __fastcall Boolean GetIsAppModule() = 0;
```

Description

GetIsAppModule is the protected read implementation of the IsAppModule (see page 15050) property.

In TAbstractWebModuleFactory (see page 15043), GetIsAppModule is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the IsAppModule (see page 15050) property.

See Also

IsAppModule (see page 15050)

77.1.3.2.5 TAbstractWebModuleFactory.GetModule Method

Creates an instance of the associated Web module.

Pascal

```
function GetModule: TComponent; virtual; abstract;
```

C++

```
virtual __fastcall TComponent * GetModule() = 0;
```

Description

Call GetModule to obtain a new instance of the Web module that the factory creates. This method should only be called once for each request message that requires the use of the Web module.

GetModule returns the Web module instance.

In TAbstractWebModuleFactory (see page 15043), GetModule is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation that creates a new Web module instance.

See Also

ComponentClass (see page 15049)

CreateMode (see page 15049)

CacheMode (see page 15048)

77.1.3.2.6 TAbstractWebModuleFactory.GetModuleName Method

Returns the value of the ModuleName (see page 15050) property.

Pascal

```
function GetModuleName: string; virtual; abstract;
```

C++

```
virtual __fastcall AnsiString GetModuleName() = 0;
```

Description

GetModuleName is the protected read implementation of the ModuleName (see page 15050) property.

In TAbstractWebModuleFactory (see page 15043), GetModuleName is abstract pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the ModuleName (see page 15050) property.

See Also

ModuleName (see page 15050)

77.1.3.2.7 TAbstractWebModuleFactory.GetWebPageInfo Method

Returns the value of the WebPageInfo (see page 15050) property.

Pascal

```
function GetWebPageInfo: TAbstractWebPageInfo; virtual;
```

C++

```
virtual __fastcall TAbstractWebPageInfo GetWebPageInfo();
```

Description

GetWebPageInfo is the protected read implementation of the WebPageInfo (see page 15050) property.

In TAbstractWebModuleFactory (see page 15043), GetWebPageInfo always returns nil (Delphi) or NULL (C++). Descendant classes that represent the factories for Web page modules override this method to return the Web page information object that describes the module's Web page.

See Also

WebPageInfo (see page 15050)

77.1.3.2.8 TAbstractWebModuleFactory.PreventDestruction Method

Prevents the WebSnap application from freeing the Web module instance.

Pascal

```
procedure PreventDestruction; virtual; abstract;
```

C++

```
virtual __fastcall PreventDestruction() = 0;
```

Description

Call PreventDestruction if the WebSnap application should not free the Web module instance when the current HTTP request message has been fully processed. For example, if another Web module contains a reference to the Web module that this factory creates, you may not want to allow the WebSnap application to free the Web module that this factory creates while the other module exists.

In TAbstractWebModuleFactory (see page 15043), PreventDestruction is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation that prevents the Web module from being freed.

See Also

CacheMode (see page 15048)

77.1.3.3 TAbstractWebModuleFactory Properties

The properties of the TAbstractWebModuleFactory class are listed here.

Public Properties

	Name	Description
R	CacheMode (see page 15048)	Indicates whether the factory can cache Web modules for reuse.
R	ComponentClass (see page 15049)	Specifies the class type of the Web module that this factory creates.
R	CreateMode (see page 15049)	Indicates when the factory creates instances of its Web module.
R	IsAppModule (see page 15050)	Indicates whether the corresponding Web module is the main Web application module.
R	ModuleName (see page 15050)	Specifies the name of the Web module class that this factory instantiates.
R	WebPageInfo (see page 15050)	Describes the attributes of the Web page that the corresponding Web module generates, if any.

77.1.3.3.1 TAbstractWebModuleFactory.CacheMode Property

Indicates whether the factory can cache Web modules for reuse.

Pascal

```
property CacheMode: TWebModuleCacheMode;
```

C++

```
__property TWebModuleCacheMode CacheMode;
```

Description

The Web module factory creates an instance of its Web module to handle a specific HTTP request message. After the WebSnap

application has finished with that request, it can free the Web module instance, or cache it so that the next time it needs to create an instance of its Web module, it can simply reuse the cached instance.

When CacheMode is caCache, the WebSnap application caches Web module instances for reuse. This can improve performance.

When CacheMode is caDestroy, the WebSnap application frees Web module instances when they are no longer needed for the current request message. This is the safest approach if changes to the Web module or any of the components it contains that are made while processing a request message can interfere with the correct handling of subsequent request messages.

See Also

CreateMode (see page 15049)

PreventDestruction (see page 15048)

77.1.3.3.2 TAbstractWebModuleFactory.ComponentClass Property

Specifies the class type of the Web module that this factory creates.

Pascal

```
property ComponentClass: TComponentClass;
```

C++

```
__property TComponentClass ComponentClass;
```

Description

ComponentClass is the class type of the Web module that the factory object creates. This is a descendant of TWebDataModule, TWebAppDataModule, TWebPageModule, or TWebAppPageModule. The WebSnap application wizard or Web module wizard generates the class declaration for the specific Web module class associated with a Web module factory.

See Also

ModuleName (see page 15050)

WebPageInfo (see page 15050)

IsAppModule (see page 15050)

77.1.3.3.3 TAbstractWebModuleFactory.CreateMode Property

Indicates when the factory creates instances of its Web module.

Pascal

```
property CreateMode: TWebModuleCreateMode;
```

C++

```
__property TWebModuleCreateMode CreateMode;
```

Description

Read CreateMode to determine whether the factory creates its Web module for every request message (crAlways), or when the WebSnap application specifically needs the Web module for the current request (crOnDemand).

Note: When the Web module factory creates the Web application module, CreateMode is always crAlways. The Web application module is always required because it contains the components that dispatch HTTP messages. For Web module factories that create any other Web modules in the application, CreateMode reflects a flag passed to the constructor.

See Also

CacheMode (see page 15048)

IsAppModule (see page 15050)

77.1.3.3.4 TAbstractWebModuleFactory.IsAppModule Property

Indicates whether the corresponding Web module is the main Web application module.

Pascal

```
property IsAppModule: Boolean;
```

C++

```
__property Boolean IsAppModule;
```

Description

WebSnap applications read IsAppModule to determine whether a Web module factory creates the single application module. WebSnap applications include one and only one application module, which holds the components responsible for dispatching HTTP requests. The Web application module is an instance of TWebAppPageModule or TWebAppDataModule.

See Also

TWebAppPageModule (see page 25394)

TWebAppDataModule (see page 25388)

ComponentClass (see page 15049)

TPageDispatcher (see page 24949)

77.1.3.3.5 TAbstractWebModuleFactory.ModuleName Property

Specifies the name of the Web module class that this factory instantiates.

Pascal

```
property ModuleName: string;
```

C++

```
__property AnsiString ModuleName;
```

Description

ModuleName is the name of the Web module class that the factory object instantiates. That is, this is the name of the class for which the ComponentClass (see page 15049) property is a class reference.

See Also

ComponentClass (see page 15049)

WebPageInfo (see page 15050)

IsAppModule (see page 15050)

FindModuleName (see page 15055)

77.1.3.3.6 TAbstractWebModuleFactory.WebPageInfo Property

Describes the attributes of the Web page that the corresponding Web module generates, if any.

Pascal

```
property WebPageInfo: TAbstractWebPageInfo;
```

C++

```
__property TAbstractWebPageInfo WebPageInfo;
```

Description

When the Web module that the factory object creates can generate a Web page, WebPageInfo describes the attributes of the Web page, such as its name, title, access rights, and so on. This information is stored in the Web module factory so that it is available even when there is no current instance of the Web module.

When the Web module that the factory object creates does not generate a Web page, WebPageInfo is nil (Delphi) or NULL (C++).

See Also

ComponentClass (see page 15049)

77.1.4 TAbstractWebModuleList Class

TAbstractWebModuleList lists the WebModules in a WebSnap application and provides access to their factory objects.

Class Hierarchy

Pascal

```
TAbstractWebModuleList = class(TObject);
```

C++

```
class TAbstractWebModuleList : public TObject;
```

File

HTTPApp

Description

TAbstractWebModuleList is the base class for TWebModuleList, which lists every Web module that has been instantiated to serve the current request. It introduces properties and methods for accessing the Web modules in the application, as well as for the Web module factory objects that create those Web module instances. All the methods in TAbstractWebModuleList are abstract or, in C++ terminology, pure virtual, meaning they have no implementation. TWebModuleList, a TAbstractWebModuleList descendant, overrides those abstract or pure virtual methods to provide a default implementation.

When a WebSnap application handles multiple requests concurrently, it includes multiple web modules lists, each on a separate thread and each associated with a different request.

The Web context, which can be accessed using the global WebContext function, provides access to the TAbstractWebModuleList object that is associated with the current request. Use the Web context's WebModules property to obtain a reference to the Web module list.

See Also

TWebModuleList (see page 25440)

TWebModuleFactoryList (see page 25436)

TAbstractWebModuleFactory (see page 15043)

WebContext

TAbstractWebContext (see page 24644)

77.1.4.1 TAbstractWebModuleList Members

The following tables list the members exposed by TAbstractWebModuleList.

Protected Methods

	Name	Description
	GetFactory (see page 15055)	This is GetFactory, a member of class TAbstractWebModuleList.
	GetFactoryCount (see page 15056)	
	GetItem (see page 15056)	This is GetItem, a member of class TAbstractWebModuleList.
	GetItemCount (see page 15056)	
	GetOnModuleAdded (see page 15056)	
	SetOnModuleAdded (see page 15057)	

Public Events

	Name	Description
	OnModuleAdded (see page 15059)	Occurs when a new Web module is added to the Items (see page 15058) property array.

Public Methods

	Name	Description
	AddModuleClass (see page 15053)	Creates a new Web module, given its class, and adds it to the Items (see page 15058) property array.
	AddModuleName (see page 15054)	Creates a new Web module, given its name, and adds it to the Items (see page 15058) property array.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindModuleClass (see page 15054)	Locates a Web module given its class reference.
	FindModuleName (see page 15055)	Locates a Web module given its name.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.

	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	Factory (see page 15057)	Lists the Web module factories for all the Web modules available in the application.
R	FactoryCount (see page 15058)	Indicates the number of Web module factories listed in the Factory (see page 15057) property array.
R	ItemCount (see page 15058)	Indicates the number of Web modules that have been instantiated in the current thread.
R	Items (see page 15058)	Lists the instantiated Web modules in the current thread.

77.1.4.2 TAbstractWebModuleList Methods

The methods of the TAbstractWebModuleList class are listed here.

Protected Methods

	Name	Description
A	GetFactory (see page 15055)	This is GetFactory, a member of class TAbstractWebModuleList.
A	GetFactoryCount (see page 15056)	
A	GetItem (see page 15056)	This is GetItem, a member of class TAbstractWebModuleList.
A	GetItemCount (see page 15056)	
A	GetOnModuleAdded (see page 15056)	
A	SetOnModuleAdded (see page 15057)	

Public Methods

	Name	Description
A	AddModuleClass (see page 15053)	Creates a new Web module, given its class, and adds it to the Items (see page 15058) property array.
A	AddModuleName (see page 15054)	Creates a new Web module, given its name, and adds it to the Items (see page 15058) property array.
A	FindModuleClass (see page 15054)	Locates a Web module given its class reference.
A	FindModuleName (see page 15055)	Locates a Web module given its name.

77.1.4.2.1 TAbstractWebModuleList.AddModuleClass Method

Creates a new Web module, given its class, and adds it to the Items (see page 15058) property array.

Pascal

```
function AddModuleClass(AClass: TComponentClass): TComponent; virtual; abstract;
```

C++

```
virtual __fastcall TComponent * AddModuleClass(TComponentClass AClass) = 0;
```

Description

AddModuleClass searches for a Web module factory that can create a Web module of the specified class. If it finds a match, it instantiates the Web module and adds it to the Items (see page 15058) property array.

AClass is a class reference to the Web module you want to instantiate. It should not match the class type of any Web module already listed in the Items (see page 15058) property array.

AddModuleClass returns the new Web module instance. If the Factory (see page 15057) property array does not include a Web module factory that can create a Web module of the specified class, AddModuleClass returns nil (Delphi) or NULL (C++).

Note: In TAbstractWebModuleList (see page 15051), AddModuleClass is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes override this method to provide an implementation.

See Also

AddModuleName (see page 15054)

Items (see page 15058)

Factory (see page 15057)

FindModuleClass (see page 15054)

77.1.4.2.2 TAbstractWebModuleList.AddModuleName Method

Creates a new Web module, given its name, and adds it to the Items (see page 15058) property array.

Pascal

```
function AddModuleName(const AClass: string): TComponent; virtual; abstract;
```

C++

```
virtual __fastcall TComponent * AddModuleName(const AnsiString AClass) = 0;
```

Description

AddModuleName searches for a Web module factory that can create a Web module of the specified name. If it finds a match, it instantiates the Web module and adds it to the Items (see page 15058) property array.

AName is the name of the Web module you want to instantiate. It should not match the name of any Web module already listed in the Items (see page 15058) property array.

AddModuleClass (see page 15053) returns the new Web module instance. If the Factory (see page 15057) property array does not include a Web module factory that can create a Web module of the specified name, AddModuleClass (see page 15053) returns nil (Delphi) or NULL (C++).

Note: In TAbstractWebModuleList (see page 15051), AddModuleName is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes override this method to provide an implementation.

See Also

AddModuleClass (see page 15053)

Items (see page 15058)

Factory (see page 15057)

FindModuleName (see page 15055)

77.1.4.2.3 TAbstractWebModuleList.FindModuleClass Method

Locates a Web module given its class reference.

Pascal

```
function FindModuleClass(AClass: TComponentClass): TComponent; virtual; abstract;
```

C++

```
virtual __fastcall TComponent * FindModuleClass(TComponentClass AClass) = 0;
```

Description

Call FindModuleClass to locate the Web module instance of a given class type. FindModuleClass searches the Items (see page 15058) property array for a Web module instance of the specified class.

AClass is a class reference to the class type of the desired Web module.

FindModuleClass returns the requested Web module instance if it exists. If there is no Web module of the specified class, FindModuleClass returns nil (Delphi) or NULL (C++).

Note: In TAbstractWebModuleList (see page 15051), FindModuleClass is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes override this method to provide an implementation.

See Also

FindModuleName (see page 15055)

Items (see page 15058)

77.1.4.2.4 TAbstractWebModuleList.FindModuleName Method

Locates a Web module given its name.

Pascal

```
function FindModuleName(const AClass: string): TComponent; virtual; abstract;
```

C++

```
virtual __fastcall TComponent * FindModuleName(const AnsiString AClass) = 0;
```

Description

Call FindModuleName to locate the Web module instance of a given name. FindModuleClass (see page 15054) searches the Items (see page 15058) property array for a Web module instance of the specified name.

AName is the name of the desired Web module.

FindModuleName returns the requested Web module instance if it exists. If there is no Web module with the specified name, FindModuleClass (see page 15054) returns nil (Delphi) or NULL (C++).

Note: In TAbstractWebModuleList (see page 15051), FindModuleClass (see page 15054) is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes override this method to provide an implementation.

See Also

FindModuleClass (see page 15054)

Items (see page 15058)

77.1.4.2.5 TAbstractWebModuleList.GetFactory Method

Pascal

```
function GetFactory(I: Integer): TAbstractWebModuleFactory; virtual; abstract;
```

C++

```
virtual __fastcall TAbstractWebModuleFactory GetFactory(int I) = 0;
```

Description

This is GetFactory, a member of class TAbstractWebModuleList.

77.1.4.2.6 TAbstractWebModuleList.GetFactoryCount Method

Pascal

```
function GetFactoryCount: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetFactoryCount() = 0;
```

See Also

GetFactory (see page 15055)

FactoryCount (see page 15058)

77.1.4.2.7 TAbstractWebModuleList.GetItem Method

Pascal

```
function GetItem(I: Integer): TComponent; virtual; abstract;
```

C++

```
virtual __fastcall TComponent * GetItem(int I) = 0;
```

Description

This is GetItem, a member of class TAbstractWebModuleList.

77.1.4.2.8 TAbstractWebModuleList.GetItemCount Method

Pascal

```
function GetItemCount: Integer; virtual; abstract;
```

C++

```
virtual __fastcall int GetItemCount() = 0;
```

See Also

GetItem (see page 15056)

ItemCount (see page 15058)

77.1.4.2.9 TAbstractWebModuleList.GetOnModuleAdded Method

Pascal

```
function GetOnModuleAdded: TModuleAddedProc; virtual; abstract;
```

C++

```
virtual __fastcall TModuleAddedProc GetOnModuleAdded() = 0;
```

See Also

OnModuleAdded (see page 15059)

SetOnModuleAdded (see page 15057)

77.1.4.2.10 TAbstractWebModuleList.SetOnModuleAdded Method

Pascal

```
procedure SetOnModuleAdded(AProc: TModuleAddedProc); virtual; abstract;
```

C++

```
virtual __fastcall SetOnModuleAdded(TModuleAddedProc AProc) = 0;
```

See Also

GetOnModuleAdded (see page 15056)

OnModuleAdded (see page 15059)

77.1.4.3 TAbstractWebModuleList Properties

The properties of the TAbstractWebModuleList class are listed here.

Public Properties

	Name	Description
R	Factory (see page 15057)	Lists the Web module factories for all the Web modules available in the application.
R	FactoryCount (see page 15058)	Indicates the number of Web module factories listed in the Factory (see page 15057) property array.
R	ItemCount (see page 15058)	Indicates the number of Web modules that have been instantiated in the current thread.
R	Items (see page 15058)	Lists the instantiated Web modules in the current thread.

77.1.4.3.1 TAbstractWebModuleList.Factory Property

Lists the Web module factories for all the Web modules available in the application.

Pascal

```
property Factory [I: Integer]: TAbstractWebModuleFactory;
```

C++

```
__property TAbstractWebModuleFactory Factory[int I];
```

Description

Read Factory to access the factory objects that instantiate Web modules for the WebSnap application. Each factory object includes methods to create or (if an instance exists) access the corresponding Web module, as well as properties that provide information about the Web module it creates.

Use the FactoryCount (see page 15058) property in conjunction with Factory to iterate over all the Web module factory objects in the WebSnap application.

I is the index of the factory object to read, where 0 identifies the first factory, 1 identifies the second factory, and so on, until FactoryCount (see page 15058) – 1 identifies the last factory.

See Also

FactoryCount (see page 15058)

Items (see page 15058)

77.1.4.3.2 TAbstractWebModuleList.FactoryCount Property

Indicates the number of Web module factories listed in the Factory (see page 15057) property array.

Pascal

```
property FactoryCount: Integer;
```

C++

```
__property int FactoryCount;
```

Description

Read FactoryCount to determine the number of Web module factory object (and hence the potential number of Web modules) in the WebSnap application. FactoryCount provides an upper bound to the index of the Factory (see page 15057) property array.

See Also

Factory (see page 15057)

ItemCount (see page 15058)

77.1.4.3.3 TAbstractWebModuleList.ItemCount Property

Indicates the number of Web modules that have been instantiated in the current thread.

Pascal

```
property ItemCount: Integer;
```

C++

```
__property int ItemCount;
```

Description

Read ItemCount to determine the number of instantiated Web modules in the current thread of the WebSnap application. ItemCount provides an upper bound to the index of the Items (see page 15058) property array.

Because ItemCount counts only the instantiated Web modules, its value is always less than or equal to the value of FactoryCount (see page 15058), which gives the number of Web module factories.

See Also

Items (see page 15058)

FactoryCount (see page 15058)

77.1.4.3.4 TAbstractWebModuleList.Items Property

Lists the instantiated Web modules in the current thread.

Pascal

```
property Items [I: Integer]: TComponent;
```

C++

```
__property TComponent * Items[int I];
```

Description

Read Items to access the Web modules that have been created to process the current HTTP request.

Use the ItemCount (see page 15058) property in conjunction with Items to iterate over all the Web modules in the current

thread.

I is the index of the object to read, where 0 identifies the first Web module, 1 identifies the second Web module, and so on, until ItemCount (see page 15058) – 1 identifies the last Web module.

Note: In Delphi, Items is the default property of TAbstractWebModuleList (see page 15051). This means that the property name may be omitted. Thus the line

Note: MyModule := WebContext.WebModules.Items[I];

Note: can be written

Note: MyModule := WebContext.WebModules[I];

Note: In C++, a similar effect to the use of Items as a default property can be achieved using the [] operator.

See Also

ItemCount (see page 15058)

Factory (see page 15057)

operator_sb

77.1.4.4 TAbstractWebModuleList Events

The events of the TAbstractWebModuleList class are listed here.

Public Events

	Name	Description
	OnModuleAdded (see page 15059)	Occurs when a new Web module is added to the Items (see page 15058) property array.

77.1.4.4.1 TAbstractWebModuleList.OnModuleAdded Event

Occurs when a new Web module is added to the Items (see page 15058) property array.

Pascal

```
property OnModuleAdded: TModuleAddedProc;
```

C++

```
__property TModuleAddedProc OnModuleAdded;
```

Description

Write an OnModuleAdded event handler to take specific action when a Web module is instantiated in the current Web context. When the WebSnap application creates a new Web module instance, it generates an OnModuleAdded event immediately after adding the instance to the Items (see page 15058) property array.

Note: Do not write an OnModuleAdded event handler if the application contains a TWebAppComponents object. TWebAppComponents uses this event to initialize the Web modules when they are added.

See Also

Items (see page 15058)

AddModuleClass (see page 15053)

AddModuleName (see page 15054)

TWebAppComponents (see page 24958)

77.1.5 TAbstractWebPageInfo Class

TAbstractWebPageInfo represents the attributes of a Web page module.

Class Hierarchy

HTTPApp.TAbstractWebPageInfo

Pascal

```
TAbstractWebPageInfo = class;
```

C++

```
class TAbstractWebPageInfo;
```

File

HTTPApp

Description

TAbstractWebPageInfo is the abstract base class for Web page information objects. It introduces a number of properties that describe the attributes of a Web page module, including

PageName (see page 15068), which is the logical name for the Web page the module generates.

IsPublished (see page 15067), which indicates whether the WebSnap application automatically displays the page in response to request messages where the pathinfo portion of the target URL matches PageName (see page 15068).

IsLoginRequired (see page 15066), which indicates whether the user must log in to access the Web page.

ViewAccess (see page 15069), which can be used to restrict access to the Web page.

PageTitle (see page 15069), which is the title that appears on the Web page.

PageFile (see page 15068), which identifies an associated HTML template that the Web page module uses to generate its Web page.

PageHREF (see page 15068), which identifies the HREF to use for references to the page that appear in hypertext links.

PageDescription (see page 15067), which describes the Web page.

Do not create instances of TAbstractWebPageInfo. It includes abstract or, in C++ terminology, pure virtual methods (methods that have no implementation) that must be overridden in a descendant class.

Web page information objects are used to set the attributes of a Web page module. An instance of a TAbstractWebPageInfo descendant, such as TWebPageInfo, is supplied to the constructor of the factory object that creates instances of the Web page module. Typically, the code to create this object and supply it to the Web page factory's constructor is generated by a Web page module wizard. You can change this generated code, which appears in the generated unit for the Web page module, to alter the properties of the Web page information object. For example, you may want to add a ViewAccess (see page 15069) string to allow your application to limit access to the Web page.

In a WebSnap application, you can access the Web page information object of any Web page module by calling the FindPageInfo method of the application's global Web context.

WebContext

77.1.5.1 TAbstractWebPageInfo Members

The following tables list the members exposed by TAbstractWebPageInfo.

Protected Methods

	Name	Description
	GetFactory (see page 15062)	Returns the value of the Factory (see page 15066) property.
V	GetIsLoginRequired (see page 15062)	Returns the value of the IsLoginRequired (see page 15066) property.
V	GetIsPublished (see page 15062)	Returns the value of the IsPublished (see page 15067) property.
V	GetPageDescription (see page 15063)	Returns the value of the PageDescription (see page 15067) property.
A	GetPageFile (see page 15063)	Returns the value of the PageFile (see page 15068) property.
V	GetPageHREF (see page 15064)	Returns the value of the PageHREF (see page 15068) property.
A	GetPageName (see page 15064)	Returns the value of the PageName (see page 15068) property.
V	GetPageTitle (see page 15064)	Returns the value of the PageTitle (see page 15069) property.
V	GetViewAccess (see page 15065)	Returns the value of the ViewAccess (see page 15069) property.
V	SetFactory (see page 15065)	Sets the value of the Factory (see page 15066) property.

Public Properties

	Name	Description
	Factory (see page 15066)	Specifies the factory object that creates instances of the Web page module this object describes.
R	IsLoginRequired (see page 15066)	Indicates whether callers must log in before accessing the associated Web page.
R	IsPublished (see page 15067)	Indicates whether the WebSnap application automatically displays the associated page in response to request messages where the pathinfo portion of the target URL matches PageName (see page 15068).
R	PageDescription (see page 15067)	Describes the Web page.
R	PageFile (see page 15068)	Identifies an associated file that the Web page module uses to generate its Web page.
R	PageHREF (see page 15068)	Identifies the HREF to use for references to the associated Web page that appear in hypertext links.
R	PageName (see page 15068)	Denotes the logical name for the Web page that the associated module generates
R	PageTitle (see page 15069)	Indicates the title that appears on the associated Web page.
R	ViewAccess (see page 15069)	Indicates the view access string that controls access to the associated Web page.

77.1.5.2 TAbstractWebPageInfo Methods

The methods of the TAbstractWebPageInfo class are listed here.

Protected Methods

	Name	Description
	GetFactory (see page 15062)	Returns the value of the Factory (see page 15066) property.

	GetIsLoginRequired (see page 15062)	Returns the value of the IsLoginRequired (see page 15066) property.
	GetIsPublished (see page 15062)	Returns the value of the IsPublished (see page 15067) property.
	GetPageDescription (see page 15063)	Returns the value of the PageDescription (see page 15067) property.
	GetPageFile (see page 15063)	Returns the value of the PageFile (see page 15068) property.
	GetPageHREF (see page 15064)	Returns the value of the PageHREF (see page 15068) property.
	GetPageName (see page 15064)	Returns the value of the PageName (see page 15068) property.
	GetPageTitle (see page 15064)	Returns the value of the PageTitle (see page 15069) property.
	GetViewAccess (see page 15065)	Returns the value of the ViewAccess (see page 15069) property.
	SetFactory (see page 15065)	Sets the value of the Factory (see page 15066) property.

77.1.5.2.1 TAbstractWebPageInfo.GetFactory Method

Returns the value of the Factory (see page 15066) property.

Pascal

```
function GetFactory: TAbstractWebPageModuleFactory;
```

C++

```
__fastcall TAbstractWebPageModuleFactory GetFactory();
```

Description

GetFactory is the protected read implementation of the Factory (see page 15066) property.

See Also

Factory (see page 15066)

SetFactory (see page 15065)

77.1.5.2.2 TAbstractWebPageInfo.GetIsLoginRequired Method

Returns the value of the IsLoginRequired (see page 15066) property.

Pascal

```
function GetIsLoginRequired: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetIsLoginRequired();
```

Description

GetIsLoginRequired is the protected read implementation of the IsLoginRequired (see page 15066) property.

In TAbstractWebPageInfo (see page 15060), GetIsLoginRequired always returns false. Descendant classes override this method to indicate when users must log in to access the associated Web page.

See Also

IsLoginRequired (see page 15066)

77.1.5.2.3 TAbstractWebPageInfo.GetIsPublished Method

Returns the value of the IsPublished (see page 15067) property.

Pascal

```
function GetIsPublished: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean GetIsPublished();
```

Description

GetIsPublished is the protected read implementation of the IsPublished (see page 15067) property.

In TAbstractWebPageInfo (see page 15060), GetIsPublished always returns false. Descendant classes override this method to indicate when the page dispatcher can automatically forward HTTP request messages that address the associated Web module.

See Also

IsPublished (see page 15067)

77.1.5.2.4 TAbstractWebPageInfo.GetPageDescription Method

Returns the value of the PageDescription (see page 15067) property.

Pascal

```
function GetPageDescription: string; virtual;
```

C++

```
virtual __fastcall AnsiString GetPageDescription();
```

Description

GetPageDescription is the protected read implementation of the PageDescription (see page 15067) property.

In TAbstractWebPageInfo (see page 15060), GetPageDescription returns the value of the PageName (see page 15068) property. Descendant classes override this method to allow page descriptions that differ from the Web page's logical name.

See Also

PageDescription (see page 15067)

PageName (see page 15068)

77.1.5.2.5 TAbstractWebPageInfo.GetPageFile Method

Returns the value of the PageFile (see page 15068) property.

Pascal

```
function GetPageFile: string; virtual; abstract;
```

C++

```
virtual __fastcall AnsiString GetPageFile() = 0;
```

Description

GetPageFile is the protected read implementation of the PageFile (see page 15068) property.

In TAbstractWebPageInfo (see page 15060), GetPageFile is abstract or, in C++ terminology, pure virtual. Descendant classes must override this method to provide an implementation for the PageFile (see page 15068) property.

See Also

PageFile (see page 15068)

77.1.5.2.6 TAbstractWebPageInfo.GetPageHREF Method

Returns the value of the PageHREF (see page 15068) property.

Pascal

```
function GetPageHREF: string; virtual;
```

C++

```
virtual __fastcall AnsiString GetPageHREF();
```

Description

GetPageHREF is the protected read implementation of the PageHREF (see page 15068) property.

In TAbstractWebPageInfo (see page 15060), GetPageHREF returns the value of the PageName (see page 15068) property. Descendant classes override this method to allow HREF values that differ from the Web page's logical name.

See Also

PageHREF (see page 15068)

PageName (see page 15068)

77.1.5.2.7 TAbstractWebPageInfo.GetPageName Method

Returns the value of the PageName (see page 15068) property.

Pascal

```
function GetPageName: string; virtual; abstract;
```

C++

```
virtual __fastcall AnsiString GetPageName() = 0;
```

Description

GetPageName is the protected read implementation of the PageName (see page 15068) property.

In TAbstractWebPageInfo (see page 15060), GetPageName is abstract or, in C++ terminology, pure virtual. Descendant classes must override this method to provide an implementation for the PageName (see page 15068) property.

See Also

PageName (see page 15068)

77.1.5.2.8 TAbstractWebPageInfo.GetPageTitle Method

Returns the value of the PageTitle (see page 15069) property.

Pascal

```
function GetPageTitle: string; virtual;
```

C++

```
virtual __fastcall AnsiString GetPageTitle();
```

Description

GetPageTitle is the protected read implementation of the PageTitle (see page 15069) property.

In TAbstractWebPageInfo (see page 15060), GetPageTitle returns the value of the PageName (see page 15068) property. Descendant classes override this method to allow Web pages to have titles that differ from their logical name.

See Also

PageTitle (see page 15069)

PageName (see page 15068)

77.1.5.2.9 TAbstractWebPageInfo.GetViewAccess Method

Returns the value of the ViewAccess (see page 15069) property.

Pascal

```
function GetViewAccess: string; virtual;
```

C++

```
virtual __fastcall AnsiString GetViewAccess();
```

Description

GetViewAccess is the protected read implementation of the ViewAccess (see page 15069) property.

In TAbstractWebPageInfo (see page 15060), GetViewAccess returns an empty string. Descendant classes override this method to allow Web pages to have view access strings.

See Also

ViewAccess (see page 15069)

77.1.5.2.10 TAbstractWebPageInfo.SetFactory Method

Sets the value of the Factory (see page 15066) property.

Pascal

```
procedure SetFactory(AFactory: TAbstractWebPageModuleFactory); virtual;
```

C++

```
virtual __fastcall SetFactory(TAbstractWebPageModuleFactory AFactory);
```

Description

SetFactory is the protected write implementation of the Factory (see page 15066) property.

AFactory is the Web page module factory object that instantiates the Web page module that this object describes.

See Also

Factory (see page 15066)

GetFactory (see page 15062)

77.1.5.3 TAbstractWebPageInfo Properties

The properties of the TAbstractWebPageInfo class are listed here.

Public Properties

	Name	Description
	Factory (see page 15066)	Specifies the factory object that creates instances of the Web page module this object describes.
R	IsLoginRequired (see page 15066)	Indicates whether callers must log in before accessing the associated Web page.

R	IsPublished (see page 15067)	Indicates whether the WebSnap application automatically displays the associated page in response to request messages where the pathinfo portion of the target URL matches PageName (see page 15068).
R	PageDescription (see page 15067)	Describes the Web page.
R	PageFile (see page 15068)	Identifies an associated file that the Web page module uses to generate its Web page.
R	PageHREF (see page 15068)	Identifies the HREF to use for references to the associated Web page that appear in hypertext links.
R	PageName (see page 15068)	Denotes the logical name for the Web page that the associated module generates
R	PageTitle (see page 15069)	Indicates the title that appears on the associated Web page.
R	ViewAccess (see page 15069)	Indicates the view access string that controls access to the associated Web page.

77.1.5.3.1 TAbstractWebPageInfo.Factory Property

Specifies the factory object that creates instances of the Web page module this object describes.

Pascal

```
property Factory: TAbstractWebPageModuleFactory;
```

C++

```
__property TAbstractWebPageModuleFactory Factory;
```

Description

Factory indicates the factory object that creates instances of the associated Web page module. If the associated Web page module is also the Web application module, Factory is an instance of TWebAppPageModuleFactory. Otherwise, it is an instance of TWebPageModuleFactory.

This property is set by the factory object's constructor.

See Also

TWebAppPageModuleFactory (see page 25012)

TWebPageModuleFactory (see page 25019)

Create_d

Create_c

77.1.5.3.2 TAbstractWebPageInfo.IsLoginRequired Property

Indicates whether callers must log in before accessing the associated Web page.

Pascal

```
property IsLoginRequired: Boolean;
```

C++

```
__property Boolean IsLoginRequired;
```

Description

Read IsLoginRequired to determine whether users must log in before accessing the associated Web page. The page dispatcher component (TPageDispatcher) checks this value to determine whether it can forward requests to the associated Web page when the caller has not yet logged in. The application can overrule the IsLoginRequired property by supplying an OnIsLoginRequired event handler to the page dispatcher.

In TAbstractWebPageInfo (see page 15060), IsLoginRequired is always false. Descendant classes override this property, initializing it to a value that is passed to the constructor.

See Also

Create_c

Create_d

IsPublished (see page 15067)

ViewAccess (see page 15069)

OnIsLoginRequired (see page 24904)

TPageDispatcher (see page 24949)

77.1.5.3.3 TAbstractWebPageInfo.IsPublished Property

Indicates whether the WebSnap application automatically displays the associated page in response to request messages where the pathinfo portion of the target URL matches PageName (see page 15068).

Pascal

```
property IsPublished: Boolean;
```

C++

```
__property Boolean IsPublished;
```

Description

Read IsPublished to determine whether the page dispatcher (TPageDispatcher) automatically calls on the associated Web page module when it receives HTTP request messages that address it by name. HTTP request messages address a Web page module when the pathinfo portion of their target URL matches the value of the PageName (see page 15068) property.

When IsPublished is false, the WebSnap application must explicitly retrieve the content that the Web page module generates in order to use the Web page module.

In TAbstractWebPageInfo (see page 15060), IsPublished is always false. Descendant classes override this property, initializing it to a value that is passed to the constructor.

See Also

PageName (see page 15068)

Create_d

Create_c

TPageDispatcher (see page 24949)

77.1.5.3.4 TAbstractWebPageInfo.PageDescription Property

Describes the Web page.

Pascal

```
property PageDescription: string;
```

C++

```
__property AnsiString PageDescription;
```

Description

Read PageDescription to obtain a brief description of the Web page that the associated Web page module generates. This property can be used, for example, to provide descriptions for a dynamically generated catalog of available Web pages.

In TAbstractWebPageInfo (see page 15060), PageDescription is the same as the value of the PageName (see page 15068) property.

See Also

PageName (see page 15068)

PageTitle (see page 15069)

77.1.5.3.5 TAbstractWebPageInfo.PageFile Property

Identifies an associated file that the Web page module uses to generate its Web page.

Pascal

```
property PageFile: string;
```

C++

```
__property AnsiString PageFile;
```

Description

Read PageFile to identify the file, if any, that the associated Web page module uses when generating its Web page. This can be the Web page that the Web page module returns, or it can be a template that the Web page module modifies to generate its final product.

In TAbstractWebPageInfo (see page 15060), the property read access method for PageFile is abstract pure virtual. Descendant classes must override the protected GetPageFile (see page 15063) method to provide an implementation for this property.

77.1.5.3.6 TAbstractWebPageInfo.PageHREF Property

Identifies the HREF to use for references to the associated Web page that appear in hypertext links.

Pascal

```
property PageHREF: string;
```

C++

```
__property AnsiString PageHREF;
```

Description

Read PageHREF to obtain the string that should be inserted in HTML code to create a hypertext link to the associated Web page.

In TAbstractWebPageInfo (see page 15060), PageHREF is the same as the value of the PageName (see page 15068) property.

See Also

PageName (see page 15068)

77.1.5.3.7 TAbstractWebPageInfo.PageName Property

Denotes the logical name for the Web page that the associated module generates

Pascal

```
property PageName: string;
```

C++

```
__property AnsiString PageName;
```

Description

Read PageName to determine the name of the associated Web page. This name is used to identify that page in server-side scripts, and as the pathinfo portion of the URL for the page when the IsPublished (see page 15067) property is true.

In TAbstractWebPageInfo (see page 15060), the property read access method for PageName is abstract pure virtual. Descendant classes must override the protected GetPageName (see page 15064) method to provide an implementation for this property.

See Also

PageTitle (see page 15069)

PageHREF (see page 15068)

IsPublished (see page 15067)

77.1.5.3.8 TAbstractWebPageInfo.PageTitle Property

Indicates the title that appears on the associated Web page.

Pascal

```
property PageTitle: string;
```

C++

```
__property AnsiString PageTitle;
```

Description

Read PageTitle to determine the title that appears on the associated Web page when viewed from a user's browser.

In TAbstractWebPageInfo (see page 15060), PageTitle is the same as the value of the PageName (see page 15068) property.

See Also

PageName (see page 15068)

77.1.5.3.9 TAbstractWebPageInfo.ViewAccess Property

Indicates the view access string that controls access to the associated Web page.

Pascal

```
property ViewAccess: string;
```

C++

```
__property AnsiString ViewAccess;
```

Description

Read ViewAccess to obtain the view access string that controls which users have access to the associated Web page. When a user tries to access the associated Web page, the page dispatcher checks the user's access rights against this string by calling the HasViewRights method of the end user adapter. Adapters in the Web page module check execute and modify rights against this string by calling the HasExecuteRights and HasModifyRights methods of the end user adapter.

In TAbstractWebPageInfo (see page 15060), ViewAccess is always an empty string. Descendant classes override this property, initializing it to a value that is passed to the constructor.

See Also

HasExecuteRights (see page 24675)

HasModifyRights (see page 24676)

HasViewRights (see page 24676)

77.1.6 TAbstractWebPageModuleFactory Class

TAbstractWebPageModuleFactory is the base class for Web module factory objects whose generated Web modules create Web pages.

Class Hierarchy

Pascal

```
TAbstractWebPageModuleFactory = class(TAbstractWebModuleFactory);
```

C++

```
class TAbstractWebPageModuleFactory : public TAbstractWebModuleFactory;
```

File

HTTPApp

Description

All WebSnap modules are registered with the WebSnap application using a factory object. In Delphi, the factory object is typically created in the initialization section of the module source file. The factory object is responsible for creating Web module instances. Applications can set flags for each factory object to indicate when it should create instances of its Web module and whether it can cache Web module instances for reuse with subsequent request messages.

TAbstractWebPageModuleFactory is the base class for all Web module factory objects that generate Web page modules. In addition to holding components that perform tasks for the WebSnap application, Web page modules can generate a Web page. The Web page is described by a Web page information object, which the Web page module factory makes available as its WebPageInfo (see page 15050) property.

Do not create instances of TAbstractWebPageModuleFactory. Most of its methods are abstract or, in C++ terminology, pure virtual, meaning they have no implementation. Instead, create instances of a TAbstractWebPageModuleFactory descendant such as TWebPageModuleFactory or TWebAppPageModuleFactory.

See Also

TWebAppPageModuleFactory (see page 25012)

TWebPageModuleFactory (see page 25019)

TWebRequestHandler (see page 25448)

TWebPageInfo (see page 25016)

77.1.6.1 TAbstractWebPageModuleFactory Members

The following tables list the members exposed by TAbstractWebPageModuleFactory.

Protected Methods

	Name	Description
	GetCacheMode (see page 15045)	Returns the value of the CacheMode (see page 15048) property.

	GetComponentClass (see page 15045)	Returns the value of the ComponentClass (see page 15049) property.
	GetCreateMode (see page 15046)	Returns the value of the CreateMode (see page 15049) property.
	GetIsAppModule (see page 15046)	Returns the value of the IsAppModule (see page 15050) property.
	GetModuleName (see page 15047)	Returns the value of the ModuleName (see page 15050) property.
	GetWebPageInfo (see page 15072)	Returns the value of the WebPageInfo (see page 15050) property.

Public Methods

	Name	Description
	Create (see page 15071)	Constructs an object and initializes its data before the object is first used.
	Destroy (see page 15071)	Disposes of an object instance.
	GetModule (see page 15046)	Creates an instance of the associated Web module.
	PreventDestruction (see page 15048)	Prevents the WebSnap application from freeing the Web module instance.

Public Properties

	Name	Description
	CacheMode (see page 15048)	Indicates whether the factory can cache Web modules for reuse.
	ComponentClass (see page 15049)	Specifies the class type of the Web module that this factory creates.
	CreateMode (see page 15049)	Indicates when the factory creates instances of its Web module.
	IsAppModule (see page 15050)	Indicates whether the corresponding Web module is the main Web application module.
	ModuleName (see page 15050)	Specifies the name of the Web module class that this factory instantiates.
	WebPageInfo (see page 15050)	Describes the attributes of the Web page that the corresponding Web module generates, if any.

77.1.6.2 TAbstractWebPageModuleFactory.Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create(AWebPageInfo: TAbstractWebPageInfo);
```

C++

```
__fastcall TAbstractWebPageModuleFactory(TAbstractWebPageInfo AWebPageInfo);
```

Description

Do not create instances of TAbstractWebPageModuleFactory (see page 15070). Instead, construct descendants of TAbstractWebPageModuleFactory (see page 15070) using the new keyword, passing any arguments for the descendant object's constructor.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

Destroy (see page 22287)

new

77.1.6.3 TAbstractWebPageModuleFactory.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TAbstractWebPageModuleFactory();
```

Description

Do not call ~TAbstractWebPageModuleFactory (see page 15070) directly. Instead, use the delete keyword when destroying VCL objects.

~TAbstractWebPageModuleFactory (see page 15070) deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

Warning: Never destroy a component from one of its own event handlers or from the event handler of a component it owns or contains. For example, don't destroy a button, or the form that owns the button, in the button's OnClick event handler.

To destroy a form, call its Release method, which destroys the form and releases the memory allocated for it after all its event handlers and those of the components it contains have executed.

delete

77.1.6.4 TAbstractWebPageModuleFactory Methods

The methods of the TAbstractWebPageModuleFactory class are listed here.

Protected Methods

	Name	Description
	GetWebPageInfo (see page 15072)	Returns the value of the WebPageInfo (see page 15050) property.

77.1.6.4.1 TAbstractWebPageModuleFactory.GetWebPageInfo Method

Returns the value of the WebPageInfo (see page 15050) property.

Pascal

```
function GetWebPageInfo: TAbstractWebPageInfo; override;
```

C++

```
virtual __fastcall TAbstractWebPageInfo GetWebPageInfo();
```

Description

GetWebPageInfo is the protected read implementation of the WebPageInfo (see page 15050) property. It returns the Web page information object that is supplied to the TAbstractWebPageModuleFactory (see page 15070) constructor.

See Also

WebPageInfo

Create_c

77.1.7 TAbstractWebRequestFile Class

TAbstractWebRequestFile describes an uploaded file from an HTTP request.

Class Hierarchy

Pascal

```
TAbstractWebRequestFile = class(TObject);
```

C++

```
class TAbstractWebRequestFile : public TObject;
```

File

HTTPApp

Description

TAbstractWebRequestFile introduces properties to describe and provide access to an uploaded file from an HTTP request. These include

FileName (see page 15077), which gives the name of the uploaded file.

FieldName (see page 15077), which gives the name of the field whose value is the uploaded file.

ContentType (see page 15076), which describes how the file data is encoded.

Stream (see page 15077), which is a stream object from which you can read the file content.

The methods that implement these properties are all abstract or, in C++ terminology, pure virtual. This means that the Web server application does not instantiate TAbstractWebRequestFile. Instead, it uses a TAbstractWebRequestFile descendant such as TWebRequestFile (which is included in WebSnap).

Each TAbstractWebRequestFile descendant describes a single uploaded file. A collection of all the uploaded files from the current request is available as the Files property of TWebRequest (see page 15161). In addition, in WebSnap applications, adapter fields that work with uploaded files surface those files using a TUpdateFileList object or IActionFieldValues interface.

Note: Support for uploaded files is only included in WebSnap. For other Web server applications, this class exists only as a placeholder for the Files property on TWebRequest (see page 15161).

See Also

TWebRequestFile (see page 18696)

TAbstractWebRequestFiles (see page 15078)

IActionFieldValues (see page 925)

TUpdateFileList (see page 24550)

TAdapterFileField (see page 23837)

77.1.7.1 TAbstractWebRequestFile Members

The following tables list the members exposed by TAbstractWebRequestFile.

Protected Methods

	Name	Description
	GetContentType (see page 15075)	Returns the value of the ContentType (see page 15076) property.
	GetFieldName (see page 15075)	Returns the value of the FieldName (see page 15077) property.
	GetFileName (see page 15075)	Returns the value of the FileName (see page 15077) property.
	GetStream (see page 15076)	Returns the value of the Stream (see page 15077) property.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	ContentType (see page 15076)	Describes how the file data is encoded.
	FieldName (see page 15077)	Indicates the name of the adapter field whose value is the contents of the file.
	FileName (see page 15077)	Indicates the name of the uploaded file.
	Stream (see page 15077)	Provides access to the contents of the uploaded file.

77.1.7.2 TAbstractWebRequestFile Methods

The methods of the TAbstractWebRequestFile class are listed here.

Protected Methods

	Name	Description
	GetContentType (see page 15075)	Returns the value of the ContentType (see page 15076) property.
	GetFieldName (see page 15075)	Returns the value of the FieldName (see page 15077) property.
	GetFileName (see page 15075)	Returns the value of the FileName (see page 15077) property.
	GetStream (see page 15076)	Returns the value of the Stream (see page 15077) property.

77.1.7.2.1 TAbstractWebRequestFile.GetContentType Method

Returns the value of the ContentType (see page 15076) property.

Pascal

```
function GetContentType: string; virtual; abstract;
```

C++

```
virtual __fastcall AnsiString GetContentType() = 0;
```

Description

GetContentType is the protected read implementation for the ContentType (see page 15076) property.

In TAbstractWebRequestFile (see page 15073), GetContentType is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the ContentType (see page 15076) property.

See Also

ContentType (see page 15076)

77.1.7.2.2 TAbstractWebRequestFile.GetFieldName Method

Returns the value of the FieldName (see page 15077) property.

Pascal

```
function GetFieldName: string; virtual; abstract;
```

C++

```
virtual __fastcall AnsiString GetFieldName() = 0;
```

Description

GetFieldName is the protected read implementation for the FieldName (see page 15077) property.

In TAbstractWebRequestFile (see page 15073), GetFieldName is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the FieldName (see page 15077) property.

See Also

FieldName (see page 15077)

77.1.7.2.3 TAbstractWebRequestFile.GetFileName Method

Returns the value of the FileName (see page 15077) property.

Pascal

```
function GetFileName: string; virtual; abstract;
```

C++

```
virtual __fastcall AnsiString GetFileName() = 0;
```

Description

GetFileName is the protected read implementation for the FileName (see page 15077) property.

In TAbstractWebRequestFile (see page 15073), GetFileName is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the FileName (see page 15077) property.

See Also

FileName (see page 15077)

77.1.7.2.4 TAbstractWebRequestFile.GetStream Method

Returns the value of the Stream (see page 15077) property.

Pascal

```
function GetStream: TStream; virtual; abstract;
```

C++

```
virtual __fastcall TStream GetStream() = 0;
```

Description

GetStream is the protected read implementation for the Stream (see page 15077) property.

In TAbstractWebRequestFile (see page 15073), GetStream is abstract or, in C++ terminology, pure virtual, meaning it has no implementation. Descendant classes must override this method to provide an implementation for the Stream (see page 15077) property.

See Also

Stream (see page 15077)

77.1.7.3 TAbstractWebRequestFile Properties

The properties of the TAbstractWebRequestFile class are listed here.

Public Properties

	Name	Description
R	ContentType (see page 15076)	Describes how the file data is encoded.
R	FieldName (see page 15077)	Indicates the name of the adapter field whose value is the contents of the file.
R	FileName (see page 15077)	Indicates the name of the uploaded file.
R	Stream (see page 15077)	Provides access to the contents of the uploaded file.

77.1.7.3.1 TAbstractWebRequestFile.ContentType Property

Describes how the file data is encoded.

Pascal

```
property ContentType: string;
```

C++

```
__property AnsiString ContentType;
```

Description

Read ContentType to determine the format of the data you can read from the Stream (see page 15077) property. ContentType is a string of the format Type/SubType, which names the MIME type and subtype used to encode the file contents.

See Also

Stream (see page 15077)

77.1.7.3.2 TAbstractWebRequestFile.FieldName Property

Indicates the name of the adapter field whose value is the contents of the file.

Pascal

```
property FieldName: string;
```

C++

```
__property AnsiString FieldName;
```

Description

Read FieldName to identify the adapter field for which this file was uploaded. This is the same as the FieldName property of the adapter field object.

See Also

FieldName (see page 23944)

FileName (see page 15077)

77.1.7.3.3 TAbstractWebRequestFile.FileName Property

Indicates the name of the uploaded file.

Pascal

```
property FileName: string;
```

C++

```
__property AnsiString FileName;
```

Description

Read FileName to obtain the name of the uploaded file.

See Also

Stream (see page 15077)

77.1.7.3.4 TAbstractWebRequestFile.Stream Property

Provides access to the contents of the uploaded file.

Pascal

```
property Stream: TStream;
```

C++

```
__property TStream Stream;
```

Description

Use Stream to read the content of the uploaded file. Call the Read method of this stream to read the file contents.

Note: The ContentType (see page 15076) property indicates the format used to encode the file contents that you read from Stream.

See Also

FileName (see page 15077)

ContentType (see page 15076)

Read (see page 2982)

77.1.8 TAbstractWebRequestFiles Class

TAbstractWebRequestFiles is a collection of TAbstractWebRequestFile (see page 15073) objects.

Class Hierarchy

Pascal

```
TAbstractWebRequestFiles = class(TObject);
```

C++

```
class TAbstractWebRequestFiles : public TObject;
```

File

HTTPApp

Description

TAbstractWebRequestFiles is the base class for objects that manage a set of Web request files objects (TAbstractWebRequestFile (see page 15073) descendants). Each Web request file object in the collection describes an uploaded file that was extracted from the current HTTP request object.

TAbstractWebRequestFiles should not be instantiated. The methods that implement its properties are abstract or, in C++ terminology, pure virtual. Instead, applications use a TAbstractWebRequestFiles descendant such as TWebRequestFiles (which is included in WebSnap).

Note: Support for uploaded files is only included in WebSnap. For other Web server applications, this class exists only as a placeholder for the Files property on TWebRequest (see page 15161).

See Also

TAbstractWebRequestFile (see page 15073)

TWebRequest (see page 15161)

TUpdateFileList (see page 24550)

TWebRequestFiles (see page 18700)

77.1.8.1 TAbstractWebRequestFiles Members

The following tables list the members exposed by TAbstractWebRequestFiles.

Protected Methods

	Name	Description
	GetCount (see page 15080)	Returns the value of the Count (see page 15081) property.
	GetItem (see page 15080)	Returns the value of the Items (see page 15081) property.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
