	OnEndDrag (see page 21656)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 21657)	Occurs when a control receives the input focus.
	OnExit (see page 21660)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 21661)	Occurs when a user presses any key while the control has focus.

	OnKeyPress (see page 21664)	Occurs when a key is pressed.
	OnKeyUp (see page 21665)	Occurs when the user releases a key that has been pressed.
	OnMeasureItem (see page 21667)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.
	OnMouseActivate (see page 21668)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 21669)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 21671)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 21672)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 21672)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 21674)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 21676)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 21677)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 21611)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 21615)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 21615)	Determines whether the user can give focus to items by typing in the list.
	AutoCompleteDelay (see page 21615)	Specifies the delay between a key press and an attempt to autocomplete the field.
	BevelEdges (see page 21616)	Specifies which edges of the control are beveled.
	BevelInner (see page 21616)	Specifies the cut of the inner bevel.
	BevelKind (see page 21617)	Specifies the control's bevel style.
	BevelOuter (see page 21617)	Specifies the cut of the outer bevel.
	BevelWidth (see page 21617)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 21618)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 21618)	Determines whether the list box has a border.
	Color (see page 21619)	Specifies the background color of the control.
	Columns (see page 21620)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 21620)	Specifies the size constraints for the control.
	Ctl3D (see page 21621)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DragCursor (see page 21621)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 21621)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 21622)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 21623)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExtendedSelect (see page 21624)	Makes list item multi-select operate with Shift and CTRL keys.
	Font (see page 21624)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	ImeMode (see page 21625)	Determines the behavior of the input method editor (IME).
	ImeName (see page 21626)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 21627)	Determines whether the list box displays the partial items.

	ItemHeight (see page 21627)	Specifies the height in pixels of an item in an owner-draw list box.
	Items (see page 21628)	Contains the strings that appear in the list box.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	MultiSelect (see page 21630)	Specifies whether the user can select more than one item.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentBiDiMode (see page 21631)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 21631)	Determines where a control looks for its color information.
	ParentCtl3D (see page 21631)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 21632)	Determines where a control looks for its font information.
	ParentShowHint (see page 21632)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 21633)	Identifies the pop-up menu associated with the control.
	ScrollWidth (see page 21637)	Specifies the width, in pixels, by which the list box can scroll horizontally.
	ShowHint (see page 21638)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Sorted (see page 21639)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 21641)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabOrder (see page 21641)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 21642)	Determines if the user can tab to a control.
	TabWidth (see page 21642)	Specifies the size of the tabs in the list box.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 21643)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

154.1.19.2 TListBox Properties

The properties of the TListBox class are listed here.

Published Properties

	Name	Description
	Align (see page 21611)	Determines how the control aligns within its container (parent control).
	Anchors (see page 21615)	Specifies how the control is anchored to its parent.
	AutoComplete (see page 21615)	Determines whether the user can give focus to items by typing in the list.
	AutoCompleteDelay (see page 21615)	Specifies the delay between a key press and an attempt to autocomplete the field.
	BevelEdges (see page 21616)	Specifies which edges of the control are beveled.
	BevelInner (see page 21616)	Specifies the cut of the inner bevel.
	BevelKind (see page 21617)	Specifies the control's bevel style.
	BevelOuter (see page 21617)	Specifies the cut of the outer bevel.
	BevelWidth (see page 21617)	Specifies the width of the inner and outer bevels.
	BiDiMode (see page 21618)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 21618)	Determines whether the list box has a border.
	Color (see page 21619)	Specifies the background color of the control.
	Columns (see page 21620)	Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.
	Constraints (see page 21620)	Specifies the size constraints for the control.
	Ctl3D (see page 21621)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DragCursor (see page 21621)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 21621)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 21622)	Determines how the control initiates drag-and-drop or drag-and-dock operations.

	Enabled (see page 21623)	Controls whether the control responds to mouse, keyboard, and timer events.
	ExtendedSelect (see page 21624)	Makes list item multi-select operate with Shift and CTRL keys.
	Font (see page 21624)	Controls the attributes of text written on or in the control.
	ImeMode (see page 21625)	Determines the behavior of the input method editor (IME).
	ImeName (see page 21626)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IntegralHeight (see page 21627)	Determines whether the list box displays the partial items.
	ItemHeight (see page 21627)	Specifies the height in pixels of an item in an owner-draw list box.
	Items (see page 21628)	Contains the strings that appear in the list box.
	MultiSelect (see page 21630)	Specifies whether the user can select more than one item.
	ParentBiDiMode (see page 21631)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 21631)	Determines where a control looks for its color information.
	ParentCtl3D (see page 21631)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 21632)	Determines where a control looks for its font information.
	ParentShowHint (see page 21632)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 21633)	Identifies the pop-up menu associated with the control.
	ScrollWidth (see page 21637)	Specifies the width, in pixels, by which the list box can scroll horizontally.
	ShowHint (see page 21638)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Sorted (see page 21639)	Specifies whether the items in a list box are arranged alphabetically.
	Style (see page 21641)	Determines whether the list box is standard or owner-draw and whether it is virtual.
	TabOrder (see page 21641)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 21642)	Determines if the user can tab to a control.
	TabWidth (see page 21642)	Specifies the size of the tabs in the list box.
	Visible (see page 21643)	Determines whether the component appears onscreen.

154.1.19.2.1 TListBox.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of

the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
```

```
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{

    begin
      pts[i].Free;
    end;
    PageControl1.Free;
  end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

154.1.19.2.2 TListBox.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

154.1.19.2.3 TListBox.AutoComplete Property

Determines whether the user can give focus to items by typing in the list.

Pascal

```
property AutoComplete: Boolean;
```

C++

```
__property Boolean AutoComplete;
```

Description

Use AutoComplete to specify whether the list box automatically updates the ItemIndex property in response to user keystrokes. When AutoComplete is true, the item with focus changes to the first item that begins with the sequence of characters that the user typed. As the user types more characters, ItemIndex may change to a later item because the string to match becomes longer.

See Also

ItemIndex

154.1.19.2.4 TListBox.AutoCompleteDelay Property

Specifies the delay between a key press and an attempt to autocomplete the field.

Pascal

```
property AutoCompleteDelay: Cardinal;
```

C++

```
__property unsigned AutoCompleteDelay;
```

Description

Specifies the delay in milliseconds between a key press and an attempt to autocomplete the field. Autocomplete will position to matching list values as you type, sometimes saving you keystrokes.

AutoCompleteDelay is only in effect when the AutoComplete (see page 21615) is true.

See Also

AutoComplete (see page 21615)

154.1.19.2.5 TListBox.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

154.1.19.2.6 TListBox.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

154.1.19.2.7 TListBox.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

154.1.19.2.8 TListBox.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelWidth (see page 6194)

154.1.19.2.9 TListBox.BevelWidth Property

Specifies the width of the inner and outer bevels.

Pascal

```
property BevelWidth: TBevelWidth;
```

C++

```
__property TBevelWidth BevelWidth;
```

Description

Use BevelWidth to specify the width, in pixels, of the inner and outer bevels.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelOuter (see page 6194)

154.1.19.2.10 TListBox.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

154.1.19.2.11 TListBox.BorderStyle Property

Determines whether the list box has a border.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to change the appearance of the outer boundary of the list box control. A list box can have a single border (bsSingle) or no visible border (bsNone).

See Also

Ctl3D (see page 6198)

154.1.19.2.12 TListBox.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

ParentColor (see page 5834)

154.1.19.2.13 TListBox.Columns Property

Specifies the number of columns, in a multi-column list box, that are visible without having to scroll.

Pascal

```
property Columns: Integer;
```

C++

```
__property int Columns;
```

Description

Use Columns to specify the number of columns, in a multi-column list box, that are visible without having to use the horizontal scroll bar.

Multi-column list boxes have a horizontal scroll bar that allows users to view multiple columns as they wrap. The default value for Columns is 0, meaning that the list box is not multi-column. That is, users can scroll only vertically and the list of items will not wrap.

For Columns values greater than 0, multiple columns accommodate the items as they wrap beyond the bottom of the list box. The Columns property specifies the number of columns that are visible without having to horizontally scroll the list box.

The width of each column depends upon both the Width property and the number of Columns.

See Also

ItemHeight (see page 21347)

Width (see page 5849)

154.1.19.2.14 TListBox.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

154.1.19.2.15 TListBox.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

154.1.19.2.16 TListBox.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

154.1.19.2.17 TListBox.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

154.1.19.2.18 TListBox.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
```

```
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

Arranging the Order of Persistent Columns

154.1.19.2.19 TListBox.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

154.1.19.2.20 TListBox.ExtendedSelect Property

Makes list item multi-select operate with Shift and CTRL keys.

Pascal

```
property ExtendedSelect: Boolean;
```

C++

```
__property Boolean ExtendedSelect;
```

Description

ExtendedSelect only has effect when the MultiSelect (see page 21630) is true.

When ExtendedSelect is true, the Shift key (in conjunction with the left mouse button, or arrow keys) is used to select a contiguous sequence of list items. And the Ctrl key is used (in conjunction with the left mouse buttton) to select non-contiguous list items.

When ExtendedSelect is false, Multi-Select operates very differently. The Shift and Ctrl keys are not recognised. List items are always selected individually in any sequence. Reselecting a selected list item will deselect it. Use the arrow and spacebar keys, or the left mouse button to make selections.

See Also

MultiSelect (see page 21630)

154.1.19.2.21 TListBox.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

154.1.19.2.22 TListBox.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode: TImeMode;
```

C++

```
__property TImeMode ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language

characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the control already has input focus, call the SetIme method.

See Also

ImeName (see page 6208)

ResetIme (see page 6174)

ResetImeComposition (see page 6175)

SetIme (see page 6181)

SetImeCompositionWindow (see page 6181)

154.1.19.2.23 TListBox.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName: TImeName;
```

C++

```
__property TImeName ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

See Also

ImeMode (see page 6207)

ResetIme (see page 6174)

SetIme (see page 6181)

DefaultIme (see page 14216)

Imes (see page 14227)

154.1.19.2.24 TListBox.IntegralHeight Property

Determines whether the list box displays the partial items.

Pascal

```
property IntegralHeight: Boolean;
```

C++

```
__property Boolean IntegralHeight;
```

Description

IntegralHeight controls the height of the list box itself.

When IntegralHeight is true, and the Style property is lsOwnerDrawFixed, the list box height will always be a multiple of the ItemHeight property value. In this case, items will never be partially displayed.

If IntegralHeight is false, the list box height can be set to any value, but the last item may not be fully displayed.

If the Style property value of the list box is lbOwnerDrawVariable, setting the IntegralHeight property to true has no effect.

See Also

ItemHeight (see page 21347)

Items (see page 21348)

Style (see page 21354)

Using TDBListBox and TDBComboBox

154.1.19.2.25 TListBox.ItemHeight Property

Specifies the height in pixels of an item in an owner-draw list box.

Pascal

```
property ItemHeight: Integer;
```

C++

```
__property int ItemHeight;
```

Description

Use ItemHeight to control the height of an item in a list box when the Style property is lbOwnerDrawFixed. The ItemHeight property can also affect the height of the list box itself. When the IntegralHeight property is true, the height of the list box is always an increment of the ItemHeight value.

If the Style property is lbStandard or lbOwnerDrawVariable, the value of ItemHeight is ignored.

See Also

DrawItem (see page 21328)

IntegralHeight (see page 21347)

Items (see page 21348)

Style (see page 21354)

Using TDBListBox and TDBComboBox

154.1.19.2.26 TListBox.Items Property

Contains the strings that appear in the list box.

Pascal

```
property Items: TStrings;
```

C++

```
__property TStrings Items;
```

Description

Use Items to add, insert, delete and move items. By default, the items in a list box are of type TStrings. Use this item type to access its methods or properties to manipulate the items in the list.

For example, the following code adds the text in the edit box to the list box as an item:

```
ListBox1.Items.Add(Edit1.Text); {Delphi }
ListBox1->Items->Add(Edit1->Text); // C++
```

C++ Examples:

```
/*
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Continue will continue listing
file sizes in a multiple selection that includes the deleted
file.  Break will stop.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
*/
#include <stdio.h>     // for FILE, fopen, fstat, fileno, fread and fclose
#include <sys\stat.h>  // for fstat and the stat struct

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < FileListBox1->Items->Count; i++)
  {
    if (FileListBox1->Selected[i])
    {
      if (!FileExists(FileListBox1->Items->Strings[i]))
      {
        MessageBeep(0);
        if (Application->MessageBox(
          AnsiString("File " + FileListBox1->Items->Strings[i] + "not found").c_str(),
          NULL,
          MB_OKCANCEL) == IDCANCEL)
          break;
        else
          continue;
      }
      FILE *F = fopen(FileListBox1->Items->Strings[i].c_str(),"r");
      struct stat statbuf;
      fstat(fileno(F), &statbuf);
      ListBox1->Items->Add(
          FileListBox1->Items->Strings[i] + ": " + IntToStr(statbuf.st_size));
      fclose(F);
    }
```

```
  }
}
/*
This example uses a list box and a button on a form. Use the
Items property editor in the Object Inspector to enter a
list of strings in the list box. When the application runs
and the button is clicked, the strings in the list box
become uppercase.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int I = 0; I < ListBox1->Items->Count; I++)
    ListBox1->Items->Strings[I] = UpperCase(ListBox1->Items->Strings[I]);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");
}
```

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File;
  i, filehandle: Integer;
begin
  for i := 0 to (FileListBox1.Items.Count - 1) do begin
  try
    if FileListBox1.Selected[i] then
    begin
      if not FileExists(FileListBox1.Items.Strings[i]) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' not found', mtError, [mbOk], 0);
        Continue;
      end;
      filehandle:=  FileOpen(FileListBox1.Items.Strings[i], 1);
      if (filehandle = -1) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' cannot be opened with access mode 1.', mtError, [mbOk], 0);
        Continue;
      end
      else
        FileClose(filehandle);

      AssignFile(F, FileListBox1.Items.Strings[i]);
      Reset(F, 1);
      ListBox1.Items.Add(
        FileListBox1.Items.Strings[i] + ': ' + IntToStr(FileSize(F)));
      CloseFile(F);
    end;
   finally
```

```
    { do something here }
    end;
  end;
end;
{
This example uses a list box and a button on a form. Use the
Items property editor in the Object Inspector to enter a
list of strings in the list box. When the application runs
and the button is clicked, the strings in the list box
become uppercase.
}
procedure TForm1.Button1Click(Sender: TObject);

OnDrawItem (see page 21358)

Selected (see page 21351)

TStrings (see page 3029)

154.1.19.2.27 TListBox.MultiSelect Property

Specifies whether the user can select more than one item.

Pascal

```
property MultiSelect: Boolean;
```

C++

```
__property Boolean MultiSelect;
```

Description

Use MultiSelect to specify whether the user can select more than one item. When MultiSelect is true, the user can select multiple items in the control, and the SelCount property indicates the number of selected items. When MultiSelect is false, the user can only select one item, which is indicated by the ItemIndex property.

Note: To implement the MultiSelect property in a TCustomMultiSelectListControl descendant, override the protected SetMultiSelect method.

See Also

SelCount (see page 5957)

ItemIndex (see page 5944)

154.1.19.2.28 TListBox.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

154.1.19.2.29 TListBox.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

154.1.19.2.30 TListBox.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

154.1.19.2.31 TListBox.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

154.1.19.2.32 TListBox.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

154.1.19.2.33 TListBox.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
```

```
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

154.1.19.2.34 TListBox.ScrollWidth Property

Specifies the width, in pixels, by which the list box can scroll horizontally.

Pascal

```
property ScrollWidth: Integer;
```

C++

```
__property int ScrollWidth;
```

Description

Use ScrollWidth to get or set the logical width of the list box. When ScrollWidth is greater than the client width of the list box, the list box gets a horizontal scroll bar. When ScrollWidth is less than or equal to ClientWidth, the horizontal scroll bar disappears.

See Also

Columns (see page 21346)

ClientWidth (see page 5811)

154.1.19.2.35 TListBox.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
```

```
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

154.1.19.2.36 TListBox.Sorted Property

Specifies whether the items in a list box are arranged alphabetically.

Pascal

```
property Sorted: Boolean;
```

C++

```
__property Boolean Sorted;
```

Description

Use Sorted to sort the items by setting its value to true. If Sorted is false, the items are unsorted. When Sorted is true, items are automatically added or inserted into the list box in alphabetical order.

Note: Sorted has no effect if Listbox's style is lbVirtual or lbVirtualOwnerDraw

C++ Examples:

```
/*
This example uses an edit box, a list box, and two buttons
on a form. The buttons are named Add and Sort. When the user
clicks the Add button, the text in the edit box is added to
the list in the list box. Before the user clicks the sort
button, any new items are added to the end of the list.
After the user clicks the Sort button, the list in the list
box is sorted and remains sorted, even if additional strings
are added.  If the user clicks the sort button again, the
list box remains sorted, but any new strings are again added
to the end of the list.
*/

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");
}

void __fastcall TForm1::AddClick(TObject *Sender)
{
  ListBox1->Items->Add(Edit1->Text);
}

void __fastcall TForm1::SortClick(TObject *Sender)
{
  ListBox1->Sorted = True;
}
```

Delphi Examples:

```
{
This example uses an edit box, a list box, and two buttons
on a form. The buttons are named Add and Sort. When the user
clicks the Add button, the text in the edit box is added to
the list in the list box. Before the user clicks the sort
button, any new items are added to the end of the list.
After the user clicks the Sort button, the list in the list
box is sorted and remains sorted, even if additional strings
are added.  If the user clicks the sort button again, the
list box remains sorted, but any new strings are again added
to the end of the list.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

procedure TForm1.AddClick(Sender: TObject);
begin
  ListBox1.Items.Add(Edit1.Text);
end;

procedure TForm1.SortClick(Sender: TObject);
begin
  ListBox1.Sorted := True;
end;
```

See Also

Items (see page 21348)

Style (see page 21354)

154.1.19.2.37 TListBox.Style Property

Determines whether the list box is standard or owner-draw and whether it is virtual.

Pascal

```
property Style: TListBoxStyle;
```

C++

```
__property TListBoxStyle Style;
```

Description

Use Style to specify whether the list box is a standard list box that displays text strings, or an owner-draw list box that can display graphical images. Owner-draw list boxes let you display items in some nonstandard way. In this case, you must write the code to paint items in the list box.

In addition, Style controls whether the list box is virtual, which means that items are supplied dynamically using event handlers. By default, Style is lbStandard, meaning that the list box is not virtual and it displays each item as a string.

154.1.19.2.38 TListBox.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

154.1.19.2.39 TListBox.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

154.1.19.2.40 TListBox.TabWidth Property

Specifies the size of the tabs in the list box.

Pascal

```
property TabWidth: Integer;
```

C++

```
__property int TabWidth;
```

Description

Set TabWidth to control the number of dialog base units displayed for each tab character that appears in the strings of a list box.

If TabWidth is set to 0, which is the default setting, the tabs default to the width specified by Windows, which is two dialog base units.

154.1.19.2.41 TListBox.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;
```

```
procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

154.1.19.3 TListBox Events

The events of the TListBox class are listed here.

Published Events

	Name	Description
	OnClick (see page 21645)	Occurs when the user clicks the control.
	OnContextPopup (see page 21647)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnData (see page 21647)	Occurs when a virtual list box needs to supply the text of an item.
	OnDataFind (see page 21648)	Occurs when a virtual list box needs to identify the index of an item given its text.
	OnDataObject (see page 21648)	Occurs when a virtual list box needs to supply the object associated with an item.
	OnDblClick (see page 21649)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 21649)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 21651)	Occurs when the user drags an object over a control.
	OnDrawItem (see page 21654)	Occurs when an item in an owner-draw list box needs to be redisplayed.
	OnEndDock (see page 21656)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 21656)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 21657)	Occurs when a control receives the input focus.
	OnExit (see page 21660)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 21661)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 21664)	Occurs when a key is pressed.
	OnKeyUp (see page 21665)	Occurs when the user releases a key that has been pressed.

	OnMeasureItem (see page 21667)	Occurs when the application needs to redisplay an item in a variable height owner-draw list box.
	OnMouseActivate (see page 21668)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 21669)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 21671)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 21672)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 21672)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 21674)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 21676)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 21677)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

154.1.19.3.1 TListBox.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
```

```
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;

154.1.19.3.2 TListBox.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

154.1.19.3.3 TListBox.OnData Event

Occurs when a virtual list box needs to supply the text of an item.

Pascal

```
property OnData: TLBGetDataEvent;
```

C++

```
__property TLBGetDataEvent OnData;
```

Description

You must supply an OnData event handler to dynamically supply the items in the list box when the Style property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnDataObject (see page 21358)

Style (see page 21354)

Count (see page 21346)

154.1.19.3.4 TListBox.OnDataFind Event

Occurs when a virtual list box needs to identify the index of an item given its text.

Pascal

```
property OnDataFind: TLBFindDataEvent;
```

C++

```
__property TLBFindDataEvent OnDataFind;
```

Description

You must supply an OnDataFind event handler to dynamically provide the mapping from list item to index when the Style property is lbVirtual or lbVirtualOwnerDraw.

See Also

OnData (see page 21357)

OnDataObject (see page 21358)

Style (see page 21354)

Count (see page 21346)

154.1.19.3.5 TListBox.OnDataObject Event

Occurs when a virtual list box needs to supply the object associated with an item.

Pascal

```
property OnDataObject: TLBGetDataObjectEvent;
```

C++

```
__property TLBGetDataObjectEvent OnDataObject;
```

Description

Supply an OnDataObject event handler to dynamically provide objects associated with the items in a virtual list box.

See Also

154.1.19.3.6 TListBox.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

154.1.19.3.7 TListBox.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
```

```
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
```

```
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

154.1.19.3.8 TListBox.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
```

```
    Accept := False;
    if (Source is TLabel) and (State = dsDragEnter) then
      (Source as TLabel).EndDrag(False);
  end;
  {
  This code comes from an application that contains a list box
  and three labels, each with a different font and color.  The
  DragMode property for each of the labels is dmAutomatic.
  The user can select a label and drag it to a list box and
  drop it. When the label is dropped, the items in the list
  box assume the color and font of the dropped label.
  }

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

154.1.19.3.9 TListBox.OnDrawItem Event

Occurs when an item in an owner-draw list box needs to be redisplayed.

Pascal

```
property OnDrawItem: TDrawItemEvent;
```

C++

```
__property TDrawItemEvent OnDrawItem;
```

Description

Use OnDrawItem to write a handler for drawing of the items in list boxes with the Style values lbOwnerDrawFixed, lbOwnerDrawVariable, or lbVirtualOwnerDraw. OnDrawItem occurs when the list box needs to display an item. OnDrawItem occurs only for owner-draw list boxes.

The size of the rectangle that contains the item is determined either by the ItemHeight property for fixed owner-draw list boxes or by the response to the OnMeasureItem event for variable owner-draw list boxes.

C++ Examples:

```
/*
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MyList = new TStringList;
  bitmap0 = new Graphics::TBitmap;
  bitmap1 = new Graphics::TBitmap;
  bitmap2 = new Graphics::TBitmap;
//  MyList->Add("Animal");
//  MyList->Add("Flowers");
//  MyList->Add("Butterfly");
//  ListBox1.Items->AddStrings(MyList);

  ImageList1->GetBitmap(0, bitmap0);
  ListBox1->Items->AddObject("Flowers", bitmap0);
  ImageList1->GetBitmap(1, bitmap1);
  ListBox1->Items->AddObject("Animal", bitmap1);
  ImageList1->GetBitmap(2, bitmap2);
  ListBox1->Items->AddObject("Butterfly", bitmap2);
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item's bitmap
  int     Offset = 2;   // default text offset width
  // note that we draw on the listbox's canvas, not on the form
  TCanvas *pCanvas = ((TListBox *)Control)->Canvas;
  pCanvas->FillRect(Rect); // clear the rectangle
  pBitmap = (Graphics::TBitmap *)((TListBox *)Control)->Items->Objects[Index];
  if (pBitmap)
  {
    pCanvas->BrushCopy(Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
pBitmap, Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
```

```
    Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
  }
  // display the text
  pCanvas->TextOut(Rect.Left + Offset, Rect.Top, ((TListBox *)Control)->Items->Strings[Index]);
}
```

Delphi Examples:

```
{
Here is a typical handler for an OnDrawItem event. In the
example, a list box with the lbOwnerDrawFixed style draws a
bitmap to the left of each string.
Select the TListBox and set the ItemHeight property to 32.
Select the ImageList and set the Layout Height and Width to
32.  Double click on the ImageList to load the images.  Be
sure to load in the correct order, logo2, Sunflower,
butterfly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  MyList := TStringList.Create;
  bitmap0 := TBitmap.Create;
  bitmap1 := TBitmap.Create;
  bitmap2 := TBitmap.Create;
//  MyList.Add('Animal');
//  MyList.Add('Flowers');
//  MyList.Add('Butterfly');
//  ListBox1.Items.AddStrings(MyList);

  ImageList1.GetBitmap(0, bitmap0);
  ListBox1.Items.AddObject('Flowers', bitmap0);
  ImageList1.GetBitmap(1, bitmap1);
  ListBox1.Items.AddObject('Animal', bitmap1);
  ImageList1.GetBitmap(2, bitmap2);
  ListBox1.Items.AddObject('Butterfly', bitmap2);
end;

procedure TForm1.ListBox1DrawItem(Control: TWinControl; Index: Integer; Rect:TRect; State:
TOwnerDrawState);
var
  Bitmap: TBitmap;      { temporary variable for the item's bitmap }
  Offset: Integer;      { text offset width }
begin
  Bitmap := TBitmap.Create;
  with (Control as TListBox).Canvas do  { draw on control canvas, not on the form }
  begin
    FillRect(Rect);       { clear the rectangle }
    Offset := 2;          { provide default offset }
    Bitmap := TBitmap((Control as TListBox).Items.Objects[Index]);  { get the bitmap }
    if Bitmap <> nil then
    begin
      BrushCopy(
        Bounds(Rect.Left + Offset, Rect.Top, Bitmap.Width, Bitmap.Height),
        Bitmap,
        Bounds(0, 0, Bitmap.Width, Bitmap.Height),
        clRed);  {render bitmap}
      Offset := Bitmap.width + 6;    { add four pixels between bitmap and text}
    end;
    TextOut(Rect.Left + Offset, Rect.Top, (Control as TListBox).Items[Index])  { display the
text }
  end;
end;
```

154.1.19.3.10 TListBox.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

OnStartDock (see page 5871)

154.1.19.3.11 TListBox.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
```

```
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

154.1.19.3.12 TListBox.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
```

```
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

154.1.19.3.13 TListBox.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also

154.1.19.3.14 TListBox.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the

OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;

154.1.19.3.15 TListBox.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
```

```
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

154.1.19.3.16 TListBox.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form’s color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
```

```
      else
        ComboBox1->Text = "KeyDown";
      Form1->Refresh();
      Memo1->Lines->Add(ComboBox1->Text);
    }
  }

  void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
  {
    if (Key == VK_F1)
    {
      Form1->Color = FormColor;
      if (ComboBox1->Text == "KeyUp")
        ComboBox1->Text = "KeyUp2";
      else
        ComboBox1->Text = "KeyUp";
      Form1->Refresh();
      Memo1->Lines->Add(ComboBox1->Text);
    }
  }
```

Delphi Examples:

```
  {
  This example changes a form’s color to aqua when the user
  presses the F1 key, even when a control on the form has the
  focus. When the user releases the key, the form returns to
  its original color.  Set the KeyPreview on the form to True.
  Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
  event to FormKeyUp.  Set the KeyPreview on the form to True.
  }
  var
    FormColor: TColor;
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    KeyPreview := True;
    FormColor := Form1.Color;
  end;

  procedure TForm1.FormKeyDown(
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := clAqua;

154.1.19.3.17 TListBox.OnMeasureItem Event

Occurs when the application needs to redisplay an item in a variable height owner-draw list box.

Pascal

```
property OnMeasureItem: TMeasureItemEvent;
```

C++

```
__property TMeasureItemEvent OnMeasureItem;
```

Description

Use OnMeasureItem to write a handler to measure items to be drawn in a list box with a Style property value of lbOwnerDrawVariable.

OnMeasureItem is of type TMeasureItemEvent which contains three parameters describing the item to measure:

Control, specifying the control containing the item.

Index, specifying the index of the item in the control.

Height, specifying the height of the item.

The Index parameter identifies the position of the item in the list box.

The Height parameter should specify the height in pixels that the given item will occupy in the control. The Height parameter is passed by reference (a var parameter), which initially contains the default height of the item or the height of the item text in the control's font. The handler can set Height to a value appropriate to the contents of the item, such as the height of a graphical image to be displayed within the item.

After the OnMeasureItem event occurs, the OnDrawItem event occurs, rendering the item with the measured size.

C++ Examples:

```
/*
Here is a typical handler for an OnMeasureItem event. The
example assumes that a variable owner-draw list box already
has bitmaps associated with each of its strings. It sets the
height of the item to the height of the associated bitmap if
that height is greater than the default height
(ListBox1.ItemHeight).  Note that TWinControl can also be
used in place of TWidgetControl on Windows.
*/
void __fastcall TForm1::ListBox1MeasureItem(TWinControl *Control, int Index,
      int &Height)
{
  Graphics::TBitmap *bitmap = (Graphics::TBitmap *)((TListBox
*)Control)->Items->Objects[Index];
  if (bitmap && bitmap->Height > Height)
    Height = bitmap->Height;
}

void __fastcall TForm1::ListBox1DrawItem(TWinControl *Control, int Index,
      TRect &Rect, TOwnerDrawState State)
{
  Graphics::TBitmap *pBitmap; // temporary variable for item’s bitmap
  int     Offset = 2;   // default text offset width
```

```
    // note that we draw on the listbox's canvas, not on the form
    TCanvas *pCanvas = ((TListBox *)Control)->Canvas;
    pCanvas->FillRect(Rect); // clear the rectangle
    pBitmap = (Graphics::TBitmap *)((TListBox *)Control)->Items->Objects[Index];
    if (pBitmap)
    {
      pCanvas->BrushCopy(Bounds(Rect.Left + Offset, Rect.Top, pBitmap->Width, pBitmap->Height),
  pBitmap, Bounds(0, 0, pBitmap->Width, pBitmap->Height), clRed); // render bitmap
      Offset += pBitmap->Width + 4;   // add four pixels between bitmap and text
    }
    // display the text
    pCanvas->TextOut(Rect.Left + Offset, Rect.Top, ((TListBox *)Control)->Items->Strings[Index]);
  }

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    Graphics::TBitmap *bitmap0 = new Graphics::TBitmap;
    Graphics::TBitmap *bitmap1 = new Graphics::TBitmap;
    Graphics::TBitmap *bitmap2 = new Graphics::TBitmap;
    bitmap0->LoadFromFile("../littleB_64.bmp");
  //  ImageList1->GetBitmap(0, bitmap0);
    ListBox1->Items->AddObject("Butterfly", bitmap0);
    ImageList1->GetBitmap(3, bitmap1);
    ListBox1->Items->AddObject("Animal", bitmap1); // no bitmap, see if it leaves this height at
  64.
    ImageList1->GetBitmap(4, bitmap2);
    ListBox1->Items->AddObject("Sunflower", bitmap2); // no bitmap, see if it leaves this height
  at 64.

  }
```

154.1.19.3.18 TListBox.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is

over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture (see page 5831)

154.1.19.3.19 TListBox.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
```

```
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
```

```
  location of the mouse pointer when the user pressed and
  released the mouse button.  While the user drags the mouse,
  the location of the top, left, bottom, and right sides of
  the rectangle are displayed in the status bar.
  }
  procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
  Y: Integer);
  begin
    StartX := X;
    StartY := Y;
  end;

  procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
  Integer);
  begin
    Form1.Canvas.Rectangle(StartX, StartY, X, Y);
    StatusBar1.Panels[0].Text := '';
    StatusBar1.Panels[1].Text := '';
    StatusBar1.Panels[2].Text := '';
    StatusBar1.Panels[3].Text := '';
  end;

  procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
  begin
    if ssLeft in Shift then { make sure button is down }
    begin
      if Y > StartY then
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
        end
      else
        begin
        StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
        StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
        end;
      if X > StartX then
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

154.1.19.3.20 TListBox.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

154.1.19.3.21 TListBox.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

154.1.19.3.22 TListBox.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

154.1.19.3.23 TListBox.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
```

```
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

Responding to a Mouse-up Action

154.1.19.3.24 TListBox.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
  property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

154.1.19.3.25 TListBox.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

154.1.20 TMemo Class

TMemo is a wrapper for a Windows multiline edit control.

Class Hierarchy

Pascal

```
TMemo = class(TCustomMemo);
```

C++

```
class TMemo : public TCustomMemo;
```

File

StdCtrls

Description

Use TMemo to put a standard Windows multiline edit control on a form. Multiline edit boxes allow the user to enter more than one line of text. They are appropriate for representing lengthy information.

TMemo implements the generic behavior introduced in TCustomMemo (see page 21362). TMemo publishes many of the properties inherited from TCustomMemo (see page 21362), but does not introduce any new behavior.

Note: Under Win 9x, there is a limit of 64k of text for this control.

154.1.20.1 TMemo Members

The following tables list the members exposed by TMemo.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.

	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Change (see page 21245)	Generates an OnChange (see page 21275) event.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateParams (see page 21248)	Initializes a window-creation parameter record passed in the Params parameter.
	CreateParams (see page 21375)	Initializes a window-creation parameter record passed in the Params parameter.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWindowHandle (see page 21248)	Creates a Windows control to represent the control.
	CreateWindowHandle (see page 21376)	Creates a window based on the window-creation parameter record.
	CreateWnd (see page 6137)	Creates the underlying window.
	CreateWnd (see page 21248)	Creates a Windows control corresponding to the edit control.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DestroyWnd (see page 21251)	Destroys the Windows control that corresponds to the edit control.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.

	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoSetMaxLength (see page 21251)	Sets the MaxLength (see page 21263) property.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetCaretPos (see page 21376)	Returns the value of the CaretPos (see page 21380) property.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSelLength (see page 21252)	Returns the SelLength (see page 21265) property.
	GetSelStart (see page 21252)	Returns the SelStart (see page 21269) property.
	GetSelText (see page 21252)	Returns the SelText (see page 21272) property.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event

	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyPress (see page 21377)	Ensures that return characters are not entered into the text when WantReturns (see page 21384) is false.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	Loaded (see page 21377)	Initializes the memo control when it is first loaded into memory.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.

	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAlignment (see page 21377)	Sets the Alignment (see page 21379) property.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetAutoSize (see page 21257)	Sets the AutoSize (see page 21260) property.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
V	SetCaretPos (see page 21378)	Sets the CaretPos (see page 21380) property.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetLines (see page 21378)	Sets the Lines (see page 21380) property.
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetScrollBars (see page 21378)	Sets the ScrollBars (see page 21381) property.
V	SetSelLength (see page 21257)	Sets the SelLength (see page 21265) property.
V	SetSelStart (see page 21257)	Sets the SelStart (see page 21269) property.
	SetWordWrap (see page 21379)	Sets the WordWrap (see page 21384) property.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.

	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSelect (see page 21260)	Determines whether all the text in the edit control is automatically selected when the control gets focus.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	AutoSize (see page 21260)	Determines whether the height of the edit control automatically resizes to accommodate the text.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	CharCase (see page 21262)	Determines the case of the text within the edit control.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	PasswordChar (see page 21265)	Indicates the character, if any, to display in place of the actual characters typed in the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 21245)	Deletes all text from the edit control.
	ClearSelection (see page 21245)	Removes the selected text from the edit control.

	ClearUndo (see page 21246)	Clears the undo buffer so that no changes to the text can be backed out.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
	CopyToClipboard (see page 21246)	Copies the selected text in the edit control to the Clipboard in CF_TEXT format.
V	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
V	Create (see page 5731)	Creates an instance of TControl (see page 5724).
V	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
V	Create (see page 21244)	Creates an instance of TCustomEdit (see page 21232).
V	Create (see page 21374)	Creates and initializes an instance of TCustomMemo (see page 21362).
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	CutToClipboard (see page 21249)	Copies the selected text to the Clipboard in CF_TEXT format and then deletes the selection.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 21250)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 21374)	Destroys an instance of TCustomMemo (see page 21362).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.

	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
V	GetControlsAlignment (see page 21376)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
V	GetSelTextBuf (see page 21253)	Copies the selected text into a buffer and returns the number of characters copied.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	PasteFromClipboard (see page 21254)	Pastes the contents of the Clipboard into edit control, replacing the current selection.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.

	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SelectAll (see page 21255)	Selects all text in the edit control.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSelTextBuf (see page 21258)	Replaces the selected text with a null-terminated string.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Undo (see page 21259)	Backs out all changes in the undo buffer.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	CanUndo (see page 21262)	Indicates whether the edit control contains changes that can be backed out.
	CaretPos (see page 21380)	Indicates the position of the caret in the client area of the memo.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.

	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
	Modified (see page 21263)	Indicates whether the user edited the text of the edit control.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	SelLength (see page 21265)	Specifies the number of characters (bytes) that are selected.
	SelStart (see page 21269)	Specifies the position of the first selected character in the text.
	SelText (see page 21272)	Specifies the selected portion of the edit control's text.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	Text (see page 21273)	Contains a text string associated with the control.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnChange (see page 21724)	Occurs when the text for the edit control may have changed.
	OnClick (see page 21725)	Occurs when the user clicks the control.
	OnContextPopup (see page 21727)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 21727)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 21728)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 21730)	Occurs when the user drags an object over a control.
	OnEndDock (see page 21732)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 21733)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 21734)	Occurs when a control receives the input focus.

	OnExit (see page 21736)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 21738)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 21741)	Occurs when a key is pressed.
	OnKeyUp (see page 21742)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 21743)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 21744)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 21747)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 21747)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 21747)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 21749)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 21752)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 21752)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 21691)	Determines how the control aligns within its container (parent control).
	Alignment (see page 21695)	Determines how the text is aligned within the memo control.
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 21695)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 21696)	Specifies which edges of the control are beveled.
	BevelInner (see page 21696)	Specifies the cut of the inner bevel.
	BevelKind (see page 21696)	Specifies the control's bevel style.
	BevelOuter (see page 21697)	Specifies the cut of the outer bevel.
	BiDiMode (see page 21697)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 21698)	Determines whether the edit control has a single line border around the client area.
	Color (see page 21698)	Specifies the background color of the control.
	Constraints (see page 21699)	Specifies the size constraints for the control.
	Ctl3D (see page 21699)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DragCursor (see page 21700)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 21700)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 21701)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 21702)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 21703)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	HideSelection (see page 21704)	Determines whether the visual indication of the selected text remains when focus shifts to another control.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	ImeMode (see page 21704)	Determines the behavior of the input method editor (IME).
	ImeName (see page 21705)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Lines (see page 21705)	Contains the individual lines of text in the memo control.
	Margins (see page 5831)	Specifies the margins for the control.

	MaxLength (see page 21706)	Specifies the maximum number of characters the user can enter into the edit control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	OEMConvert (see page 21707)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 21707)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 21708)	Determines where a control looks for its color information.
	ParentCtl3D (see page 21708)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 21709)	Determines where a control looks for its font information.
	ParentShowHint (see page 21709)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 21710)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 21714)	Determines whether the user can change the text of the edit control.
	ScrollBars (see page 21715)	Determines whether the memo control has scroll bars.
	ShowHint (see page 21717)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 21718)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 21719)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 21719)	Determines whether the component appears onscreen.
	WantReturns (see page 21721)	Determines whether the user can insert return characters into the text.
	WantTabs (see page 21721)	Determines whether the user can insert tab characters into the text.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.
	WordWrap (see page 21722)	Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

154.1.20.2 TMemo Properties

The properties of the TMemo class are listed here.

Published Properties

	Name	Description
	Align (see page 21691)	Determines how the control aligns within its container (parent control).
	Alignment (see page 21695)	Determines how the text is aligned within the memo control.
	Anchors (see page 21695)	Specifies how the control is anchored to its parent.
	BevelEdges (see page 21696)	Specifies which edges of the control are beveled.
	BevelInner (see page 21696)	Specifies the cut of the inner bevel.
	BevelKind (see page 21696)	Specifies the control's bevel style.
	BevelOuter (see page 21697)	Specifies the cut of the outer bevel.
	BiDiMode (see page 21697)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 21698)	Determines whether the edit control has a single line border around the client area.
	Color (see page 21698)	Specifies the background color of the control.
	Constraints (see page 21699)	Specifies the size constraints for the control.
	Ctl3D (see page 21699)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DragCursor (see page 21700)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 21700)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 21701)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 21702)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 21703)	Controls the attributes of text written on or in the control.
	HideSelection (see page 21704)	Determines whether the visual indication of the selected text remains when focus shifts to another control.

	ImeMode (see page 21704)	Determines the behavior of the input method editor (IME).
	ImeName (see page 21705)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	Lines (see page 21705)	Contains the individual lines of text in the memo control.
	MaxLength (see page 21706)	Specifies the maximum number of characters the user can enter into the edit control.
	OEMConvert (see page 21707)	Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.
	ParentBiDiMode (see page 21707)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 21708)	Determines where a control looks for its color information.
	ParentCtl3D (see page 21708)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 21709)	Determines where a control looks for its font information.
	ParentShowHint (see page 21709)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 21710)	Identifies the pop-up menu associated with the control.
	ReadOnly (see page 21714)	Determines whether the user can change the text of the edit control.
	ScrollBars (see page 21715)	Determines whether the memo control has scroll bars.
	ShowHint (see page 21717)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 21718)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 21719)	Determines if the user can tab to a control.
	Visible (see page 21719)	Determines whether the component appears onscreen.
	WantReturns (see page 21721)	Determines whether the user can insert return characters into the text.
	WantTabs (see page 21721)	Determines whether the user can insert tab characters into the text.
	WordWrap (see page 21722)	Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

154.1.20.2.1 TMemo.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
```

```
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
```

```
}

var
  I: Integer;

procedure TForm1.Button1Click(Sender: TObject);
var
  ProgressBar: TProgressBar;
begin
  ProgressBar := TProgressBar.Create(Self);
  with ProgressBar do
  begin
    Parent := Self;
    Align := alBottom;
  end;
end;
{
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
}
var
  PageControl1: TPageControl;
  pts: array[0..3] of TTabSheet;
const
  TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

procedure TForm1.FormCreate(Sender: TObject);
const
  colorpalette: Array[0..11] of TColor = (
    clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
    clNavy, clMaroon, clLime, clOlive, clPurple);
var
  i: Integer;
begin
  PageControl1 := TPageControl.Create(Self);
  PageControl1.Parent := Self;
  PageControl1.Align := alClient;
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i]:= TTabSheet.Create(PageControl1);
    with pts[i] do
    begin
      PageControl := PageControl1;
      Name := 'ts' + TabTitles[i];
      Caption := TabTitles[i];
      Brush.Color := colorPalette[i];
   end;
  end;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  i: Integer;
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

Parent (see page 5832)

Anchors (see page 5802)

154.1.20.2.2 TMemo.Alignment Property

Determines how the text is aligned within the memo control.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

Use Alignment to change the way the text is formatted by the memo control. Alignment can take one of the following values:

Value	Meaning
taLeftJustify	Align text to the left side of the control
taCenter	Center text horizontally in the control.
taRightJustify	Align text to the right side of the control.

See Also

SetAlignment (see page 21377)

Text (see page 5842)

Displaying and Editing Text in a Memo Control

154.1.20.2.3 TMemo.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

154.1.20.2.4 TMemo.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

154.1.20.2.5 TMemo.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

154.1.20.2.6 TMemo.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

154.1.20.2.7 TMemo.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelWidth (see page 6194)

154.1.20.2.8 TMemo.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

154.1.20.2.9 TMemo.BorderStyle Property

Determines whether the edit control has a single line border around the client area.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Use BorderStyle to affect the sharpness with which the client area of the edit control stands out. BorderStyle can have a value of either bsSingle or bsNone. If BorderStyle is bsSingle, the edit control has a single-line border around the client area. If BorderStyle is bsNone, there will be no border.

154.1.20.2.10 TMemo.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
```

```
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

154.1.20.2.11 TMemo.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

154.1.20.2.12 TMemo.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

154.1.20.2.13 TMemo.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

154.1.20.2.14 TMemo.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

154.1.20.2.15 TMemo.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
```

```
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

Arranging the Order of Persistent Columns

154.1.20.2.16 TMemo.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

154.1.20.2.17 TMemo.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;
```

```
procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

See Also

DesktopFont (see page 5818)

Displaying and Editing Text in a Memo Control

154.1.20.2.18 TMemo.HideSelection Property

Determines whether the visual indication of the selected text remains when focus shifts to another control.

Pascal

```
property HideSelection: Boolean;
```

C++

```
__property Boolean HideSelection;
```

Description

Set HideSelection to false to provide visual feedback of the selected portion of the text even when the edit control does not have focus. Set HideSelection to true to show the selection only when the edit control has focus. HideSelection does not affect the actual value of the selection, only the visual indication. Always setting HideSelection to false can make forms with many edit controls look too busy.

SelLength (see page 21265)

SelStart (see page 21269)

SelText (see page 21272)

SetSelTextBuf (see page 21258)

154.1.20.2.19 TMemo.ImeMode Property

Determines the behavior of the input method editor (IME).

Pascal

```
property ImeMode: TImeMode;
```

C++

```
__property TImeMode ImeMode;
```

Description

Set ImeMode to configure the way an IME processes user keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeMode allows a control to influence the type of conversion performed by the IME so that it is appropriate for the input expected by the control. For example, a control that only accepts numeric input might specify an ImeMode of imClose, as no conversion is necessary for numeric input.

Note: The value of ImeMode only takes effect when the control receives focus. To change the value of ImeMode when the

control already has input focus, call the SetIme method.

See Also

ImeName (see page 6208)

ResetIme (see page 6174)

ResetImeComposition (see page 6175)

SetIme (see page 6181)

SetImeCompositionWindow (see page 6181)

154.1.20.2.20 TMemo.ImeName Property

Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

Pascal

```
property ImeName: TImeName;
```

C++

```
__property TImeName ImeName;
```

Description

Set ImeName to specify which IME to use for converting keystrokes. An IME is a front-end input processor for Asian language characters. The IME hooks all keyboard input, converts it to Asian characters in a conversion window, and sends the converted characters or strings on to the application.

ImeName must specify one of the IMEs that has been installed through the Windows control panel. The property inspector provides a drop-down list of all currently installed IMEs on the system. At runtime, applications can obtain a list of currently installed IMEs from the global Screen variable.

If ImeName specifies an unavailable IME, the IME that was active when the application started is used instead. No exception is generated.

Note: The value of ImeName only takes effect when the control receives focus. To change the value of ImeName after the control has input focus, call the SetIme method.

See Also

ImeMode (see page 6207)

ResetIme (see page 6174)

SetIme (see page 6181)

DefaultIme (see page 14216)

Imes (see page 14227)

154.1.20.2.21 TMemo.Lines Property

Contains the individual lines of text in the memo control.

Pascal

```
property Lines: TStrings;
```

C++

```
__property TStrings Lines;
```

Description

Use Lines to manipulate text in an memo control on a line-by-line basis. Lines is a TStrings object, so the TStrings methods may be used for Lines to perform manipulations such as counting the lines of text, adding new lines, deleting lines, or replacing lines with new text.

To work with all the text at once, use the Text property. To manipulate individual lines of text, the Lines property works better.

Note: Although Lines is implemented as a TStrings descendant, it does not implement the support for associating objects with the strings in the list.

C++ Examples:

```
/*
This example uses a button and a memo control on a form.
When the user clicks the button, the content of the specified
file is loaded into the memo, and the fifth line of the file
is written across the top of the form.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Memo1->Lines->LoadFromFile("../readme.txt");
  Caption = Memo1->Lines->Strings[4];
}
```

Delphi Examples:

```
{
This example uses a button and a memo control on a form.
When the user clicks the button, the content of the specified
file is loaded into the memo, and the fifth line of the file
is written across the top of the form.
}

procedure TForm1.Button1Click(Sender: TObject);
begin
  Memo1.Lines.LoadFromFile('readme.txt');
  Caption:= Memo1.Lines[4];
end;
```

See Also

TStrings (see page 3029)

SetLines (see page 21378)

Text (see page 5842)

WordWrap (see page 21384)

154.1.20.2.22 TMemo.MaxLength Property

Specifies the maximum number of characters the user can enter into the edit control.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that can be entered into the edit control. A value of 0 indicates that there is no

application-defined limit on the length.

Use MaxLength to limit the length of the text in an edit control if that text will be copied into a fixed-length buffer.

Note: Setting MaxLength will not truncate the existing text, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered into an edit control.

Note: The unit of MaxLength is characters (not bytes) if the application is using themes.

See Also

Text (see page 5842)

Displaying and Editing Text in a Memo Control

Displaying and Editing Text in a Rich Edit Memo Control

154.1.20.2.23 TMemo.OEMConvert Property

Determines whether characters typed in the edit control are converted from ANSI to OEM and then back to ANSI.

Pascal

```
property OEMConvert: Boolean;
```

C++

```
__property Boolean OEMConvert;
```

Description

To ensure that any characters typed in the edit control can be unambiguously converted to the OEM character set, set OEMConvert to true. This causes all characters to be converted from ANSI to OEM and then back to ANSI as they are typed. Set OEMConvert to false to avoid the overhead of this conversion when it does not matter whether the text can be unambiguously mapped to an OEM string.

OEMConvert is most useful for edit controls used to enter file names when the application does not use Unicode file names.

See Also

Text (see page 5842)

154.1.20.2.24 TMemo.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

154.1.20.2.25 TMemo.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

154.1.20.2.26 TMemo.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

154.1.20.2.27 TMemo.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

154.1.20.2.28 TMemo.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

154.1.20.2.29 TMemo.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
```

```
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
```

```
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
```

```
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

154.1.20.2.30 TMemo.ReadOnly Property

Determines whether the user can change the text of the edit control.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

To restrict the edit control to display only, set the ReadOnly property to true. Set ReadOnly to false to allow the contents of the edit control to be edited.

Setting ReadOnly to true ensures that the text is not altered, while still allowing the user to select text. The selected text can then be manipulated by the application, or copied to the Clipboard.

See Also

CopyToClipboard (see page 21246)

GetSelTextBuf (see page 21253)

154.1.20.2.31 TMemo.ScrollBars Property

Determines whether the memo control has scroll bars.

Pascal

```
property ScrollBars: TScrollStyle;
```

C++

```
__property TScrollStyle ScrollBars;
```

Description

Use ScrollBars to give a multiline edit control horizontal or vertical scroll bars. ScrollBars can take one of the following values:

Value	Meaning
ssNone	The control has no scroll bars.
ssHorizontal	The control has a single scroll bar on the bottom edge.
ssVertical	The control has a single scroll bar on the right edge.
ssBoth	The control has a scroll bar on both the bottom and right edges.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->Lines->Clear();
  for (int i = 0; i < 500; i++)
  {
    RichEdit1->Text = RichEdit1->Text + AnsiString("This is sentence ") + IntToStr(i) + ".  ";
    if ((i % 2) == 0) {
      RichEdit1->Text = RichEdit1->Text + AnsiString("\n");
    }
  }
  RichEdit1->SelStart = 0; // move text cursor to top of edit
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  RichEdit1->HideScrollBars = CheckBox1->Checked;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  TScrollStyle ScrollBarA[4] = {ssBoth, ssHorizontal, ssNone, ssVertical };
  RichEdit1->ScrollBars = ScrollBarA[RadioGroup1->ItemIndex];
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Caption = "Scroll Bars";
  RadioGroup1->Items->Clear();
  RadioGroup1->Items->Add("ssBoth");
  RadioGroup1->Items->Add("ssHorizontal");
  RadioGroup1->Items->Add("ssNone");
  RadioGroup1->Items->Add("ssVertical");
```

```
  CheckBox1->Caption = "Hide Scroll Bars";
  CheckBox1->Checked = true;
  Button1->Caption = "Load Text";
  RichEdit1->Text = "Just a little text.";
  RichEdit1->WordWrap = False;
}
```

Delphi Examples:

```
{
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
}
procedure TForm1.Button1Click(Sender: TObject);

Displaying and Editing Text in a Memo Control

154.1.20.2.32 TMemo.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
```

```
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

ShowHint (see page 13721)

Displaying Fly-over Help

154.1.20.2.33 TMemo.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the

control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

154.1.20.2.34 TMemo.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

154.1.20.2.35 TMemo.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
```

```
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

154.1.20.2.36 TMemo.WantReturns Property

Determines whether the user can insert return characters into the text.

Pascal

```
property WantReturns: Boolean;
```

C++

```
__property Boolean WantReturns;
```

Description

Set WantReturns to true to allow users to enter return characters into the text. Set WantReturns to false to allow the form to handle return characters instead.

For example, in a form with a default button (such as an OK button) and a memo control, if WantReturns is false, pressing Enter chooses the default button. If WantReturns is true, pressing Enter inserts a return character in the text.

Note: If WantReturns is false, users can still enter return characters into the text by pressing Ctrl+Enter.

See Also

Text (see page 5842)

WantTabs (see page 21384)

WordWrap (see page 21384)

154.1.20.2.37 TMemo.WantTabs Property

Determines whether the user can insert tab characters into the text.

Pascal

```
property WantTabs: Boolean;
```

C++

```
__property Boolean WantTabs;
```

Description

Set WantTabs to true to allow users to enter tab characters into the text. Set WantTabs to false if you want the tab character to select the next control on the form instead.

Note: If WantTabs is true, users can tab into the edit control, but they can't tab out.

WantReturns (see page 21384)

Displaying and Editing Text in a Memo Control

Displaying and Editing Text in a Rich Edit Memo Control

154.1.20.2.38 TMemo.WordWrap Property

Determines whether the edit control inserts soft carriage returns so text wraps at the right margin.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to make the edit control wrap text at the right margin so it fits in the client area. The wrapping is cosmetic only. The text does not include any return characters that were not explicitly entered. Set WordWrap to false to have the edit control show a separate line only where return characters were explicitly entered into the text.

Note: There should be no use for a horizontal scroll bar if WordWrap is true.

C++ Examples:

```
/*
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  RichEdit1->Lines->Clear();
  for (int i = 0; i < 500; i++)
  {
    RichEdit1->Text = RichEdit1->Text + AnsiString("This is sentence ") + IntToStr(i) + ".  ";
    if ((i % 2) == 0) {
      RichEdit1->Text = RichEdit1->Text + AnsiString("\n");
    }
  }
  RichEdit1->SelStart = 0; // move text cursor to top of edit
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  RichEdit1->HideScrollBars = CheckBox1->Checked;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  TScrollStyle ScrollBarA[4] = {ssBoth, ssHorizontal, ssNone, ssVertical };
  RichEdit1->ScrollBars = ScrollBarA[RadioGroup1->ItemIndex];
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Caption = "Scroll Bars";
  RadioGroup1->Items->Clear();
  RadioGroup1->Items->Add("ssBoth");
  RadioGroup1->Items->Add("ssHorizontal");
  RadioGroup1->Items->Add("ssNone");
  RadioGroup1->Items->Add("ssVertical");
  CheckBox1->Caption = "Hide Scroll Bars";
```

```
  CheckBox1->Checked = true;
  Button1->Caption = "Load Text";
  RichEdit1->Text = "Just a little text.";
  RichEdit1->WordWrap = False;
}
```

Delphi Examples:

```
{
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  RichEdit1.Lines.Clear;
  for I := 0 to 500 do
  begin
    RichEdit1.Text :=
      RichEdit1.Text + 'test line ' + IntToStr(I) + ' ';
    if (i mod 4 = 0) then
      RichEdit1.Text := RichEdit1.Text + Chr(13);
  end;
  // move text cursor to top of editend;
  RichEdit1.SelStart := 0;
end;

procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  RichEdit1.HideScrollbars := CheckBox1.Checked;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
const
  ScrollBarA: array[0..3] of TScrollStyle = (
    ssBoth,
    ssHorizontal,
    ssNone,
    ssVertical);
begin
  RichEdit1.ScrollBars :=
    ScrollBarA[RadioGroup1.ItemIndex];
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  with RadioGroup1, Items do
  begin
    Caption := 'Scroll Bars';
    Clear;
    Add('ssBoth');
    Add('ssHorizontal');
    Add('ssNone');
    Add('ssVertical');
  end;
  with CheckBox1 do
  begin
    Caption := 'HideScrollBars';
    Checked := True;
  end;
  Button1.Caption := 'Loaded';
  RichEdit1.Text := 'Just a little text.';
  RichEdit1.WordWrap := False;
```

```
end;

154.1.20.3 TMemo Events

The events of the TMemo class are listed here.

Published Events

	Name	Description
	OnChange (see page 21724)	Occurs when the text for the edit control may have changed.
	OnClick (see page 21725)	Occurs when the user clicks the control.
	OnContextPopup (see page 21727)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 21727)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 21728)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 21730)	Occurs when the user drags an object over a control.
	OnEndDock (see page 21732)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 21733)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 21734)	Occurs when a control receives the input focus.
	OnExit (see page 21736)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 21738)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 21741)	Occurs when a key is pressed.
	OnKeyUp (see page 21742)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 21743)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 21744)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 21747)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 21747)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 21747)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 21749)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 21752)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 21752)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

154.1.20.3.1 TMemo.OnChange Event

Occurs when the text for the edit control may have changed.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to take specific action whenever the text for the edit control may have changed. Use the Modified property to see if a change actually occurred. The Text property of the edit control will already be updated to reflect any changes. This event provides the first opportunity to respond to modifications that the user types into the edit control.

See Also

Change (see page 21245)

Text (see page 5842)

154.1.20.3.2 TMemo.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
```

```
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

154.1.20.3.3 TMemo.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

AutoPopup (see page 16178)

154.1.20.3.4 TMemo.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

154.1.20.3.5 TMemo.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
```

```
      end;
    end;
  end;
```

154.1.20.3.6 TMemo.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
```

```
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

154.1.20.3.7 TMemo.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

OnStartDock (see page 5871)

154.1.20.3.8 TMemo.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

154.1.20.3.9 TMemo.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
```

```
    ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
```

```
    else if myActiveControl is TRichEdit then
      with myActiveControl as TRichEdit do
        SelAttributes.Assign(TFontDialog(Sender).Font)
    else
      Beep;
  end;
  {
  This example uses an edit box and a memo control on a form.
  When either the edit box or the memo is the active control,
  it is colored yellow. When the active control becomes
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;

  procedure TForm1.Memo1Exit(Sender: TObject);
  begin
    Memo1.Color := clWindow;
  end;
```

154.1.20.3.10 TMemo.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.

154.1.20.3.11 TMemo.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
```

```
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var

154.1.20.3.12 TMemo.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

154.1.20.3.13 TMemo.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/

154.1.20.3.14 TMemo.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

OnMouseUp (see page 5867)

MouseCapture (see page 5831)

154.1.20.3.15 TMemo.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form’s unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
```

```
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.

154.1.20.3.16 TMemo.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

154.1.20.3.17 TMemo.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

154.1.20.3.18 TMemo.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
```

```
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{

154.1.20.3.19 TMemo.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:

154.1.20.3.20 TMemo.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

154.1.20.3.21 TMemo.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

154.1.21 TRadioButton Class

TRadioButton is a wrapper for a system radio button.

Class Hierarchy

Pascal

```
TRadioButton = class(TButtonControl);
```

C++

```
class TRadioButton : public TButtonControl;
```

File

StdCtrls

Description

Use TRadioButton to add a radio button to a form. Radio buttons present a set of mutually exclusive options to the user- that is, only one radio button in a set can be selected at a time. When the user selects a radio button, the previously selected radio button becomes unselected. Radio buttons are frequently grouped in a radio group box (TGroupBox (see page 21474)). Add the group box to the form first, then get the radio buttons from the Component palette and put them into the group box. Or you can add a TRadioGroup, a group that already has radio buttons in it, so that you do not have to get the buttons from the Tool Palette.

By default, all radio buttons that are directly contained in the same windowed control container, such as a TRadioGroup or TPanel, are grouped. For example, two radio buttons on a form can be checked at the same time only if they are contained in separate containers, such as two different group boxes.

154.1.21.1 TRadioButton Members

The following tables list the members exposed by TRadioButton.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
V	ActionChange (see page 20992)	Updates the button control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.

	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 21765)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 21765)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus

	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetActionLinkClass (see page 20993)	Returns the appropriate action link class that is associated with button controls.
	GetChecked (see page 21766)	Returns whether the button control is checked.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).

	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
V	SetChecked (see page 21766)	Sets the Checked property.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.

	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WndProc (see page 20994)	Handles Windows messages.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.

	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	ClicksDisabled (see page 20996)	This is ClicksDisabled, a member of class TButtonControl.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 21764)	Creates an instance of TRadioButton (see page 21753).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).

	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 21766)	Returns the alignment of any text in the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.

	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
	SetDesignVisible (see page 6178)	Makes a control visible at design time.
	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Update (see page 5789)	Processes any pending paint messages immediately.
	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	AlignDisabled (see page 6192)	Indicates child control realignment disabled.

	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnClick (see page 21793)	Occurs when the user clicks the control.
	OnContextPopup (see page 21795)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 21796)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 21796)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 21798)	Occurs when the user drags an object over a control.
	OnEndDock (see page 21801)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 21801)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 21802)	Occurs when a control receives the input focus.
	OnExit (see page 21805)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 21806)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 21809)	Occurs when a key is pressed.
	OnKeyUp (see page 21810)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 21812)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 21813)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 21815)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 21815)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 21815)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 21818)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 21820)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 21821)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Action (see page 21767)	Designates the action associated with the control.
	Align (see page 21768)	Determines how the control aligns within its container (parent control).
	Alignment (see page 21771)	Determines the position of the caption relative to the radio button.
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 21772)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 21772)	Specifies the bi-directional mode for the control.
	Caption (see page 21773)	Specifies a text string that identifies the control to the user.
	Checked (see page 21775)	Determines whether the option represented by the radio button is selected.
	Color (see page 21776)	Specifies the background color of the control.
	Constraints (see page 21776)	Specifies the size constraints for the control.
	Ctl3D (see page 21777)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DragCursor (see page 21777)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 21778)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 21778)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 21780)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 21780)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic

	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentBiDiMode (see page 21781)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 21782)	Determines where a control looks for its color information.
	ParentCtl3D (see page 21782)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 21783)	Determines where a control looks for its font information.
	ParentShowHint (see page 21783)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 21784)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 21788)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 21790)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 21790)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 21791)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.
	WordWrap (see page 21792)	Specifies whether the button text wraps to fit the width of the control.

154.1.21.2 TRadioButton.Create Constructor

Creates an instance of TRadioButton (see page 21753).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TRadioButton(TComponent * AOwner);
```

Description

Call Create to instantiate a radio button at runtime. Radio buttons added to forms at design time are created automatically.

AOwner is the component, typically a form, that becomes the value of the Owner property. The Owner is responsible for freeing the radio button object.

See Also

Owner (see page 2807)

154.1.21.3 TRadioButton Methods

The methods of the TRadioButton class are listed here.

Protected Methods

	Name	Description
	CreateParams (see page 21765)	Initializes a window-creation parameter data structure.
	CreateWnd (see page 21765)	Creates the underlying window.
	GetChecked (see page 21766)	Returns whether the button control is checked.

	SetChecked (see page 21766)	Sets the Checked property.

Public Methods

	Name	Description
	GetControlsAlignment (see page 21766)	Returns the alignment of any text in the control.

154.1.21.3.1 TRadioButton.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

AddBiDiModeExStyle (see page 6128)

154.1.21.3.2 TRadioButton.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams (see page 6135)

CreateWindowHandle (see page 6137)

Perform (see page 5776)

DestroyWnd (see page 6141)

154.1.21.3.3 TRadioButton.GetChecked Method

Returns whether the button control is checked.

Pascal

```
function GetChecked: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetChecked();
```

Description

GetChecked is the read implementation of the Checked property.

See Also

Checked (see page 20995)

154.1.21.3.4 TRadioButton.GetControlsAlignment Method

Returns the alignment of any text in the control.

Pascal

```
function GetControlsAlignment: TAlignment; override;
```

C++

```
virtual __fastcall TAlignment GetControlsAlignment();
```

Description

Use GetControlsAlignment to determine the orientation of text in controls that do not have an Alignment (see page 21771) property.

GetControlsAlignment overrides the inherited method, returning taRightJustify if UseRightToLeftAlignment returns false. If UseRightToLeftAlignment returns true, GetControlsAlignment returns the opposite of the Alignment (see page 21771) property.

154.1.21.3.5 TRadioButton.SetChecked Method

Sets the Checked property.

Pascal

```
procedure SetChecked(Value: Boolean); override;
```

C++

```
virtual __fastcall SetChecked(Boolean Value);
```

Description

SetChecked is the write implementer for the Checked property.

See Also

Checked (see page 20995)

154.1.21.4 TRadioButton Properties

The properties of the TRadioButton class are listed here.

Published Properties

	Name	Description
	Action (see page 21767)	Designates the action associated with the control.
	Align (see page 21768)	Determines how the control aligns within its container (parent control).
	Alignment (see page 21771)	Determines the position of the caption relative to the radio button.
	Anchors (see page 21772)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 21772)	Specifies the bi-directional mode for the control.
	Caption (see page 21773)	Specifies a text string that identifies the control to the user.
	Checked (see page 21775)	Determines whether the option represented by the radio button is selected.
	Color (see page 21776)	Specifies the background color of the control.
	Constraints (see page 21776)	Specifies the size constraints for the control.
	Ctl3D (see page 21777)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DragCursor (see page 21777)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 21778)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 21778)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 21780)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 21780)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 21781)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 21782)	Determines where a control looks for its color information.
	ParentCtl3D (see page 21782)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 21783)	Determines where a control looks for its font information.
	ParentShowHint (see page 21783)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 21784)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 21788)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 21790)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 21790)	Determines if the user can tab to a control.
	Visible (see page 21791)	Determines whether the component appears onscreen.
	WordWrap (see page 21792)	Specifies whether the button text wraps to fit the width of the control.

154.1.21.4.1 TRadioButton.Action Property

Designates the action associated with the control.

Pascal

```
property Action: TBasicAction;
```

C++

```
__property TBasicAction Action;
```

Description

Action is the action object that is associated with the control. Actions allow an application to centralize the response to user commands. When a control is associated with an action, the action determines the appropriate properties and events of the control (such as whether the control is enabled or how it responds to an OnClick event).

To create actions at design time, place an action list component on a form or data module. Double click the action list to bring up the action list editor. Add actions in the editor using its context menu. Once the actions have been added using the action list

editor, they appear in the drop-down list for the Action property in the Object Inspector.

154.1.21.4.2 TRadioButton.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;
```

```
  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
```

```
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;

  end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

154.1.21.4.3 TRadioButton.Alignment Property

Determines the position of the caption relative to the radio button.

Pascal

```
property Alignment: TLeftRight;
```

C++

```
__property TLeftRight Alignment;
```

Description

Set Alignment to determine whether the caption of the radio button should appear to the left of the radio button (taLeftJustify) or to the right of the radio button (taRightJustify).

Note: Do not confuse the Alignment property with the alignment of the caption in the text area of the radio button. The caption always appears left aligned. Alignment only controls on which side of the button the text area appears.

See Also

Caption (see page 5806)

154.1.21.4.4 TRadioButton.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

154.1.21.4.5 TRadioButton.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

154.1.21.4.6 TRadioButton.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption: TCaption;
```

C++

```
__property TCaption Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long as the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
```

```
    {
      TToolButton *button = new TToolButton(toolBar);
      button->Parent = toolBar;
      button->Caption = captions->Strings[i];
      if (button->Caption == "|")
        button->Style = tbsSeparator;
      else
        button->Style = tbsButton;
    }
  }

  TToolBar *myToolBar;

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    myToolBar = new TToolBar(this);
    myToolBar->Parent = this;
    TStringList *captions = new TStringList();
    captions->Add("New");
    captions->Add("Save");
    captions->Add("|");
    captions->Add("Cut");
    captions->Add("Copy");
    captions->Add("Paste");
    AddButtons(myToolBar, captions);
    delete captions;
    myToolBar->ShowCaptions = True;
    myToolBar->Height = 40;
  }

  void __fastcall TForm1::FormDestroy(TObject *Sender)
  {
    for (int I = myToolBar->ButtonCount - 1; I >= 0; I--)
      delete myToolBar->Buttons[I];
    delete myToolBar;
  }
```

Delphi Examples:

```
  {
  The following code keeps the size of the label control
  constant, even though the length of the label's caption
  changes. As a result, the caption of the label is probably
  too long to display in the label when the user clicks the
  button:
  }
  procedure TForm1.Button1Click(Sender: TObject);
  begin
    Label1.AutoSize := False;
    Label1.Caption :=
      'This string is too long as the caption of this label';
  end;
  {
  This example requires a TPageControl populated by several
  TabSheets, a TEdit and a TButton. When the button is
  clicked, the caption of the active tab changes to that of
  the TEdit.  These lines of code could also be written:
  PageControl1.ActivePage.Caption := Edit1.Text;
  This would obviate the need for a TTabSheet variable since
  PageControl1.->ActivePage is already of type TTabSheet.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    sheet: TTabSheet;
  begin
    sheet := PageControl1.ActivePage;
    sheet.Caption := Edit1.Text;
```

```
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

154.1.21.4.7 TRadioButton.Checked Property

Determines whether the option represented by the radio button is selected.

Pascal

```
property Checked: Boolean;
```

C++

```
__property Boolean Checked;
```

Description

Read Checked to determine whether the radio button is selected. Set Checked to true to select the radio button and deselect all other radio buttons in the same container. Set Checked to false to deselect the radio button, leaving no radio button in the group selected.

See Also

TRadioGroup (see page 13115)

154.1.21.4.8 TRadioButton.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

154.1.21.4.9 TRadioButton.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

154.1.21.4.10 TRadioButton.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

154.1.21.4.11 TRadioButton.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

154.1.21.4.12 TRadioButton.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

154.1.21.4.13 TRadioButton.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
```

```
  OnDragOver event handler must be implemented to accept the
  drop.
  */
  void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
        int X, int Y)
  {
    if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
      return;
    THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
    TNodeAttachMode AttachMode;
    TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
    if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
      AttachMode = naAddChild;
    else if (HT.Contains(htNowhere))
      AttachMode = naAdd;
    else if (HT.Contains(htOnIndent))
      AttachMode = naInsert;
    else
      return;
    TreeView1->Selected->MoveTo(Item, AttachMode);
  }

  void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
        int X, int Y, TDragState State, bool &Accept)
  {
    Accept = (Source == (TObject *)TreeView1);
  }
```

Delphi Examples:

```
  {
  The following code uses GetNodeAt to add a dragged node as a
  child of the node under the mouse when it is dropped.  This
  example requires a populated TreeView.  Also, the TTreeView
  DragMode property set to dmAutomatic, and the TTreeView
  OnDragOver event handler must be implemented to accept the
  drop.
  }
  procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
  var
    AnItem: TTreeNode;
    AttachMode: TNodeAttachMode;
    HT: THitTests;
  begin
    if TreeView1.Selected = nil then Exit;
    HT := TreeView1.GetHitTestInfoAt(X, Y);
    AnItem := TreeView1.GetNodeAt(X, Y);
    if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
    begin
      if (htOnItem in HT) or (htOnIcon in HT) then
        AttachMode := naAddChild
      else if htNowhere in HT then AttachMode := naAdd
      else if htOnIndent in HT then AttachMode := naInsert;
      TreeView1.Selected.MoveTo(AnItem, AttachMode);
    end;
  end;

  procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TTreeView;
  end;
```

DragKind (see page 5819)

Arranging the Order of Persistent Columns

154.1.21.4.14 TRadioButton.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

154.1.21.4.15 TRadioButton.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
```

```
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

DesktopFont (see page 5818)

ParentFont (see page 5834)

Displaying and Editing Text in a Memo Control

154.1.21.4.16 TRadioButton.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

154.1.21.4.17 TRadioButton.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

154.1.21.4.18 TRadioButton.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

154.1.21.4.19 TRadioButton.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

154.1.21.4.20 TRadioButton.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

154.1.21.4.21 TRadioButton.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
```

```
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
```

```
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
```

```
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

type

154.1.21.4.22 TRadioButton.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

154.1.21.4.23 TRadioButton.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

154.1.21.4.24 TRadioButton.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

154.1.21.4.25 TRadioButton.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
```

```
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

154.1.21.4.26 TRadioButton.WordWrap Property

Specifies whether the button text wraps to fit the width of the control.

Pascal

```
property WordWrap: Boolean;
```

C++

```
__property Boolean WordWrap;
```

Description

Set WordWrap to true to allow the display of multiple lines of text. When WordWrap is true, text that is too wide for the control wraps at the right margin.

Set WordWrap to false to limit the text to a single line. When WordWrap is false, text that is too wide for the control appears truncated.

154.1.21.5 TRadioButton Events

The events of the TRadioButton class are listed here.

Published Events

	Name	Description
	OnClick (see page 21793)	Occurs when the user clicks the control.
	OnContextPopup (see page 21795)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 21796)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 21796)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 21798)	Occurs when the user drags an object over a control.
	OnEndDock (see page 21801)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 21801)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 21802)	Occurs when a control receives the input focus.
	OnExit (see page 21805)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 21806)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 21809)	Occurs when a key is pressed.
	OnKeyUp (see page 21810)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 21812)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 21813)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 21815)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 21815)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 21815)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 21818)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 21820)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 21821)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

154.1.21.5.1 TRadioButton.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.

- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

Adding Silent Video Clips to an Application

154.1.21.5.2 TRadioButton.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple

times for each context menu invocation.

AutoPopup (see page 16178)

154.1.21.5.3 TRadioButton.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

154.1.21.5.4 TRadioButton.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
```

```
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
```

```
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

154.1.21.5.5 TRadioButton.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor

property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{

  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
```

```
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

154.1.21.5.6 TRadioButton.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

154.1.21.5.7 TRadioButton.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
```

```
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

154.1.21.5.8 TRadioButton.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter

event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
```

```
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

154.1.21.5.9 TRadioButton.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

154.1.21.5.10 TRadioButton.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR

message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
```

```
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := clAqua;
      if (ComboBox1.Text = 'KeyDown') then
        ComboBox1.Text := 'KeyDown2'
      else
        ComboBox1.Text := 'KeyDown';
      WriteLn(ComboBox1.Text);
    end;
  end;

  procedure TForm1.FormKeyUp(
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := FormColor;
      if (ComboBox1.Text = 'KeyUp') then
        ComboBox1.Text := 'KeyUp2'
      else
        ComboBox1.Text := 'KeyUp';
      WriteLn(ComboBox1.Text);
    end;
  end;
  {
  The following code aborts a print job if the user presses
  Esc. Note that you should set KeyPreview to true to ensure
  that the OnKeyDown event handler of Form1 is called.
  }

  uses Printers;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    I, X, Y: Integer;
    Memo1 : TMemo;
    r: TRect;
  begin
    Memo1 := TMemo.Create(Form1);
    Memo1.Parent := Form1;
    Memo1.Visible := True;
    Memo1.Width := 700;
    if (OpenDialog1.Execute) then
    begin
      Memo1.Lines.LoadFromFile(OpenDialog1.FileName);

      Printer.BeginDoc;
      X := 200;
      Y := 200;
      for I := 0 to 140 do
        if (not Printer.Aborted) then
        begin
          Printer.Canvas.TextOut(X, Y, Memo1.Lines[I]);
          Y := Y + 80;
          if (Y > (Printer.PageHeight - 300)) then
          begin
            Y := 200;
            Printer.NewPage;
            Sleep(1000);  // to give you time to abort!
          end;
        end;
      if (not Printer.Aborted) then Printer.EndDoc;
    end;
  end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
   KeyPreview := True;
end;

procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word; Shift: TShiftState);
begin
if (Key=VK_ESCAPE) and Printer.Printing then
  begin

154.1.21.5.11 TRadioButton.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
```

```
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

154.1.21.5.12 TRadioButton.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form’s color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.

154.1.21.5.13 TRadioButton.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

154.1.21.5.14 TRadioButton.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
```

```
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
```

```
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
        end
      else
        begin
        StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
        StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
        end;
    end;
  end;
```

154.1.21.5.15 TRadioButton.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

154.1.21.5.16 TRadioButton.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

154.1.21.5.17 TRadioButton.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.

154.1.21.5.18 TRadioButton.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:

154.1.21.5.19 TRadioButton.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

154.1.21.5.20 TRadioButton.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

154.1.22 TScrollBar Class

TScrollBar is a Windows scroll bar, which is used to scroll the contents of a window, form, or control.

Class Hierarchy

Pascal

```
TScrollBar = class(TWinControl);
```

C++

```
class TScrollBar : public TWinControl;
```

File

StdCtrls

Description

Use TScrollBar to add a free-standing scroll bar to a form. Many controls have properties that add scroll bars which are an integral part of the control (TControlScrollBar objects). TScrollBar allows controls that do not have integrated scroll bars or groupings of controls to be scrolled when the user manipulates the TScrollBar object.

When the bi-directional mode of a scroll bar is changed, its coordinate system is reversed. Position (see page 21858) zero in left-to-right mode is the left side, and position zero in right-to-left mode is the right side.

Specialized Input Controls

154.1.22.1 TScrollBar Members

The following tables list the members exposed by TScrollBar.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.

	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Change (see page 21833)	This is Change, a member of class TScrollBar.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 21833)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWnd (see page 21834)	Creates the underlying window.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.

	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
V	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
V	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
V	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
V	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
V	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.

	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.

	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	Scroll (see page 21834)	This is Scroll, a member of class TScrollBar.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.

	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.

	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 21832)	Creates and initializes an instance of TScrollBar (see page 21821).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.

	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetParams (see page 21834)	Sets the Position (see page 21858), Max (see page 21847), and Min (see page 21849) property values all at once.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.

	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnChange (see page 21866)	Occurs immediately after the value of Position (see page 21858) changes.
	OnContextPopup (see page 21867)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 21868)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 21870)	Occurs when the user drags an object over a control.
	OnEndDock (see page 21872)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 21873)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 21874)	Occurs when a control receives the input focus.
	OnExit (see page 21876)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 21878)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 21880)	Occurs when a key is pressed.
	OnKeyUp (see page 21882)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 21883)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 21884)	Occurs when the user moves the mouse outside of a control.
	OnScroll (see page 21884)	Occurs when the user scrolls the scroll bar with the mouse or keyboard.
	OnStartDock (see page 21886)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 21886)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 21835)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 21839)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 21840)	Specifies the bi-directional mode for the control.

	Constraints (see page 21840)	Specifies the size constraints for the control.
	Ctl3D (see page 21841)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DragCursor (see page 21841)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 21841)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 21842)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 21843)	Controls whether the control responds to mouse, keyboard, and timer events.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Kind (see page 21844)	Specifies whether the scroll bar is horizontal or vertical.
	LargeChange (see page 21845)	Determines how much Position (see page 21858) changes when the user clicks the scroll bar on either side of the thumb tab or presses PgUp or PgDn.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Max (see page 21847)	Specifies the maximum position represented by the scroll bar.
	Min (see page 21849)	Specifies the minimum position represented by the scroll bar.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	PageSize (see page 21851)	Specifies the size of the thumb tab.
	ParentBiDiMode (see page 21852)	Specifies whether the control uses its parent's BiDiMode.
	ParentCtl3D (see page 21853)	Determines where a component looks to determine if it should appear three dimensional.
	ParentShowHint (see page 21853)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 21853)	Identifies the pop-up menu associated with the control.
	Position (see page 21858)	Indicates the current position of the scroll bar.
	ShowHint (see page 21860)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SmallChange (see page 21861)	Determines how much Position (see page 21858) changes when the user clicks the arrow buttons on the scroll bar or presses the arrow keys on the keyboard.
	TabOrder (see page 21863)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 21864)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 21864)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

154.1.22.2 TScrollBar.Create Constructor

Creates and initializes an instance of TScrollBar (see page 21821).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TScrollBar(TComponent * AOwner);
```

Description

Call Create to create an instance of TScrollBar (see page 21821) at runtime. Scroll (see page 21834) bars placed on a form at design time are created automatically.

AOwner is the component that is responsible for freeing the scroll bar. This becomes the value of the Owner property.

See Also

Owner (see page 2807)

154.1.22.3 TScrollBar Methods

The methods of the TScrollBar class are listed here.

Protected Methods

	Name	Description
	Change (see page 21833)	This is Change, a member of class TScrollBar.
V	CreateParams (see page 21833)	Initializes a window-creation parameter data structure.
V	CreateWnd (see page 21834)	Creates the underlying window.
	Scroll (see page 21834)	This is Scroll, a member of class TScrollBar.

Public Methods

	Name	Description
	SetParams (see page 21834)	Sets the Position (see page 21858), Max (see page 21847), and Min (see page 21849) property values all at once.

154.1.22.3.1 TScrollBar.Change Method

Pascal

```
procedure Change; dynamic;
```

C++

```
__fastcall Change();
```

Description

This is Change, a member of class TScrollBar.

154.1.22.3.2 TScrollBar.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call

to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

AddBiDiModeExStyle (see page 6128)

154.1.22.3.3 TScrollBar.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams (see page 6135)

CreateWindowHandle (see page 6137)

Perform (see page 5776)

DestroyWnd (see page 6141)

154.1.22.3.4 TScrollBar.Scroll Method

Pascal

```
procedure Scroll(ScrollCode: TScrollCode; var ScrollPos: Integer); dynamic;
```

C++

```
__fastcall Scroll(TScrollCode ScrollCode, int ScrollPos);
```

Description

This is Scroll, a member of class TScrollBar.

154.1.22.3.5 TScrollBar.SetParams Method

Sets the Position (see page 21858), Max (see page 21847), and Min (see page 21849) property values all at once.

Pascal

```
procedure SetParams(APosition: Integer; AMin: Integer; AMax: Integer);
```

C++

```
__fastcall SetParams(int APosition, int AMin, int AMax);
```

Description

Use the SetParams method to set the Position (see page 21858), Min (see page 21849), and Max (see page 21847) property values all at once, preventing repaints that would occur if each property value were set separately.

See Also

Max (see page 21847)

Min (see page 21849)

Position (see page 21858)

154.1.22.4 TScrollBar Properties

The properties of the TScrollBar class are listed here.

Published Properties

	Name	Description
	Align (see page 21835)	Determines how the control aligns within its container (parent control).
	Anchors (see page 21839)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 21840)	Specifies the bi-directional mode for the control.
	Constraints (see page 21840)	Specifies the size constraints for the control.
	Ctl3D (see page 21841)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DragCursor (see page 21841)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 21841)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 21842)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 21843)	Controls whether the control responds to mouse, keyboard, and timer events.
	Kind (see page 21844)	Specifies whether the scroll bar is horizontal or vertical.
	LargeChange (see page 21845)	Determines how much Position (see page 21858) changes when the user clicks the scroll bar on either side of the thumb tab or presses PgUp or PgDn.
	Max (see page 21847)	Specifies the maximum position represented by the scroll bar.
	Min (see page 21849)	Specifies the minimum position represented by the scroll bar.
	PageSize (see page 21851)	Specifies the size of the thumb tab.
	ParentBiDiMode (see page 21852)	Specifies whether the control uses its parent's BiDiMode.
	ParentCtl3D (see page 21853)	Determines where a component looks to determine if it should appear three dimensional.
	ParentShowHint (see page 21853)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 21853)	Identifies the pop-up menu associated with the control.
	Position (see page 21858)	Indicates the current position of the scroll bar.
	ShowHint (see page 21860)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	SmallChange (see page 21861)	Determines how much Position (see page 21858) changes when the user clicks the arrow buttons on the scroll bar or presses the arrow keys on the keyboard.
	TabOrder (see page 21863)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 21864)	Determines if the user can tab to a control.
	Visible (see page 21864)	Determines whether the component appears onscreen.

154.1.22.4.1 TScrollBar.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
```

```
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
```

```
    Split: TSplitter;
    Files: TFileListBox;
    Dirs: TDirectoryListBox;
  begin
    { first add a directory list box to the form }
    Dirs := TDirectoryListBox.Create(Form1);
    { line it up on the left of the form }
    Dirs.Parent := Form1;
    Dirs.Align := alLeft;
    Dirs.Width := Form1.ClientWidth div 3;
  { now add the splitter to divide the directory pane from the file pane }
    Split := TSplitter.Create(Form1);
    Split.Parent := Form1;
    { make sure the splitter is to the right of the directory list box! }
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane – a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

  var

Parent (see page 5832)

Anchors (see page 5802)

154.1.22.4.2 TScrollBar.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

154.1.22.4.3 TScrollBar.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

154.1.22.4.4 TScrollBar.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

154.1.22.4.5 TScrollBar.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

154.1.22.4.6 TScrollBar.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

154.1.22.4.7 TScrollBar.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

154.1.22.4.8 TScrollBar.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
```

```
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;

Arranging the Order of Persistent Columns

154.1.22.4.9 TScrollBar.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

154.1.22.4.10 TScrollBar.Kind Property

Specifies whether the scroll bar is horizontal or vertical.

Pascal

```
property Kind: TScrollBarKind;
```

C++

```
__property TScrollBarKind Kind;
```

Description

Set Kind to indicate the orientation of the scroll bar. These are the possible values:

Value	Meaning
sbHorizontal	Scroll (see page 21834) bar is horizontal
sbVertical	Scroll (see page 21834) bar is vertical

C++ Examples:

```
/*
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RadioGroup1->Items->Add("Vertical");
  RadioGroup1->Items->Add("Horizontal");
  RadioGroup1->ItemIndex = 2;
}

void __fastcall TForm1::RadioGroup1Click(TObject *Sender)
{
  if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Vertical")
    ScrollBar1->Kind = sbVertical;
  else if (RadioGroup1->Items->Strings[RadioGroup1->ItemIndex] == "Horizontal")
    ScrollBar1->Kind = sbHorizontal;
}
```

Delphi Examples:

```
{
This example uses a radio group box and a scroll bar on a
form. When the user selects one of the radio buttons, the
scroll bar changes orientation accordingly.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  RadioGroup1.Items.Add('Vertical');
  RadioGroup1.Items.Add('Horizontal');
  RadioGroup1.ItemIndex := 2;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);
begin
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Vertical' then
    ScrollBar1.Kind := sbVertical;
  if RadioGroup1.Items[RadioGroup1.ItemIndex] = 'Horizontal' then
    ScrollBar1.Kind := sbHorizontal;
end;
```

154.1.22.4.11 TScrollBar.LargeChange Property

Determines how much Position (see page 21858) changes when the user clicks the scroll bar on either side of the thumb tab or presses PgUp or PgDn.

Pascal

```
property LargeChange: TScrollBarInc;
```

C++

```
__property TScrollBarInc LargeChange;
```

Description

Set LargeChange to specify how much to change the value of Position (see page 21858) when the user clicks on the side of the thumb tab (that is, on the thumb tab track, but not on the thumb tab itself). The Max (see page 21847) and Min (see page 21849) properties define the total range over which Position (see page 21858) can vary.

For example, if Max (see page 21847) is 30000 and Min (see page 21849) is 0, the scroll box can assume 30,000 positions. If the LargeChange property setting is 10000 and the Position (see page 21858) property is 0, the user can click the scroll bar track three times after the thumb tab before it moves all the way to the end of the scroll bar (30000 / 10000 = 3).

LargeChange should correspond to the portion of this range that the user sees in one page or screen, expressed in the logical units used by the Max (see page 21847), Min (see page 21849), and Position (see page 21858) properties.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorPalette[12] = {clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
```

```
  // First, initialize the page control
  PageControl1->TabWidth = PageControl1->ClientWidth/4 - 1;
  PageControl1->ActivePage = PageControl1->Pages[0];
  for (int i = 0; i < PageControl1->PageCount; i++)
    PageControl1->Pages[i]->Brush->Color = colorPalette[i];
  /* set up the scrollbar to reflect
     the structure of the page control */
  ScrollBar1->Max = PageControl1->PageCount - 1;
  ScrollBar1->Min = 0;
  ScrollBar1->SmallChange = 1;
  // set LargeChange to a single row of tabs
  ScrollBar1->LargeChange = PageControl1->ClientWidth / PageControl1->TabWidth;
}

void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  ScrollBar1->Position = ((TPageControl *)Sender)->ActivePage->PageIndex;
}

void __fastcall TForm1::ScrollBar1Scroll(TObject *Sender,
      TScrollCode ScrollCode, int &ScrollPos)
{
  PageControl1->ActivePage = PageControl1->Pages[ScrollPos];
}
```

Delphi Examples:

```
{
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set

154.1.22.4.12 TScrollBar.Max Property

Specifies the maximum position represented by the scroll bar.

Pascal

```
property Max: Integer;
```

C++

```
__property int Max;
```

Description

Set Max to the maximum value the Position (see page 21858) property can take. The Max and Min (see page 21849) properties define the total range over which Position (see page 21858) can vary.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)

154.1.22.4.13 TScrollBar.Min Property

Specifies the minimum position represented by the scroll bar.

Pascal

```
property Min: Integer;
```

C++

```
__property int Min;
```

Description

Set Min to the minimum value the Position (see page 21858) property can take. The Min and Max (see page 21847) properties define the total range over which Position (see page 21858) can vary.

C++ Examples:

```
/*

154.1.22.4.14 TScrollBar.PageSize Property

Specifies the size of the thumb tab.

Pascal

```
property PageSize: Integer;
```

C++

```
__property int PageSize;
```

Description

PageSize is the size of the thumb tab, measured in the same units as Position (see page 21858), Min (see page 21849), and Max (see page 21847) (not pixels).

C++ Examples:

```
/*
The following code sets the thumb tab of a scroll bar so
that it represents the proportion of the scrolling range
that is visible:
*/
void __fastcall SetThumbTab()
{
  // Get the minimum (default) size of the thumb tab
  int MinHeight = GetSystemMetrics(SM_CYVTHUMB);
  // Get the size of the scrollbar track
  int TrackHeight = Form1->ScrollBar1->ClientHeight - 2*GetSystemMetrics(SM_CYVSCROLL);
  // set PageSize to represent the visible portion of the scrolling range:
  Form1->ScrollBar1->PageSize = TrackHeight/(Form1->ScrollBar1->Max - Form1->ScrollBar1->Min +
1);
  // Don't let the thumb tab get too small
  if (Form1->ScrollBar1->PageSize < MinHeight)
  Form1->ScrollBar1->PageSize = MinHeight;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const AnsiString Path = "../overview.rtf";
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile(Path);
  SetThumbTab();
}
//---------------------------------------------------------------------------
void __fastcall TForm1::RichEdit1Change(TObject *Sender)
{
 SetThumbTab();
}
//---------------------------------------------------------------------------
void __fastcall TForm1::ScrollBar1Change(TObject *Sender)
{
 SetThumbTab();
}
//---------------------------------------------------------------------------
void __fastcall TForm1::RichEdit1EndDrag(TObject *Sender, TObject *Target,
      int X, int Y)
{
 SetThumbTab();
}
```

Delphi Examples:

```
{
```

```
The following code sets the thumb tab of a scroll bar so
that it represents the proportion of the scrolling range
that is visible:
}
procedure SetThumbTab(wincontrol: TWinControl);
var
  TrackHeight: Integer; { the size of the scroll bar track }
  MinHeight: Integer; { the default size of the thumb tab }
begin
  MinHeight := GetSystemMetrics(SM_CYVTHUMB); { save default size }
  with Form1.ScrollBar1 do
  begin
    TrackHeight := wincontrol.ClientHeight - 2 * GetSystemMetrics(SM_CYVSCROLL);
    PageSize := TrackHeight div (Max - Min + 1);
    if PageSize < MinHeight then PageSize := MinHeight;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
const
  Path = 'OverView.RTF';
begin
  RichEdit1.PlainText := False;
  RichEdit1.Lines.LoadFromFile(Path);
  SetThumbTab(RichEdit1);
end;
procedure TForm1.RichEdit1Change(Sender: TObject);
begin
  SetThumbTab(RichEdit1);
end;
```

Min (see page 21849)

Max (see page 21847)

ClientHeight (see page 5808)

LargeChange (see page 21845)

154.1.22.4.15 TScrollBar.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

154.1.22.4.16 TScrollBar.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

154.1.22.4.17 TScrollBar.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

154.1.22.4.18 TScrollBar.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
```

```
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
```

```
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
```

```
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.

154.1.22.4.19 TScrollBar.Position Property

Indicates the current position of the scroll bar.

Pascal

```
property Position: Integer;
```

C++

```
__property int Position;
```

Description

Read Position to determine the current position of the thumb tab. This value can be used to determine how to scroll any components controlled by the scroll bar. When the user scrolls the scroll bar, the value of Position changes. Set Position to programmatically move the thumb tab of the scroll bar.

The number of possible positions on the scroll bar is determined by the difference between the Max (see page 21847) property and the Min (see page 21849) property. If Position has the same value as Min (see page 21849), the thumb tab appears at the far left of a horizontal scroll bar or the top of a vertical scroll bar. If Position has the same value as Max (see page 21847), the thumb tab appears at the far right of a horizontal scroll bar or the bottom of a vertical scroll bar.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
```

```
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/

154.1.22.4.20 TScrollBar.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
```

```
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin

154.1.22.4.21 TScrollBar.SmallChange Property

Determines how much Position (see page 21858) changes when the user clicks the arrow buttons on the scroll bar or presses the arrow keys on the keyboard.

Pascal

```
property SmallChange: TScrollBarInc;
```

C++

```
__property TScrollBarInc SmallChange;
```

Description

Set SmallChange to specify how much to change the value of Position (see page 21858) when the user clicks on the arrow buttons. The Max (see page 21847) and Min (see page 21849) properties define the total range over which Position (see page 21858) can vary.

For example, if Max (see page 21847) is 100 and Min (see page 21849) is 0, the scroll box can assume 100 positions. If the SmallChange property setting is 5 and the Position (see page 21858) property is 0, the user can click the down or right arrow button 20 times before the thumb tab is moved all the way to the end of the scroll bar.

SmallChange should correspond to the portion of this range that the user sees as one line or one item, expressed in the logical units used by the Max (see page 21847), Min (see page 21849), and Position (see page 21858) properties.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  const TColor colorPalette[12] = {clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};
  // First, initialize the page control
  PageControl1->TabWidth = PageControl1->ClientWidth/4 - 1;
  PageControl1->ActivePage = PageControl1->Pages[0];
  for (int i = 0; i < PageControl1->PageCount; i++)
    PageControl1->Pages[i]->Brush->Color = colorPalette[i];
  /* set up the scrollbar to reflect
     the structure of the page control */
  ScrollBar1->Max = PageControl1->PageCount - 1;
  ScrollBar1->Min = 0;
  ScrollBar1->SmallChange = 1;
  // set LargeChange to a single row of tabs
  ScrollBar1->LargeChange = PageControl1->ClientWidth / PageControl1->TabWidth;
}

void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  ScrollBar1->Position = ((TPageControl *)Sender)->ActivePage->PageIndex;
}

void __fastcall TForm1::ScrollBar1Scroll(TObject *Sender,
      TScrollCode ScrollCode, int &ScrollPos)
{
  PageControl1->ActivePage = PageControl1->Pages[ScrollPos];
}
```

Delphi Examples:

```
{
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;

154.1.22.4.22 TScrollBar.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

154.1.22.4.23 TScrollBar.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

154.1.22.4.24 TScrollBar.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

154.1.22.5 TScrollBar Events

The events of the TScrollBar class are listed here.

Published Events

	Name	Description
	OnChange (see page 21866)	Occurs immediately after the value of Position (see page 21858) changes.
	OnContextPopup (see page 21867)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDragDrop (see page 21868)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 21870)	Occurs when the user drags an object over a control.
	OnEndDock (see page 21872)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 21873)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 21874)	Occurs when a control receives the input focus.
	OnExit (see page 21876)	Occurs when the input focus shifts away from one control to another.
	OnKeyDown (see page 21878)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 21880)	Occurs when a key is pressed.
	OnKeyUp (see page 21882)	Occurs when the user releases a key that has been pressed.
	OnMouseEnter (see page 21883)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 21884)	Occurs when the user moves the mouse outside of a control.
	OnScroll (see page 21884)	Occurs when the user scrolls the scroll bar with the mouse or keyboard.
	OnStartDock (see page 21886)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 21886)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

154.1.22.5.1 TScrollBar.OnChange Event

Occurs immediately after the value of Position (see page 21858) changes.

Pascal

```
property OnChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnChange;
```

Description

Write an OnChange event handler to control another object or group of objects using TScrollBar (see page 21821). Adjust the objects controlled by the scroll bar to reflect the new value of Position (see page 21858).

OnChange occurs whether the value of Position (see page 21858) is changed by the user or programmatically. If the value of Position (see page 21858) is changed by the user, OnChange occurs immediately after the OnScroll (see page 21884) event.

See Also

OnScroll (see page 21884)

Position (see page 21858)

154.1.22.5.2 TScrollBar.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

TPopupMenu (see page 16169)

PopupMenu (see page 5835)

AutoPopup (see page 16178)

154.1.22.5.3 TScrollBar.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
```

```
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

154.1.22.5.4 TScrollBar.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}
```

```
/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
```

```
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

154.1.22.5.5 TScrollBar.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

OnStartDock (see page 5871)

154.1.22.5.6 TScrollBar.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;

154.1.22.5.7 TScrollBar.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
```

```
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
```

```
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

154.1.22.5.8 TScrollBar.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK

button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

154.1.22.5.9 TScrollBar.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
```

```
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}

154.1.22.5.10 TScrollBar.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

154.1.22.5.11 TScrollBar.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/

154.1.22.5.12 TScrollBar.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

154.1.22.5.13 TScrollBar.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

154.1.22.5.14 TScrollBar.OnScroll Event

Occurs when the user scrolls the scroll bar with the mouse or keyboard.

Pascal

```
property OnScroll: TScrollEvent;
```

C++

```
__property TScrollEvent OnScroll;
```

Description

Write an OnScroll to alter the way the scrollbar adjusts its position when the user scrolls the scroll bar.

C++ Examples:

```
/*
This example shows how to use a scroll bar to navigate the
pages of a page control.  To run this example, place a
scroll bar and a page control on a form.  Right click the
page control and add 12 pages to it.  Add the following code
to the OnCreate event of the form, the OnChange event of the
page control, and the OnScroll event of the scroll bar.
Note that the LargeChange and SmallChange properties are set
to automatically change the active page by one tab or one
row respectively.  The OnScroll event is used to make the
actual change in the page control, while the OnChange event
of the page control ensures that the scroll bar is kept in
sync with changes made directly to the page control.
*/

154.1.22.5.15 TScrollBar.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

154.1.22.5.16 TScrollBar.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

154.1.23 TStaticText Class

TStaticText is a windowed control that displays text on a form.

Class Hierarchy

Pascal

```
TStaticText = class(TCustomStaticText);
```

C++

```
class TStaticText : public TCustomStaticText;
```

File

StdCtrls

Description

The TStaticText component functions like TLabel (see page 21544), except that it descends from TWinControl and therefore has a window handle. Use TStaticText instead of TLabel (see page 21544) when the component's accelerator key must belong to a windowed control—for example, on an ActiveX property page.

Display Controls

154.1.23.1 TStaticText Members

The following tables list the members exposed by TStaticText.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.

	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
V	CreateParams (see page 21398)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWnd (see page 6137)	Creates the underlying window.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
V	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
V	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
V	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
V	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
V	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.

	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.

	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
V	Loaded (see page 21399)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 21399)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetAutoSize (see page 21399)	This is SetAutoSize, a member of class TCustomStaticText.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.

	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.

	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 5731)	Creates an instance of TControl (see page 5724).
	Create (see page 6123)	Creates an instance of TWinControl (see page 6112).
	Create (see page 21397)	Creates and initializes a TCustomStaticText (see page 21387) instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2766)	Disposes of the component and its owned components.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.

	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.

	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.

R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnClick (see page 21926)	Occurs when the user clicks the control.

	OnContextPopup (see page 21928)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 21928)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 21929)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 21931)	Occurs when the user drags an object over a control.
	OnEndDock (see page 21933)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 21934)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 21935)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 21936)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 21938)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 21938)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 21939)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 21941)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 21943)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 21944)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 21899)	Determines how the control aligns within its container (parent control).
	Alignment (see page 21902)	Determines how text is aligned within the component.
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 21903)	Specifies how the control is anchored to its parent.
	AutoSize (see page 21903)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 21904)	Specifies which edges of the control are beveled.
	BevelInner (see page 21904)	Specifies the cut of the inner bevel.
	BevelKind (see page 21904)	Specifies the control's bevel style.
	BevelOuter (see page 21905)	Specifies the cut of the outer bevel.
	BiDiMode (see page 21905)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 21906)	Determines the appearance of the control's border.
	Caption (see page 21906)	Specifies a text string that identifies the control to the user.
	Color (see page 21909)	Specifies the background color of the control.
	Constraints (see page 21909)	Specifies the size constraints for the control.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DragCursor (see page 21910)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 21910)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 21911)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 21912)	Controls whether the control responds to mouse, keyboard, and timer events.
	FocusControl (see page 21913)	Links the component with another windowed control.
	Font (see page 21913)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.

	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentBiDiMode (see page 21914)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 21915)	Determines where a control looks for its color information.
	ParentFont (see page 21915)	Determines where a control looks for its font information.
	ParentShowHint (see page 21916)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 21916)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 21921)	Enables accelerator characters.
	ShowHint (see page 21921)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabOrder (see page 21923)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 21923)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Transparent (see page 21924)	Specifies whether the background of the image obscures objects below the image object.
	Visible (see page 21924)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

154.1.23.2 TStaticText Properties

The properties of the TStaticText class are listed here.

Published Properties

	Name	Description
	Align (see page 21899)	Determines how the control aligns within its container (parent control).
	Alignment (see page 21902)	Determines how text is aligned within the component.
	Anchors (see page 21903)	Specifies how the control is anchored to its parent.
	AutoSize (see page 21903)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 21904)	Specifies which edges of the control are beveled.
	BevelInner (see page 21904)	Specifies the cut of the inner bevel.
	BevelKind (see page 21904)	Specifies the control's bevel style.
	BevelOuter (see page 21905)	Specifies the cut of the outer bevel.
	BiDiMode (see page 21905)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 21906)	Determines the appearance of the control's border.
	Caption (see page 21906)	Specifies a text string that identifies the control to the user.
	Color (see page 21909)	Specifies the background color of the control.
	Constraints (see page 21909)	Specifies the size constraints for the control.
	DragCursor (see page 21910)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 21910)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 21911)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 21912)	Controls whether the control responds to mouse, keyboard, and timer events.
	FocusControl (see page 21913)	Links the component with another windowed control.
	Font (see page 21913)	Controls the attributes of text written on or in the control.
	ParentBiDiMode (see page 21914)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 21915)	Determines where a control looks for its color information.
	ParentFont (see page 21915)	Determines where a control looks for its font information.
	ParentShowHint (see page 21916)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 21916)	Identifies the pop-up menu associated with the control.
	ShowAccelChar (see page 21921)	Enables accelerator characters.
	ShowHint (see page 21921)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

	TabOrder (see page 21923)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 21923)	Determines if the user can tab to a control.
	Transparent (see page 21924)	Specifies whether the background of the image obscures objects below the image object.
	Visible (see page 21924)	Determines whether the component appears onscreen.

154.1.23.2.1 TStaticText.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
```

```
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;

Anchors (see page 5802)

154.1.23.2.2 TStaticText.Alignment Property

Determines how text is aligned within the component.

Pascal

```
property Alignment: TAlignment;
```

C++

```
__property TAlignment Alignment;
```

Description

The possible values of Alignment are

Value	Meaning
taLeftJustify	Text is aligned at the left of the control.
taCenter	Text is centered in the control.
taRightJustify	Text is aligned at the right of the control.

See Also

Font (see page 5823)

Caption (see page 5806)

154.1.23.2.3 TStaticText.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

154.1.23.2.4 TStaticText.AutoSize Property

Specifies whether the control sizes itself automatically to accommodate its contents.

Pascal

```
property AutoSize: Boolean;
```

C++

```
__property Boolean AutoSize;__property Boolean AutoSize;
```

Description

Use AutoSize to specify whether the control sizes itself automatically. When AutoSize is true, the control resizes automatically when its contents change.

By default, AutoSize is false.

See Also

Constraints (see page 5812)

CanAutoSize (see page 5741)

154.1.23.2.5 TStaticText.BevelEdges Property

Specifies which edges of the control are beveled.

Pascal

```
property BevelEdges: TBevelEdges;
```

C++

```
__property TBevelEdges BevelEdges;
```

Description

Use BevelEdges to get or set which edges of the control are beveled. The BevelInner, BevelOuter, and BevelKind properties determine the appearance of the specified edges.

See Also

BevelInner (see page 6193)

BevelOuter (see page 6194)

BevelKind (see page 6193)

154.1.23.2.6 TStaticText.BevelInner Property

Specifies the cut of the inner bevel.

Pascal

```
property BevelInner: TBevelCut;
```

C++

```
__property TBevelCut BevelInner;
```

Description

Use BevelInner to specify whether the inner bevel has a raised, lowered, or flat look.

The inner bevel appears immediately inside the outer bevel. If there is no outer bevel (BevelOuter is bvNone), the inner bevel appears immediately inside the border.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelKind (see page 6193)

BevelWidth (see page 6194)

BorderWidth (see page 6195)

154.1.23.2.7 TStaticText.BevelKind Property

Specifies the control's bevel style.

Pascal

```
property BevelKind: TBevelKind;
```

C++

```
__property TBevelKind BevelKind;
```

Description

Use BevelKind to modify the appearance of a bevel. BevelKind influences how sharply the bevel stands out.

BevelKind, in combination with BevelWidth and the cut of the bevel specified by BevelInner or BevelOuter, can create a variety of effects. Experiment with various combinations to get the look you want.

See Also

BevelEdges (see page 6192)

BevelOuter (see page 6194)

BevelInner (see page 6193)

BevelWidth (see page 6194)

154.1.23.2.8 TStaticText.BevelOuter Property

Specifies the cut of the outer bevel.

Pascal

```
property BevelOuter: TBevelCut;
```

C++

```
__property TBevelCut BevelOuter;
```

Description

Use BevelInner to specify whether the outer bevel has a raised, lowered, or flat look.

The outer bevel appears immediately inside the border and outside the inner bevel.

See Also

BevelEdges (see page 6192)

BevelInner (see page 6193)

BevelKind (see page 6193)

BevelWidth (see page 6194)

154.1.23.2.9 TStaticText.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

154.1.23.2.10 TStaticText.BorderStyle Property

Determines the appearance of the control's border.

Pascal

```
property BorderStyle: TStaticBorderStyle;
```

C++

```
__property TStaticBorderStyle BorderStyle;
```

Description

Use BorderStyle to specify the appearance of the border, if any, that appears around the text.

154.1.23.2.11 TStaticText.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption: TCaption;
```

C++

```
__property TCaption Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long as the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this);
  myToolBar->Parent = this;
  TStringList *captions = new TStringList();
  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions);
  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int I = myToolBar->ButtonCount - 1; I >= 0; I--)
    delete myToolBar->Buttons[I];
  delete myToolBar;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long as the caption of this label';
end;
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
```

```
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

154.1.23.2.12 TStaticText.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

154.1.23.2.13 TStaticText.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

154.1.23.2.14 TStaticText.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

154.1.23.2.15 TStaticText.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

154.1.23.2.16 TStaticText.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
```

```
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

Arranging the Order of Persistent Columns

154.1.23.2.17 TStaticText.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

EnableControls (see page 6934)

Enabling Mouse

154.1.23.2.18 TStaticText.FocusControl Property

Links the component with another windowed control.

Pascal

```
property FocusControl: TWinControl;
```

C++

```
__property TWinControl * FocusControl;
```

Description

Use the FocusControl property to link the TCustomStaticText instance with another windowed control. If the text of Caption includes an accelerator key, the component specified by FocusControl receives focus when the accelerator is pressed.

See Also

Caption (see page 5806)

FocusControl (see page 21306)

TWinControl (see page 6112)

154.1.23.2.19 TStaticText.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
```

```
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

Displaying and Editing Text in a Memo Control

154.1.23.2.20 TStaticText.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern

locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

154.1.23.2.21 TStaticText.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

154.1.23.2.22 TStaticText.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

154.1.23.2.23 TStaticText.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

154.1.23.2.24 TStaticText.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
```

```
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
```

```
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
```

```
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CopyToClipboard
  else
    Beep;
end;

procedure TForm1.Cut1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.CutToClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.CutToClipboard
  else
    Beep;
end;

procedure TForm1.Paste1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
    Edit1.PasteFromClipboard
  else if PopupMenu1.PopupComponent = Edit2 then
    Edit2.PasteFromClipboard
  else
    Beep;
end;
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}
```

```
type
  TForm1 = class(TForm)

154.1.23.2.25 TStaticText.ShowAccelChar Property

Enables accelerator characters.

Pascal

```
property ShowAccelChar: Boolean;
```

C++

```
__property Boolean ShowAccelChar;
```

Description

If ShowAccelChar is true, an ampersand in the component's Caption text appears as an underline and makes the character after it into an accelerator key. If ShowAccelChar is false, ampersands appear as ampersands.

See Also

Caption (see page 5806)

154.1.23.2.26 TStaticText.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

Displaying Fly-over Help

154.1.23.2.27 TStaticText.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

154.1.23.2.28 TStaticText.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

154.1.23.2.29 TStaticText.Transparent Property

Specifies whether the background of the image obscures objects below the image object.

Pascal

```
property Transparent: Boolean;
```

C++

```
__property Boolean Transparent;
```

Description

Set Transparent to true to allow objects behind the TCustomStaticText object to show through the background of the image. Set Transparent to false to make the background of the image opaque.

154.1.23.2.30 TStaticText.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
```

```
    }
    PageControl1Change(Sender);
  }
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

154.1.23.3 TStaticText Events

The events of the TStaticText class are listed here.

Published Events

	Name	Description
	OnClick (see page 21926)	Occurs when the user clicks the control.
	OnContextPopup (see page 21928)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 21928)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 21929)	Occurs when the user drops an object being dragged.

	OnDragOver (see page 21931)	Occurs when the user drags an object over a control.
	OnEndDock (see page 21933)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 21934)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnMouseActivate (see page 21935)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 21936)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 21938)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 21938)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 21939)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 21941)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 21943)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 21944)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

154.1.23.3.1 TStaticText.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
```

```
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

154.1.23.3.2 TStaticText.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

154.1.23.3.3 TStaticText.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

OnClick (see page 5851)

Responding to User Actions at Runtime

154.1.23.3.4 TStaticText.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
```

```
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

154.1.23.3.5 TStaticText.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
```

```
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
```

```
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
    end;
  end;
end;
```

154.1.23.3.6 TStaticText.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

OnStartDock (see page 5871)

154.1.23.3.7 TStaticText.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
```

```
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

154.1.23.3.8 TStaticText.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate

event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

MouseCapture (see page 5831)

154.1.23.3.9 TStaticText.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
```

```
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.

154.1.23.3.10 TStaticText.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

154.1.23.3.11 TStaticText.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

154.1.23.3.12 TStaticText.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form’s unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
```

```
      {
        StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
        StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
      }
      if (X > StartX)
      {
        StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
        StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
      }
      else
      {
        StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
        StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
      }
    }
  }
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
```

```
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
      end;
  end;
end;
```

154.1.23.3.13 TStaticText.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/

Responding to a Mouse-up Action

154.1.23.3.14 TStaticText.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

154.1.23.3.15 TStaticText.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

154.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCheckBoxState (see page 21945)	TCheckBoxState indicates the state of a check box control.
	TComboBoxStyle (see page 21946)	TComboBoxStyle is the type for the Style property of combo box controls that are defined in the StdCtrls (see page 20907) unit.
	TEditCharCase (see page 21946)	TEditCharCase indicates how a control forces the case of characters, if at all.
	TEllipsisPosition (see page 21947)	Specifies how ellipsis is placed in text not fitting in allocated rectangle.
	TListBoxStyle (see page 21948)	TListBoxStyle specifies the way a listbox control gets its data and how it is drawn.
	TScrollCode (see page 21949)	TScrollCode indicates what action the user performed on a scroll bar.
	TScrollStyle (see page 21950)	Identifies a set of scrollbars by their orientation.
	TStaticBorderStyle (see page 21951)	TStaticBorderStyle determines the appearance of the border on a static text control.
	TTextLayout (see page 21951)	TTextLayout indicates where text appears within the client area of a control.

Records

	Name	Description
	TSelection (see page 21950)	TSelection definese the start and position of a selection.

154.2.1 StdCtrls.TCheckBoxState Enumeration

TCheckBoxState indicates the state of a check box control.

Pascal

```
TCheckBoxState = (
  cbUnchecked,
  cbChecked,
  cbGrayed
);
```

C++

```
enum TCheckBoxState {
  cbUnchecked,
  cbChecked,
  cbGrayed
};
```

File

StdCtrls

Description

Following are the possible values of TCheckBoxState:

Value	Meaning
cbUnchecked	The check box has no check mark, indicating that the user has not selected the option.
cbChecked	The check box has a check mark in it, indicating that the user has selected the option.

cbGrayed	The check box has a check mark in it, but it is grayed.

154.2.2 StdCtrls.TComboBoxStyle Enumeration

TComboBoxStyle is the type for the Style property of combo box controls that are defined in the StdCtrls (see page 20907) unit.

Pascal

```
TComboBoxStyle = (
  csDropDown,
  csSimple,
  csDropDownList,
  csOwnerDrawFixed,
  csOwnerDrawVariable
);
```

C++

```
enum TComboBoxStyle {
  csDropDown,
  csSimple,
  csDropDownList,
  csOwnerDrawFixed,
  csOwnerDrawVariable
};
```

File

StdCtrls

Description

These are the values in the TComboBoxStyle type:

Value	Meaning
csDropDown	Creates a drop-down list with an edit box for manually entered text. All items are strings of the same height.
csSimple	Creates an edit box with a fixed list (list box) underneath. The length of the list is determined by the Height of the combo box.
csDropDownList	Creates a drop-down list with no edit box; the user cannot enter text manually. All items are strings of the same height.
csOwnerDrawFixed	Creates an owner-draw drop-down list with no edit box. Each item in the list is the height specified by the ItemHeight property.
csOwnerDrawVariable	Creates an owner-draw drop-down list with no edit box. List items can have varying heights.

154.2.3 StdCtrls.TEditCharCase Enumeration

TEditCharCase indicates how a control forces the case of characters, if at all.

Pascal

```
TEditCharCase = (
```

```
    ecNormal,
    ecUpperCase,
    ecLowerCase
  );
```

C++

```
  enum TEditCharCase {
    ecNormal,
    ecUpperCase,
    ecLowerCase
  };
```

File

StdCtrls

Description

TEditCharCase specifies what case is given to text typed into a control. It can have one of the following values:

Value	Meaning
ecLowerCase	The text is converted to lowercase.
ecNormal	The text appears in mixed case. It is not forced into any case.
ecUpperCase	The text is converted to uppercase.

154.2.4 StdCtrls.TEllipsisPosition Enumeration

Specifies how ellipsis is placed in text not fitting in allocated rectangle.

Pascal

```
  TEllipsisPosition = (
    epNone,
    epPathEllipsis,
    epEndEllipsis,
    epWordEllipsis
  );
```

C++

```
  enum TEllipsisPosition {
    epNone,
    epPathEllipsis,
    epEndEllipsis,
    epWordEllipsis
  };
```

File

StdCtrls

Description

TEllipsisPosition specifies how an ellipsis is placed in text that does not fit in its allocated rectangle. The constants here correspond to constants specifying ellipsis placement in the **dwDTFormat** parameter of the Windows **DrawText** and **DrawTextEx** functions.

The following table lists values for TEllipsisPosition:

Value	Meaning
epNone	An ellipsis is not inserted.
epPathEllipsis	Replaces text in the middle with an ellipsis so that the resulting text fits in the rectangle specified. If the text contains backslash (\) characters, treat the text as a path and attempt to preserve as much text as possible after the last backslash. Corresponds to a value of DT_PATH_ELLIPSIS in the **dwDTFormat** parameter.
epEndEllipsis	Replaces text at the end with an ellipsis so that the resulting text fits in the rectangle specified. Any word not fitting in the rectangle is truncated without adding an ellipsis. Corresponds to a value of DT_END_ELLIPSIS in the **dwDTFormat** parameter.
epWordEllipsis	Truncates any word that doesn't fit in the rectangle and adds ellipses. Corresponds to a value of DT_WORD_ELLIPSIS in the **dwDTFormat** parameter.

154.2.5 StdCtrls.TListBoxStyle Enumeration

TListBoxStyle specifies the way a listbox control gets its data and how it is drawn.

Pascal

```
TListBoxStyle = (
  lbStandard,
  lbOwnerDrawFixed,
  lbOwnerDrawVariable,
  lbVirtual,
  lbVirtualOwnerDraw
);
```

C++

```
enum TListBoxStyle {
  lbStandard,
  lbOwnerDrawFixed,
  lbOwnerDrawVariable,
  lbVirtual,
  lbVirtualOwnerDraw
};
```

File

StdCtrls

Description

The following table lists the values for the TListBoxStyle type:

Value	Meaning
lbStandard	All items are strings, with each item the same height.
lbOwnerDrawFixed	The list box is owner-drawn, but each item in the list box is the height specified by the ItemHeight property. Each time an item is displayed in an lbOwnerDrawFixed list box, the OnDrawItem event occurs. The event handler for OnDrawItem draws the specified item. The ItemHeight property determines the height of each of the items.
lbOwnerDrawVariable	The list box is owner-drawn, and items in the list box can be of varying heights. Each time an item is displayed in an lbOwnerDrawVariable list box, two events occur. The first is the OnMeasureItem event. The code for the OnMeasureItem handler can set the height of each item. Then the OnDrawItem event occurs. The code for the OnDrawItem handler draws each item in the list box using the size specified by the OnMeasureItem handler.

lbVirtual	The list box is virtual, but all items are strings with the same height. You must indicate the number of items in the list box by setting the Count property. You must supply the items in the list box using an OnData event handler. If the items have associated objects, you must supply them using an OnDataObject event handler. In addition, you must supply an OnDataFind event handler to provide the mapping from the strings in the list box to their indexes.
lbVirtualOwnerDraw	The list box is virtual and owner-drawn. All items are the same height. As with lbOwnerDrawFixed, the item height is specified by the ItemHeight property, and you must draw items using an OnDrawItem event handler. As with lbVirtual, you must set the Count property and supply OnData and OnDataFind event handlers to provide the mapping between items and indexes. If items are associated with objects, you must also supply an OnDataObject event handler.

154.2.6 StdCtrls.TScrollCode Enumeration

TScrollCode indicates what action the user performed on a scroll bar.

Pascal

```
TScrollCode = (
  scLineUp,
  scLineDown,
  scPageUp,
  scPageDown,
  scPosition,
  scTrack,
  scTop,
  scBottom,
  scEndScroll
);
```

C++

```
enum TScrollCode {
  scLineUp,
  scLineDown,
  scPageUp,
  scPageDown,
  scPosition,
  scTrack,
  scTop,
  scBottom,
  scEndScroll
};
```

File

StdCtrls

Description

TScrollCode describes the type of scrolling action requested. It can be any of the following values:

Value	Meaning
scLineUp	User clicked the top or left scroll arrow or pressed the Up or Left arrow key.
scLineDown	User clicked the bottom or right scroll arrow or pressed the Down or Right arrow key.
scPageUp	User clicked the area to the left of the thumb tab or pressed the PgUp key.
scPageDown	User clicked the area to the right of the thumb tab or pressed the PgDn key.
scPosition	User positioned the thumb tab and released it.

scTrack	User is moving the thumb tab.
scTop	User moved the thumb tab to the top or far left on the scroll bar.
scBottom	User moved the thumb tab to the bottom or far right on the scroll bar.
scEndScroll	User finished moving the thumb tab on the scroll bar.

154.2.7 StdCtrls.TScrollStyle Enumeration

Identifies a set of scrollbars by their orientation.

Pascal

```
TScrollStyle = (
  ssNone,
  ssHorizontal,
  ssVertical,
  ssBoth
);
```

C++

```
enum TScrollStyle {
  ssNone,
  ssHorizontal,
  ssVertical,
  ssBoth
};
```

File

StdCtrls

Description

TScrollStyle can have one of the following values:

Value	Meaning
ssNone	No scrollbars are indicated.
ssHorizontal	Only a horizontal scrollbar.
ssVertical	Only a vertical scrollbar.
ssBoth	Both a horizontal and a vertical scrollbar.

154.2.8 StdCtrls.TSelection Record

TSelection definese the start and position of a selection.

Pascal

```
TSelection = record
  EndPos: Integer;
  StartPos: Integer;
end;
```

C++

```
struct TSelection {
  int EndPos;
  int StartPos;
};
```

File

StdCtrls

Description

TSelection is used internally in Delphi to hold the start and end position of a selection.

154.2.9 StdCtrls.TStaticBorderStyle Enumeration

TStaticBorderStyle determines the appearance of the border on a static text control.

Pascal

```
TStaticBorderStyle = (
  sbsNone,
  sbsSingle,
  sbsSunken
);
```

C++

```
enum TStaticBorderStyle {
  sbsNone,
  sbsSingle,
  sbsSunken
};
```

File

StdCtrls

Description

These are the values in the TStaticBorderStyle type:

Value	Meaning
sbsNone	No visible border.
sbsSingle	Single-line border.
sbsSunken	Raised border.

154.2.10 StdCtrls.TTextLayout Enumeration

TTextLayout indicates where text appears within the client area of a control.

Pascal

```
TTextLayout = (
  tlTop,
  tlCenter,
  tlBottom
```

```
);
```

C++

```
enum TTextLayout {
  tlTop,
  tlCenter,
  tlBottom
};
```

File

StdCtrls

Description

The following table describes the possible values:

Value	Meaning
tlTop	The text appears at the top of the its control.
tlCenter	The text is vertically centered in the control.
tlBottom	The text appears along the bottom of the control.

154.3 Types

The following table lists types in this documentation.

Types

Name	Description
TButtonActionLinkClass (see page 21953)	This is type StdCtrls.TButtonActionLinkClass.
TCustomComboBoxStringsClass (see page 21953)	TCustomComboBoxStringsClass describes a descendant of TCustomComboBoxStrings (see page 21225).
TDrawItemEvent (see page 21954)	TScrollEvent (see page 21957) is the type of an OnScroll event handler.
TLBFindDataEvent (see page 21954)	TLBFindDataEvent is the type of the list box OnDataFind event handler.
TLBGetDataEvent (see page 21955)	TLBGetDataEvent is the type of the list box OnData event handler.
TLBGetDataObjectEvent (see page 21955)	TLBGetDataObjectEvent is the type of the list box OnDataObject event handler.
TMeasureItemEvent (see page 21955)	TMeasureItemEvent is the type for the OnMeasureItem event handler.
TOwnerDrawState (see page 21956)	Indicates state information that can influence how an item is drawn.
TScrollEvent (see page 21957)	This is type StdCtrls.TScrollEvent.

154.3.1 StdCtrls.TButtonActionLinkClass Type

Pascal

```
TButtonActionLinkClass = class of TButtonActionLink;
```

C++

```
TButtonActionLink TButtonActionLinkClass;
```

File

StdCtrls

Description

This is type StdCtrls.TButtonActionLinkClass.

154.3.2 StdCtrls.TCustomComboBoxStringsClass Type

TCustomComboBoxStringsClass describes a descendant of TCustomComboBoxStrings (see page 21225).

Pascal

```
TCustomComboBoxStringsClass = class of TCustomComboBoxStrings;
```

C++

```
TCustomComboBoxStrings TCustomComboBoxStringsClass;
```

File

StdCtrls

Description

TCustomComboBoxStringsClass is the type for a class reference of TCustomComboBoxStrings (see page 21225) or any of its

descendants. It is a pointer to the runtime type information (RTTI) for the class type.

154.3.3 StdCtrls.TDrawItemEvent Type

TScrollEvent (see page 21957) is the type of an OnScroll event handler.

Pascal

```
TDrawItemEvent = procedure (Control: TWinControl; Index: Integer; Rect: TRect; State:
TOwnerDrawState) of object;
```

C++

```
(Control: TWinControl; Index: Integer; Rect: TRect; State: TOwnerDrawState) (
TDrawItemEvent)();
```

File

StdCtrls

Description

TScrollEvent (see page 21957) defines the type of method procedure that you must define in order to implement the OnScroll event of a visual component such as TScroll.

The OnScroll event occurs when the user scrolls a scroll bar with the mouse or keyboard.

Sender is a reference to the component invoking the OnScroll event.

ScrollCode defines the user scroll action that was performed.

ScrollPos provides the new scroll position.

OnScroll

TScrollCode (see page 21949)

154.3.4 StdCtrls.TLBFindDataEvent Type

TLBFindDataEvent is the type of the list box OnDataFind event handler.

Pascal

```
TLBFindDataEvent = function (Control: TWinControl; FindString: string): Integer of object;
```

C++

```
(Control: TWinControl; FindString: string): Integer ( TLBFindDataEvent)();
```

File

StdCtrls

Description

Control is the virtual list box whose item index is needed.

FindString is the text of the item whose index is needed.

The event handler returns the index of the item identified by FindString. This return value must be in the range from 0 to one less

than the value of the Count property.

154.3.5 StdCtrls.TLBGetDataEvent Type

TLBGetDataEvent is the type of the list box OnData event handler.

Pascal

```
TLBGetDataEvent = procedure (Control: TWinControl; Index: Integer; var Data: string) of object;
```

C++

```
(Control: TWinControl; Index: Integer; var Data: string) ( TLBGetDataEvent)();
```

File

StdCtrls

Description

Control is the virtual list box whose item is needed.

Index is the index of the desired item. Index must be less than the value of the Count property.

Data returns the string that is the value of the specified item.

154.3.6 StdCtrls.TLBGetDataObjectEvent Type

TLBGetDataObjectEvent is the type of the list box OnDataObject event handler.

Pascal

```
TLBGetDataObjectEvent = procedure (Control: TWinControl; Index: Integer; var DataObject:
TObject) of object;
```

C++

```
(Control: TWinControl; Index: Integer; var DataObject: TObject) ( TLBGetDataObjectEvent)();
```

File

StdCtrls

Description

Control is the virtual list box that contains the item associated with the object.

Index is the index of the desired item. Index must be less than the value of the Count property.

DataObject returns the object associated with the specified item.

154.3.7 StdCtrls.TMeasureItemEvent Type

TMeasureItemEvent is the type for the OnMeasureItem event handler.

Pascal

```
TMeasureItemEvent = procedure (Control: TWinControl; Index: Integer; var Height: Integer) of
```

```
object;
```

C++

```
(Control: TWinControl; Index: Integer; var Height: Integer) ( TMeasureItemEvent)();
```

File

StdCtrls

Description

TMeasureItemEvent is the type for event handlers on custom-drawn controls that allow different items in a list to have different heights.

Control is a reference to the control that contains the item.

Index is the index of the item in the Items property.

Height is the default height of the item, in pixels. The event handler can reset Height to the appropriate value.

154.3.8 StdCtrls.TOwnerDrawState Type

Indicates state information that can influence how an item is drawn.

Pascal

```
TOwnerDrawState = Windows.TOwnerDrawState;
```

C++

```
Windows.TOwnerDrawState TOwnerDrawState;
```

File

StdCtrls

Description

TOwnerDrawState is used by event handlers in owner-draw controls to indicate the state of an item about to be drawn. It is a set that includes zero or more of the following:

Value	Meaning
odSelected	The item is selected.
odGrayed	The item should appear grayed.
odDisabled	The item is disabled.
odChecked	The item should appear checked. (This does not apply to all objects)
odFocused	Keyboard input is directed to the item.
odDefault	The item is the default item (This does not apply to all objects)
odHotLight	The item is hot-lighted because under the mouse (only if the operating system supports hot-lighting)
odInactive	The item and its associated menu are inactive
odNoAccel	Any underline of an accelerator character should be skipped when drawing the control
odNoFocusRect	Do not display visual cues that indicate focus
odReserved1	Not currently used.
odReserved2	Not currently used.

odComboBoxEdit	The drawing takes place in the edit box of a combo box control.

154.3.9 StdCtrls.TScrollEvent Type

Pascal

```
TScrollEvent = procedure (Sender: TObject; ScrollCode: TScrollCode; var ScrollPos: Integer) of
object;
```

C++

```
(Sender: TObject; ScrollCode: TScrollCode; var ScrollPos: Integer) ( TScrollEvent)();
```

File

StdCtrls

Description

This is type StdCtrls.TScrollEvent.

155 StrUtils Namespace

This is namespace StrUtils.

Topics

Name	Description
Functions (see page 21962)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 21992)	The following table lists structs, records, enums in this documentation.
Types (see page 21993)	The following table lists types in this documentation.
Variables (see page 21995)	The following table lists variables in this documentation.
Constants (see page 21997)	The following table lists constants in this documentation.

Constants

Name	Description
WordDelimiters (see page 21997)	This is constant StrUtils.WordDelimiters.

Functions

	Name	Description
	AnsiContainsStr (see page 21963)	Indicates whether one string is a (case-sensitive) substring of another.
	AnsiContainsText (see page 21964)	Indicates whether one string is a (case-insensitive) substring of another.
	AnsiEndsStr (see page 21964)	Indicates whether one string is a (case-sensitive) suffix of another.
	AnsiEndsText (see page 21965)	Indicates whether one string is a (case-insensitive) suffix of another.
	AnsiIndexStr (see page 21965)	Provides the index of a specified string in an array of strings.
	AnsiIndexText (see page 21966)	Provides the index of a specified string in an array of strings.
	AnsiLeftStr (see page 21966)	Returns the substring of a specified length that appears at the start of a string.
	AnsiMatchStr (see page 21967)	Indicates whether an array of strings contains an exact match to a specified string.
	AnsiMatchText (see page 21967)	Indicates whether an array of strings contains a case-insensitive match to a specified string.
	AnsiMidStr (see page 21968)	Returns the substring of a specified length that appears at a specified position in a string.
	AnsiReplaceStr (see page 21969)	Replaces all occurrences of a substring with another string.
	AnsiReplaceText (see page 21969)	Replaces all case-insensitive matches of a substring with another string.
	AnsiResemblesText (see page 21970)	Indicates whether two strings are similar.
	AnsiReverseString (see page 21970)	Returns reversed string.
	AnsiRightStr (see page 21971)	Returns the substring of a specified length that appears at the end of a string.
	AnsiStartsStr (see page 21971)	Indicates whether one string is a (case-sensitive) prefix of another.
	AnsiStartsText (see page 21972)	Indicates whether one string is a (case-insensitive) prefix of another.

	ContainsStr (see page 21972)	Performs a case sensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	ContainsText (see page 21973)	Performs a case insensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	DecodeSoundexInt (see page 21973)	Converts an integer representation of a Soundex (see page 21986) encoding into the corresponding phonetic string.
	DecodeSoundexWord (see page 21974)	Converts a Word representation of a Soundex (see page 21986) encoding into the corresponding phonetic string.
	DupeString (see page 21974)	Returns the concatenation of a string with itself a specified number of repeats.
	EndsStr (see page 21975)	Determines if string AText ends with substring ASubText using a case sensitive string comparison. Returns true if AText ends with ASubText.
	EndsText (see page 21975)	Determines if string AText ends with substring ASubText using a case insensitive string comparison. Returns true if AText ends with ASubText.
	IfThen (see page 21976)	Conditionally returns one of two specified values.
	IndexStr (see page 21976)	IndexStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	IndexText (see page 21977)	IndexText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	LeftBStr (see page 21977)	Returns the substring of a specified number of bytes that appears at the start of a string.
	LeftStr (see page 21978)	Returns the substring of a specified length that appears at the start of a string.
	LeftStr (see page 21978)	Returns the substring of a specified length that appears at the start of a string.
	MatchStr (see page 21979)	MatchStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.
	MatchText (see page 21979)	MatchText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.
	MidBStr (see page 21980)	Returns the substring of a specified number of bytes that appears at a specified position in a string.
	MidStr (see page 21980)	Returns the substring of a specified length that appears at a specified position in a string.
	MidStr (see page 21980)	Returns the substring of a specified length that appears at a specified position in a string.
	PosEx (see page 21981)	Returns the index value of a substring.
	RandomFrom (see page 21981)	Returns a randomly selected element from an array.
	ReplaceStr (see page 21982)	ReplaceStr replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case sensitive.
	ReplaceText (see page 21982)	ReplaceText replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case insensitive.
	ResemblesText (see page 21983)	ResemblesText uses a Soundex (see page 21986) method to determine if string AText and string AOther are similar. The result is True if the two strings a similar according to the Soundex (see page 21986) method, and false otherwise.
	ReverseString (see page 21983)	Returns the reverse of a specified string.
	RightBStr (see page 21984)	Returns the substring of a specified number of bytes that appears at the end of a string.
	RightStr (see page 21984)	Returns the substring of a specified length that appears at the end of a string.
	RightStr (see page 21984)	Returns the substring of a specified length that appears at the end of a string.
	SearchBuf (see page 21985)	Locates a substring within a text buffer.
	Soundex (see page 21986)	Converts a string into its Soundex representation.
	SoundexCompare (see page 21986)	Compares the Soundex (see page 21986) representations of two strings.
	SoundexInt (see page 21987)	Converts a string into an integer that represents its phonetic value.
	SoundexProc (see page 21987)	Indicates whether two strings are similar.
	SoundexSimilar (see page 21988)	Indicates whether two strings are similar.
	SoundexWord (see page 21989)	Converts a string into a Word that represents its phonetic value.
	StartsStr (see page 21989)	Enter a short sentence, starting with a verb, that states the basic purpose of the property.

	StartsText (see page 21990)	StartsText determines if the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.
	StuffString (see page 21990)	Inserts a substring into a specified position of a string, replacing the current characters.

Structs, Records, Enums

	Name	Description
	TStringSeachOption (see page 21992)	TStringSeachOption is an enumeration that describes the behavior of string searches.

Types

Name	Description
TCompareTextProc (see page 21993)	TCompareTextProc is a function pointer which specifies a function to compare two string values, AText, and AOther, and return true if these two values are equivilant.
TSoundexIntLength (see page 21993)	TSoundexIntLength The maximum calculation length for the SoundexInt (see page 21987) function. The integer value can be from 1 to 8.
TSoundexLength (see page 21994)	TSoundexLength The maximum calculation length of the SoundEx function. This value determines how many characters to use when generating the soundex string form the source string.
TStringSearchOptions (see page 21994)	TStringSearchOptions is set of the enumeration TStringSeachOption (see page 21992).

Variables

Name	Description
AnsiResemblesProc (see page 21995)	Controls (see page 5711) the algorithm used by AnsiResemblesText (see page 21970) to determine when two strings are similar.
ResemblesProc (see page 21995)	Controls (see page 5711) the algorithm used by AnsiResemblesText (see page 21970) to determine when two strings are similar. It is the same as AnsiResemblesProc (see page 21995).

155.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	AnsiContainsStr (see page 21963)	Indicates whether one string is a (case-sensitive) substring of another.
	AnsiContainsText (see page 21964)	Indicates whether one string is a (case-insensitive) substring of another.
	AnsiEndsStr (see page 21964)	Indicates whether one string is a (case-sensitive) suffix of another.
	AnsiEndsText (see page 21965)	Indicates whether one string is a (case-insensitive) suffix of another.
	AnsiIndexStr (see page 21965)	Provides the index of a specified string in an array of strings.
	AnsiIndexText (see page 21966)	Provides the index of a specified string in an array of strings.
	AnsiLeftStr (see page 21966)	Returns the substring of a specified length that appears at the start of a string.
	AnsiMatchStr (see page 21967)	Indicates whether an array of strings contains an exact match to a specified string.
	AnsiMatchText (see page 21967)	Indicates whether an array of strings contains a case-insensitive match to a specified string.
	AnsiMidStr (see page 21968)	Returns the substring of a specified length that appears at a specified position in a string.
	AnsiReplaceStr (see page 21969)	Replaces all occurrences of a substring with another string.
	AnsiReplaceText (see page 21969)	Replaces all case-insensitive matches of a substring with another string.
	AnsiResemblesText (see page 21970)	Indicates whether two strings are similar.
	AnsiReverseString (see page 21970)	Returns reversed string.
	AnsiRightStr (see page 21971)	Returns the substring of a specified length that appears at the end of a string.
	AnsiStartsStr (see page 21971)	Indicates whether one string is a (case-sensitive) prefix of another.
	AnsiStartsText (see page 21972)	Indicates whether one string is a (case-insensitive) prefix of another.
	ContainsStr (see page 21972)	Performs a case sensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	ContainsText (see page 21973)	Performs a case insensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.
	DecodeSoundexInt (see page 21973)	Converts an integer representation of a Soundex (see page 21986) encoding into the corresponding phonetic string.
	DecodeSoundexWord (see page 21974)	Converts a Word representation of a Soundex (see page 21986) encoding into the corresponding phonetic string.
	DupeString (see page 21974)	Returns the concatenation of a string with itself a specified number of repeats.
	EndsStr (see page 21975)	Determines if string AText ends with substring ASubText using a case sensitive string comparison. Returns true if AText ends with ASubText.
	EndsText (see page 21975)	Determines if string AText ends with substring ASubText using a case insensitive string comparison. Returns true if AText ends with ASubText.
	IfThen (see page 21976)	Conditionally returns one of two specified values.
	IndexStr (see page 21976)	IndexStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	IndexText (see page 21977)	IndexText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.
	LeftBStr (see page 21977)	Returns the substring of a specified number of bytes that appears at the start of a string.
	LeftStr (see page 21978)	Returns the substring of a specified length that appears at the start of a string.
	LeftStr (see page 21978)	Returns the substring of a specified length that appears at the start of a string.
	MatchStr (see page 21979)	MatchStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.
	MatchText (see page 21979)	MatchText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.

	MidBStr (see page 21980)	Returns the substring of a specified number of bytes that appears at a specified position in a string.
	MidStr (see page 21980)	Returns the substring of a specified length that appears at a specified position in a string.
	MidStr (see page 21980)	Returns the substring of a specified length that appears at a specified position in a string.
	PosEx (see page 21981)	Returns the index value of a substring.
	RandomFrom (see page 21981)	Returns a randomly selected element from an array.
	ReplaceStr (see page 21982)	ReplaceStr replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case sensitive.
	ReplaceText (see page 21982)	ReplaceText replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case insensitive.
	ResemblesText (see page 21983)	ResemblesText uses a Soundex (see page 21986) method to determine if string AText and string AOther are similar. The result is True if the two strings a similar according to the Soundex (see page 21986) method, and false otherwise.
	ReverseString (see page 21983)	Returns the reverse of a specified string.
	RightBStr (see page 21984)	Returns the substring of a specified number of bytes that appears at the end of a string.
	RightStr (see page 21984)	Returns the substring of a specified length that appears at the end of a string.
	RightStr (see page 21984)	Returns the substring of a specified length that appears at the end of a string.
	SearchBuf (see page 21985)	Locates a substring within a text buffer.
	Soundex (see page 21986)	Converts a string into its Soundex representation.
	SoundexCompare (see page 21986)	Compares the Soundex (see page 21986) representations of two strings.
	SoundexInt (see page 21987)	Converts a string into an integer that represents its phonetic value.
	SoundexProc (see page 21987)	Indicates whether two strings are similar.
	SoundexSimilar (see page 21988)	Indicates whether two strings are similar.
	SoundexWord (see page 21989)	Converts a string into a Word that represents its phonetic value.
	StartsStr (see page 21989)	Enter a short sentence, starting with a verb, that states the basic purpose of the property.
	StartsText (see page 21990)	StartsText determines if the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.
	StuffString (see page 21990)	Inserts a substring into a specified position of a string, replacing the current characters.

155.1.1 StrUtils.AnsiContainsStr Function

Indicates whether one string is a (case-sensitive) substring of another.

Pascal

```
function AnsiContainsStr(const AText: string; const ASubText: string): Boolean;
```

C++

```
Boolean AnsiContainsStr(const AnsiString AText, const AnsiString ASubText);
```

File

StrUtils

Description

AnsiContainsStr returns true if the string specified by ASubText appears as a substring of the string specified by AText. Comparison is performed case-sensitively.

See Also

AnsiResemblesText (see page 21970)

AnsiStartsStr (see page 21971)

AnsiEndsStr (see page 21964)

AnsiCompareStr

Pos

StringReplace

AnsiContainsText (see page 21964)

155.1.2 StrUtils.AnsiContainsText Function

Indicates whether one string is a (case-insensitive) substring of another.

Pascal

```
function AnsiContainsText(const AText: string; const ASubText: string): Boolean;
```

C++

```
Boolean AnsiContainsText(const AnsiString AText, const AnsiString ASubText);
```

File

StrUtils

Description

AnsiContainsText returns true if the string specified by ASubText appears as a substring of the string specified by AText. Comparison is performed case-insensitively and based on the current system locale.

See Also

AnsiResemblesText (see page 21970)

AnsiStartsText (see page 21972)

AnsiEndsText (see page 21965)

AnsiCompareText

Pos

StringReplace

AnsiContainsStr (see page 21963)

155.1.3 StrUtils.AnsiEndsStr Function

Indicates whether one string is a (case-sensitive) suffix of another.

Pascal

```
function AnsiEndsStr(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean AnsiEndsStr(const AnsiString ASubText, const AnsiString AText);
```

File

StrUtils

Description

AnsiEndsStr returns true if the string specified by ASubText appears as the trailing part of the string specified by AText. Comparison is performed case-sensitively.

See Also

AnsiStartsStr (see page 21971)

AnsiContainsStr (see page 21963)

Pos

RightStr (see page 21984)

AnsiEndsText (see page 21965)

155.1.4 StrUtils.AnsiEndsText Function

Indicates whether one string is a (case-insensitive) suffix of another.

Pascal

```
function AnsiEndsText(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean AnsiEndsText(const AnsiString ASubText, const AnsiString AText);
```

File

StrUtils

Description

AnsiEndsText returns true if the string specified by ASubText appears as the trailing part of the string specified by AText. Comparison is performed case-insensitively and based on the current system locale.

See Also

AnsiStartsText (see page 21972)

AnsiContainsText (see page 21964)

Pos

RightStr (see page 21984)

155.1.5 StrUtils.AnsiIndexStr Function

Provides the index of a specified string in an array of strings.

Pascal

```
function AnsiIndexStr(const AText: string; const AValues: array of string): Integer;
```

C++

```
int AnsiIndexStr(const AnsiString AText, const array of string AValues);
```

File

StrUtils

Description

AnsiIndexStr returns the 0-offset index of the first string it finds in AValues that matches AText case-sensitively. If the string specified by AText does not have an exact match in AValues, AnsiIndexStr returns –1.

See Also

AnsiMatchStr (see page 21967)

RandomFrom (see page 21981)

AnsiIndexText (see page 21966)

155.1.6 StrUtils.AnsiIndexText Function

Provides the index of a specified string in an array of strings.

Pascal

```
function AnsiIndexText(const AText: string; const AValues: array of string): Integer;
```

C++

```
int AnsiIndexText(const AnsiString AText, const array of string AValues);
```

File

StrUtils

Description

AnsiIndexText returns the 0-offset index of the first string it finds in AValues that matches AText case-insensitively. If the string specified by AText does not have a (possibly case-insensitive) match in AValues, AnsiIndexText returns –1. Comparisons are based on the current system locale.

See Also

AnsiMatchText (see page 21967)

RandomFrom (see page 21981)

AnsiIndexStr (see page 21965)

155.1.7 StrUtils.AnsiLeftStr Function

Returns the substring of a specified length that appears at the start of a string.

Pascal

```
function AnsiLeftStr(const AText: AnsiString; const ACount: Integer): AnsiString;
```

C++

```
AnsiString AnsiLeftStr(const AnsiString AText, const int ACount);
```

File

StrUtils

Description

AnsiLeftStr returns the leading characters of AText up to a length of ACount characters.

See Also

Copy

TrimLeft

AnsiStartsText (see page 21972)

AnsiStartsStr (see page 21971)

LeftStr (see page 21978)

LeftBStr (see page 21977)

155.1.8 StrUtils.AnsiMatchStr Function

Indicates whether an array of strings contains an exact match to a specified string.

Pascal

```
function AnsiMatchStr(const AText: string; const AValues: array of string): Boolean;
```

C++

```
Boolean AnsiMatchStr(const AnsiString AText, const array of string AValues);
```

File

StrUtils

Description

Call AnsiMatchStr to determine whether the string specified by AText matches one of the strings in AValues. Comparisons are case-sensitive.

See Also

AnsiIndexStr (see page 21965)

AnsiSameStr

AnsiMatchText (see page 21967)

155.1.9 StrUtils.AnsiMatchText Function

Indicates whether an array of strings contains a case-insensitive match to a specified string.

Pascal

```
function AnsiMatchText(const AText: string; const AValues: array of string): Boolean;
```

C++

```
Boolean AnsiMatchText(const AnsiString AText, const array of string AValues);
```

File

StrUtils

Description

Call AnsiMatchText to determine whether the string specified by AText matches one of the strings in AValues. Comparisons are case-insensitive and use the current system locale.

AText is the string to locate.

AValues is the array of strings to search.

Note: AValues_Size is the index of the last element in AValues (one less than the number of elements).

AnsiMatchText returns true if AText (or a string that matches except for case) appears in AValues, false if it does not appear in the array.

See Also

AnsiIndexText (see page 21966)

AnsiSameText

ANsiMatchStr

155.1.10 StrUtils.AnsiMidStr Function

Returns the substring of a specified length that appears at a specified position in a string.

Pascal

```
function AnsiMidStr(const AText: AnsiString; const AStart: Integer; const ACount: Integer):
AnsiString;
```

C++

```
AnsiString AnsiMidStr(const AnsiString AText, const int AStart, const int ACount);
```

File

StrUtils

Description

AnsiMidStr returns a substring Count characters at AText[AStart].

If AStart is larger than the length of AText, AnsiMidStr returns an empty string.

If Count specifies more characters than are available, only the characters from AText[AStart] to the end of AText are returned.

RightStr (see page 21984)

MidStr (see page 21980)

MidBStr (see page 21980)

155.1.11 StrUtils.AnsiReplaceStr Function

Replaces all occurrences of a substring with another string.

Pascal

```
function AnsiReplaceStr(const AText: string; const AFromText: string; const AToText: string):
string;
```

C++

```
AnsiString AnsiReplaceStr(const AnsiString AText, const AnsiString AFromText, const AnsiString
AToText);
```

File

StrUtils

Description

Call AnsiReplaceStr to scan the string specified by AText and replace all occurrences of the string specified by AFromText with the string specified by AToText. Occurrences of AFromText are identified by a case-sensitive comparison. The identification of substrings is not recursive: if the substitution of AToText results in a new match for AFromText, that match is not replaced.

See Also

AnsiContainsStr (see page 21963)

AnsiReplaceText (see page 21969)

ANsiMatchStr

StringReplace

SearchBuf (see page 21985)

StuffString (see page 21990)

155.1.12 StrUtils.AnsiReplaceText Function

Replaces all case-insensitive matches of a substring with another string.

Pascal

```
function AnsiReplaceText(const AText: string; const AFromText: string; const AToText: string):
string;
```

C++

```
AnsiString AnsiReplaceText(const AnsiString AText, const AnsiString AFromText, const
AnsiString AToText);
```

File

StrUtils

Description

Call AnsiReplaceText to scan the string specified by AText and replace all occurrences of the string specified by AFromText with the string specified by AToText. Occurrences of AFromText are identified by a case-insensitive comparison that uses the current system locale. The identification of substrings is not recursive: if the substitution of AToText results in a new match for

AFromText, that match is not replaced.

See Also

AnsiContainsText (see page 21964)

AnsiReplaceStr (see page 21969)

StringReplace

SearchBuf (see page 21985)

StuffString (see page 21990)

155.1.13 StrUtils.AnsiResemblesText Function

Indicates whether two strings are similar.

Pascal

```
function AnsiResemblesText(const AText: string; const AOther: string): Boolean;
```

C++

```
Boolean AnsiResemblesText(const AnsiString AText, const AnsiString AOther);
```

File

StrUtils

Description

AnsiResemblesText returns true if the string specified by AText is "similar" to the string specified by AOther, or false if the two strings are not sufficiently similar.

The algorithm that controls whether AnsiResemblesText considers two strings similar is specified by the AnsiResemblesProc (see page 21995) variable. By default, AnsiResemblesProc (see page 21995) is set to SoundExProc, which converts both strings to a phonetic representation using a SoundEx algorithm and compares up to 4 characters of the resulting phonetic representation. By changing the function assigned to AnsiResemblesProc (see page 21995), you can change the comparison made by AnsiResemblesText.

See Also

AnsiResemblesProc (see page 21995)

SoundExProc

155.1.14 StrUtils.AnsiReverseString Function

Returns reversed string.

Pascal

```
function AnsiReverseString(const AText: AnsiString): AnsiString;
```

C++

```
AnsiString AnsiReverseString(const AnsiString AText);
```

File

StrUtils

Description

AnsiReverseString returns AText with its characters reversed.

155.1.15 StrUtils.AnsiRightStr Function

Returns the substring of a specified length that appears at the end of a string.

Pascal

```
function AnsiRightStr(const AText: AnsiString; const ACount: Integer): AnsiString;
```

C++

```
AnsiString AnsiRightStr(const AnsiString AText, const int ACount);
```

File

StrUtils

Description

AnsiRightStr returns the trailing characters of AText up to a length of ACount characters. Thus, for example, if AText is the string "Programmer" and ACount is 7, AnsiRightStr returns the string "grammer".

See Also

Copy

TrimRight

AnsiEndsText (see page 21965)

AnsiEndsStr (see page 21964)

RightStr (see page 21984)

RightBStr (see page 21984)

155.1.16 StrUtils.AnsiStartsStr Function

Indicates whether one string is a (case-sensitive) prefix of another.

Pascal

```
function AnsiStartsStr(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean AnsiStartsStr(const AnsiString ASubText, const AnsiString AText);
```

File

StrUtils

Description

AnsiStartsStr returns true if the string specified by ASubText appears as the leading part of the string specified by AText.

Comparison is performed case-sensitively.

See Also

AnsiEndsStr (see page 21964)

AnsiContainsStr (see page 21963)

Pos

LeftStr (see page 21978)

AnsiStartsText (see page 21972)

155.1.17 StrUtils.AnsiStartsText Function

Indicates whether one string is a (case-insensitive) prefix of another.

Pascal

```
function AnsiStartsText(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean AnsiStartsText(const AnsiString ASubText, const AnsiString AText);
```

File

StrUtils

Description

AnsiStartsText returns true if the string specified by ASubText appears as the leading part of the string specified by AText. Comparison is performed case-insensitively and uses the current system locale.

See Also

AnsiEndsText (see page 21965)

AnsiContainsText (see page 21964)

Pos

LeftStr (see page 21978)

AnsiStartsStr (see page 21971)

155.1.18 StrUtils.ContainsStr Function

Performs a case sensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.

Pascal

```
function ContainsStr(const AText: string; const ASubText: string): Boolean;
```

C++

```
Boolean ContainsStr(const AnsiString AText, const AnsiString ASubText);
```

File

StrUtils

Description

For a case insensitive search, use the ContainsText (see page 21973) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

ContainsText (see page 21973)

155.1.19 StrUtils.ContainsText Function

Performs a case insensitive search for substring ASubText in string AText. Returns true if one or more instances of ASubText exist in AText.

Pascal

```
function ContainsText(const AText: string; const ASubText: string): Boolean;
```

C++

```
Boolean ContainsText(const AnsiString AText, const AnsiString ASubText);
```

File

StrUtils

Description

For a case sensitive search, use the ContainsStr (see page 21972) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

ContainsStr (see page 21972)

155.1.20 StrUtils.DecodeSoundexInt Function

Converts an integer representation of a Soundex (see page 21986) encoding into the corresponding phonetic string.

Pascal

```
function DecodeSoundexInt(AValue: Integer): string;
```

C++

```
AnsiString DecodeSoundexInt(int AValue);
```

File

StrUtils

Description

Call DecodeSoundexInt to convert the integer representation of a string returned by the SoundexInt (see page 21987) function into the corresponding Soundex (see page 21986) string representation.

A Soundex (see page 21986) representation of a string is a phonetic encoding where each character of the Soundex (see page 21986) representation represents a family of similar phonemes.

See Also

SoundexInt (see page 21987)

DecodeSoundexWord (see page 21974)

Soundex (see page 21986)

155.1.21 StrUtils.DecodeSoundexWord Function

Converts a Word representation of a Soundex (see page 21986) encoding into the corresponding phonetic string.

Pascal

```
function DecodeSoundexWord(AValue: Word): string;
```

C++

```
AnsiString DecodeSoundexWord(Word AValue);
```

File

StrUtils

Description

Call DecodeSoundexWord to convert the unsigned 16-bit representation of a string returned by the SoundexWord (see page 21989) function into the corresponding Soundex (see page 21986) string representation.

A Soundex (see page 21986) representation of a string is a phonetic encoding where each character of the Soundex (see page 21986) representation represents a family of similar phonemes.

See Also

SoundexWord (see page 21989)

DecodeSoundexInt (see page 21973)

Soundex (see page 21986)

155.1.22 StrUtils.DupeString Function

Returns the concatenation of a string with itself a specified number of repeats.

Pascal

```
function DupeString(const AText: string; ACount: Integer): string;
```

C++

```
AnsiString DupeString(const AnsiString AText, int ACount);
```

File

StrUtils

Description

DupeString returns a string containing ACount repeats of the string specified by AText. For example,

S := DupeString('Ha', 5);

sets S to the string 'HaHaHaHaHa'.

See Also

StringOfChar

StringReplace

155.1.23 StrUtils.EndsStr Function

Determines if string AText ends with substring ASubText using a case sensitive string comparison. Returns true if AText ends with ASubText.

Pascal

```
function EndsStr(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean EndsStr(const AnsiString ASubText, const AnsiString AText);
```

File

StrUtils

Description

For a case insensitive comparison, use the EndsText (see page 21975) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

EndsText (see page 21975)

155.1.24 StrUtils.EndsText Function

Determines if string AText ends with substring ASubText using a case insensitive string comparison. Returns true if AText ends with ASubText.

Pascal

```
function EndsText(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean EndsText(const AnsiString ASubText, const AnsiString AText);
```

File

StrUtils

Description

For a case sensitive comparison, use the EndsStr (see page 21975) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

EndsStr (see page 21975)

155.1.25 StrUtils.IfThen Function

Conditionally returns one of two specified values.

Pascal

```
function IfThen(AValue: Boolean; const ATrue: string; AFalse: string = ''): string; overload;
```

C++

```
AnsiString IfThen(Boolean AValue, const AnsiString ATrue, AnsiString AFalse = '');
```

File

StrUtils

Description

IfThen checks the expression passed as AValue and returns ATrue if it evaluates to true, or AFalse if it evaluates to false. In Delphi, if the AFalse parameter is omitted, IfThen returns 0 or an empty string when AValue evaluates to False.

155.1.26 StrUtils.IndexStr Function

IndexStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.

Pascal

```
function IndexStr(const AText: string; const AValues: array of string): Integer;
```

C++

```
int IndexStr(const AnsiString AText, const array of string AValues);
```

File

StrUtils

Description

For a case insensitive comparison, use the IndexText (see page 21977) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

IndexText (see page 21977)

155.1.27 StrUtils.IndexText Function

IndexText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns the zero-based index of the first match in the array, or -1 if no match is found.

Pascal

```
function IndexText(const AText: string; const AValues: array of string): Integer;
```

C++

```
int IndexText(const AnsiString AText, const array of string AValues);
```

File

StrUtils

Description

For a case sensitive comparison, use the IndexStr (see page 21976) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

IndexStr (see page 21976)

155.1.28 StrUtils.LeftBStr Function

Returns the substring of a specified number of bytes that appears at the start of a string.

Pascal

```
function LeftBStr(const AText: AnsiString; const AByteCount: Integer): AnsiString;
```

C++

```
AnsiString LeftBStr(const AnsiString AText, const int AByteCount);
```

File

StrUtils

Description

LeftBStr returns the leading bytes of AText up to a length of AByteCount bytes.

Note: LeftBStr assumes all characters are one byte long, and does not behave correctly if AText contains multi-byte characters. To handle all strings correctly, use LeftStr (see page 21978).

See Also

Copy

TrimLeft

AnsiStartsText (see page 21972)

AnsiStartsStr (see page 21971)

AnsiLeftStr (see page 21966)

LeftStr (see page 21978)

155.1.29 StrUtils.LeftStr Function

Returns the substring of a specified length that appears at the start of a string.

Pascal

```
function LeftStr(const AText: AnsiString; const ACount: Integer): AnsiString; overload;
function LeftStr(const AText: WideString; const ACount: Integer): WideString; overload;
```

C++

```
AnsiString LeftStr(const AnsiString AText, const int ACount);
BSTR LeftStr(const BSTR AText, const int ACount);
```

File

StrUtils

Description

LeftStr returns the leading characters of AText up to a length of ACount characters.

Note: If AText is an AnsiString and the current locale uses multi-byte characters, LeftStr may return more than ACount bytes. To return a specific number of bytes, use LeftBStr (see page 21977).

See Also

Copy

TrimLeft

AnsiStartsText (see page 21972)

AnsiStartsStr (see page 21971)

AnsiLeftStr (see page 21966)

LeftBStr (see page 21977)

155.1.30 StrUtils.MatchStr Function

MatchStr determines if any of the strings in the array AValues match the string specified by AText using a case sensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.

Pascal

```
function MatchStr(const AText: string; const AValues: array of string): Boolean;
```

C++

```
Boolean MatchStr(const AnsiString AText, const array of string AValues);
```

File

StrUtils

Description

For a case insensitive match, use the MatchText (see page 21979) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

MatchText (see page 21979)

155.1.31 StrUtils.MatchText Function

MatchText determines if any of the strings in the array AValues match the string specified by AText using a case insensitive comparison. It returns true if at least one of the strings in the array match, or false if none of the strings match.

Pascal

```
function MatchText(const AText: string; const AValues: array of string): Boolean;
```

C++

```
Boolean MatchText(const AnsiString AText, const array of string AValues);
```

File

StrUtils

Description

For a case sensitive comparison, use the MatchStr (see page 21979) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

MatchStr (see page 21979)

155.1.32 StrUtils.MidBStr Function

Returns the substring of a specified number of bytes that appears at a specified position in a string.

Pascal

```
function MidBStr(const AText: AnsiString; const AByteStart: Integer; const AByteCount:
Integer): AnsiString;
```

C++

```
AnsiString MidBStr(const AnsiString AText, const int AByteStart, const int AByteCount);
```

File

StrUtils

Description

MidBStr returns a substring AByteCount bytes beginning at AByteStart bytes.

If AByteStart is larger than the length of AText in bytes, MidBStr returns an empty string.

If AByteCount specifies more bytes than are available, only the available bytes are returned.

Note: MidBStr assumes all characters are one byte long, and does not behave correctly if AText contains multi-byte characters. To handle all strings correctly, use MidStr (see page 21980).

See Also

Copy

LeftStr (see page 21978)

RightStr (see page 21984)

AnsiMidStr (see page 21968)

MidStr (see page 21980)

155.1.33 StrUtils.MidStr Function

Returns the substring of a specified length that appears at a specified position in a string.

Pascal

```
function MidStr(const AText: AnsiString; const AStart: Integer; const ACount: Integer):
AnsiString; overload;
function MidStr(const AText: WideString; const AStart: Integer; const ACount: Integer):
WideString; overload;
```

C++

```
AnsiString MidStr(const AnsiString AText, const int AStart, const int ACount);
BSTR MidStr(const BSTR AText, const int AStart, const int ACount);
```

File

StrUtils

Description

MidStr returns a substring Count characters at AText[AStart].

If AStart is larger than the length of AText, MidStr returns an empty string.

If Count specifies more characters than are available, only the characters from AText[AStart] to the end of AText are returned.

Note: If AText is an AnsiString and the current locale uses multi-byte characters, MidStr may return more than ACount bytes. To return a specific number of bytes, use MidBStr (see page 21980).

See Also

Copy

LeftStr (see page 21978)

RightStr (see page 21984)

AnsiMidStr (see page 21968)

MidBStr (see page 21980)

155.1.34 StrUtils.PosEx Function

Returns the index value of a substring.

Pascal

```
function PosEx(const SubStr: string; const S: string; Offset: Integer = 1): Integer;
```

C++

```
int PosEx(const AnsiString SubStr, const AnsiString S, int Offset = 1);
```

File

StrUtils

Description

PosEx returns the index of SubStr in S, beginning the search at Offset. If Offset is 1 (default), PosEx is equivalent to Pos.

PosEx returns 0 if SubStr is not found, if Offset is greater than the length of S, or if Offset is less than 1.

See Also

Pos

155.1.35 StrUtils.RandomFrom Function

Returns a randomly selected element from an array.

Pascal

```
function RandomFrom(const AValues: array of string): string; overload;
```

C++

```
AnsiString RandomFrom(const array of string AValues);
```

File

StrUtils

Description

RandomFrom returns a randomly selected element from the array passed as the AValues argument. In C++, AValues_Size is the index of the last array element (one less than the number of elements.)

To initialize the random number generator, add a single call Randomize or assign a value to the RandSeed variable before making any calls to RandomFrom.

See Also

Randomize

RandSeed

155.1.36 StrUtils.ReplaceStr Function

ReplaceStr replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case sensitive.

Pascal

```
function ReplaceStr(const AText: string; const AFromText: string; const AToText: string):
string;
```

C++

```
AnsiString ReplaceStr(const AnsiString AText, const AnsiString AFromText, const AnsiString
AToText);
```

File

StrUtils

Description

For a case insensitive replacement, use the ReplaceText (see page 21982) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

ReplaceText (see page 21982)

155.1.37 StrUtils.ReplaceText Function

ReplaceText replaces all instances of string AFromText to string AToText in the source string AText and returns this value as the result. The replacement is case insensitive.

Pascal

```
function ReplaceText(const AText: string; const AFromText: string; const AToText: string):
string;
```

C++

```
AnsiString ReplaceText(const AnsiString AText, const AnsiString AFromText, const AnsiString AToText);
```

File

StrUtils

Description

For a case sensitive replacement, use the ReplaceStr (see page 21982) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

ReplaceStr (see page 21982)

155.1.38 StrUtils.ResemblesText Function

ResemblesText uses a Soundex (see page 21986) method to determine if string AText and string AOther are similar. The result is True if the two strings a similar according to the Soundex (see page 21986) method, and false otherwise.

Pascal

```
function ResemblesText(const AText: string; const AOther: string): Boolean;
```

C++

```
Boolean ResemblesText(const AnsiString AText, const AnsiString AOther);
```

File

StrUtils

See Also

Commonly Used Long String Routines

String Types

String Constants

AnsiResemblesText (see page 21970)

155.1.39 StrUtils.ReverseString Function

Returns the reverse of a specified string.

Pascal

```
function ReverseString(const AText: string): string;
```

C++

```
AnsiString ReverseString(const AnsiString AText);
```

File

StrUtils

Description

ReverseString returns the string specified by AText with the characters in reverse order.

See Also

DupeString (see page 21974)

155.1.40 StrUtils.RightBStr Function

Returns the substring of a specified number of bytes that appears at the end of a string.

Pascal

```
function RightBStr(const AText: AnsiString; const AByteCount: Integer): AnsiString;
```

C++

```
AnsiString RightBStr(const AnsiString AText, const int AByteCount);
```

File

StrUtils

Description

RightBStr returns the trailing bytes of AText up to a length of AByteCount bytes.

Note: RightBStr assumes all characters are one byte long, and does not behave correctly if AText contains multi-byte characters. To handle all strings correctly, use RightStr (see page 21984).

See Also

Copy

TrimRight

AnsiEndsText (see page 21965)

AnsiEndsStr (see page 21964)

AnsiRightStr (see page 21971)

155.1.41 StrUtils.RightStr Function

Returns the substring of a specified length that appears at the end of a string.

Pascal

```
function RightStr(const AText: AnsiString; const ACount: Integer): AnsiString; overload;
function RightStr(const AText: WideString; const ACount: Integer): WideString; overload;
```

C++

```
AnsiString RightStr(const AnsiString AText, const int ACount);
BSTR RightStr(const BSTR AText, const int ACount);
```

File

StrUtils

Description

RightStr returns the trailing characters of AText up to a length of ACount characters. Thus, for example, if AText is the string "Programmer" and ACount is 7, RightStr returns the string "grammer".

Note: If AText is an AnsiString and the current locale uses multi-byte characters, RightStr may return more than ACount bytes. To return a specific number of bytes, use RightBStr (see page 21984).

See Also

Copy

TrimRight

AnsiEndsText (see page 21965)

AnsiEndsStr (see page 21964)

AnsiRightStr (see page 21971)

155.1.42 StrUtils.SearchBuf Function

Locates a substring within a text buffer.

Pascal

```
function SearchBuf(Buf: PChar; BufLen: Integer; SelStart: Integer; SelLength: Integer;
SearchString: String; Options: TStringSearchOptions = [soDown]): PChar;
```

C++

```
const char * SearchBuf(const char * Buf, int BufLen, int SelStart, int SelLength, AnsiString
SearchString, TStringSearchOptions Options = [soDown]);
```

File

StrUtils

Description

Call SearchBuf to search for a specified search string within a text buffer.

Buf is the text buffer to search.

BufLen is the length, in bytes, of Buf.

SelStart is the first character of the search when Options indicates a backward search (does not include soDown). The first character in Buf has position 0.

SelLength is the number of characters after SelStart that the search begins when Options indicates a forward search (includes soDown).

SearchString is the string to find in Buf.

Options determines whether the search runs forward (soDown) or backward from SelStart or SelStart+SelLength, whether the search is case sensitive (soMatchCase), and whether the matching string must be a whole word (soWholeWord).

If SearchBuf finds a match, it returns a pointer to the first character of the matching string in Buf. If it does not find a match, SearchBuf returns nil (Delphi) or NULL (C++).

See Also

TFindDialog

155.1.43 StrUtils.Soundex Function

Converts a string into its Soundex representation.

Pascal

```
function Soundex(const AText: string; ALength: TSoundexLength = 4): string;
```

C++

```
AnsiString Soundex(const AnsiString AText, TSoundexLength ALength = 4);
```

File

StrUtils

Description

Soundex converts the string specified by AText into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It returns up to the first ALength Soundex codes in the resulting string representation.

See Also

SoundexWord (see page 21989)

SoundexInt (see page 21987)

SoundexSimilar (see page 21988)

SoundexCompare (see page 21986)

SoundexProc (see page 21987)

155.1.44 StrUtils.SoundexCompare Function

Compares the Soundex (see page 21986) representations of two strings.

Pascal

```
function SoundexCompare(const AText: string; const AOther: string; ALength: TSoundexLength =
4): Integer;
```

C++

```
int SoundexCompare(const AnsiString AText, const AnsiString AOther, TSoundexLength ALength =
4);
```

File

StrUtils

Description

SoundexCompare uses a Soundex (see page 21986) algorithm to convert the strings specified by AText and AOther into phonetic representations where each character of the resulting string represents one of six families of similar phonemes. It then compares the first ALength characters of the resulting representations by calling AnsiCompareStr.

SoundexCompare returns 0 if the first ALength characters of the phonetic representations are identical, a value less then 0 if the representation of AText is less than the representation of AOther, and a value greater than 0 if the representation of AText is greater than the representation of AOther.

See Also

SoundexSimilar (see page 21988)

SoundexWord (see page 21989)

SoundexInt (see page 21987)

AnsiCompareStr

Soundex (see page 21986)

SoundexProc (see page 21987)

155.1.45 StrUtils.SoundexInt Function

Converts a string into an integer that represents its phonetic value.

Pascal

```
function SoundexInt(const AText: string; ALength: TSoundexIntLength = 4): Integer;
```

C++

```
int SoundexInt(const AnsiString AText, TSoundexIntLength ALength = 4);
```

File

StrUtils

Description

SoundexInt uses a Soundex (see page 21986) algorithm to convert the string specified by AText into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then returns an integer that uniquely represents the first ALength Soundex (see page 21986) codes in that string representation.

Note: The TSoundexIntLength (see page 21993) type represents an integer between 1 and 8. This is because the size of the integer return value limits the number of Soundex (see page 21986) codes that can be used in the final representation.

See Also

SoundexSimilar (see page 21988)

SoundexWord (see page 21989)

DecodeSoundexInt (see page 21973)

SoundexCompare (see page 21986)

Soundex (see page 21986)

SoundexProc (see page 21987)

155.1.46 StrUtils.SoundexProc Function

Indicates whether two strings are similar.

Pascal

```
function SoundexProc(const AText: string; const AOther: string): Boolean;
```

C++

```
Boolean SoundexProc(const AnsiString AText, const AnsiString AOther);
```

File

StrUtils

Description

SoundexProc returns true if the string specified by AText is "similar" to the string specified by AOther, or false if the two strings are not sufficiently similar. SoundexProc is the default value of the AnsiResemblesProc (see page 21995) variable, which provides the underlying implementation of AnsiResemblesText (see page 21970).

SoundexProc uses a Soundex (see page 21986) algorithm to convert both strings into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then compares up to 4 digits in the resulting representation, returning true if they are all the same and false if they are not.

Note: SoundexProc is the same as the SoundexSimilar (see page 21988) function using an ALength value of 4.

See Also

AnsiResemblesProc (see page 21995)

SoundexSimilar (see page 21988)

SoundexCompare (see page 21986)

SOundexInt

Soundex (see page 21986)

AnsiResemblesText (see page 21970)

155.1.47 StrUtils.SoundexSimilar Function

Indicates whether two strings are similar.

Pascal

```
function SoundexSimilar(const AText: string; const AOther: string; ALength: TSoundexLength =
4): Boolean;
```

C++

```
Boolean SoundexSimilar(const AnsiString AText, const AnsiString AOther, TSoundexLength ALength
= 4);
```

File

StrUtils

Description

SoundexSimilar returns true if the string specified by AText is "similar" to the string specified by AOther, or false if the two strings are not sufficiently similar.

SoundexSimilar uses a Soundex (see page 21986) algorithm to convert both strings into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then compares up to ALength digits in the

resulting representation, returning true if they are all the same and false if they are not.

SOundexCompare

SoundexWord (see page 21989)

SoundexInt (see page 21987)

Soundex (see page 21986)

SoundexProc (see page 21987)

155.1.48 StrUtils.SoundexWord Function

Converts a string into a Word that represents its phonetic value.

Pascal

```
function SoundexWord(const AText: string): Word;
```

C++

```
Word SoundexWord(const AnsiString AText);
```

File

StrUtils

Description

SoundexWord uses a Soundex (see page 21986) algorithm to convert the string specified by AText into a phonetic representation where each character of the resulting string represents one of six families of similar phonemes. It then returns an unsigned 16-bit value that uniquely represents the first 4 Soundex (see page 21986) codes in that string representation.

See Also

SoundexSimilar (see page 21988)

SoundexInt (see page 21987)

DecodeSoundexWord (see page 21974)

SoundexCompare (see page 21986)

Soundex (see page 21986)

SoundexProc (see page 21987)

155.1.49 StrUtils.StartsStr Function

Enter a short sentence, starting with a verb, that states the basic purpose of the property.

Pascal

```
function StartsStr(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean StartsStr(const AnsiString ASubText, const AnsiString AText);
```

File

StrUtils

Description

For a case insensitive comparison, use the StartsText (see page 21990) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

StartsText (see page 21990)

155.1.50 StrUtils.StartsText Function

StartsText determines if the substring ASubText begins the string AText using a case insensitive algorithm. If ASubText matches the begining of AText, the result is true, otherwise it is false.

Pascal

```
function StartsText(const ASubText: string; const AText: string): Boolean;
```

C++

```
Boolean StartsText(const AnsiString ASubText, const AnsiString AText);
```

File

StrUtils

Description

For a case sensitive comparison, use the StartsStr (see page 21989) routine.

See Also

Commonly Used Long String Routines

String Types

String Constants

StartsStr (see page 21989)

155.1.51 StrUtils.StuffString Function

Inserts a substring into a specified position of a string, replacing the current characters.

Pascal

```
function StuffString(const AText: string; AStart: Cardinal; ALength: Cardinal; const ASubText:
string): string;
```

C++

```
AnsiString StuffString(const AnsiString AText, unsigned AStart, unsigned ALength, const
AnsiString ASubText);
```

File

StrUtils

Description

StuffString returns a new string that is constructed by replacing the characters of AText specified by AStart and ALength with the string specified by ASubText.

AText is the string to which ASubText is added. It is not modified by StuffString.

AStart is the index of the first character in AText to be replaced, where 1 identifies the first character, 2 identifies the second character, and so on.

ALength is the number of characters in AText that are replaced by ASubText. If ALength is 0, ASubText is inserted into AText without removing any characters. If AText is negative, the characters preceding the insertion point are duplicated after the occurrence of ASubText in the result string.

ASubText is the substring to insert into AText, replacing the characters specified by AStart and ALength.

155.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TStringSeachOption (see page 21992)	TStringSeachOption is an enumeration that describes the behavior of string searches.

155.2.1 StrUtils.TStringSeachOption Enumeration

TStringSeachOption is an enumeration that describes the behavior of string searches.

Pascal

```
TStringSeachOption = (
  soDown,
  soMatchCase,
  soWholeWord
);
```

C++

```
enum TStringSeachOption {
  soDown,
  soMatchCase,
  soWholeWord
};
```

File

StrUtils

Description

Note the unusual spelling. TStringSeachOptioncan have one of the following values:

Value	Meaning
soDown	A forward search is performed through the target text from the specified start point to the end of the search buffer. If soDown is not specified a reverse search is performed from the start point to the begining of the search buffer.
soMatchCase	Performs a case sensitive search.
soWholeWord	Match whole words, not pieces of words. Whole words are determined using standard identifier parser rules.

String Types

String Constants

TStringSearchOptions (see page 21994)

155.3 Types

The following table lists types in this documentation.

Types

Name	Description
TCompareTextProc (see page 21993)	TCompareTextProc is a function pointer which specifies a function to compare two string values, AText, and AOther, and return true if these two values are equivilant.
TSoundexIntLength (see page 21993)	TSoundexIntLength The maximum calculation length for the SoundexInt (see page 21987) function. The integer value can be from 1 to 8.
TSoundexLength (see page 21994)	TSoundexLength The maximum calculation length of the SoundEx function. This value determines how many characters to use when generating the soundex string form the source string.
TStringSearchOptions (see page 21994)	TStringSearchOptions is set of the enumeration TStringSeachOption (see page 21992).

155.3.1 StrUtils.TCompareTextProc Type

TCompareTextProc is a function pointer which specifies a function to compare two string values, AText, and AOther, and return true if these two values are equivilant.

Pascal

```
TCompareTextProc = function (const AText, AOther: string): Boolean;
```

C++

```
(const AText, AOther: string): Boolean ( TCompareTextProc)();
```

File

StrUtils

See Also

TStringSeachOption (see page 21992)

155.3.2 StrUtils.TSoundexIntLength Type

TSoundexIntLength The maximum calculation length for the SoundexInt (see page 21987) function. The integer value can be from 1 to 8.

Pascal

```
TSoundexIntLength = 1..8;
```

C++

```
1..8 TSoundexIntLength;
```

File

StrUtils

Description

This value determines how many characters to use when generating the soundex string from the source string. There is a maximum of 8 characters due to the maximum capacity of the Integer type.

See Also

SoundexLength

155.3.3 StrUtils.TSoundexLength Type

TSoundexLength The maximum calculation length of the SoundEx function. This value determines how many characters to use when generating the soundex string form the source string.

Pascal

```
TSoundexLength = 1..MaxInt;
```

C++

```
1..MaxInt TSoundexLength;
```

File

StrUtils

See Also

SoundexIntLength

155.3.4 StrUtils.TStringSearchOptions Type

TStringSearchOptions is set of the enumeration TStringSeachOption (see page 21992).

Pascal

```
TStringSearchOptions = set of TStringSeachOption;
```

C++

```
TStringSeachOption TStringSearchOptions;
```

File

StrUtils

Description

Note the unusual spelling of the enumeration.

See Also

TStringSeachOption (see page 21992)

155.4 Variables

The following table lists variables in this documentation.

Variables

Name	Description
AnsiResemblesProc (see page 21995)	Controls (see page 5711) the algorithm used by AnsiResemblesText (see page 21970) to determine when two strings are similar.
ResemblesProc (see page 21995)	Controls (see page 5711) the algorithm used by AnsiResemblesText (see page 21970) to determine when two strings are similar. It is the same as AnsiResemblesProc (see page 21995).

155.4.1 StrUtils.AnsiResemblesProc Variable

Controls (see page 5711) the algorithm used by AnsiResemblesText (see page 21970) to determine when two strings are similar.

Pascal

```
AnsiResemblesProc: TCompareTextProc = SoundexProc;
```

C++

```
TCompareTextProc AnsiResemblesProc = SoundexProc;
```

File

StrUtils

Description

The AnsiResemblesText (see page 21970) function uses the function assigned to AnsiResemblesProc to determine when two strings should be considered similar. By default, AnsiResemblesProc is set to SoundExProc.

To make AnsiResemblesText (see page 21970) use a different algorithm, you can change AnsiResemblesProc to another function. For example, you can change the number of phonemes compared by using a function that assigns a different length to SoundExSimilar than then default value of 4. Alternately, you can create a function that uses a different algorithm entirely.

See Also

AnsiResemblesText (see page 21970)

SoundExSimilar

155.4.2 StrUtils.ResemblesProc Variable

Controls (see page 5711) the algorithm used by AnsiResemblesText (see page 21970) to determine when two strings are similar. It is the same as AnsiResemblesProc (see page 21995).

Pascal

```
ResemblesProc: TCompareTextProc = SoundexProc;
```

C++

```
TCompareTextProc ResemblesProc = SoundexProc;
```

File

StrUtils

Description

The AnsiResemblesText (see page 21970) function uses the function assigned to ResemblesProc to determine when two strings should be considered similar. By default, ResemblesProc is set to SoundExProc.

To make AnsiResemblesText (see page 21970) use a different algorithm, you can change ResemblesProc to another function. For example, you can change the number of phonemes compared by using a function that assigns a different length to SoundExSimilar than then default value of 4. Alternately, you can create a function that uses a different algorithm entirely.

155.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
WordDelimiters (see page 21997)	This is constant StrUtils.WordDelimiters.

155.5.1 StrUtils.WordDelimiters Constant

Pascal

```
WordDelimiters: set of Char = [#0..#255] - ['a'..'z','A'..'Z','1'..'9','0'];
```

C++

```
set of Char WordDelimiters = [#0..#255] - ['a'..'z','A'..'Z','1'..'9','0'];
```

File

StrUtils

Description

This is constant StrUtils.WordDelimiters.

156 SvcMgr Namespace

This is namespace SvcMgr.

Topics

Name	Description
Classes (see page 22001)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 22047)	The following table lists structs, records, enums in this documentation.
Types (see page 22051)	The following table lists types in this documentation.
Variables (see page 22054)	The following table lists variables in this documentation.
Constants (see page 22055)	The following table lists constants in this documentation.

Classes

	Name	Description
	TDependencies (see page 22001)	TDependencies is a container for TDependency (see page 22005) objects.
	TDependency (see page 22005)	TDependency object represents a dependent service or load ordering group used by TService (see page 22011) objects.
	TEventLogger (see page 22009)	This is class SvcMgr.TEventLogger.
	TService (see page 22011)	TService encapsulates a Windows NT service.
	TServiceApplication (see page 22032)	TServiceApplication encapsulates a Windows NT service application.
	TServiceThread (see page 22040)	TServiceThread represents the thread associated with a specific service (TService (see page 22011) object).

Constants

Name	Description
CM_SERVICE_CONTROL_CODE (see page 22055)	This is constant SvcMgr.CM_SERVICE_CONTROL_CODE.

Structs, Records, Enums

	Name	Description
	TCurrentStatus (see page 22047)	TCurrentStatus indicates the state of a service.
	TErrorSeverity (see page 22048)	TErrorSeverity indicates the severity of a failure and implies the corresponding response by a service startup program.
	TServiceType (see page 22048)	TServiceType indicates the type of a service.
	TStartType (see page 22049)	TStartType indicates how a service starts up.

Types

Name	Description
TContinueEvent (see page 22051)	This is type SvcMgr.TContinueEvent.

TPauseEvent (see page 22051)	This is type SvcMgr.TPauseEvent.
TServiceController (see page 22052)	This is type SvcMgr.TServiceController.
TServiceEvent (see page 22052)	This is type SvcMgr.TServiceEvent.
TStartEvent (see page 22052)	This is type SvcMgr.TStartEvent.
TStopEvent (see page 22053)	This is type SvcMgr.TStopEvent.

Variables

Name	Description
Application (see page 22054)	This is variable SvcMgr.Application.

156.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TDependencies (see page 22001)	TDependencies is a container for TDependency (see page 22005) objects.
	TDependency (see page 22005)	TDependency object represents a dependent service or load ordering group used by TService (see page 22011) objects.
	TEventLogger (see page 22009)	This is class SvcMgr.TEventLogger.
	TService (see page 22011)	TService encapsulates a Windows NT service.
	TServiceApplication (see page 22032)	TServiceApplication encapsulates a Windows NT service application.
	TServiceThread (see page 22040)	TServiceThread represents the thread associated with a specific service (TService (see page 22011) object).

156.1.1 TDependencies Class

TDependencies is a container for TDependency (see page 22005) objects.

Class Hierarchy

Pascal

```
TDependencies = class(TCollection);
```

C++

```
class TDependencies : public TCollection;
```

File

SvcMgr

Description

TDependencies is a collection of TDependency (see page 22005) objects, each of which represents a dependent service or load ordering group for a service (TService (see page 22011) instance). TDependencies objects are the implementation of the Dependencies property of TService (see page 22011).

See Also

TDependency (see page 22005)

TService (see page 22011)

TService (see page 22011)

TService (see page 22011)

156.1.1.1 TDependencies Members

The following tables list the members exposed by TDependencies.

Protected Methods

	Name	Description
V	Added (see page 2736)	Responds when items are added to the collection.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2740)	Responds when the collection or any of its items changes.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	Deleting (see page 2741)	Responds when items are deleted from the collection.
	GetAttr (see page 2743)	Returns the name of a custom attribute that can be retrieved using the GetItemAttr (see page 2745) method.
	GetAttrCount (see page 2744)	Returns the number of custom attributes associated with items in the collection.
	GetItem (see page 2744)	Returns a specified item in the collection.
	GetItemAttr (see page 2745)	Returns the value of a custom attribute assigned to one of the collection's items.
V	GetOwner (see page 22004)	Returns the owner of an object.
V	Notify (see page 2746)	Responds when items are added to or removed from the collection.
	SetItem (see page 2747)	Copies the properties of another item to a specified item in the collection.
V	SetItemName (see page 2747)	Initializes the name of a newly inserted collection item.
V	Update (see page 2747)	Updates the collection to reflect changes to its items.

Protected Properties

	Name	Description
R	NextID (see page 2752)	Specifies a unique ID that can be assigned to the next added collection item.
	PropName (see page 2752)	Specifies the name of the property that the collection implements.
R	UpdateCount (see page 2753)	Counts the number of times BeginUpdate (see page 2739) was called without a corresponding call to EndUpdate (see page 2742).

Public Methods

	Name	Description
	Add (see page 2736)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2736)	Copies the contents of another collection to the object where the method is executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BeginUpdate (see page 2739)	Suspends screen repainting.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 2741)	Deletes all items from the collection.
	Create (see page 22003)	Creates an instance of a TDependencies (see page 22001) object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 2741)	Deletes a single item from the collection.
V	Destroy (see page 2735)	Destroys the collection and each item in it.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	EndUpdate (see page 2742)	Re-enables screen repainting.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindItemID (see page 2743)	Returns the item with the specified ID.

	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 2744)	Returns a TCollection (see page 2731) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2745)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 2746)	Creates a new TCollectionItem (see page 2755) instance and adds it to the Items (see page 2751) array.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Owner (see page 2746)	Returns the Owner of the collection.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Capacity (see page 2748)	Provides access to the internal TList (see page 2868) Capacity property.
R	Count (see page 2749)	Returns the number of items in the collection.
R	ItemClass (see page 2751)	Indicates the class to which the collection's items belong.
	Items (see page 22004)	Lists the dependency objects in the dependencies collection.

156.1.1.2 TDependencies.Create Constructor

Creates an instance of a TDependencies (see page 22001) object.

Pascal

```
constructor Create(Owner: TPersistent);
```

C++

```
__fastcall TDependencies(TPersistent * Owner);
```

Description

Applications should not need to call the constructor directly. Instances of TService (see page 22011) create the TDependencies (see page 22001) object from their own constructors. The Owner parameter is the TService (see page 22011) instance that uses the TDependencies (see page 22001) object to implement its Dependencies property.

Create sets the TDependency (see page 22005) owner to the Owner parameter and calls the inherited Create.

See Also

Create (see page 2734)

TService (see page 22011)

156.1.1.3 TDependencies Methods

The methods of the TDependencies class are listed here.

Protected Methods

	Name	Description
	GetOwner (see page 22004)	Returns the owner of an object.

156.1.1.3.1 TDependencies.GetOwner Method

Returns the owner of an object.

Pascal

```
function GetOwner: TPersistent; override;
```

C++

```
virtual __fastcall TPersistent * GetOwner();
```

Description

GetOwner is used by the GetNamePath method to find the owner of a persistent object. GetNamePath and GetOwner are introduced in TPersistent so descendants such as collections can appear in the Object Inspector. As implemented in TPersistent, GetOwner returns nil (Delphi) or NULL (C++).

For TCollection, GetOwner returns the owner of the collection. For collection items, it returns the collection object into which the collection item has been inserted. For TComponent it is the value of the Owner property.

See Also

GetNamePath (see page 2932)

TCollection (see page 2731)

TComponent (see page 2762)

Owner (see page 2807)

156.1.1.4 TDependencies Properties

The properties of the TDependencies class are listed here.

Public Properties

	Name	Description
	Items (see page 22004)	Lists the dependency objects in the dependencies collection.

156.1.1.4.1 TDependencies.Items Property

Lists the dependency objects in the dependencies collection.

Pascal

```
property Items [Index: Integer]: TDependency;
```

C++

```
__property TDependency Items[int Index];
```

Description

The value of the Index parameter corresponds to the Index property of each TDependency (see page 22005) object in the collection. It represents the position of the dependency object in the dependencies collection.

Note: In Delphi, Items is the default property of TDependencies (see page 22001). This means that you can omit the property

names. For example

Note: Service1.Dependencies.Items[i]

Note: can be written

Note: Service1.Dependencies[i]

Note: In C++, Items can be accessed using the [] operator, to achieve an affect similar to the default property in Delphi.

Index (see page 2762)

operator_[]

156.1.2 TDependency Class

TDependency object represents a dependent service or load ordering group used by TService (see page 22011) objects.

Class Hierarchy

Pascal

```
TDependency = class(TCollectionItem);
```

C++

```
class TDependency : public TCollectionItem;
```

File

SvcMgr

Description

A TDependency object represents a new service or load ordering group that must start before the service represented by a TService (see page 22011) object. Collections of dependency objects are TDependencies (see page 22001) objects. TService (see page 22011) has Dependencies and LoadGroup properties that use dependency collections. Each dependency has a Name (see page 22008) property that identifies the service or load ordering group, and a boolean IsGroup (see page 22008) property to indicate whether the dependency represents a load ordering group.

See Also

TDependencies (see page 22001)

TService (see page 22011)

TService (see page 22011)

Service Name Properties

156.1.2.1 TDependency Members

The following tables list the members exposed by TDependency.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 2758)	Updates the collection to reflect changes to the collection item.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	GetDisplayName (see page 22007)	Returns the name of the collection item as it appears in the collection editor.
	GetOwner (see page 2759)	Returns the collection to which this item belongs.
	GetOwner (see page 2932)	Returns the owner of an object.
	SetCollection (see page 2759)	Sets the value of the Collection (see page 2761) property.
	SetDisplayName (see page 2760)	Sets the name of the collection item as it appears in the collection editor.
	SetIndex (see page 2760)	Moves the collection item to a specified position in the parent collection.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2757)	Creates and initializes a TCollectionItem (see page 2755) instance.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 2757)	Destroys the TCollectionItem (see page 2755) instance and frees its memory.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2759)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.

	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	Collection (see page 2761)	Specifies the TCollection (see page 2731) instance to which the TCollectionItem (see page 2755) belongs.
	DisplayName (see page 2761)	The name displayed in the Collection (see page 2761) editor.
	ID (see page 2761)	A unique, permanent index for the item.
	Index (see page 2762)	Returns the item's position in the Items array of TCollection (see page 2731).

Published Properties

	Name	Description
	IsGroup (see page 22008)	Indicates whether the dependency represents a load ordering group for a service (TService (see page 22011) object).
	Name (see page 22008)	Identifies the dependent service or load ordering group used by a TService (see page 22011) object.

156.1.2.2 TDependency Methods

The methods of the TDependency class are listed here.

Protected Methods

	Name	Description
	GetDisplayName (see page 22007)	Returns the name of the collection item as it appears in the collection editor.

156.1.2.2.1 TDependency.GetDisplayName Method

Returns the name of the collection item as it appears in the collection editor.

Pascal

```
function GetDisplayName: string; override;
```

C++

```
virtual __fastcall AnsiString GetDisplayName();
```

Description

GetDisplayName is the protected read implementation of the DisplayName property.

See Also

DisplayName (see page 2761)

GetNamePath (see page 2759)

156.1.2.3 TDependency Properties

The properties of the TDependency class are listed here.

Published Properties

	Name	Description
	IsGroup (see page 22008)	Indicates whether the dependency represents a load ordering group for a service (TService (see page 22011) object).

	Name (see page 22008)	Identifies the dependent service or load ordering group used by a TService (see page 22011) object.

156.1.2.3.1 TDependency.IsGroup Property

Indicates whether the dependency represents a load ordering group for a service (TService (see page 22011) object).

Pascal

```
property IsGroup: Boolean;
```

C++

```
__property Boolean IsGroup;
```

Description

IsGroup indicates whether the dependency represents a load ordering group.

Note: : Because services and service groups share the same name space, group names must be prefixed by the SC_GROUP_IDENTIFIER character to distinguish them from service names. If IsGroup is set to true, SC_GROUP_IDENTIFIER will automatically be prefixed to the Dependency name (Name (see page 22008) property). DisplayName is not modified.

See Also

Name (see page 22008)

LoadGroup (see page 22023)

156.1.2.3.2 TDependency.Name Property

Identifies the dependent service or load ordering group used by a TService (see page 22011) object.

Pascal

```
property Name: String;
```

C++

```
__property AnsiString Name;
```

Description

Name is the name identifying the service or load ordering group. If Name is the name of a service, Name reflects the actual ServiceStartName of a TService (see page 22011) instance.

The property editor for the Dependencies property of TService (see page 22011) technically uses the dependency's DisplayName to identify the dependency service in its collection list. However, Name and DisplayName are nearly always the same.

Dependency objects that are load ordering groups are prefixed by SC_GROUP_IDENTIFIER. Setting the IsGroup (see page 22008) property handles prefixing the Name automatically.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and service objects. For more information, see Service name properties.

156.1.3 TEventLogger Class

Class Hierarchy

System::TObject → SvcMgr.TEventLogger

Pascal

```
TEventLogger = class(TObject);
```

C++

```
class TEventLogger : public TObject;
```

File

SvcMgr

Description

This is class SvcMgr.TEventLogger.

156.1.3.1 TEventLogger Members

The following tables list the members exposed by TEventLogger.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22010)	This is Create, a member of class TEventLogger.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22010)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	LogMessage (see page 22011)	This is LogMessage, a member of class TEventLogger.

	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

156.1.3.2 TEventLogger.Create Constructor

Pascal

```
constructor Create(Name: String);
```

C++

```
__fastcall TEventLogger(AnsiString Name);
```

Description

This is Create, a member of class TEventLogger.

156.1.3.3 TEventLogger.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TEventLogger();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 22300)

156.1.3.4 TEventLogger Methods

The methods of the TEventLogger class are listed here.

Public Methods

	Name	Description
	LogMessage (see page 22011)	This is LogMessage, a member of class TEventLogger.

156.1.3.4.1 TEventLogger.LogMessage Method

Pascal

```
procedure LogMessage(Message: String; EventType: DWord = 1; Category: Word = 0; ID: DWord = 0);
```

C++

```
__fastcall LogMessage(AnsiString Message, DWord EventType = 1, Word Category = 0, DWord ID =
0);
```

Description

This is LogMessage, a member of class TEventLogger.

156.1.4 TService Class

TService encapsulates a Windows NT service.

Class Hierarchy

Pascal

```
TService = class(TDataModule);
```

C++

```
class TService : public TDataModule;
```

File

SvcMgr

Description

TService encapsulates a Windows NT service in an NT service application. A Win32 service is accessed via the Service Control Manager and can be started automatically at system boot, by a user through the Services control panel applet, or by a Win32-based application that uses the service functions. Services can execute even when no user is logged on to the system. Windows NT also supports a driver service that does not interact with the SCM.

Service Name Properties

Service Threads

156.1.4.1 TService Members

The following tables list the members exposed by TService.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	Controller (see page 22017)	This is Controller, a member of class TService.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2830)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DoContinue (see page 22017)	This is DoContinue, a member of class TService.
V	DoCreate (see page 2831)	This is DoCreate, a member of class TDataModule.
V	DoCustomControl (see page 22017)	This is DoCustomControl, a member of class TService.
V	DoDestroy (see page 2831)	This is DoDestroy, a member of class TDataModule.
V	DoInterrogate (see page 22017)	This is DoInterrogate, a member of class TService.
V	DoPause (see page 22018)	This is DoPause, a member of class TService.
V	DoShutdown (see page 22018)	This is DoShutdown, a member of class TService.
V	DoStart (see page 22018)	This is DoStart, a member of class TService.
V	DoStop (see page 22018)	This is DoStop, a member of class TService.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 2831)	This is GetChildren, a member of class TDataModule.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 2831)	This is HandleCreateException, a member of class TDataModule.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Main (see page 22019)	This is Main, a member of class TService.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 2832)	This is ReadState, a member of class TDataModule.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.

	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 2829)	Generates an OnCreate (see page 2833) event.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 2830)	Generates an OnDestroy (see page 2834) event.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 2766)	Allocates memory and constructs a safely initialized instance of a component.
	Create (see page 2827)	Creates an instance of a data module.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	CreateNew (see page 22015)	Instantiates and initializes a TService (see page 22011) object.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22016)	Disposes of a TService (see page 22011) instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.

	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
A	GetServiceController (see page 22018)	Returns the service's registered handler function.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	LogMessage (see page 22019)	Sends an error message to the event log.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	ReportStatus (see page 22020)	Updates the Service Control Manager's status information for the calling service.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	DesignOffset (see page 2832)	Specifies the design offset for the data module at design time.
	DesignSize (see page 2832)	Specifies the design size for the data module at design time.
	ErrCode (see page 22022)	Contains the service specific error code returned on starting or stopping the service.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	Param (see page 22024)	Lists the parameters to the service.
R	ParamCount (see page 22024)	Indicates the number of startup parameters for the service.
R	ServiceThread (see page 22025)	Identifies the dedicated thread for the service.
	Status (see page 22026)	Indicates the current state of the service.
R	Terminated (see page 22027)	Indicates whether the service thread has terminated.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

	Win32ErrCode (see page 22028)	Indicates the Win32 error code reported by the service if a service specific code is not defined.

Published Events

	Name	Description
	AfterInstall (see page 22028)	Occurs immediately after the service is registered with the Windows Service Control manager.
	AfterUninstall (see page 22029)	Occurs immediately after the service is removed from the Service Control manager's database.
	BeforeInstall (see page 22029)	Occurs before the service is first registered with the Windows Service Control manager.
	BeforeUninstall (see page 22030)	Occurs immediately before the service is removed from the Service Control manager's database.
	OnContinue (see page 22030)	Occurs when the Service Control manager resumes the service after it has been paused.
	OnCreate (see page 2833)	Occurs when an application instantiates a data module.
	OnDestroy (see page 2834)	Occurs when the data module is about to be destroyed.
	OnExecute (see page 22030)	Occurs when the thread associated with the service starts up.
	OnPause (see page 22031)	Occurs when the Service Control manager pauses the service temporarily.
	OnShutdown (see page 22031)	Occurs when the system running the service application is about to shut down.
	OnStart (see page 22031)	OnStartup occurs when the service first starts up, before the OnExecute (see page 22030) event.
	OnStop (see page 22032)	Occurs when the Service Control manager stops the service.

Published Properties

	Name	Description
	AllowPause (see page 22021)	Indicates whether clients are allowed to pause the service.
	AllowStop (see page 22021)	Indicates whether clients are allowed to stop the service.
	Dependencies (see page 22021)	Lists the services or load ordering groups on which the service depends.
	DisplayName (see page 22022)	Identifies the service in the Windows Service Control Manager.
	ErrorSeverity (see page 22022)	Indicates the severity of service startup failure.
	Interactive (see page 22023)	Indicates whether the service is interactive with the Windows desktop.
	LoadGroup (see page 22023)	Names of the load ordering group that includes the service.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	OldCreateOrder (see page 2833)	Specifies when OnCreate (see page 2833) and OnDestroy (see page 2834) events occur.
	Password (see page 22024)	Specifies the password, optionally used depending upon the ServiceStartName (see page 22025), for accessing the service.
	ServiceStartName (see page 22025)	ServiceStartName is the name used in the Service Control Manager Startup dialog to start the service.
	ServiceType (see page 22026)	Identifies the type of the service as Win32, device driver, or file system driver.
	StartType (see page 22026)	Indicates when or how the service starts.
	Tag (see page 2808)	Stores an integer value as part of a component.
	TagID (see page 22026)	Specifies a unique tag for the service within its LoadGroup (see page 22023).
	WaitHint (see page 22027)	Specifies the estimated time, in milliseconds, between a call from the Windows Service Control Manager and the service reporting its status.

156.1.4.2 TService.CreateNew Constructor

Instantiates and initializes a TService (see page 22011) object.

Pascal

```
constructor CreateNew(AOwner: TComponent; Dummy: Integer); override;
```

C++

```
virtual __fastcall TService(TComponent * AOwner, int Dummy);
```

Description

Call CreateNew to instantiate a service object at runtime. Services added at design time are created automatically. The AOwner parameter specifies the TServiceApplication (see page 22032) object that is responsible for ultimately freeing the service. The Dummy parameter is not used. Use CreateNew rather than the Create constructor to instantiate a new service object at runtime. CreateNew does not attempt to stream in an associated DFM file that indicates any components added to the service at design time.

See Also

Owner (see page 2807)

Create (see page 22003)

TServiceApplication (see page 22032)

156.1.4.3 TService.Destroy Destructor

Disposes of a TService (see page 22011) instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TService();
```

Description

Destroy frees the memory associated with the objects for the Params and Dependencies (see page 22021) properties that were created in the constructor, and for the EventLogger object created in the LogMessage (see page 22019) method. Then it calls the inherited Destroy.

See Also

Free (see page 22300)

LogMessage (see page 22019)

156.1.4.4 TService Methods

The methods of the TService class are listed here.

Protected Methods

	Name	Description
	Controller (see page 22017)	This is Controller, a member of class TService.
V	DoContinue (see page 22017)	This is DoContinue, a member of class TService.
V	DoCustomControl (see page 22017)	This is DoCustomControl, a member of class TService.
V	DoInterrogate (see page 22017)	This is DoInterrogate, a member of class TService.
V	DoPause (see page 22018)	This is DoPause, a member of class TService.
V	DoShutdown (see page 22018)	This is DoShutdown, a member of class TService.
V	DoStart (see page 22018)	This is DoStart, a member of class TService.
V	DoStop (see page 22018)	This is DoStop, a member of class TService.
	Main (see page 22019)	This is Main, a member of class TService.

Public Methods

	Name	Description
	GetServiceController (see page 22018)	Returns the service's registered handler function.
	LogMessage (see page 22019)	Sends an error message to the event log.
	ReportStatus (see page 22020)	Updates the Service Control Manager's status information for the calling service.

156.1.4.4.1 TService.Controller Method

Pascal

```
procedure Controller(CtrlCode: DWord);
```

C++

```
__fastcall Controller(DWord CtrlCode);
```

Description

This is Controller, a member of class TService.

156.1.4.4.2 TService.DoContinue Method

Pascal

```
function DoContinue: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoContinue();
```

Description

This is DoContinue, a member of class TService.

156.1.4.4.3 TService.DoCustomControl Method

Pascal

```
function DoCustomControl(CtrlCode: DWord): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoCustomControl(DWord CtrlCode);
```

Description

This is DoCustomControl, a member of class TService.

156.1.4.4.4 TService.DoInterrogate Method

Pascal

```
procedure DoInterrogate; virtual;
```

C++

```
virtual __fastcall DoInterrogate();
```

Description

This is DoInterrogate, a member of class TService.

156.1.4.4.5 TService.DoPause Method

Pascal

```
function DoPause: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoPause();
```

Description

This is DoPause, a member of class TService.

156.1.4.4.6 TService.DoShutdown Method

Pascal

```
procedure DoShutdown; virtual;
```

C++

```
virtual __fastcall DoShutdown();
```

Description

This is DoShutdown, a member of class TService.

156.1.4.4.7 TService.DoStart Method

Pascal

```
procedure DoStart; virtual;
```

C++

```
virtual __fastcall DoStart();
```

Description

This is DoStart, a member of class TService.

156.1.4.4.8 TService.DoStop Method

Pascal

```
function DoStop: Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoStop();
```

Description

This is DoStop, a member of class TService.

156.1.4.4.9 TService.GetServiceController Method

Returns the service's registered handler function.

Pascal

```
function GetServiceController: TServiceController; virtual; abstract;
```

C++

```
virtual __fastcall TServiceController GetServiceController() = 0;
```

Description

GetServiceController returns the handler for the service. You do not need to call this function directly. The service object's main function calls it automatically.

Note: Each service in the service application has a main function for that service. When a request is made to start the service, the main thread of the service calls the RegisterServiceCtrlHandler function to register this control handler function. TService (see page 22011) automatically calls RegisterServiceCtrlHandler and returns this handler function. Because this function cannot be a class method (member function), the Service application wizard generates code that creates a non-member handler, (ServiceController) for your service object. This routine returns the service object's Handler (Controller (see page 22017)).

156.1.4.4.10 TService.LogMessage Method

Sends an error message to the event log.

Pascal

```
procedure LogMessage(Message: String; EventType: DWord = 1; Category: Integer = 0; ID: Integer
= 0);
```

C++

```
__fastcall LogMessage(AnsiString Message, DWord EventType = 1, int Category = 0, int ID = 0);
```

Description

LogMessage sends an error message to the event log when an error or exception occurs. By default the EventType is EVENTLOG_ERROR_TYPE (usually indicating a loss of functionality or data) and the category and ID are zero. For example, if a service cannot be loaded as the system boots, it can log an error event, and the category and ID are zero.

The EventType specifies the type of event being logged. This parameter can be one of the following values:

Value	Meaning
EVENTLOG_WARNING_TYPE	Warning event
EVENTLOG_INFORMATION_TYPE	Information event
EVENTLOG_AUDIT_SUCCESS	Success Audit event
EVENTLOG_AUDIT_FAILURE	Failure Audit event

EVENTLOG_ERROR_TYPEError event

The Category parameter specifies the event category, which is source-specific information and can have any value.

The ID parameter specifies the event identifier, which is the message that goes with this event as an entry in the message file associated with the event source.

156.1.4.4.11 TService.Main Method

Pascal

```
procedure Main(Argc: DWord; Argv: PLPSTR);
```

C++

```
__fastcall Main(DWord Argc, PLPSTR Argv);
```

Description

This is Main, a member of class TService.

156.1.4.4.12 TService.ReportStatus Method

Updates the Service Control Manager's status information for the calling service.

Pascal

```
procedure ReportStatus;
```

C++

```
__fastcall ReportStatus();
```

Description

ReportStatus sends current status information about the calling service to the Service Control Manager.

See Also

LogMessage (see page 22019)

Status (see page 22026)

WaitHint (see page 22027)

156.1.4.5 TService Properties

The properties of the TService class are listed here.

Public Properties

	Name	Description
	ErrCode (see page 22022)	Contains the service specific error code returned on starting or stopping the service.
R	Param (see page 22024)	Lists the parameters to the service.
R	ParamCount (see page 22024)	Indicates the number of startup parameters for the service.
R	ServiceThread (see page 22025)	Identifies the dedicated thread for the service.
	Status (see page 22026)	Indicates the current state of the service.
R	Terminated (see page 22027)	Indicates whether the service thread has terminated.
	Win32ErrCode (see page 22028)	Indicates the Win32 error code reported by the service if a service specific code is not defined.

Published Properties

	Name	Description
	AllowPause (see page 22021)	Indicates whether clients are allowed to pause the service.
	AllowStop (see page 22021)	Indicates whether clients are allowed to stop the service.
	Dependencies (see page 22021)	Lists the services or load ordering groups on which the service depends.
	DisplayName (see page 22022)	Identifies the service in the Windows Service Control Manager.
	ErrorSeverity (see page 22022)	Indicates the severity of service startup failure.
	Interactive (see page 22023)	Indicates whether the service is interactive with the Windows desktop.
	LoadGroup (see page 22023)	Names of the load ordering group that includes the service.
	Password (see page 22024)	Specifies the password, optionally used depending upon the ServiceStartName (see page 22025), for accessing the service.
	ServiceStartName (see page 22025)	ServiceStartName is the name used in the Service Control Manager Startup dialog to start the service.
	ServiceType (see page 22026)	Identifies the type of the service as Win32, device driver, or file system driver.
	StartType (see page 22026)	Indicates when or how the service starts.

	TagID (see page 22026)	Specifies a unique tag for the service within its LoadGroup (see page 22023).
	WaitHint (see page 22027)	Specifies the estimated time, in milliseconds, between a call from the Windows Service Control Manager and the service reporting its status.

156.1.4.5.1 TService.AllowPause Property

Indicates whether clients are allowed to pause the service.

Pascal

```
property AllowPause: Boolean;
```

C++

```
__property Boolean AllowPause;
```

Description

AllowPause indicates whether clients of the service can pause and resume the service by calling the Windows API ControlService function. When AllowPause is true, an OnPause (see page 22031) event occurs before the service pauses, and an OnContinue (see page 22030) event occurs when the service resumes.

See Also

OnPause (see page 22031)

OnContinue (see page 22030)

156.1.4.5.2 TService.AllowStop Property

Indicates whether clients are allowed to stop the service.

Pascal

```
property AllowStop: Boolean;
```

C++

```
__property Boolean AllowStop;
```

Description

AllowStop indicates whether clients of the service can stop it by calling the Windows API ControlService function. When AllowStop is true, an OnStop (see page 22032) event occurs before the service stops.

See Also

OnStop (see page 22032)

156.1.4.5.3 TService.Dependencies Property

Lists the services or load ordering groups on which the service depends.

Pascal

```
property Dependencies: TDependencies;
```

C++

```
__property TDependencies Dependencies;
```

Description

Dependencies is a container for TDependency (see page 22005) objects, which are dependent services or load ordering groups that must start before this service. If the container is empty, the service has no dependencies.

Dependency on a service means that this service can only run if the service it depends on is running. Dependency on a group means that this service can run if at least one member of the group is running after an attempt to start all members of the group.

See Also

TDependency (see page 22005)

LoadGroup (see page 22023)

156.1.4.5.4 TService.DisplayName Property

Identifies the service in the Windows Service Control Manager.

Pascal

```
property DisplayName: String;
```

C++

```
__property AnsiString DisplayName;
```

Description

DisplayName contains a string, with a maximum length of 256 characters, that is the name of the service as displayed in the Service Control Manager. User interface programs use DisplayName to identify the service. DisplayName is case-preserved in the Service Control Manager, however display name comparisons are always case-insensitive.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and service objects. For more information, see Service name properties.

See Also

Name (see page 2805)

ServiceStartName (see page 22025)

156.1.4.5.5 TService.ErrCode Property

Contains the service specific error code returned on starting or stopping the service.

Pascal

```
property ErrCode: DWord;
```

C++

```
__property DWord ErrCode;
```

Description

ErrCode specifies a service specific error code that the service returns when an error occurs while the service is starting or stopping. If ErrCode is not defined, the Win32ErrCode (see page 22028) property is used instead.

See Also

ReportStatus (see page 22020)

Win32ErrCode (see page 22028)

156.1.4.5.6 TService.ErrorSeverity Property

Indicates the severity of service startup failure.

Pascal

```
property ErrorSeverity: TErrorSeverity;
```

C++

```
__property TErrorSeverity ErrorSeverity;
```

Description

ErrorSeverity indicates the severity if this service fails to start during startup of the service application.

See Also

ErrCode (see page 22022)

ReportStatus (see page 22020)

Win32ErrCode (see page 22028)

156.1.4.5.7 TService.Interactive Property

Indicates whether the service is interactive with the Windows desktop.

Pascal

```
property Interactive: Boolean;
```

C++

```
__property Boolean Interactive;
```

Description

Interactive indicates whether the service can interact with the Windows desktop. Interactive only has an effect when ServiceType (see page 22026) is stWin32. For more information about creating interactive NT services, see the Microsoft Help.

See Also

ServiceType (see page 22026)

156.1.4.5.8 TService.LoadGroup Property

Names of the load ordering group that includes the service.

Pascal

```
property LoadGroup: String;
```

C++

```
__property AnsiString LoadGroup;
```

Description

LoadGroup is the name of the load-ordering group that includes the service. This is used by other services that have dependencies on the load ordering group (See Dependencies (see page 22021)). The registry lists load-ordering groups at HKEY_LOCAL_MACHINE\System (see page 22079)\CurrentControlSet\Control\ServiceGroupOrder. The order in which services are loaded depends on the order of the load groups in the Registry (see page 18633) and the dependencies listed in service Dependencies (see page 22021) properties.

Because services and service groups share the same name space, the SC_GROUP_IDENTIFIER character must prefix group names to distinguish them from service names. This is automatically prefixed if the TDependency (see page 22005)'s IsGroup property is true.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and

service objects. For more information, see Service name properties.

See Also

Dependencies (see page 22021)

TagID (see page 22026)

156.1.4.5.9 TService.Param Property

Lists the parameters to the service.

Pascal

```
property Param [Index: Integer]: String;
```

C++

```
__property AnsiString Param[int Index];
```

Description

Param is an indexed property that contains the parameters to the service. These parameters are typed into the Startup Parameters input window in the Service Control Manager.

See Also

ParamCount (see page 22024)

156.1.4.5.10 TService.ParamCount Property

Indicates the number of startup parameters for the service.

Pascal

```
property ParamCount: Integer;
```

C++

```
__property int ParamCount;
```

Description

ParamCount is the number of parameters for the service. These parameters are typed into the Startup Parameters input window in the Service Control Manager.

See Also

Param (see page 22024)

156.1.4.5.11 TService.Password Property

Specifies the password, optionally used depending upon the ServiceStartName (see page 22025), for accessing the service.

Pascal

```
property Password: String;
```

C++

```
__property AnsiString Password;
```

Description

Password is the password for the account name specified by the ServiceStartName (see page 22025) property if the ServiceType (see page 22026) is stWin32.

If Password is nil (Delphi) or NULL (C++), or if it points to an empty string, the service has no password. If ServiceType (see page 22026) is stDevice or stFileSystem, this parameter is ignored.

See Also

ServiceStartName (see page 22025)

156.1.4.5.12 TService.ServiceStartName Property

ServiceStartName is the name used in the Service Control Manager Startup dialog to start the service.

Pascal

```
property ServiceStartName: String;
```

C++

```
__property AnsiString ServiceStartName;
```

Description

ServiceStartName is the name used to start the service.

If ServiceType (see page 22026) is stWin32, ServiceStartName is the account name (in the form "DomainName\Username") which the service process is logged on as when it runs. If the account belongs to the built-in domain, ".\Username" can be specified. If the service application includes more than one service, leave ServiceStartName blank, and leave the Password (see page 22024) property blank.

If the service type is not stWin32, ServiceStartName is the driver object name (\FileSytems\Rdr or \Driver\Xns) which the input and output system uses to load the device driver. With device drivers or file systems drivers, you can leave ServiceStartName blank and the I/O system will create a default name based on the service name.

Note: A dependency can be a service. If this is true, do not confuse the various name-related properties of dependency and service objects. For more information, see Service name properties.

See Also

Password (see page 22024)

156.1.4.5.13 TService.ServiceThread Property

Identifies the dedicated thread for the service.

Pascal

```
property ServiceThread: TServiceThread;
```

C++

```
__property TServiceThread ServiceThread;
```

Description

ServiceThread is the instance of the TServiceThread (see page 22040) class that is the dedicated thread for the service. Each service in the service application has a dedicated thread that contains a loop in its Execute method for processing service requests. Often a service will spawn a new thread, derived from TThread, to free the service thread to continue processing service requests.

See Also

ProcessRequests (see page 22046)

TThread (see page 3108)

156.1.4.5.14 TService.ServiceType Property

Identifies the type of the service as Win32, device driver, or file system driver.

Pascal

```
property ServiceType: TServiceType;
```

C++

```
__property TServiceType ServiceType;
```

Description

ServiceType indicates the type of service. ServiceType can be stWin32 (a Win32 service – the default), stDevice (a device driver), or stFileSystem (a file system driver).

See Also

Interactive (see page 22023)

156.1.4.5.15 TService.StartType Property

Indicates when or how the service starts.

Pascal

```
property StartType: TStartType;
```

C++

```
__property TStartType StartType;
```

Description

StartType specifies how and why the service starts

156.1.4.5.16 TService.Status Property

Indicates the current state of the service.

Pascal

```
property Status: TCurrentStatus;
```

C++

```
__property TCurrentStatus Status;
```

Description

Status indicates the current state of the service. The status information is displayed in the Service Control Manager.

See Also

ReportStatus (see page 22020)

156.1.4.5.17 TService.TagID Property

Specifies a unique tag for the service within its LoadGroup (see page 22023).

Pascal

```
property TagID: DWord;
```

C++

```
__property DWord TagID;
```

Description

TagID is the unique tag value for this service in its LoadGroup (see page 22023). If no tag is requested, this property is 0. Tags are only evaluated when the ServiceType (see page 22026) is not stWin32 and the StartType (see page 22026) is stBoot or stSystem.

See Also

Dependencies (see page 22021)

LoadGroup (see page 22023)

156.1.4.5.18 TService.Terminated Property

Indicates whether the service thread has terminated.

Pascal

```
property Terminated: Boolean;
```

C++

```
__property Boolean Terminated;
```

Description

Terminated indicates whether the dedicated thread that the service is running in has terminated.

See Also

Terminated (see page 3142)

Terminate (see page 3126)

156.1.4.5.19 TService.WaitHint Property

Specifies the estimated time, in milliseconds, between a call from the Windows Service Control Manager and the service reporting its status.

Pascal

```
property WaitHint: Integer;
```

C++

```
__property int WaitHint;
```

Description

WaitHint specifies the amount of time, in milliseconds, that can elapse between a pending start, stop, pause, or continue operation and the service setting its status with a call to the Windows API. Normally this is handled automatically. If the service performs a lengthy operation of more than WaitHint time in one of its event handlers, you should call ReportStatus (see page 22020) method to update to the Service Control Manager.

See Also

ReportStatus (see page 22020)

156.1.4.5.20 TService.Win32ErrCode Property

Indicates the Win32 error code reported by the service if a service specific code is not defined.

Pascal

```
property Win32ErrCode: DWord;
```

C++

```
__property DWord Win32ErrCode;
```

Description

Win32ErrCode specifies a Win32 error code that the service uses to report an error that occurs when it is starting or stopping. If an error code specific to the service is defined, this property is automatically set to ERROR_SERVICE_SPECIFIC_ERROR and the service specific error is reported instead.

See Also

ErrCode (see page 22022)

ReportStatus (see page 22020)

156.1.4.6 TService Events

The events of the TService class are listed here.

Published Events

	Name	Description
	AfterInstall (see page 22028)	Occurs immediately after the service is registered with the Windows Service Control manager.
	AfterUninstall (see page 22029)	Occurs immediately after the service is removed from the Service Control manager's database.
	BeforeInstall (see page 22029)	Occurs before the service is first registered with the Windows Service Control manager.
	BeforeUninstall (see page 22030)	Occurs immediately before the service is removed from the Service Control manager's database.
	OnContinue (see page 22030)	Occurs when the Service Control manager resumes the service after it has been paused.
	OnExecute (see page 22030)	Occurs when the thread associated with the service starts up.
	OnPause (see page 22031)	Occurs when the Service Control manager pauses the service temporarily.
	OnShutdown (see page 22031)	Occurs when the system running the service application is about to shut down.
	OnStart (see page 22031)	OnStartup occurs when the service first starts up, before the OnExecute (see page 22030) event.
	OnStop (see page 22032)	Occurs when the Service Control manager stops the service.

156.1.4.6.1 TService.AfterInstall Event

Occurs immediately after the service is registered with the Windows Service Control manager.

Pascal

```
property AfterInstall: TServiceEvent;
```

C++

```
__property TServiceEvent AfterInstall;
```

Description

Write an AfterInstall event handler to take specific action immediately after the service is registered. Install services by running

the service application with the INSTALL switch.

See Also

AfterUninstall (see page 22029)

OnStart (see page 22031)

OnExecute (see page 22030)

OnCreate (see page 2833)

BeforeInstall (see page 22029)

156.1.4.6.2 TService.AfterUninstall Event

Occurs immediately after the service is removed from the Service Control manager's database.

Pascal

```
property AfterUninstall: TServiceEvent;
```

C++

```
__property TServiceEvent AfterUninstall;
```

Description

Write an AfterUninstall event handler to take specific action immediately after the service is removed. Uninstall services by running the service application with the UNINSTALL switch.

See Also

AfterInstall (see page 22028)

OnStop (see page 22032)

BeforeUninstall (see page 22030)

Destroy (see page 2829)

OnShutdown (see page 22031)

156.1.4.6.3 TService.BeforeInstall Event

Occurs before the service is first registered with the Windows Service Control manager.

Pascal

```
property BeforeInstall: TServiceEvent;
```

C++

```
__property TServiceEvent BeforeInstall;
```

Description

Write a BeforeInstall event handler to take specific action immediately before the service is first registered. Install services by running the service application with the INSTALL switch.

See Also

AfterInstall (see page 22028)

OnStart (see page 22031)

OnExecute (see page 22030)

OnCreate (see page 2833)

BeforeUninstall (see page 22030)

156.1.4.6.4 TService.BeforeUninstall Event

Occurs immediately before the service is removed from the Service Control manager's database.

Pascal

```
property BeforeUninstall: TServiceEvent;
```

C++

```
__property TServiceEvent BeforeUninstall;
```

Description

Write a BeforeUninstall event handler to take specific action immediately before the service is removed. Uninstall services by running the service application with the UNINSTALL switch.

See Also

AfterUninstall (see page 22029)

OnStop (see page 22032)

BeforeInstall (see page 22029)

Destroy (see page 2829)

OnShutdown (see page 22031)

156.1.4.6.5 TService.OnContinue Event

Occurs when the Service Control manager resumes the service after it has been paused.

Pascal

```
property OnContinue: TContinueEvent;
```

C++

```
__property TContinueEvent OnContinue;
```

Description

Write an OnContinue event handler to take specific action when the Service Control manager resumes the service after it has been paused.

See Also

OnPause (see page 22031)

156.1.4.6.6 TService.OnExecute Event

Occurs when the thread associated with the service starts up.

Pascal

```
property OnExecute: TServiceEvent;
```

C++

```
__property TServiceEvent OnExecute;
```

Description

If you are not spawning a new thread to handle individual service requests in an OnStart (see page 22031) event handler, this is where you implement the service. When the OnExecute event handler finishes, the service thread terminates. Most OnExecute event handlers contain a loop that calls the service thread's ProcessRequests method so that other service requests are not locked out.

See Also

ProcessRequests (see page 22046)

OnStart (see page 22031)

156.1.4.6.7 TService.OnPause Event

Occurs when the Service Control manager pauses the service temporarily.

Pascal

```
property OnPause: TPauseEvent;
```

C++

```
__property TPauseEvent OnPause;
```

Description

Write an OnPause event handler to take specific action when the service is temporarily paused.

See Also

OnContinue (see page 22030)

156.1.4.6.8 TService.OnShutdown Event

Occurs when the system running the service application is about to shut down.

Pascal

```
property OnShutdown: TServiceEvent;
```

C++

```
__property TServiceEvent OnShutdown;
```

Description

Write an OnShutdown event handler to take specific action just before the service shuts down. The service application terminates immediately after OnShutdown.

See Also

OnStop (see page 22032)

OnStart (see page 22031)

OnPause (see page 22031)

156.1.4.6.9 TService.OnStart Event

OnStartup occurs when the service first starts up, before the OnExecute (see page 22030) event.

Pascal

```
property OnStart: TStartEvent;
```

C++

```
__property TStartEvent OnStart;
```

Description

This event should be used to initialize the service. For example, if each service request is handled in a separate thread (a good idea if handling the request takes much time) the thread for a request is spawned in an OnStart event handler.

See Also

OnStop (see page 22032)

OnContinue (see page 22030)

OnExecute (see page 22030)

156.1.4.6.10 TService.OnStop Event

Occurs when the Service Control manager stops the service.

Pascal

```
property OnStop: TStopEvent;
```

C++

```
__property TStopEvent OnStop;
```

Description

Write an OnStop event handler to take specific action when the service stops.

See Also

OnShutdown (see page 22031)

OnStart (see page 22031)

OnPause (see page 22031)

156.1.5 TServiceApplication Class

TServiceApplication encapsulates a Windows NT service application.

Class Hierarchy

Pascal

```
TServiceApplication = class(TComponent);
```

C++

```
class TServiceApplication : public TComponent;
```

File

SvcMgr

Description

TServiceApplication encapsulates a Windows NT application type known as a service. TServiceApplication provides the fundamental behavior of this type of application. Each Service project automatically declares an Application (see page 22054) variable of type TServiceApplication as the instance of the application. The Application (see page 22054) variable is added to a project by selecting File | New from the menu of the IDE main window and selecting Service Application (see page 22054) in the New Items dialog.

TServiceApplication contains TService (see page 22011) objects, each of which encapsulates a Windows NT service. The service application object provides methods to create service objects and to install, register, dispatch, and uninstall services.

When the service application is run using the /INSTALL switch, it registers the services it contains. When run using the /UNINSTALL switch, it unregisters its services. Unless the application is run with the /SILENT switch, the service application shows a confirmation message after successfully installing or uninstalling its services.

Note: Do not add the Forms (see page 13657) or Httpapp units to the uses list of the project (Delphi) or includ the unit header for these units in the project source (C++). Those units declare conflicting Application (see page 22054) variables of types TApplication and TWebApplication, respectively.

See Also

Application (see page 22054)

TService (see page 22011)

Service Applications

Service Name\ Properties

156.1.5.1 TServiceApplication Members

The following tables list the members exposed by TServiceApplication.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DispatchServiceMain (see page 22037)	This is DispatchServiceMain, a member of class TServiceApplication.
	DoHandleException (see page 22037)	This is DoHandleException, a member of class TServiceApplication.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (displDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.

	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	Hook (see page 22038)	This is Hook, a member of class TServiceApplication.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RegisterServices (see page 22038)	This is RegisterServices, a member of class TServiceApplication.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	Create (see page 22036)	Instantiates a TServiceApplication (see page 22032) object.
V	CreateForm (see page 22037)	Creates the service object or objects for the service application.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22036)	Disposes of an instance of a TServiceApplication (see page 22032) object.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.

	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	Initialize (see page 22038)	Sets the initial state of the application and hides any associated MainForm.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	Installing (see page 22038)	This is Installing, a member of class TServiceApplication.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Run (see page 22039)	Installs, registers, and adds services to its component list, and creates a thread for the service application.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	DelayInitialize (see page 22039)	This is DelayInitialize, a member of class TServiceApplication.
	DesignInfo (see page 2805)	Contains information used by the Form designer.

R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	ServiceCount (see page 22039)	Indicates the number of services in the service application.
	Title (see page 22040)	Indicates the name of the title application.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

156.1.5.2 TServiceApplication.Create Constructor

Instantiates a TServiceApplication (see page 22032) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TServiceApplication(TComponent * AOwner);
```

Description

Applications do not need to call the constructor directly. TServiceApplication (see page 22032) is instantiated by selecting File | New from the menu of the IDE main window and selecting Service Application (see page 22054) in the New Items dialog. An Application (see page 22054) variable of type TServiceApplication (see page 22032) is declared and initialized as the instance of the application.

156.1.5.3 TServiceApplication.Destroy Destructor

Disposes of an instance of a TServiceApplication (see page 22032) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TServiceApplication();
```

Description

You do not need to call the destructor directly. TServiceApplication (see page 22032) is destroyed when your application closes.

The destructor frees the memory associated with sub-objects.

See Also

Free (see page 22300)

156.1.5.4 TServiceApplication Methods

The methods of the TServiceApplication class are listed here.

Protected Methods

	Name	Description
	DispatchServiceMain (see page 22037)	This is DispatchServiceMain, a member of class TServiceApplication.
	DoHandleException (see page 22037)	This is DoHandleException, a member of class TServiceApplication.
	Hook (see page 22038)	This is Hook, a member of class TServiceApplication.
	RegisterServices (see page 22038)	This is RegisterServices, a member of class TServiceApplication.

Public Methods

	Name	Description
V	CreateForm (see page 22037)	Creates the service object or objects for the service application.
V	Initialize (see page 22038)	Sets the initial state of the application and hides any associated MainForm.
	Installing (see page 22038)	This is Installing, a member of class TServiceApplication.
V	Run (see page 22039)	Installs, registers, and adds services to its component list, and creates a thread for the service application.

156.1.5.4.1 TServiceApplication.CreateForm Method

Creates the service object or objects for the service application.

Pascal

```
procedure CreateForm(InstanceClass: TComponentClass; var Reference); virtual;
```

C++

```
virtual __fastcall CreateForm(TComponentClass InstanceClass,  Reference);
```

Description

Do not call CreateForm in an application. The module manager calls CreateForm internally to register the service objects of the service application.

CreateForm instantiates a TService (see page 22011) object for each service contained in the service application. CreateForm is called automatically, for the first service, when the service application is first created. Subsequently, CreateForm is called for each new service added to the application. To add a new service, select File | New from the menu of the IDE main window and choose Service in the New Items dialog.

156.1.5.4.2 TServiceApplication.DispatchServiceMain Method

Pascal

```
procedure DispatchServiceMain(Argc: DWord; Argv: PLPSTR);
```

C++

```
__fastcall DispatchServiceMain(DWord Argc, PLPSTR Argv);
```

Description

This is DispatchServiceMain, a member of class TServiceApplication.

156.1.5.4.3 TServiceApplication.DoHandleException Method

Pascal

```
procedure DoHandleException(E: Exception); dynamic;
```

C++

```
__fastcall DoHandleException(Exception E);
```

Description

This is DoHandleException, a member of class TServiceApplication.

156.1.5.4.4 TServiceApplication.Hook Method

Pascal

```
function Hook(var Message: TMessage): Boolean;
```

C++

```
__fastcall Boolean Hook(TMessage Message);
```

Description

This is Hook, a member of class TServiceApplication.

156.1.5.4.5 TServiceApplication.Initialize Method

Sets the initial state of the application and hides any associated MainForm.

Pascal

```
procedure Initialize; virtual;
```

C++

```
virtual __fastcall Initialize();
```

Description

Initialize sets the initial state of the application to hide any main form that may be associated with the application. Service applications are rarely interactive and do not typically have a form associated with them. If a form has been added to the application, Initialize hides it on start. Initialize then follows the standard (default) VCL application initialization process.

156.1.5.4.6 TServiceApplication.Installing Method

Pascal

```
function Installing: Boolean;
```

C++

```
__fastcall Boolean Installing();
```

Description

This is Installing, a member of class TServiceApplication.

156.1.5.4.7 TServiceApplication.RegisterServices Method

Pascal

```
procedure RegisterServices(Install: Boolean; Silent: Boolean);
```

C++

```
__fastcall RegisterServices(Boolean Install, Boolean Silent);
```

Description

This is RegisterServices, a member of class TServiceApplication.

156.1.5.4.8 TServiceApplication.Run Method

Installs, registers, and adds services to its component list, and creates a thread for the service application.

Pascal

```
procedure Run; virtual;
```

C++

```
virtual __fastcall Run();
```

Description

Run handles installing and uninstalling services, depending on the command line switches. When the service application is run using the /INSTALL switch, it registers the services it contains. When run using the /UNINSTALL switch, it unregisters its services. Unless the application is run with the /SILENT switch, the service application shows a confirmation message after successfully installing or uninstalling its services.

If not called with the /INSTALL or /UNINSTALL switch, Run creates a service application thread that responds to Windows messages from clients. Note that this thread is for the application and differs from the dedicated TServiceThread (see page 22040) instances associated with individual services in the application.

156.1.5.5 TServiceApplication Properties

The properties of the TServiceApplication class are listed here.

Public Properties

	Name	Description
	DelayInitialize (see page 22039)	This is DelayInitialize, a member of class TServiceApplication.
R	ServiceCount (see page 22039)	Indicates the number of services in the service application.
	Title (see page 22040)	Indicates the name of the title application.

156.1.5.5.1 TServiceApplication.DelayInitialize Property

Pascal

```
property DelayInitialize: Boolean;
```

C++

```
__property Boolean DelayInitialize;
```

Description

This is DelayInitialize, a member of class TServiceApplication.

156.1.5.5.2 TServiceApplication.ServiceCount Property

Indicates the number of services in the service application.

Pascal

```
property ServiceCount: Integer;
```

C++

```
__property int ServiceCount;
```

Description

ServiceCount is the number of services in the service application. Each service is encapsulated by a TService (see page 22011) instance and has its own dedicated service thread.

Note: If the Service application requires a user name and password, the application must implement only a single service.

See Also

TService (see page 22011)

156.1.5.5.3 TServiceApplication.Title Property

Indicates the name of the title application.

Pascal

```
property Title: string;
```

C++

```
__property AnsiString Title;
```

Description

Title is the name of the service application. This text string appears below the icon of the application when it is minimized.

156.1.6 TServiceThread Class

TServiceThread represents the thread associated with a specific service (TService (see page 22011) object).

Class Hierarchy

Pascal

```
TServiceThread = class(TThread);
```

C++

```
class TServiceThread : public TThread;
```

File

SvcMgr

Description

TServiceThread is the thread associated with a service. Each service application has one or more service objects, each of which has its own dedicated thread. TServiceThread instances represent those threads.

Note: Service threads.

See Also

TService (see page 22011)

TService (see page 22011)

TServiceApplication (see page 22032)

TServiceThread

IDH

Service Threads

156.1.6.1 TServiceThread Members

The following tables list the members exposed by TServiceThread.

Protected Methods

	Name	Description
	CheckThreadError (see page 3114)	This is the overview for the CheckThreadError method overload.
V	DoTerminate (see page 3115)	Generates an OnTerminate (see page 3148) event.
V	Execute (see page 22042)	Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Protected Properties

	Name	Description
	ReturnValue (see page 3141)	Specifies the value returned to other waiting threads when the thread finishes executing.
R	Terminated (see page 3142)	Indicates whether the thread has been asked to terminate.

Public Events

	Name	Description
	OnTerminate (see page 3148)	Occurs after the thread's Execute (see page 3115) method has returned and before the thread is destroyed.

Public Methods

	Name	Description
V	AfterConstruction (see page 3114)	Executes the thread when the thread is created with CreateSuspended set to false.
	Create (see page 22042)	Instantiates and initializes a TServiceThread (see page 22040) object.
V	Destroy (see page 3113)	Destroys the thread object and releases the memory allocated to it.
	ProcessRequests (see page 22046)	Allows clients to invoke the service associated with the service thread.
	Queue (see page 3119)	This is the overview for the Queue method overload.
	RemoveQueuedEvents (see page 3120)	Remove queued method calls.
	Resume (see page 3120)	Restarts the execution of a suspended thread.
	StaticQueue (see page 3124)	Asynchronously executes a method call within the main thread.
	StaticSynchronize (see page 3125)	Executes a method call within the main thread.
	Suspend (see page 3125)	Pauses a running thread.
	Synchronize (see page 3126)	This is the overview for the Synchronize method overload.
	Terminate (see page 3126)	Signals the thread to terminate by setting the Terminated (see page 3142) property to true.
	WaitFor (see page 3132)	Waits for the thread to terminate and then returns the value of the ReturnValue (see page 3141) property.

Public Properties

	Name	Description
R	FatalException (see page 3133)	Determines whether the thread object is automatically destroyed when the thread terminates.
	FreeOnTerminate (see page 3134)	Determines whether the thread object is automatically destroyed when the thread terminates.
R	Handle (see page 3137)	Indicates the thread's handle (Windows only).
	Priority (see page 3138)	Determines the thread's scheduling priority relative to other threads in the process.
	Suspended (see page 3142)	Indicates whether a thread is suspended.
R	ThreadID (see page 3148)	Identifies the thread throughout the system.

156.1.6.2 TServiceThread.Create Constructor

Instantiates and initializes a TServiceThread (see page 22040) object.

Pascal

```
constructor Create(Service: TService);
```

C++

```
__fastcall TServiceThread(TService Service);
```

Description

Applications do not need to call the constructor directly. Instances of TService (see page 22011) create the TServiceThread (see page 22040) object on startup. The Service parameter is the TService (see page 22011) instance for which the TServiceThread (see page 22040) is the dedicated thread.

The constructor sets the FreeOnTerminate property to true and then calls the base class constructor so that the thread object is created with its Suspended property set to false.

See Also

FreeOnTerminate (see page 3134)

Suspended (see page 3142)

156.1.6.3 TServiceThread Methods

The methods of the TServiceThread class are listed here.

Protected Methods

	Name	Description
	Execute (see page 22042)	Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Public Methods

	Name	Description
	ProcessRequests (see page 22046)	Allows clients to invoke the service associated with the service thread.

156.1.6.3.1 TServiceThread.Execute Method

Provides an abstract or pure virtual method to contain the code which executes when the thread is run.

Pascal

```
procedure Execute; override;
```

C++

```
virtual __fastcall Execute();
```

Description

Override Execute and insert the code that should be executed when the thread runs. Execute is responsible for checking the value of the Terminated property to determine if the thread needs to exit.

A thread executes when Create is called if CreateSuspended set to false, or when Resume is first called after the thread is created if CreateSuspended set to true.

Note: Do not use the properties and methods of other objects directly in the Execute method of a thread. Instead, separate the

use of other objects into a separate procedure call, and call that procedure by passing it as a parameter to the Synchronize method.

C++ Examples:

```
/*
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread's FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes. To
create the extension choose the
File | New | Other | Thread Object menu.
*/
bool mythreadRunning;
bool youthreadRunning;

class TMyThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TMyThread(bool suspended);
};

__fastcall TMyThread::TMyThread(bool suspended)
    : TThread(suspended)
{
}

class TYouThread : public TThread
{
__published:    // IDE-managed Components
private:    // User declarations
protected:  // User declarations
    void __fastcall Execute();
public:     // User declarations
    __fastcall TYouThread(bool suspended);
};

__fastcall TYouThread::TYouThread(bool suspended)
    : TThread(suspended)
{
}

void __fastcall TMyThread::Execute()
{
  Form1->Memo1->Lines->Add("Process has been running for this many seconds:");
  for (int I = 0; I <= 10; I++)
  {
    Form1->Memo1->Lines->Add("Low priority process " + IntToStr(I));
    Sleep(1000);
  }
  mythreadRunning = FALSE;
}

void __fastcall TYouThread::Execute()
{
  Form1->Memo3->Lines->Add("Second low priority process has been running for this many
seconds:");
  for (int I = 0; I <= 10; I++)
  {
    Form1->Memo3->Lines->Add("Second low priority process " + IntToStr(I));
```

```
    Sleep(1000);
  }
  youthreadRunning = FALSE;
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TMyThread *SecondProcess; // TMyThread is a custom descendant of TThread
  if (mythreadRunning == FALSE)
  {
    mythreadRunning = TRUE;
    SecondProcess = new TMyThread(True); // create suspended – secondprocess does not run yet
    SecondProcess->FreeOnTerminate = True; // don't need to cleanup after terminate
    SecondProcess->Priority = tpLower;  // set the priority to lower than normal
    SecondProcess->Resume(); // now run the thread
  }
  else
    MessageDlg("This thread is still running.  You are going to hurt yourself!",
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  Form1->Memo2->Lines->Add("Do some work in the main process for 10 seconds:");
  for (int I = 0; I <= 10; I++)
  {
    Form1->Memo2->Lines->Add("Main process " + IntToStr(I));
    Sleep(1000);
  }
}

void __fastcall TForm1::Button3Click(TObject *Sender)
{
  TYouThread *SecondProcess; // TMyThread is a custom descendant of TThread
  if (youthreadRunning == FALSE)
  {
    youthreadRunning = TRUE;
    SecondProcess = new TYouThread(True); // create suspended – secondprocess does not run yet
    SecondProcess->FreeOnTerminate = True; // don't need to cleanup after terminate
    SecondProcess->Priority = tpLower;  // set the priority to lower than normal
    SecondProcess->Resume(); // now run the thread
  }
  else
    MessageDlg("This thread is still running.  You are going to hurt yourself!",
      mtInformation, TMsgDlgButtons() << mbOK, 0);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  mythreadRunning = FALSE;
  youthreadRunning = FALSE;
}
```

Delphi Examples:

```
{
This example shows how to create a thread and start it
running at a lower priority than the main execution thread.
Set the thread’s FreeOnTerminate property is True, so that
there is no need to free the thread when it finishes.  The
Execute procedure must be overridden in the extension class
of TThread or an "Abstract Error" will result. To create the
extension choose the File | New | Other | Thread Object menu.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if (mythreadRunning = FALSE) then
```

```
  begin
    mythreadRunning:= TRUE;
    MyProcess := TMyThread.Create(True); { create suspended - secondprocess does not run yet }
    MyProcess.FreeOnTerminate := True; { don't need to cleanup after terminate }
    MyProcess.Priority := tpLower;  // set the priority to lower than normal
    MyProcess.Resume; { now run the thread }
  end
  else
    MessageDlg('This thread is still running.  You are going to hurt yourself!',
      mtInformation, [mbOk], 0);
end;

procedure TForm1.Button4Click(Sender: TObject);
begin
  if mythreadRunning then MyProcess.Terminate();
end;

procedure TMyThread.Execute;
var I: Integer;
begin
  Form1.Memo1.Lines.Add('Process has been running for this many seconds:');
  for I := 0 to 10 do
  begin
    if Terminated then break;
    Form1.Memo1.Lines.Add('Low priority process ' + InttoStr(I));
    Sleep(1000);
  end;
  mythreadRunning:= FALSE;
end;

procedure TYouThread.Execute;
var I: Integer;
begin
  Form1.Memo3.Lines.Add('Second low priority process has been running for this many seconds:');
  for I := 0 to 10 do
  begin
    if Terminated then break;
    Form1.Memo3.Lines.Add('Second low priority process ' + InttoStr(I));
    Sleep(1000);
  end;
    youthreadRunning:= FALSE;
end;

procedure TForm1.Button2Click(Sender: TObject);
var   I: Integer;
begin
  Form1.Memo2.Lines.Add('Do some work in the main process for 10 seconds:');
  for I := 0 to 10 do
  begin
    Form1.Memo2.Lines.Add('Main process ' + InttoStr(I));
    Sleep(1000);
  end;
end;

procedure TForm1.Button3Click(Sender: TObject);
begin
  if (youthreadRunning = FALSE) then
  begin
    youthreadRunning:= TRUE;
    YouProcess := TYouThread.Create(True); { create suspended – secondprocess does not run yet
}
    YouProcess.FreeOnTerminate := True; { don't need to cleanup after terminate }
    YouProcess.Priority := tpLower;  // set the priority to lower than normal
    YouProcess.Resume; { now run the thread }
  end
  else
```

```
    MessageDlg('This thread is still running.  You are going to hurt yourself!',
      mtInformation, [mbOk], 0);
end;

procedure TForm1.Button5Click(Sender: TObject);
begin
  if youthreadRunning then YouProcess.Terminate();
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  mythreadRunning:= FALSE;
  youthreadRunning:= FALSE;
end;
```

156.1.6.3.2 TServiceThread.ProcessRequests Method

Allows clients to invoke the service associated with the service thread.

Pascal

```
procedure ProcessRequests(WaitForMessage: Boolean);
```

C++

```
__fastcall ProcessRequests(Boolean WaitForMessage);
```

Description

TServiceThread (see page 22040)'s ProcessRequests is called in the Execute (see page 22042) method after any associated service's OnExecute event handler has finished executing. For more information about optimizing service execution by spawning individual threads for each service request, see the Developer's Guide.

OnExecute (see page 22030)

156.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TCurrentStatus (see page 22047)	TCurrentStatus indicates the state of a service.
	TErrorSeverity (see page 22048)	TErrorSeverity indicates the severity of a failure and implies the corresponding response by a service startup program.
	TServiceType (see page 22048)	TServiceType indicates the type of a service.
	TStartType (see page 22049)	TStartType indicates how a service starts up.

156.2.1 SvcMgr.TCurrentStatus Enumeration

TCurrentStatus indicates the state of a service.

Pascal

```
TCurrentStatus = (
  csStopped,
  csStartPending,
  csStopPending,
  csRunning,
  csContinuePending,
  csPausePending,
  csPaused
);
```

C++

```
enum TCurrentStatus {
  csStopped,
  csStartPending,
  csStopPending,
  csRunning,
  csContinuePending,
  csPausePending,
  csPaused
};
```

File

SvcMgr

Description

TCurrentStatus can have one of the following values:

Value	Meaning
csStopped	The service is not running.
csStartPending	The service is starting.
csStopPending	The service is stopping.
csRunning	The service is running.

csContinuePending	The service continue is pending.
csPausePending	The service pause is pending.
csPaused	The service is paused

156.2.2 SvcMgr.TErrorSeverity Enumeration

TErrorSeverity indicates the severity of a failure and implies the corresponding response by a service startup program.

Pascal

```
TErrorSeverity = (
  esIgnore,
  esNormal,
  esSevere,
  esCritical
);
```

C++

```
enum TErrorSeverity {
  esIgnore,
  esNormal,
  esSevere,
  esCritical
};
```

File

SvcMgr

Description

TErrorSeverity can have one of the following values:

Value	What the startup program does
esIgnore	Logs the error and continues.
esNormal	Logs the error and displays a message, but continues.
esSevere	Logs the error but continues only if the last-known-good configuration is being started; otherwise the last-known-good configuration is started instead.
esCritical	Logs the error and starts up the last-known-good configuration instead. If this is the last-known-good configuration, the startup operation fails.

156.2.3 SvcMgr.TServiceType Enumeration

TServiceType indicates the type of a service.

Pascal

```
TServiceType = (
  stWin32,
  stDevice,
  stFileSystem
);
```

C++

```
enum TServiceType {
  stWin32,
  stDevice,
  stFileSystem
};
```

File

SvcMgr

Description

TServiceType can have one of the following values:

Value	Meaning
stWin32	a Win32 service.
stDevice	a device driver.
stFileSystem	a file system driver.

156.2.4 SvcMgr.TStartType Enumeration

TStartType indicates how a service starts up.

Pascal

```
TStartType = (
  stBoot,
  stSystem,
  stAuto,
  stManual,
  stDisabled
);
```

C++

```
enum TStartType {
  stBoot,
  stSystem,
  stAuto,
  stManual,
  stDisabled
};
```

File

SvcMgr

Description

The following table lists the possible values of TStartType:

StartType value	Service is started
stBoot(used only when ServiceType is not stWin32)	by the operating system loader
stSystem(used only when ServiceType is not stWin32)	after boot systems are initialized
stAuto	automatically during system startup

stManual	when a process calls the Windows StartService function
stDisabled	the service can't be started except by an administrator

156.3 Types

The following table lists types in this documentation.

Types

Name	Description
TContinueEvent (see page 22051)	This is type SvcMgr.TContinueEvent.
TPauseEvent (see page 22051)	This is type SvcMgr.TPauseEvent.
TServiceController (see page 22052)	This is type SvcMgr.TServiceController.
TServiceEvent (see page 22052)	This is type SvcMgr.TServiceEvent.
TStartEvent (see page 22052)	This is type SvcMgr.TStartEvent.
TStopEvent (see page 22053)	This is type SvcMgr.TStopEvent.

156.3.1 SvcMgr.TContinueEvent Type

Pascal

```
TContinueEvent = procedure (Sender: TService; var Continued: Boolean) of object;
```

C++

```
(Sender: TService; var Continued: Boolean) ( TContinueEvent)();
```

File

SvcMgr

Description

This is type SvcMgr.TContinueEvent.

156.3.2 SvcMgr.TPauseEvent Type

Pascal

```
TPauseEvent = procedure (Sender: TService; var Paused: Boolean) of object;
```

C++

```
(Sender: TService; var Paused: Boolean) ( TPauseEvent)();
```

File

SvcMgr

Description

This is type SvcMgr.TPauseEvent.

156.3.3 SvcMgr.TServiceController Type

Pascal

```
TServiceController = procedure (CtrlCode: DWord);
```

C++

```
(CtrlCode: DWord) ( TServiceController)();
```

File

SvcMgr

Description

This is type SvcMgr.TServiceController.

156.3.4 SvcMgr.TServiceEvent Type

Pascal

```
TServiceEvent = procedure (Sender: TService) of object;
```

C++

```
(Sender: TService) ( TServiceEvent)();
```

File

SvcMgr

Description

This is type SvcMgr.TServiceEvent.

156.3.5 SvcMgr.TStartEvent Type

Pascal

```
TStartEvent = procedure (Sender: TService; var Started: Boolean) of object;
```

C++

```
(Sender: TService; var Started: Boolean) ( TStartEvent)();
```

File

SvcMgr

Description

This is type SvcMgr.TStartEvent.

156.3.6 SvcMgr.TStopEvent Type

Pascal

```
TStopEvent = procedure (Sender: TService; var Stopped: Boolean) of object;
```

C++

```
(Sender: TService; var Stopped: Boolean) ( TStopEvent)();
```

File

SvcMgr

Description

This is type SvcMgr.TStopEvent.

156.4 Variables

The following table lists variables in this documentation.

Variables

Name	Description
Application (see page 22054)	This is variable SvcMgr.Application.

156.4.1 SvcMgr.Application Variable

Pascal

```
Application: TServiceApplication = nil;
```

C++

```
TServiceApplication Application = nil;
```

File

SvcMgr

Description

This is variable SvcMgr.Application.

156.5 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CM_SERVICE_CONTROL_CODE (see page 22055)	This is constant SvcMgr.CM_SERVICE_CONTROL_CODE.

156.5.1 SvcMgr.CM_SERVICE_CONTROL_CODE Constant

Pascal

```
CM_SERVICE_CONTROL_CODE = WM_USER + 1;
```

C++

```
CM_SERVICE_CONTROL_CODE = WM_USER + 1;
```

File

SvcMgr

Description

This is constant SvcMgr.CM_SERVICE_CONTROL_CODE.

157 SyncObjs Namespace

This is namespace SyncObjs.

Topics

Name	Description
Classes (see page 22058)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 22078)	The following table lists structs, records, enums in this documentation.

Classes

	Name	Description
	TCriticalSection (see page 22058)	TCriticalSection allows a thread in a multi-threaded application to temporarily block other threads from accessing a block of code.
	TEvent (see page 22063)	TEvent represents an external event.
	THandleObject (see page 22066)	THandleObject is the base class for all thread synchronization objects that use a handle.
	TMutex (see page 22071)	This is class SyncObjs.TMutex.
	TSimpleEvent (see page 22074)	TSimpleEvent represents an unnamed manual event object.
	TSynchroObject (see page 22075)	TSynchroObject is the base class for all thread synchronization objects.

Structs, Records, Enums

	Name	Description
	TWaitResult (see page 22078)	TWaitResult indicates the reason an event object stopped waiting for its signal.

157.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TCriticalSection (see page 22058)	TCriticalSection allows a thread in a multi-threaded application to temporarily block other threads from accessing a block of code.
	TEvent (see page 22063)	TEvent represents an external event.
	THandleObject (see page 22066)	THandleObject is the base class for all thread synchronization objects that use a handle.
	TMutex (see page 22071)	This is class SyncObjs.TMutex.
	TSimpleEvent (see page 22074)	TSimpleEvent represents an unnamed manual event object.
	TSynchroObject (see page 22075)	TSynchroObject is the base class for all thread synchronization objects.

157.1.1 TCriticalSection Class

TCriticalSection allows a thread in a multi-threaded application to temporarily block other threads from accessing a block of code.

Class Hierarchy

Pascal

```
TCriticalSection = class(TSynchroObject);
```

C++

```
class TCriticalSection : public TSynchroObject;
```

File

SyncObjs

Description

Use TCriticalSection to safeguard operations that may be disrupted if another thread executes certain sections of code before the operation is completed. Critical sections work like gates that allow only a single thread to enter at a time. Because they block the execution of other threads, overusing critical sections can seriously interfere with performance.

Critical sections must be global in scope so that they are available to all threads. In every thread, any action that could interfere with the operations safeguarded by the critical section should only take place after calling the Acquire (see page 22061) or Enter (see page 22061) method. Threads that do not use the critical section for relevant operations can introduce bugs.

See Also

TThread (see page 3108)

TCOMCriticalSection

Using Critical Sections

157.1.1.1 TCriticalSection Members

The following tables list the members exposed by TCriticalSection.

Protected Fields

	Name	Description
	FSection (see page 22060)	This is FSection, a member of class TCriticalSection.

Public Methods

	Name	Description
V	Acquire (see page 22061)	Binds the critical section to the calling thread.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22059)	Creates an instance of TCriticalSection (see page 22058).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22060)	Destroys an instance of TCriticalSection (see page 22058).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Enter (see page 22061)	Blocks other threads when the calling thread enters a thread-sensitive section.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Leave (see page 22062)	Allows other threads to use the critical section.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Release (see page 22062)	Allows other threads to use the critical section.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	TryEnter (see page 22062)	This is TryEnter, a member of class TCriticalSection.

157.1.1.2 TCriticalSection.Create Constructor

Creates an instance of TCriticalSection (see page 22058).

Pascal

```
constructor Create;
```

C++

```
__fastcall TCriticalSection();
```

Description

Call Create to create and initialize an instance of TCriticalSection (see page 22058). A TCriticalSection (see page 22058) object can be created for a single object that contains thread-sensitive code, or as a global object to be shared by several threads.

See Also

Create (see page 22287)

157.1.1.3 TCriticalSection.Destroy Destructor

Destroys an instance of TCriticalSection (see page 22058).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCriticalSection();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TCriticalSection (see page 22058) object is not nil, and only then calls Destroy.

See Also

Free (see page 22300)

157.1.1.4 TCriticalSection Fields

The fields of the TCriticalSection class are listed here.

Protected Fields

	Name	Description
	FSection (see page 22060)	This is FSection, a member of class TCriticalSection.

157.1.1.4.1 TCriticalSection.FSection Field

Pascal

```
FSection: TRTLCriticalSection;
```

C++

```
TRTLCriticalSection FSection;
```

Description

This is FSection, a member of class TCriticalSection.

157.1.1.5 TCriticalSection Methods

The methods of the TCriticalSection class are listed here.

Public Methods

	Name	Description
	Acquire (see page 22061)	Binds the critical section to the calling thread.
	Enter (see page 22061)	Blocks other threads when the calling thread enters a thread-sensitive section.
	Leave (see page 22062)	Allows other threads to use the critical section.
	Release (see page 22062)	Allows other threads to use the critical section.
	TryEnter (see page 22062)	This is TryEnter, a member of class TCriticalSection.

157.1.1.5.1 TCriticalSection.Acquire Method

Binds the critical section to the calling thread.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire to block all other threads from acquiring this critical section until the Release (see page 22062) or Leave (see page 22062) method is called. Acquire does the same thing as the Enter (see page 22061) method.

See Also

Enter (see page 22061)

Leave (see page 22062)

Release (see page 22062)

Using Critical Sections

157.1.1.5.2 TCriticalSection.Enter Method

Blocks other threads when the calling thread enters a thread-sensitive section.

Pascal

```
procedure Enter;
```

C++

```
__fastcall Enter();
```

Description

Call Enter to block all other threads from entering code protected by this critical section until the Leave (see page 22062) or Release (see page 22062) method is called. Enter calls the Acquire (see page 22061) method to bind the critical section to the calling thread.

See Also

Acquire (see page 22061)

Leave (see page 22062)

Release (see page 22062)

157.1.1.5.3 TCriticalSection.Leave Method

Allows other threads to use the critical section.

Pascal

```
procedure Leave;
```

C++

```
__fastcall Leave();
```

Description

Call Leave at the end of a thread-sensitive section of code. Each call to Leave should be balanced by a call to Enter (see page 22061) or Acquire (see page 22061) at the beginning of the thread-sensitive section. Leave calls Release (see page 22062) to allow other threads to acquire the critical section.

See Also

Acquire (see page 22061)

Enter (see page 22061)

Release (see page 22062)

157.1.1.5.4 TCriticalSection.Release Method

Allows other threads to use the critical section.

Pascal

```
procedure Release; override;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release when the thread no longer needs to block other threads from executing code that is protected by this critical section. Each call to Release should be balance by an earlier call to Acquire (see page 22061) or Enter (see page 22061) that blocked other threads from executing. Release does the same thing as the Leave (see page 22062) method.

See Also

Acquire (see page 22061)

Enter (see page 22061)

Leave (see page 22062)

Using Critical Sections

157.1.1.5.5 TCriticalSection.TryEnter Method

Pascal

```
function TryEnter: Boolean;
```

C++

```
__fastcall Boolean TryEnter();
```

Description

This is TryEnter, a member of class TCriticalSection.

157.1.2 TEvent Class

TEvent represents an external event.

Class Hierarchy

Pascal

```
TEvent = class(THandleObject);
```

C++

```
class TEvent : public THandleObject;
```

File

SyncObjs

Description

Use TEvent to signal that an event has occurred or a state has been reached.

In a multi-threaded application, use TEvent to allow one thread to signal to other threads that an event has occurred.

The handle of a TEvent object can also be used to communicate with other processes, so that an application can coordinate the timing of events with other applications. For example, use the handle of a TEvent object to wait until another process is ready to transfer information.

In a single-threaded application, use TEvent to coordinate between sections of code that respond to asynchronous events such as system events.

TThread (see page 3108)

Waiting for a Task to Be Completed

157.1.2.1 TEvent Members

The following tables list the members exposed by TEvent.

Protected Fields

	Name	Description
	FHandle (see page 22069)	This is FHandle, a member of class THandleObject.
	FLastError (see page 22069)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 22069)	This is FUseCOMWait, a member of class THandleObject.

Public Methods

	Name	Description
	Acquire (see page 22076)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.

V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22064)	This is the overview for the Create constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22068)	Destroys an instance of THandleObject (see page 22066).
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Release (see page 22076)	Provides the interface for a method that releases the synchronization object for use by other threads.
	ResetEvent (see page 22066)	Turns off the signal of the event object.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetEvent (see page 22066)	Turns on the signal of the event object.
V	WaitFor (see page 22070)	This is WaitFor, a member of class THandleObject.

Public Properties

	Name	Description
R	Handle (see page 22070)	Specifies the handle of the Windows object used by THandleObject (see page 22066).
R	LastError (see page 22070)	Indicates the Windows error code obtained from Handle (see page 22070).

157.1.2.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TEvent.Create (Boolean) (see page 22065)	Instantiates a TEvent (see page 22063) object to represent an event object.
	TEvent.Create (PSecurityAttributes, Boolean, Boolean, string, Boolean) (see page 22065)	Instantiates a TEvent (see page 22063) object to represent an event object.

157.1.2.2.1 TEvent.Create Constructor (Boolean)

Instantiates a TEvent (see page 22063) object to represent an event object.

Pascal

```
constructor Create(EventAttributes: PSecurityAttributes; ManualReset: Boolean; InitialState:
Boolean; const Name: string; UseCOMWait: Boolean = False); overload;
constructor Create(UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TEvent(PSecurityAttributes EventAttributes, Boolean ManualReset, Boolean
InitialState, const AnsiString Name, Boolean UseCOMWait = False);
__fastcall TEvent(Boolean UseCOMWait = False);
```

Description

Call Create to create a TEvent (see page 22063) object. Create can generate a new event object or can provide access to an existing named event object.

Set the EventAttributes parameter to specify the access rights and inheritance capabilities of the new event object. Calling Create with EventAttributes set to nil (Delphi) or NULL (C++) creates an event object with a default set of security attributes. If the TEvent (see page 22063) object is created to access an existing named event object, only the bInheritHandle field of EventAttributes is used, as the access rights were determined when the event object was created.

Set ManualReset to specify whether the signal of the TEvent (see page 22063) object can only be turned off by a call to the ResetEvent (see page 22066) method, or whether it is automatically reset when a single waiting thread is released. When ManualReset is true, the TEvent (see page 22063) signal stays set until the ResetEvent (see page 22066) method turns it off. When ManualReset is false, the signal is automatically turned off when only a single thread waits on the signal and that thread is released. If the TEvent (see page 22063) object is created to access an existing named event object, the ManualReset parameter is ignored.

Set InitialState to indicate whether the TEvent (see page 22063) object should be created with the signal set, or turned off. When InitialState is true, the TEvent (see page 22063) object is created with the signal set. If the TEvent (see page 22063) object is created to access an existing named event object, the InitialState parameter is ignored.

Set Name to provide a name for a new event object or to specify an existing named event object. If no other thread or process will need to access the event object to wait for its signal, Name can be left blank. Name can be a string of up to 260 characters, not including the backslash character (\). If Name is used to specify an existing event object, the value must match the name of the existing event in a case-sensitive comparison. If Name matches the name of an existing semaphore, mutex, or file-mapping object, the TEvent (see page 22063) object will be created with Handle (see page 22070) set to 0 and all method calls will fail.

See Also

Handle (see page 22070)

ResetEvent (see page 22066)

157.1.2.3 TEvent Methods

The methods of the TEvent class are listed here.

Public Methods

	Name	Description
	ResetEvent (see page 22066)	Turns off the signal of the event object.
	SetEvent (see page 22066)	Turns on the signal of the event object.

157.1.2.3.1 TEvent.ResetEvent Method

Turns off the signal of the event object.

Pascal

```
procedure ResetEvent;
```

C++

```
__fastcall ResetEvent();
```

Description

Call ResetEvent to signal that the event has not occurred or the desired state was not achieved. Other threads or processes that wait for the event will wait until the signal is turned on again by the SetEvent (see page 22066) method, the event object is destroyed, or the waiting process times out.

See Also

SetEvent (see page 22066)

WaitFor

Waiting for a Task to Be Completed

157.1.2.3.2 TEvent.SetEvent Method

Turns on the signal of the event object.

Pascal

```
procedure SetEvent;
```

C++

```
__fastcall SetEvent();
```

Description

Call SetEvent to signal that the event has occurred or the desired state was achieved. Other threads or processes that wait for the event will resume execution with a return value indicating that the signal was set.

See Also

ResetEvent (see page 22066)

WaitFor

Waiting for a Task to Be Completed

157.1.3 THandleObject Class

THandleObject is the base class for all thread synchronization objects that use a handle.

Class Hierarchy

Pascal

```
THandleObject = class(TSynchroObject);
```

C++

```
class THandleObject : public TSynchroObject;
```

File

SyncObjs

Description

Use THandleObject as a base class when defining an object that uses a handle when coordinating the execution of different threads in a multi-threaded application. Handled synchronization objects include event objects that allow threads to signal when critical events have occurred.

Do not create instances of THandleObject. THandleObject is a base class that introduces properties for managing the handle of a synchronization object but does not provide a mechanism for acquiring that handle. Descendants of THandleObject must acquire the appropriate type of handle.

See Also

TThread (see page 3108)

TEvent (see page 22063)

157.1.3.1 THandleObject Members

The following tables list the members exposed by THandleObject.

Protected Fields

	Name	Description
	FHandle (see page 22069)	This is FHandle, a member of class THandleObject.
	FLastError (see page 22069)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 22069)	This is FUseCOMWait, a member of class THandleObject.

Public Methods

	Name	Description
V	Acquire (see page 22076)	Provides the interface for a method that devotes the synchronization object to a thread.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22068)	This is Create, a member of class THandleObject.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22068)	Destroys an instance of THandleObject (see page 22066).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.

	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Release (see page 22076)	Provides the interface for a method that releases the synchronization object for use by other threads.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	WaitFor (see page 22070)	This is WaitFor, a member of class THandleObject.

Public Properties

	Name	Description
R	Handle (see page 22070)	Specifies the handle of the Windows object used by THandleObject (see page 22066).
R	LastError (see page 22070)	Indicates the Windows error code obtained from Handle (see page 22070).

157.1.3.2 THandleObject.Create Constructor

Pascal

```
constructor Create(UseCOMWait: Boolean = False);
```

C++

```
__fastcall THandleObject(Boolean UseCOMWait = False);
```

Description

This is Create, a member of class THandleObject.

157.1.3.3 THandleObject.Destroy Destructor

Destroys an instance of THandleObject (see page 22066).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~THandleObject();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the THandleObject (see page 22066) reference is not nil and only then calls Destroy.

See Also

Free (see page 22300)

Handle (see page 22070)

157.1.3.4 THandleObject Fields

The fields of the THandleObject class are listed here.

Protected Fields

	Name	Description
	FHandle (see page 22069)	This is FHandle, a member of class THandleObject.
	FLastError (see page 22069)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 22069)	This is FUseCOMWait, a member of class THandleObject.

157.1.3.4.1 THandleObject.FHandle Field

Pascal

```
FHandle: THandle;
```

C++

```
THandle FHandle;
```

Description

This is FHandle, a member of class THandleObject.

157.1.3.4.2 THandleObject.FLastError Field

Pascal

```
FLastError: Integer;
```

C++

```
int FLastError;
```

Description

This is FLastError, a member of class THandleObject.

157.1.3.4.3 THandleObject.FUseCOMWait Field

Pascal

```
FUseCOMWait: Boolean;
```

C++

```
Boolean FUseCOMWait;
```

Description

This is FUseCOMWait, a member of class THandleObject.

157.1.3.5 THandleObject Methods

The methods of the THandleObject class are listed here.

Public Methods

	Name	Description
	WaitFor (see page 22070)	This is WaitFor, a member of class THandleObject.

157.1.3.5.1 THandleObject.WaitFor Method

Pascal

```
function WaitFor(Timeout: LongWord): TWaitResult; virtual;
```

C++

```
virtual __fastcall TWaitResult WaitFor(LongWord Timeout);
```

Description

This is WaitFor, a member of class THandleObject.

157.1.3.6 THandleObject Properties

The properties of the THandleObject class are listed here.

Public Properties

	Name	Description
R	Handle (see page 22070)	Specifies the handle of the Windows object used by THandleObject (see page 22066).
R	LastError (see page 22070)	Indicates the Windows error code obtained from Handle (see page 22070).

157.1.3.6.1 THandleObject.Handle Property

Specifies the handle of the Windows object used by THandleObject (see page 22066).

Pascal

```
property Handle: THandle;
```

C++

```
__property THandle Handle;
```

Description

Read Handle to obtain the Windows handle for the synchronization object. Use Handle when making Windows API calls that require a handle to the synchronization object.

THandleObject (see page 22066) provides no mechanism for setting the Handle property. Descendants of THandleObject (see page 22066) set the Handle property to the handle for whatever Windows synchronization object they represent.

See Also

Destroy (see page 22068)

157.1.3.6.2 THandleObject.LastError Property

Indicates the Windows error code obtained from Handle (see page 22070).

Pascal

```
property LastError: Integer;
```

C++

```
__property int LastError;
```

Description

Read LastError when an operation of the THandleObject (see page 22066) fails. LastError returns the Windows error code

that represents the reason for the failure. If no operation failed, LastError is 0.

See Also

Handle (see page 22070)

157.1.4 TMutex Class

Class Hierarchy

System::TObject → SyncObjs.TSynchroObject → SyncObjs.THandleObject → SyncObjs.TMutex

Pascal

```
TMutex = class(THandleObject);
```

C++

```
class TMutex : public THandleObject;
```

File

SyncObjs

Description

This is class SyncObjs.TMutex.

157.1.4.1 TMutex Members

The following tables list the members exposed by TMutex.

Protected Fields

	Name	Description
	FHandle (see page 22069)	This is FHandle, a member of class THandleObject.
	FLastError (see page 22069)	This is FLastError, a member of class THandleObject.
	FUseCOMWait (see page 22069)	This is FUseCOMWait, a member of class THandleObject.

Public Methods

	Name	Description
V	Acquire (see page 22073)	Provides the interface for a method that devotes the synchronization object to a thread.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22072)	This is the overview for the Create constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22068)	Destroys an instance of THandleObject (see page 22066).
V	Destroy (see page 22287)	Disposes of an object instance.

	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Release (see page 22074)	Provides the interface for a method that releases the synchronization object for use by other threads.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	WaitFor (see page 22070)	This is WaitFor, a member of class THandleObject.

Public Properties

	Name	Description
	Handle (see page 22070)	Specifies the handle of the Windows object used by THandleObject (see page 22066).
	LastError (see page 22070)	Indicates the Windows error code obtained from Handle (see page 22070).

157.1.4.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TMutex.Create (Boolean) (see page 22072)	This is Create, a member of class TMutex.
	TMutex.Create (LongWord, Boolean, string, Boolean) (see page 22073)	This is Create, a member of class TMutex.
	TMutex.Create (PSecurityAttributes, Boolean, string, Boolean) (see page 22073)	This is Create, a member of class TMutex.

157.1.4.2.1 TMutex.Create Constructor (Boolean)

Pascal

```
constructor Create(UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TMutex(Boolean UseCOMWait = False);
```

Description

This is Create, a member of class TMutex.

157.1.4.2.2 TMutex.Create Constructor (LongWord, Boolean, string, Boolean)

Pascal

```
constructor Create(DesiredAccess: LongWord; InheritHandle: Boolean; const Name: string;
UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TMutex(LongWord DesiredAccess, Boolean InheritHandle, const AnsiString Name,
Boolean UseCOMWait = False);
```

Description

This is Create, a member of class TMutex.

157.1.4.2.3 TMutex.Create Constructor (PSecurityAttributes, Boolean, string, Boolean)

Pascal

```
constructor Create(MutexAttributes: PSecurityAttributes; InitialOwner: Boolean; const Name:
string; UseCOMWait: Boolean = False); overload;
```

C++

```
__fastcall TMutex(PSecurityAttributes MutexAttributes, Boolean InitialOwner, const AnsiString
Name, Boolean UseCOMWait = False);
```

Description

This is Create, a member of class TMutex.

157.1.4.3 TMutex Methods

The methods of the TMutex class are listed here.

Public Methods

	Name	Description
	Acquire (see page 22073)	Provides the interface for a method that devotes the synchronization object to a thread.
	Release (see page 22074)	Provides the interface for a method that releases the synchronization object for use by other threads.

157.1.4.3.1 TMutex.Acquire Method

Provides the interface for a method that devotes the synchronization object to a thread.

Pascal

```
procedure Acquire; override;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire from the thread that needs to use the synchronization object. The Acquire method for TSynchroObject does nothing other than provide the interface for a method that can start the synchronization object working on behalf of the calling thread.

See Also

Release (see page 22076)

157.1.4.3.2 TMutex.Release Method

Provides the interface for a method that releases the synchronization object for use by other threads.

Pascal

```
procedure Release; override;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release from a thread that is finished using the synchronization object. The Release method for TSynchroObject does nothing other than provide the interface for a method that can unbind the synchronization object from the calling thread.

See Also

Acquire (see page 22076)

157.1.5 TSimpleEvent Class

TSimpleEvent represents an unnamed manual event object.

Class Hierarchy

Pascal

```
TSimpleEvent = class(TEvent);
```

C++

```
class TSimpleEvent : public TEvent;
```

File

SyncObjs

Description

Use TSimpleEvent to coordinate between threads that all have access to the same simple event object. TSimpleEvent can also be used in a single-threaded application to coordinate sections of code that respond to different asynchronous events such as system messages or user actions.

Because TSimpleEvent represents an unnamed event object, a single TSimpleEvent object must be within the scope of all code that uses it. To coordinate with code that is out of scope, or with other applications, use a named TEvent (see page 22063) object.

See Also

TThread (see page 3108)

TEvent (see page 22063)

157.1.6 TSynchroObject Class

TSynchroObject is the base class for all thread synchronization objects.

Class Hierarchy

Pascal

```
TSynchroObject = class(TObject);
```

C++

```
class TSynchroObject : public TObject;
```

File

SyncObjs

Description

Use TSynchroObject as a base class when defining an object that coordinates the execution of different threads in a multi-threaded application. Synchronization objects include critical sections that temporarily block the execution of other threads which may interfere with the successful completion of a section of code, and event objects that allow threads to signal when critical events have occurred.

See Also

TCriticalSection (see page 22058)

TEvent (see page 22063)

TThread (see page 3108)

157.1.6.1 TSynchroObject Members

The following tables list the members exposed by TSynchroObject.

Public Methods

	Name	Description
	Acquire (see page 22076)	Provides the interface for a method that devotes the synchronization object to a thread.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.

	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Release (see page 22076)	Provides the interface for a method that releases the synchronization object for use by other threads.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

157.1.6.2 TSynchroObject Methods

The methods of the TSynchroObject class are listed here.

Public Methods

	Name	Description
V	Acquire (see page 22076)	Provides the interface for a method that devotes the synchronization object to a thread.
V	Release (see page 22076)	Provides the interface for a method that releases the synchronization object for use by other threads.

157.1.6.2.1 TSynchroObject.Acquire Method

Provides the interface for a method that devotes the synchronization object to a thread.

Pascal

```
procedure Acquire; virtual;
```

C++

```
virtual __fastcall Acquire();
```

Description

Call Acquire from the thread that needs to use the synchronization object. The Acquire method for TSynchroObject (see page 22075) does nothing other than provide the interface for a method that can start the synchronization object working on behalf of the calling thread.

See Also

Release (see page 22076)

157.1.6.2.2 TSynchroObject.Release Method

Provides the interface for a method that releases the synchronization object for use by other threads.

Pascal

```
procedure Release; virtual;
```

C++

```
virtual __fastcall Release();
```

Description

Call Release from a thread that is finished using the synchronization object. The Release method for TSynchroObject (see page 22075) does nothing other than provide the interface for a method that can unbind the synchronization object from the calling thread.

See Also

Acquire (see page 22076)

157.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TWaitResult (see page 22078)	TWaitResult indicates the reason an event object stopped waiting for its signal.

157.2.1 SyncObjs.TWaitResult Enumeration

TWaitResult indicates the reason an event object stopped waiting for its signal.

Pascal

```
TWaitResult = (
  wrSignaled,
  wrTimeout,
  wrAbandoned,
  wrError
);
```

C++

```
enum TWaitResult {
  wrSignaled,
  wrTimeout,
  wrAbandoned,
  wrError
};
```

File

SyncObjs

Description

TWaitResult includes the following values:

Value	Meaning
wrSignaled	The signal of the event object was set.
wrTimeOut	The time specified by the TimeOut parameter elapsed without the signal being set.
wrAbandoned	The event object was destroyed before the TimeOut period elapsed.
wrError	An error occurred while waiting. Check the LastError property for an error code giving more information.

158 System Namespace

This is namespace System.

Topics

Name	Description
Classes (see page 22092)	The following table lists classes in this documentation.
Interfaces (see page 22394)	The following table lists interfaces in this documentation.
Functions (see page 22400)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 22552)	The following table lists structs, records, enums in this documentation.
Types (see page 22579)	The following table lists types in this documentation.
Variables (see page 22629)	The following table lists variables in this documentation.
Constants (see page 22660)	The following table lists constants in this documentation.

Classes

	Name	Description
	AnsiString (see page 22093)	System::AnsiString is the C++ analog for the Delphi long string type.
	AutoCmd (see page 22127)	System::AutoCmd represents a command that can be executed by an Automation interface wrapped by a Variant (see page 22307) class.
	Currency (see page 22145)	System::Currency is the C++ implementation of the Delphi System::Currency data type.
	CurrencyBase (see page 22166)	This is class System::CurrencyBase.
	DelphiInterface (see page 22167)	System::DelphiInterface is a C++ implementation of the Delphi interface.
	DynamicArray (see page 22172)	System::DynamicArray is the C++ analog for the Delphi dynamic array type.
	DynArrayException (see page 22182)	This is class System::DynArrayException.
	DynArrayNullData (see page 22183)	This is class System::DynArrayNullData.
	DynArrayOutOfRange (see page 22183)	This is class System::DynArrayOutOfRange.
	Function (see page 22184)	System::Function represents a method on an Automation interface that returns a value.
	NamedParm (see page 22187)	NamedParm represents a named parameter assigned to a TAutoCmd descendant.
	OleVariant (see page 22193)	System::OleVariant is a C++ implementation of the Delphi intrinsic type System::OleVariant.
	OpenArray (see page 22216)	This is class System::OpenArray.
	OpenArrayCount (see page 22223)	This is class System::OpenArrayCount.
	Procedure (see page 22230)	System::Procedure represents a method on an Automation interface that does not return a value.
	PropertyGet (see page 22233)	PropertyGet represents a property access method on an Automation interface.
	PropertySet (see page 22236)	PropertySet represents a property access method on an Automation interface.

	SmallString (see page 22239)	This is class System::SmallString.
	SmallStringBase (see page 22242)	This is class System::SmallStringBase.
	sPointer (see page 22243)	This is class System::sPointer.
	StaticArray (see page 22245)	This is class System::StaticArray.
	TAggregatedObject (see page 22248)	System::TAggregatedObject provides the functionality for an inner object of an aggregate by implementing the IInterface (see page 22396) methods to delegate to the controlling IInterface (see page 22396).
	TClassHelperBase (see page 22251)	This is class System.TClassHelperBase.
	TContainedObject (see page 22253)	System::TContainedObject implements the IInterface (see page 22396) interface as an inner object in an aggregate.
	TDateTime (see page 22256)	System::TDateTime is the C++ analog for the Delphi System::TDateTime data type.
	TDateTimeBase (see page 22275)	This is class System::TDateTimeBase.
	TInterfacedObject (see page 22276)	System::TInterfacedObject is a base for simple classes that need a basic IInterface (see page 22396) implementation.
	TMetaClass (see page 22281)	System::TMetaClass is the C++ representation of the Delphi class-reference type.
	TObject (see page 22285)	System::TObject is the ultimate ancestor of all objects and components.
	Variant (see page 22307)	System::Variant is a C++ implementation of the Delphi intrinsic type System::Variant.
	VariantError (see page 22375)	This is class System::VariantError.
	WideString (see page 22377)	System::WideString represents strings of 16-bit characters.

Constants

Name	Description
CompilerVersion (see page 22662)	Designates the version number of the Delphi compiler.
CPUi386 (see page 22662)	This is constant System.CPUi386.
CPUi486 (see page 22663)	This is constant System.CPUi486.
CPUPentium (see page 22663)	This is constant System.CPUPentium.
E_NOINTERFACE (see page 22663)	This is constant System.E_NOINTERFACE.
E_NOTIMPL (see page 22664)	This is constant System.E_NOTIMPL.
E_UNEXPECTED (see page 22664)	This is constant System.E_UNEXPECTED.
fmClosed (see page 22664)	This is constant System.fmClosed.
fmInOut (see page 22665)	This is constant System.fmInOut.
fmInput (see page 22665)	This is constant System.fmInput.
fmOutput (see page 22665)	This is constant System.fmOutput.
MaxInt (see page 22666)	The maximum value of the Integer data type.
MaxLongint (see page 22666)	The maximum value of the Longint data type.
NumSmallBlockTypes (see page 22666)	NumSmallBlockTypes is the number of small memory block types employed by the default memory manager.
opAdd (see page 22667)	opAdd defines an addition operation.
opAnd (see page 22667)	opAnd defines a logical and operation.
opCmpEQ (see page 22668)	opCmpEQ defines an equality comparison operator.
opCmpGE (see page 22668)	opCmpGE defines a greater than or equal comparison operator.
opCmpGT (see page 22669)	opCmpGT defines a greater than comparison operator.
opCmpLE (see page 22669)	opCmpLE defines a less than or equal comparison operator.
opCmpLT (see page 22670)	opCmpLT defines a less than comparison operator.
opCmpNE (see page 22670)	opCmpNE defines an inequality comparison operator.
opCompare (see page 22671)	opCompare defines a comparison operation.
opDivide (see page 22671)	opDivide defines a divide operation.
opIntDivide (see page 22672)	opIntDivide defines an integer divide operation.
opModulus (see page 22672)	opModulus defines a modulus operation.
opMultiply (see page 22673)	opMultiply defines a multiply operation.
opNegate (see page 22673)	opNegate defines a negate operation.
opNot (see page 22674)	opNot defines a binary negation operation.
opOr (see page 22674)	opOr defines a logical or operation.
opShiftLeft (see page 22675)	opShiftLeft defines a bitwise shift left operation.
opShiftRight (see page 22675)	opShiftRight defines a bitwise shift right operation.

opSubtract (see page 22676)	opSubtract defines a subtraction operation.
opXor (see page 22676)	opXor defines a logical exclusive or operation.
RTLVersion (see page 22677)	Designates the version number of the Delphi runtime library.
S_FALSE (see page 22677)	This is constant System.S_FALSE.
S_OK (see page 22677)	This is constant System.S_OK.
sLineBreak (see page 22678)	Represents the character(s) used to generate a line feed.
tfCRLF (see page 22678)	This is constant System.tfCRLF.
varAny (see page 22678)	Represents a Variant (see page 22307) that can hold any value.
varArray (see page 22679)	Represents a Variant (see page 22307) that holds dynamic array data.
varBoolean (see page 22680)	Represents a Variant (see page 22307) that holds WordBool data.
varByRef (see page 22680)	Represents a Variant (see page 22307) that points to another variable.
varByte (see page 22681)	Represents a Variant (see page 22307) that holds byte data.
varCurrency (see page 22681)	Represents a Variant (see page 22307) that holds a monetary floating point value.
varDate (see page 22682)	Represents a Variant (see page 22307) that holds a TDateTime (see page 22256) value.
varDispatch (see page 22682)	Represents a Variant (see page 22307) that has been assigned an IDispatch (see page 22394) value.
varDouble (see page 22683)	Represents a Variant (see page 22307) that holds a floating point value.
varEmpty (see page 22683)	Represents a Variant (see page 22307) that has not yet been assigned a value.
varError (see page 22684)	Represents a Variant (see page 22307) that holds a 32 bit error code.
varInt64 (see page 22684)	Represents a Variant (see page 22307) that holds Int64 data.
varInteger (see page 22685)	Represents a Variant (see page 22307) that holds Integer data.
varLongWord (see page 22685)	Represents a Variant (see page 22307) that holds LongWord data.
varNull (see page 22686)	Represents a Variant (see page 22307) that holds a null value.
varOleStr (see page 22686)	Represents a Variant (see page 22307) that has been assigned a COM interface type string value.
varShortInt (see page 22687)	Represents a Variant (see page 22307) that holds ShortInt data.
varSingle (see page 22687)	Represents a Variant (see page 22307) that holds byte data.
varSmallint (see page 22688)	This is constant System.varSmallint.
varStrArg (see page 22688)	Represents a Variant (see page 22307) that has holds a COM compatible string value.
varString (see page 22688)	Represents a Variant (see page 22307) that holds string data.
varTypeMask (see page 22689)	Defines a mask for filtering out the meta data part of a Variant (see page 22307) data type.
varUnknown (see page 22690)	Represents a Variant (see page 22307) that holds an unknown value.
varVariant (see page 22690)	Represents a Variant (see page 22307) data type.
varWord (see page 22691)	Represents a Variant (see page 22307) that holds Word data.
vmtAddRef (see page 22691)	This is constant System.vmtAddRef.
vmtAfterConstruction (see page 22691)	This is constant System.vmtAfterConstruction.
vmtAutoTable (see page 22692)	This is constant System.vmtAutoTable.
vmtBeforeDestruction (see page 22692)	This is constant System.vmtBeforeDestruction.
vmtClassName (see page 22692)	This is constant System.vmtClassName.
vmtCreateObject (see page 22693)	This is constant System.vmtCreateObject.
vmtDefaultHandler (see page 22693)	This is constant System.vmtDefaultHandler.
vmtDestroy (see page 22693)	This is constant System.vmtDestroy.
vmtDispatch (see page 22694)	This is constant System.vmtDispatch.
vmtDynamicTable (see page 22694)	This is constant System.vmtDynamicTable.
vmtFieldTable (see page 22694)	This is constant System.vmtFieldTable.
vmtFreeInstance (see page 22695)	This is constant System.vmtFreeInstance.
vmtInitTable (see page 22695)	This is constant System.vmtInitTable.
vmtInstanceSize (see page 22695)	This is constant System.vmtInstanceSize.
vmtIntfTable (see page 22696)	This is constant System.vmtIntfTable.
vmtMethodTable (see page 22696)	This is constant System.vmtMethodTable.
vmtNewInstance (see page 22696)	This is constant System.vmtNewInstance.

vmtParent (see page 22697)	This is constant System.vmtParent.
vmtQueryInterface (see page 22697)	This is constant System.vmtQueryInterface.
vmtRelease (see page 22697)	This is constant System.vmtRelease.
vmtSafeCallException (see page 22698)	This is constant System.vmtSafeCallException.
vmtSelfPtr (see page 22698)	This is constant System.vmtSelfPtr.
vmtTypeInfo (see page 22698)	This is constant System.vmtTypeInfo.
vtAnsiString (see page 22699)	vtAnsiString defines an AnsiString (see page 22093) TVarData (see page 22571) VType value.
vtBoolean (see page 22699)	vtBoolean defines a Boolean TVarData (see page 22571) VType value.
vtChar (see page 22700)	vtChar defines a Char TVarData (see page 22571) VType value.
vtClass (see page 22700)	vtClass defines a TClass (see page 22611) TVarData (see page 22571) VType value.
vtCurrency (see page 22701)	vtCurrency defines a Currency (see page 22145) TVarData (see page 22571) VType value.
vtExtended (see page 22701)	vtExtended defines an Extended TVarData (see page 22571) VType value.
vtInt64 (see page 22702)	vtInt64 defines an Int64 TVarData (see page 22571) VType value.
vtInteger (see page 22702)	vtInteger defines an Integer TVarData (see page 22571) VType value.
vtInterface (see page 22703)	vtInterface defines an Interface pointer TVarData (see page 22571) VType value.
vtObject (see page 22703)	vtObject defines a TObject (see page 22285) TVarData (see page 22571) VType value.
vtPChar (see page 22704)	vtPChar defines a PChar TVarData (see page 22571) VType value.
vtPointer (see page 22704)	vtPointer defines a Pointer TVarData (see page 22571) VType value.
vtPWideChar (see page 22705)	vtPWideChar defines a PWideChar TVarData (see page 22571) VType value.
vtString (see page 22705)	vtString defines a Variant (see page 22307) TVarData (see page 22571) VType value.
vtVariant (see page 22706)	This is constant System.vtVariant.
vtWideChar (see page 22706)	vtWideChar defines a WideChar TVarData (see page 22571) VType value.
vtWideString (see page 22706)	vtWideString defines a WideString (see page 22377) TVarData (see page 22571) VType value.

Functions

	Name	Description
	!= (see page 22405)	This is function System::!=.
	__currMul (see page 22405)	This is function System::__currMul.
	_CVR_PROBE (see page 22405)	This is function System._CVR_PROBE.
	_CVR_STMTPROBE (see page 22406)	This is function System._CVR_STMTPROBE.
	_roundToInt64 (see page 22406)	This is function System::_roundToInt64.
	+ (see page 22406)	This is function System::+.
	< (see page 22407)	This is function System::<.
	<< (see page 22407)	This is function System::<<.
	<< (see page 22407)	This is function System::<<.
	<< (see page 22408)	This is function System::<<.
	<= (see page 22408)	This is function System::<=.
	== (see page 22408)	This is function System::==.
	> (see page 22409)	This is function System::>.
	>= (see page 22409)	This is function System::>=.
	>> (see page 22409)	This is function System::>>.
	>> (see page 22410)	This is function System::>>.
	Abs (see page 22410)	Returns an absolute value.
	AcquireExceptionObject (see page 22410)	Retains access to exception object.
	AddModuleUnloadProc (see page 22411)	AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.
	AddModuleUnloadProc (see page 22411)	AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.
	Addr (see page 22412)	Returns a pointer to a specified object.
	AllocMem (see page 22413)	AllocMem allocates a memory block and initializes each byte to zero.

	AnsiToUtf8 (see page 22415)	Converts a string encoded in Ansi to UTF-8.
	Append (see page 22415)	Prepares an existing file for adding text to the end.
	ArcTan (see page 22416)	Calculates the arctangent of a given number.
	Assert (see page 22417)	Tests whether a Boolean expression is true.
	Assert (see page 22417)	Tests whether a Boolean expression is true.
	Assigned (see page 22419)	Tests for a nil (unassigned) pointer or procedural variable.
	AssignFile (see page 22420)	Associates the name of an external file with a file variable.
	AttemptToUseSharedMemoryManager (see page 22422)	Attempts to use a shared memory manager.
	BeginThread (see page 22422)	Spawns a separate thread of execution.
	BlockRead (see page 22423)	Reads one or more records from an open file into a variable.
	BlockRead (see page 22423)	Reads one or more records from an open file into a variable.
	BlockWrite (see page 22425)	Writes one or more records from a variable to an open file.
	BlockWrite (see page 22425)	Writes one or more records from a variable to an open file.
	Break (see page 22426)	Causes the flow of control to exit a for, while, or repeat statement.
	ChDir (see page 22429)	Changes the current directory.
	ChDir (see page 22429)	Changes the current directory.
	Chr (see page 22430)	Returns the character for a specified ASCII value.
	Close (see page 22432)	Terminates the association between a file variable and an external file.
	CloseFile (see page 22433)	Terminates the association between file variable and an external disk file.
	CompToCurrency (see page 22435)	Converts a Comp value to a Currency (see page 22145) value.
	CompToDouble (see page 22435)	Converts a Comp value to a double value.
	Concat (see page 22436)	Concatenates two or more strings into one.
	Concat (see page 22436)	Concatenates two or more strings into one.
	Concat (see page 22436)	Concatenates two or more strings into one.
	Continue (see page 22437)	Allows the flow of control to proceed to the next iteration of for, while, or repeat statements.
	Copy (see page 22438)	Returns a substring of a string or a segment of a dynamic array.
	Cos (see page 22440)	Calculates the cosine of an angle.
	CurrencyToComp (see page 22441)	Converts a Currency (see page 22145) value to a Comp value.
	Dec (see page 22441)	Decrements a variable by 1 or N.
	Dec (see page 22441)	Decrements a variable by 1 or N.
	Delete (see page 22443)	Removes a substring from a string.
	Dispose (see page 22444)	Releases memory allocated for a dynamic variable.
	DoubleToComp (see page 22446)	Converts a double value to a Comp.
	DynArrayClear (see page 22446)	This is function System.DynArrayClear.
	DynArrayDim (see page 22446)	This is function System.DynArrayDim.
	DynArraySetLength (see page 22447)	This is function System.DynArraySetLength.
	EndThread (see page 22447)	Terminates the execution of a thread.
	EnumModules (see page 22447)	Executes a callback for all the modules in an application.
	EnumModules (see page 22447)	Executes a callback for all the modules in an application.
	EnumResourceModules (see page 22448)	Executes a callback for all resource modules in an application.
	EnumResourceModules (see page 22448)	Executes a callback for all resource modules in an application.
	Eof (see page 22449)	Tests whether the file position is at the end of a file.
	Eof (see page 22449)	Tests whether the file position is at the end of a file.
	Eof (see page 22449)	Tests whether the file position is at the end of a file.
	Eoln (see page 22450)	Tests whether the file pointer is at the end of a line.
	Eoln (see page 22450)	Tests whether the file pointer is at the end of a line.
	Erase (see page 22451)	Deletes an external file.
	Error (see page 22451)	Error is used to generate a run-time exception.
	ExceptAddr (see page 22452)	Returns the address at which the current exception was raised.
	ExceptObject (see page 22452)	Returns current exception object.
	Exclude (see page 22453)	Removes an element from a Delphi set or removes an event handler in .NET applications.
	Exit (see page 22453)	Exits from the current procedure.
	Exp (see page 22455)	Returns the exponential of X.

	Exp (see page 22455)	Returns the exponential of X.
	FilePos (see page 22456)	Returns the current file position.
	FileSize (see page 22457)	Returns the number of records in a file.
	FillChar (see page 22459)	Fills contiguous bytes with a specified value.
	Finalize (see page 22460)	Uninitializes a dynamically allocated variable.
	Finalize (see page 22460)	Uninitializes a dynamically allocated variable.
	FindClassHInstance (see page 22461)	Returns the instance handle for the module in which a class type is defined.
	FindHInstance (see page 22461)	Returns the instance handle of the module that contains a specified address.
	FindResourceHInstance (see page 22462)	Returns the instance handle of the resource module associated with a specified HInstance.
	Flush (see page 22462)	Empties the buffer of a text file opened for output.
	FPower10 (see page 22463)	This is function System.FPower10.
	Frac (see page 22463)	Returns the fractional part of a real number.
	FreeMem (see page 22464)	FreeMem frees a memory block.
	FreeMem (see page 22464)	FreeMem frees a memory block.
	FreeMemory (see page 22466)	FreeMemory frees a memory block.
	Get8087CW (see page 22466)	Returns the value of the 8087 code word.
	GetDir (see page 22467)	Returns the current directory.
	GetHeapStatus (see page 22468)	Returns the current status of the memory manager.
	GetLastError (see page 22469)	Returns the last error reported by an operating system API call.
	GetMem (see page 22469)	GetMem allocates a memory block.
	GetMemory (see page 22470)	GetMemory allocates a memory block.
	GetMemoryManager (see page 22472)	Returns the entry points of the currently installed memory manager.
	GetMemoryManager (see page 22472)	Returns the entry points of the currently installed memory manager.
	GetMemoryManagerState (see page 22472)	Fetches state information for the Memory Manager.
	GetMemoryMap (see page 22473)	Fetches the memory map.
	GetMinimumBlockAlignment (see page 22473)	Gets the minimum memory block alignment.
	GetModuleFileName (see page 22474)	Returns the fully qualified name for a module, given its handle.
	GetVariantManager (see page 22474)	Returns the entry points of the routines that define variant behavior.
	Halt (see page 22475)	Initiates abnormal termination of a program.
	Halt (see page 22475)	Initiates abnormal termination of a program.
	Hi (see page 22476)	Returns the high-order byte of X as an unsigned value.
	High (see page 22476)	Returns the highest value in the range of an argument.
	Inc (see page 22478)	Increments an ordinal value by one or N.
	Inc (see page 22478)	Increments an ordinal value by one or N.
	Include (see page 22479)	Adds an element to a Delphi set or adds an event handler in .NET applications.
	Initialize (see page 22480)	Initializes a dynamically allocated variable.
	Initialize (see page 22480)	Initializes a dynamically allocated variable.
	Insert (see page 22480)	Inserts a substring into a string beginning at a specified point.
	Int (see page 22481)	Returns the integer part of a real number.
	IOResult (see page 22482)	Returns the status of the last I/O operation performed.
	IsMemoryManagerSet (see page 22483)	Indicates whether the memory manager has been overridden using the SetMemoryManager (see page 22523) procedure.
	IsVariantManagerSet (see page 22483)	Indicates whether variant support is implemented in an application.
	Length (see page 22484)	Returns the number of characters in a string or elements in an array.
	Ln (see page 22485)	Returns the natural log of a real expression.
	Lo (see page 22486)	Returns the low order Byte of argument X.
	LoadResourceModule (see page 22486)	This is function System.LoadResourceModule.
	LoadResString (see page 22487)	This is function System.LoadResString.
	Low (see page 22487)	Returns the lowest value in a range.
	MkDir (see page 22488)	Creates a new subdirectory.
	MkDir (see page 22488)	Creates a new subdirectory.
	Move (see page 22490)	Copies bytes from a source to a destination.
	New (see page 22491)	Creates a new dynamic variable and sets P to point to it.
	Odd (see page 22493)	Returns true if argument is an odd number.

	OleStrToString (see page 22493)	Copies data received from a COM interface to a string.
	OleStrToStrVar (see page 22494)	Copies a string from its COM representation to an existing Delphi string.
	Ord (see page 22494)	Returns the ordinal value of an ordinal-type expression.
	ParamCount (see page 22495)	Returns the number of parameters passed on the command line.
	ParamStr (see page 22496)	Returns a specified parameter from the command-line.
	Pi (see page 22497)	Returns 3.1415926535897932385.
	Pos (see page 22497)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pos (see page 22497)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pred (see page 22499)	Returns the predecessor of the argument.
	Ptr (see page 22501)	Converts a specified address to a pointer.
	PUCS4Chars (see page 22501)	Converts a UCS4 string to a null-terminated array of UCS4 characters.
	RaiseList (see page 22502)	This is function System.RaiseList.
	Random (see page 22502)	Generates random numbers within a specified range.
	Random (see page 22502)	Generates random numbers within a specified range.
	Randomize (see page 22503)	Initializes the random number generator with a random value.
	Read (see page 22504)	Read reads data from a file.
	Read (see page 22504)	Read reads data from a file.
	Read (see page 22504)	Read reads data from a file.
	Read (see page 22504)	Read reads data from a file.
	ReadLn (see page 22506)	Reads a line of text from a file.
	ReadLn (see page 22506)	Reads a line of text from a file.
	ReadLn (see page 22506)	Reads a line of text from a file.
	ReadLn (see page 22506)	Reads a line of text from a file.
	ReallocMem (see page 22507)	ReallocMem reallocates a memory block.
	ReallocMemory (see page 22508)	ReallocMemory resizes a memory block.
	RegisterExpectedMemoryLeak (see page 22508)	Registers an expected memory leak.
	RegisterModule (see page 22509)	This is function System.RegisterModule.
	ReleaseExceptionObject (see page 22509)	Releases exception object acquired by AcquireExceptionObject (see page 22410).
	RemoveModuleUnloadProc (see page 22510)	RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.
	RemoveModuleUnloadProc (see page 22510)	RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.
	Rename (see page 22510)	Changes the name of an external file.
	Rename (see page 22510)	Changes the name of an external file.
	Reset (see page 22511)	Opens an existing file.
	Reset (see page 22511)	Opens an existing file.
	Reset (see page 22511)	Opens an existing file.
	Reset (see page 22511)	Opens an existing file.
	Rewrite (see page 22513)	Creates a new file and opens it.
	Rewrite (see page 22513)	Creates a new file and opens it.
	RmDir (see page 22515)	Deletes an empty subdirectory.
	RmDir (see page 22515)	Deletes an empty subdirectory.
	Round (see page 22516)	Returns the value of X rounded to the nearest whole number.
	RunError (see page 22517)	Stops execution and generates a runtime error.
	RunError (see page 22517)	Stops execution and generates a runtime error.
	Seek (see page 22518)	Moves the current position of a file to a specified component.
	SeekEof (see page 22519)	Returns the end-of-file status of a file, ignoring whitespace.
	SeekEof (see page 22519)	Returns the end-of-file status of a file, ignoring whitespace.
	SeekEoln (see page 22520)	Returns the end-of-line status of a file, ignoring whitespace.
	SeekEoln (see page 22520)	Returns the end-of-line status of a file, ignoring whitespace.
	Set8087CW (see page 22520)	Sets both the control word in the floating point unit and the variable NoErrMsg (see page 22652) declared in the system unit.
	SetInOutRes (see page 22521)	This is function System.SetInOutRes.

	SetLastError (see page 22521)	SetLastError sets the last API error code.
	SetLength (see page 22522)	Sets the length of a string or dynamic-array variable.
	SetLineBreakStyle (see page 22522)	Determines the end-of-line and end-of-file conventions for text file I/O.
	SetMemoryManager (see page 22523)	Sets entry points of the memory manager.
	SetMemoryManager (see page 22523)	Sets entry points of the memory manager.
	SetMinimumBlockAlignment (see page 22524)	Sets the minimum memory block alignment.
	SetMultiByteConversionCodePage (see page 22524)	SetMultiByteConversionCodePage overrides the default multi byte code conversion page.
	SetRaiseList (see page 22525)	This is function System.SetRaiseList.
	SetString (see page 22525)	Sets the contents and length of the given string.
	SetTextBuf (see page 22526)	Assigns an I/O buffer to a text file.
	SetTextBuf (see page 22526)	Assigns an I/O buffer to a text file.
	SetVariantManager (see page 22527)	Sets the entry points of routines that define variant behavior.
	ShareMemoryManager (see page 22527)	Shares the module's memory manager.
	Sin (see page 22528)	Returns the sine of the angle in radians.
	SizeOf (see page 22528)	Returns the number of bytes occupied by a variable or type.
	Slice (see page 22529)	Returns a sub-section of an array.
	Sqr (see page 22529)	Returns the square of a number.
	Sqr (see page 22529)	Returns the square of a number.
	Sqrt (see page 22530)	Returns the square root of X.
	Str (see page 22530)	Formats a string and returns it to a variable.
	Str (see page 22530)	Formats a string and returns it to a variable.
	StringOfChar (see page 22531)	Returns a string with a specified number of repeating characters.
	StringOfChar (see page 22531)	Returns a string with a specified number of repeating characters.
	StringToOleStr (see page 22531)	Allocates memory and copies an AnsiStringa string to the OLE format.
	StringToWideChar (see page 22532)	Returns a UNICODE string from an AnsiString (see page 22093).
	Succ (see page 22532)	Returns the successor of an argument.
	Swap (see page 22533)	Exchanges high order byte with the low order byte of an integer or word.
	SysAllocMem (see page 22533)	This is function System.SysAllocMem.
	SysFreeMem (see page 22534)	Frees the memory pointed to by a specified pointer.
	SysGetMem (see page 22534)	Allocates a specified number of bytes and returns a pointer to them.
	SysReallocMem (see page 22535)	Returns a pointer to a specified number of bytes, preserving the values pointed to by the Pointer parameter.
	SysRegisterExpectedMemoryLeak (see page 22536)	This is function System.SysRegisterExpectedMemoryLeak.
	SysUnregisterExpectedMemoryLeak (see page 22536)	This is function System.SysUnregisterExpectedMemoryLeak.
	TextStart (see page 22536)	This is function System.TextStart.
	Trunc (see page 22537)	Truncates a real number to an integer.
	Truncate (see page 22537)	Deletes all the records after the current file position.
	UCS4StringToWideString (see page 22538)	Converts a string of 4-byte Unicode characters into a WideString (see page 22377) value.
	UnicodeToUtf8 (see page 22538)	Converts a string of Unicode characters into a UTF-8 string.
	UnicodeToUtf8 (see page 22538)	Converts a string of Unicode characters into a UTF-8 string.
	UniqueString (see page 22539)	Ensures that a given string has a reference count of one.
	UniqueString (see page 22539)	Ensures that a given string has a reference count of one.
	UnregisterExpectedMemoryLeak (see page 22539)	Unregisters an expected memory leak.
	UnregisterModule (see page 22540)	This is function System.UnregisterModule.
	UpCase (see page 22540)	Converts a character to uppercase.
	UTF8Decode (see page 22541)	Converts a UTF8 string to a Unicode string (WideString (see page 22377)).
	UTF8Encode (see page 22541)	Converts a WideString (see page 22377) value to a UTF8 string.
	Utf8ToAnsi (see page 22542)	Converts a UTF8 string to a string of Ansi characters.
	Utf8ToUnicode (see page 22542)	Converts a string of UTF-8 characters to a Unicode string.
	Utf8ToUnicode (see page 22542)	Converts a string of UTF-8 characters to a Unicode string.
	Val (see page 22543)	Converts a string to a numeric representation.
	VarArrayRedim (see page 22544)	Resizes a Variant (see page 22307) array.
	VarArrayRedim (see page 22544)	This is function System::VarArrayRedim.

	VarCast (see page 22545)	This is function System::VarCast.
	VarClear (see page 22545)	Empties a Variant (see page 22307), so that it is unassigned.
	VarClear (see page 22546)	This is function System::VarClear.
	WideCharLenToString (see page 22546)	Converts Unicode characters to single or multi byte character data.
	WideCharLenToStrVar (see page 22546)	WideCharLenToStrVar converts Unicode characters to single or multi byte character data.
	WideCharToString (see page 22547)	Converts null-terminated Unicode string to single or multi byte character data.
	WideCharToStrVar (see page 22547)	Converts Unicode string to a single or multi byte character data.
	WideStringToUCS4String (see page 22548)	Converts a WideString (see page 22377) value to a string of 4-byte Unicode characters.
	Write (see page 22548)	Writes to either a typed file or a text file
	Write (see page 22548)	Writes to either a typed file or a text file
	Write (see page 22548)	Writes to either a typed file or a text file
	Write (see page 22548)	Writes to either a typed file or a text file
	WriteLn (see page 22550)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 22550)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 22550)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 22550)	Writes to a text file and adds an end-of-line marker.

Interfaces

	Name	Description
	IDispatch (see page 22394)	This is class System.IDispatch.
	IInterface (see page 22396)	IInterface is the base class for all interfaces defined in Delphi code.
	IInvokable (see page 22398)	IInvokable is the base class for invokable interfaces.

Structs, Records, Enums

	Name	Description
	PackageInfoTable (see page 22553)	This is record System.PackageInfoTable.
	PackageUnitEntry (see page 22553)	This is record System.PackageUnitEntry.
	TCallDesc (see page 22553)	TCallDesc is the dispatch call descriptor for variants, and PCallDesc (see page 22588) is a pointer to this descriptior.
	TChunkStatus (see page 22554)	TChunkStatus enumerates the possible states of a chunk of memory.
	TCVModInfo (see page 22555)	This is record System.TCVModInfo.
	TDispatchMessage (see page 22555)	This is record System.TDispatchMessage.
	TDispDesc (see page 22556)	This is record System.TDispDesc.
	TDynArrayTypeInfo (see page 22556)	This is record System.TDynArrayTypeInfo.
	TFileRec (see page 22557)	TFileRec is the internal format for typed and untyped files in the Delphi language.
	TGUID (see page 22558)	TGUID is a structured form of the value that uniquely identifies an interface.
	THeapStatus (see page 22558)	THeapStatus represents information about the global heap.
	TInitContext (see page 22560)	This is record System.TInitContext.
	TInterfaceEntry (see page 22560)	This is record System::TInterfaceEntry.
	TInterfaceTable (see page 22561)	This is record System::TInterfaceTable.
	TLibModule (see page 22561)	TLibModule describes a module that is compiled with the application.
	TMemoryManager (see page 22562)	TMemoryManager defines the memory block entry points.
	TMemoryManagerEx (see page 22563)	TMemoryManagerEx defines extended memory block entry points.
	TMemoryManagerState (see page 22564)	TMemoryManagerState holds statistics about memory allocations.
	TMethod (see page 22565)	TMethod stores Code and Data fields to represent a method.
	TMinimumBlockAlignment (see page 22566)	TMinimumBlockAlignment defines the mimimum byte alignment for memory block allocation.
	TModuleUnloadRec (see page 22566)	This is record System.TModuleUnloadRec.
	TResStringRec (see page 22567)	This is record System.TResStringRec.
	TRuntimeError (see page 22567)	This is record System.TRuntimeError.
	TSmallBlockTypeState (see page 22568)	TSmallBlockTypeState holds statistics about a small memory block.
	TTextLineBreakStyle (see page 22569)	TTextLineBreakStyle indicates the default set of characters used to divide lines in text.
	TTextRec (see page 22569)	TTextRec is the internal format for text files.

	TVarArray (see page 22570)	This is record System.TVarArray.
	TVarArrayBound (see page 22571)	This is record System.TVarArrayBound.
	TVarData (see page 22571)	TVarData represents Variant (see page 22307) information.
	TVariantManager (see page 22575)	TVariantManager defines entry points for variant conversion routines and other procedures that define variant behavior.
	TVarRec (see page 22577)	This is class System::TVarRec.
	TCallDesc (see page 22578)	This is type System::TCallDesc.
	TDispDesc (see page 22578)	This is type System::TDispDesc.

Types

Name	Description
ArrayOfboolean (see page 22581)	This is type System::ArrayOfboolean.
ArrayOfbyte (see page 22582)	This is type System::ArrayOfbyte.
ArrayOfdouble (see page 22582)	This is type System::ArrayOfdouble.
ArrayOfint (see page 22582)	This is type System::ArrayOfint.
ArrayOflong (see page 22583)	This is type System::ArrayOflong.
ArrayOfshort (see page 22583)	This is type System::ArrayOfshort.
ArrayOfstring (see page 22583)	This is type System::ArrayOfstring.
ArrayOfwidestring (see page 22584)	This is type System::ArrayOfwidestring.
GetPackageInfoTable (see page 22584)	This is type System.GetPackageInfoTable.
HGLOBAL (see page 22584)	This is type System.HGLOBAL.
HINST (see page 22585)	This is type System.HINST.
HMODULE (see page 22585)	This is type System.HMODULE.
HRESULT (see page 22585)	This is type System.HRESULT.
HRSRC (see page 22586)	This is type System.HRSRC.
IntegerArray (see page 22586)	This is type System.IntegerArray.
IUnknown (see page 22586)	IUnknown is a special base interface.
PackageInfo (see page 22587)	This is type System.PackageInfo.
PAnsiString (see page 22587)	PAnsiString is a pointer to an AnsiString (see page 22093) variable.
PBoolean (see page 22587)	PBoolean is a pointer to a Boolean variable.
PByte (see page 22588)	PByte is a pointer to a Byte variable.
PCallDesc (see page 22588)	This is type System::PCallDesc.
PCardinal (see page 22589)	PCardinal is a pointer to a Cardinal variable.
PComp (see page 22589)	PComp is a pointer to a Comp variable.
PCurrency (see page 22589)	PCurrency is a pointer to a Currency (see page 22145) variable.
PCVModInfo (see page 22590)	This is type System.PCVModInfo.
PDate (see page 22590)	PDate is a pointer to a Date variable.
PDateTime (see page 22591)	PDateTime is a pointer to a TDateTime (see page 22256) variable.
PDispatch (see page 22591)	This is type System.PDispatch.
PDispDesc (see page 22591)	This is type System::PDispDesc.
PDouble (see page 22592)	PDouble is a pointer to a Double variable.
PDynArrayTypeInfo (see page 22592)	This is type System.PDynArrayTypeInfo.
PError (see page 22592)	This is type System.PError.
PExtended (see page 22593)	PExtended is a pointer to an Extended variable.
PGUID (see page 22593)	PGUID is a pointer to a TGUID (see page 22558) variable.
PInitContext (see page 22593)	This is type System.PInitContext.
PInt64 (see page 22594)	PInt64 is a pointer to an Int64 variable.
PInteger (see page 22594)	PInteger is a pointer to an Integer variable.
PIntegerArray (see page 22595)	PIntegerArray is a pointer to an IntegerArray (see page 22586) variable.
PInterfaceEntry (see page 22595)	This is type System::PInterfaceEntry.
PInterfaceTable (see page 22595)	This is type System::PInterfaceTable.
PLibModule (see page 22596)	PLibModule is a pointer to a TLibModule (see page 22561) variable.
PLongint (see page 22596)	This is type System.PLongint.
PLongWord (see page 22596)	PLongWord is a pointer to a LongWord variable.

PMemoryManager (see page 22597)	PMemoryManager is a pointer to a TMemoryManager (see page 22562) variable.
PMemoryManagerEx (see page 22597)	PMemoryManagerEx is a pointer to a TMemoryManagerEx (see page 22563) variable.
PModuleUnloadRec (see page 22598)	This is type System.PModuleUnloadRec.
PointerArray (see page 22598)	This is type System.PointerArray.
POleVariant (see page 22598)	This is type System.POleVariant.
PPAnsiChar (see page 22599)	This is type System.PPAnsiChar.
PPChar (see page 22599)	This is type System.PPChar.
PPCharArray (see page 22599)	This is type System.PPCharArray.
PPDispatch (see page 22600)	This is type System.PPDispatch.
PPointer (see page 22600)	PPointer is a pointer to a Pointer variable.
PPointerArray (see page 22600)	PPointerArray is a pointer to a PointerArray (see page 22598) variable.
PPUnknown (see page 22601)	This is type System.PPUnknown.
PPWideChar (see page 22601)	This is type System.PPWideChar.
PResStringRec (see page 22601)	This is type System.PResStringRec.
PShortInt (see page 22602)	PShortInt is a pointer to a ShortInt variable.
PShortString (see page 22602)	PShortString is a pointer to a ShortString variable.
PSingle (see page 22602)	PSingle is a pointer to a Single variable.
PSmallInt (see page 22603)	PSmallInt is a pointer to a SmallInt variable.
PString (see page 22603)	PString is a pointer to a String variable.
PTextBuf (see page 22604)	This is type System.PTextBuf.
PUCS2Char (see page 22604)	This is type System.PUCS2Char.
PUCS4Char (see page 22604)	This is type System.PUCS4Char.
PUCS4CharArray (see page 22605)	This is type System.PUCS4CharArray.
PUnitEntryTable (see page 22605)	This is type System.PUnitEntryTable.
PUnknown (see page 22605)	PUnknown is a pointer to an IUnknown (see page 22586) variable.
PUTF8String (see page 22606)	This is type System.PUTF8String.
PVarArray (see page 22606)	This is type System.PVarArray.
PVarArrayBoundArray (see page 22606)	This is type System.PVarArrayBoundArray.
PVarArrayCoorArray (see page 22607)	This is type System.PVarArrayCoorArray.
PVarData (see page 22607)	This is type System.PVarData.
PVariant (see page 22607)	PVariant is a pointer to a Variant (see page 22307) variable.
PVariantManager (see page 22608)	This is type System.PVariantManager.
PVarRec (see page 22608)	This is type System::PVarRec.
PWideString (see page 22608)	PWideString is a pointer to a WideString (see page 22377) variable.
PWord (see page 22609)	PWord is a pointer to a Word variable.
PWordBool (see page 22609)	PWordBool is a pointer to a WordBool variable.
SCODE (see page 22609)	This is type System::SCODE.
TAssertErrorProc (see page 22610)	This is type System.TAssertErrorProc.
TBooleanDynArray (see page 22610)	This is type System::TBooleanDynArray.
TBoundArray (see page 22610)	This is type System.TBoundArray.
TByteDynArray (see page 22611)	This is type System::TByteDynArray.
TCardinalDynArray (see page 22611)	This is type System::TCardinalDynArray.
TClass (see page 22611)	TClass defines the metaclass for TObject (see page 22285).
TDateTime (see page 22612)	TDateTime represents a date-and-time value in the Delphi language.
TDLLProc (see page 22613)	This is type System.TDLLProc.
TDLLProcEx (see page 22613)	This is type System.TDLLProcEx.
TDoubleDynArray (see page 22614)	This is type System::TDoubleDynArray.
TEnumModuleFunc (see page 22614)	This is type System.TEnumModuleFunc.
TEnumModuleFuncLW (see page 22614)	This is type System.TEnumModuleFuncLW.
TFileIOFunc (see page 22615)	This is type System.TFileIOFunc.
THandle (see page 22615)	THandle is a general purpose data reference (handle).
TInt64DynArray (see page 22615)	This is type System::TInt64DynArray.
TIntegerDynArray (see page 22616)	This is type System::TIntegerDynArray.

TInterfacedClass (see page 22616)	TInterfacedClass defines the metaclass for TInterfacedObject (see page 22276).
TLongWordDynArray (see page 22616)	This is type System::TLongWordDynArray.
TMemoryMap (see page 22617)	TMemoryMap is a map of an application's address space as an array of TChunkStatus (see page 22554) values.
TModuleUnloadProc (see page 22617)	TModuleUnloadProc dehines a procedure that can be called during package unload.
TModuleUnloadProcLW (see page 22618)	This is type System.TModuleUnloadProcLW.
TPCharArray (see page 22618)	This is type System.TPCharArray.
TResourceHandle (see page 22619)	This is type System.TResourceHandle.
TSafeCallErrorProc (see page 22619)	This is type System.TSafeCallErrorProc.
TShortIntDynArray (see page 22619)	This is type System::TShortIntDynArray.
TSingleDynArray (see page 22620)	This is type System::TSingleDynArray.
TSmallBlockTypeStates (see page 22620)	TSmallBlockTypeStates is an array of small memory block information records.
TSmallIntDynArray (see page 22620)	This is type System::TSmallIntDynArray.
TStringDynArray (see page 22621)	This is type System::TStringDynArray.
TSystemThreadEndProc (see page 22621)	This is type System.TSystemThreadEndProc.
TSystemThreadFuncProc (see page 22621)	This is type System.TSystemThreadFuncProc.
TTextBuf (see page 22622)	This is type System.TTextBuf.
TTextIOFunc (see page 22622)	This is type System.TTextIOFunc.
TThreadFunc (see page 22622)	TThreadFunc defines a new thread of execution.
TUCS4CharArray (see page 22623)	This is type System.TUCS4CharArray.
TVarArrayBoundArray (see page 22623)	This is type System.TVarArrayBoundArray.
TVarArrayCoorArray (see page 22623)	This is type System.TVarArrayCoorArray.
TVarOp (see page 22624)	TVarOp defines a Variant (see page 22307) operation.
TVarType (see page 22625)	This is type System.TVarType.
TWideStringDynArray (see page 22625)	This is type System::TWideStringDynArray.
TWordDynArray (see page 22626)	This is type System::TWordDynArray.
UCS2Char (see page 22626)	This is type System.UCS2Char.
UCS4Char (see page 22626)	UCS4Char is used for working with 4–byte Unicode characters.
UCS4String (see page 22627)	UCS4String is used for working with 4–byte Unicode characters.
UnitEntryTable (see page 22627)	This is type System.UnitEntryTable.
UTF8String (see page 22627)	This is type System.UTF8String.

Variables

Name	Description
AbstractErrorProc (see page 22630)	AbstractErrorProc defines a callback routine for abstract method call errors.
AllocMemCount (see page 22630)	Represents the total number of allocated memory blocks in a Delphi application.
AllocMemSize (see page 22631)	Represents the total size of allocated memory blocks.
AssertErrorProc (see page 22633)	Points to the assertion error-handler.
CmdLine (see page 22635)	Points to the command-line arguments specified when the application is invoked.
CmdShow (see page 22635)	Specifies the flags for displaying the application's main window.
DebugHook (see page 22636)	DebugHook is set if an application is running under the IDE debugger.
Default8087CW (see page 22636)	Specifies the Default 8087 control word.
DefaultTextLineBreakStyle (see page 22636)	Specifies the characters that are used by default to separate lines in text.
DispCallByIDProc (see page 22637)	This is variable System.DispCallByIDProc.
DLLProc (see page 22637)	Points to a procedure invoked by a DLL entry point.
envp (see page 22638)	This is variable System.envp.
ErrorAddr (see page 22638)	Contains the address of a statement causing a runtime error.
ErrorProc (see page 22639)	Points to the RTL runtime error handler.
ErrOutput (see page 22640)	ErrOutput specifies a write-only Text file associated with the process's error output file.
ExceptClsProc (see page 22640)	ExceptClsProc defines a pointer to a function called during exception handling.
ExceptionClass (see page 22641)	This is variable System.ExceptionClass.
ExceptObjProc (see page 22641)	ExceptObjProc defines a pointer to a function called during exception handling.
ExceptProc (see page 22641)	Points to the lowest-level exception handler.

ExitCode (see page 22642)	Contains the application's exit code.
ExitProc (see page 22643)	Points to a program's exit procedure (provided for backward compatibility).
ExitProcessProc (see page 22644)	Specifies the last procedure to execute before the application shuts down.
FileMode (see page 22644)	Indicates the access mode on typed and untyped files opened by the Reset (see page 22511) procedure.
HeapAllocFlags (see page 22645)	Indicates how the memory manager obtains memory from the operating system.
HPrevInst (see page 22645)	This is variable System.HPrevInst.
InitProc (see page 22646)	InitProc is the last installed initialization procedure.
Input (see page 22647)	Specifies a read-only Text file associated with the processes standard Input file.
IsConsole (see page 22647)	Indicates whether the module was compiled as a console application.
IsLibrary (see page 22648)	Indicates whether the module is a shared library.
IsMultiThread (see page 22648)	Indicates whether the application spawned additional threads using BeginThread (see page 22422) or TThread objects.
JITEnable (see page 22649)	Controls (see page 5711) when the just-in-time debugger is called.
LibModuleList (see page 22650)	Lists module records for enumeration procedures.
MainInstance (see page 22650)	Indicates the instance handle for the main executable.
MainThreadID (see page 22651)	Indicates the instance handle for the current module's main thread of execution.
MaxDispArgs (see page 22651)	This is variable System::MaxDispArgs.
ModuleUnloadList (see page 22651)	This is variable System.ModuleUnloadList.
NeverSleepOnMMThreadContention (see page 22652)	Dictates memory manager behavior during a thread contention.
NoErrMsg (see page 22652)	Controls (see page 5711) whether the application displays an error message when a runtime error occurs.
Output (see page 22653)	Specifies a write-only Text file associated with the process's standard output file.
RaiseExceptionProc (see page 22653)	Points to RaiseException Windows function.
RandSeed (see page 22654)	RandSeed stores the built-in random number generator's seed.
ReportMemoryLeaksOnShutdown (see page 22654)	Report memory leaks on shutdown.
RTLUnwindProc (see page 22655)	This is variable System.RTLUnwindProc.
SafeCallErrorProc (see page 22655)	SafeCallErrorProc defines a procedure that is called when a safecall routine incurs an error.
SystemThreadEndProc (see page 22656)	This is variable System.SystemThreadEndProc.
SystemThreadFuncProc (see page 22656)	This is variable System.SystemThreadFuncProc.
Test8086 (see page 22656)	This is variable System.Test8086.
Test8087 (see page 22657)	This is variable System.Test8087.
TestFDIV (see page 22657)	This is variable System.TestFDIV.
VarAddRefProc (see page 22657)	This is variable System.VarAddRefProc.
VarClearProc (see page 22658)	This is variable System.VarClearProc.
VarCopyProc (see page 22658)	This is variable System.VarCopyProc.
VarToLStrProc (see page 22658)	This is variable System.VarToLStrProc.
VarToWStrProc (see page 22659)	This is variable System.VarToWStrProc.

158.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	AnsiString (see page 22093)	System::AnsiString is the C++ analog for the Delphi long string type.
	AutoCmd (see page 22127)	System::AutoCmd represents a command that can be executed by an Automation interface wrapped by a Variant (see page 22307) class.
	Currency (see page 22145)	System::Currency is the C++ implementation of the Delphi System::Currency data type.
	CurrencyBase (see page 22166)	This is class System::CurrencyBase.
	DynArrayException (see page 22182)	This is class System::DynArrayException.
	DynArrayNullData (see page 22183)	This is class System::DynArrayNullData.
	DynArrayOutOfRange (see page 22183)	This is class System::DynArrayOutOfRange.
	Function (see page 22184)	System::Function represents a method on an Automation interface that returns a value.
	NamedParm (see page 22187)	NamedParm represents a named parameter assigned to a TAutoCmd descendant.
	Procedure (see page 22230)	System::Procedure represents a method on an Automation interface that does not return a value.
	PropertyGet (see page 22233)	PropertyGet represents a property access method on an Automation interface.
	PropertySet (see page 22236)	PropertySet represents a property access method on an Automation interface.
	TAggregatedObject (see page 22248)	System::TAggregatedObject provides the functionality for an inner object of an aggregate by implementing the IInterface (see page 22396) methods to delegate to the controlling IInterface (see page 22396).
	TClassHelperBase (see page 22251)	This is class System.TClassHelperBase.
	TContainedObject (see page 22253)	System::TContainedObject implements the IInterface (see page 22396) interface as an inner object in an aggregate.
	TDateTime (see page 22256)	System::TDateTime is the C++ analog for the Delphi System::TDateTime data type.
	TDateTimeBase (see page 22275)	This is class System::TDateTimeBase.
	TInterfacedObject (see page 22276)	System::TInterfacedObject is a base for simple classes that need a basic IInterface (see page 22396) implementation.
	TMetaClass (see page 22281)	System::TMetaClass is the C++ representation of the Delphi class-reference type.
	TObject (see page 22285)	System::TObject is the ultimate ancestor of all objects and components.
	Variant (see page 22307)	System::Variant is a C++ implementation of the Delphi intrinsic type System::Variant.
	VariantError (see page 22375)	This is class System::VariantError.
	WideString (see page 22377)	System::WideString represents strings of 16-bit characters.

Structures

	Name	Description
	StaticArray (see page 22245)	This is class System::StaticArray.

Templates

	Name	Description
	DelphiInterface (see page 22167)	System::DelphiInterface is a C++ implementation of the Delphi interface.
	DynamicArray (see page 22172)	System::DynamicArray is the C++ analog for the Delphi dynamic array type.
	OleVariant (see page 22193)	System::OleVariant is a C++ implementation of the Delphi intrinsic type System::OleVariant.
	OpenArray (see page 22216)	This is class System::OpenArray.
	OpenArrayCount (see page 22223)	This is class System::OpenArrayCount.
	SmallString (see page 22239)	This is class System::SmallString.

	SmallStringBase (see page 22242)	This is class System::SmallStringBase.
	sPointer (see page 22243)	This is class System::sPointer.

158.1.1 AnsiString Class

System::AnsiString is the C++ analog for the Delphi long string type.

Class Hierarchy

System::AnsiString

Pascal

```
AnsiString = class;
```

C++

```
class AnsiString;
```

File

dstring.h

Description

Delphi utilizes several string types. The most important is the long string type, more commonly known as System::AnsiString. Support for this type includes the following features:

strings as large as available memory;

efficient use of memory through shared references;

routines and operators that evaluate strings based on the current locale.

Despite its name, System::AnsiString is not restricted to the ANSI character set, and can utilize any character set supported by the current locale definition, including multi-byte character sets.

System::AnsiString variables that have not been assigned an initial value contain a zero-length string.

To utilize the C++ streaming operators (**<<** and **>>**) with System::AnsiString, you must `iostream` before including `system.hpp` and use `AnsiString::c_str (see page 22105)()` to return the internal string representation. The following example demonstrates the usage of AnsiString with stream operators:

```
#include <iostream>
#include <system.hpp>
int main() {
  AnsiString HelloStr = "hello";
  std::cout << HelloStr.c_str();
}
```

Note: Delphi also supports System::AnsiString, but implements it as a primitive type rather than a class. By default, variables declared as type String are System::AnsiString.

See Also

System::WideString (see page 22377)

System::AnsiString::[] (see page 22123)

System::AnsiString::= (see page 22125)

System::AnsiString::== (see page 22126)

System::AnsiString::!= (see page 22123)

System::AnsiString::> (see page 22126)

System::AnsiString::>= (see page 22126)

System::AnsiString::< (see page 22124)

System::AnsiString::<= (see page 22125)

System::AnsiString::+ (see page 22124)

System::AnsiString::+= (see page 22124)

158.1.1.1 AnsiString Members

The following tables list the members exposed by AnsiString.

Enumerations

	Name	Description
	TStringFloatFormat (see page 22101)	This is record System::AnsiString::TStringFloatFormat.
	TStringMbcsByteType (see page 22101)	This is record System::AnsiString::TStringMbcsByteType.

Structures

	Name	Description
	StrRec (see page 22100)	This is record System::AnsiString::StrRec.

Protected Methods

	Name	Description
	GetRec (see page 22112)	This is the overview for the GetRec method overload.
	ThrowIfOutOfRange (see page 22119)	This is ThrowIfOutOfRange, a member of class AnsiString.

Public Friends

Name	Description
AnsiString __fastcall operator +(const char*, const AnsiString& rhs) (see page 22127)	This is friend AnsiString __fastcall operator +(const char*, const AnsiString& rhs).

Public Methods

	Name	Description
	~AnsiString (see page 22096)	This is ~AnsiString, a member of class AnsiString.
	AnsiCompare (see page 22103)	Compares the System::AnsiString::AnsiString (see page 22097) to another specified string (case-sensitively).
	AnsiCompareIC (see page 22104)	Compares the System::AnsiString::AnsiString (see page 22097) to another specified string (case insensitively).
	AnsiLastChar (see page 22104)	Returns a pointer to the last full character in the System::AnsiString::AnsiString (see page 22097).
	AnsiPos (see page 22104)	Returns the index at which the specified substring begins.
	AnsiString (see page 22096)	This is the overview for the AnsiString constructor overload.
	ByteType (see page 22105)	Indicates the kind of byte that occupies a specified position in the System::AnsiString::AnsiString (see page 22097).
	c_str (see page 22105)	Returns the System::AnsiString::AnsiString (see page 22097) converted to null-terminated character array.
	cat_printf (see page 22106)	Appends to the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.
	cat_sprintf (see page 22106)	Appends the result of a given format string and its arguments to the end of the System::AnsiString::AnsiString (see page 22097).
	cat_vprintf (see page 22107)	Appends the result of a given format string and its arguments to the end of the System::AnsiString::AnsiString (see page 22097).
	CurrToStr (see page 22107)	Converts a currency value to its string representation.

	CurrToStrF (see page 22108)	Converts a currency value to its string representation using the indicated float format convention.
	data (see page 22108)	Returns a pointer to the underlying string System::AnsiString::data.
	Delete (see page 22108)	Removes a specified number of characters from the string.
	FloatToStrF (see page 22109)	Returns the string representation of a floating-point value.
	FmtLoadStr (see page 22110)	Formats output using a resourced format string.
	Format (see page 22110)	System::AnsiString::Formats a string assembled from an System::AnsiString::AnsiString (see page 22097), format, and a series of array arguments, args.
	FormatFloat (see page 22110)	Formats the floating-point value given by value using the format string given by format.
	Insert (see page 22112)	System::AnsiString::Inserts a specified string into the System::AnsiString::AnsiString (see page 22097).
	IntToHex (see page 22113)	Converts a number into a string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 22113)	Returns true if the specified character matches any character in the delimiters string.
	IsEmpty (see page 22113)	Returns true if the System::AnsiString::AnsiString (see page 22097) is empty.
	IsLeadByte (see page 22114)	Returns true if the specified byte is a lead byte.
	IsPathDelimiter (see page 22114)	Returns true if the specified character is '\'.
	IsTrailByte (see page 22114)	Returns true if the specified byte is of type mbTrailByte.
	LastDelimiter (see page 22115)	Returns the index of the rightmost character that matches any character in the delimiters string.
	Length (see page 22115)	Returns the length of the System::AnsiString::AnsiString (see page 22097).
	LoadStr (see page 22115)	This is the overview for the LoadStr method overload.
	LoadString (see page 22116)	Loads a string from the compiled resources of a specified module.
	LowerCase (see page 22116)	Returns a lower-case version of System::AnsiString::AnsiString (see page 22097).
	Pos (see page 22117)	Returns the index at which a specified substring begins.
	printf (see page 22117)	Sets the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.
	SetLength (see page 22117)	Changes the length of the System::AnsiString::AnsiString (see page 22097).
	sprintf (see page 22118)	Sets the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.
	StringOfChar (see page 22118)	Returns a string with the specified number of characters.
	SubString (see page 22118)	Returns a specified substring of the System::AnsiString::AnsiString (see page 22097).
	ToDouble (see page 22119)	Converts the string to a floating-point value.
	ToInt (see page 22119)	Converts a string to an integer, throwing an exception if the string is invalid.
	ToIntDef (see page 22120)	Converts the string to an integer, returning a default value if the string is invalid.
	Trim (see page 22120)	Returns a new System::AnsiString::AnsiString (see page 22097) without leading spaces, trailing spaces, or control characters.
	TrimLeft (see page 22120)	Returns a new System::AnsiString::AnsiString (see page 22097) without leading spaces or control characters.
	TrimRight (see page 22120)	Returns a new System::AnsiString::AnsiString (see page 22097) without trailing spaces or control characters.
	Unique (see page 22121)	Makes the System::AnsiString::AnsiString (see page 22097) unique.
	UpperCase (see page 22121)	Returns an upper-case version of this System::AnsiString::AnsiString (see page 22097).
	vprintf (see page 22121)	Sets the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.
	WideChar (see page 22122)	Converts the System::AnsiString::AnsiString (see page 22097) to a wide-character array.
	WideCharBufSize (see page 22122)	Returns the size of the buffer required by the WideChar (see page 22122) function.

Public Operators

	Name	Description
	!= (see page 22123)	Compares two strings.
	[] (see page 22123)	This is the overview for the [] operator overload.

	+ (see page 22124)	Concatenates two System::AnsiString::AnsiString (see page 22097) values.
	+= (see page 22124)	Append (see page 22415) an System::AnsiString::AnsiString (see page 22097).
	< (see page 22124)	Compares two strings.
	<= (see page 22125)	Compares two strings.
	= (see page 22125)	Assigns the string rhs to this System::AnsiString::AnsiString (see page 22097).
	== (see page 22126)	Compares the System::AnsiString::AnsiString (see page 22097) with a specified string, returning true if they are the same.
	> (see page 22126)	Compares two strings.
	>= (see page 22126)	Compares two strings.

158.1.1.2 AnsiString::~AnsiString Destructor

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~AnsiString();
```

Description

This is ~AnsiString, a member of class AnsiString.

158.1.1.3 AnsiString Constructor

This is the overview for the AnsiString constructor overload.

Overload List

	Name	Description
	AnsiString::AnsiString () (see page 22097)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (__int64) (see page 22097)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (AnsiString&) (see page 22097)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (char) (see page 22098)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (char*) (see page 22098)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (char*, unsigned int) (see page 22098)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (double) (see page 22098)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (int) (see page 22098)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (long) (see page 22099)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (short) (see page 22099)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (unsigned __int64) (see page 22099)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (unsigned int) (see page 22099)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (unsigned long) (see page 22100)	This is AnsiString, a member of class AnsiString.

	AnsiString::AnsiString (unsigned short) (see page 22100)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (wchar_t*) (see page 22100)	This is AnsiString, a member of class AnsiString.
	AnsiString::AnsiString (WideString &) (see page 22097)	This is AnsiString, a member of class AnsiString.

158.1.1.3.1 AnsiString::AnsiString Constructor ()

Pascal

```
constructor Create;
```

C++

```
__fastcall AnsiString();
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.2 AnsiString::AnsiString Constructor (AnsiString&)

Pascal

```
constructor Create(const src: AnsiString&);
```

C++

```
__fastcall AnsiString(const AnsiString& src);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.3 AnsiString::AnsiString Constructor (WideString &)

Pascal

```
constructor Create(const src: WideString &);
```

C++

```
__fastcall AnsiString(const WideString & src);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.4 AnsiString::AnsiString Constructor (__int64)

Pascal

```
constructor Create(: __int64);
```

C++

```
__fastcall AnsiString(__int64);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.5 AnsiString::AnsiString Constructor (char)

Pascal

```
constructor Create(src: char);
```

C++

```
__fastcall AnsiString(char src);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.6 AnsiString::AnsiString Constructor (char*)

Pascal

```
constructor Create(const src: char*);
```

C++

```
__fastcall AnsiString(const char* src);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.7 AnsiString::AnsiString Constructor (char*, unsigned int)

Pascal

```
constructor Create(const src: char*; len: unsigned int);
```

C++

```
__fastcall AnsiString(const char* src, unsigned int len);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.8 AnsiString::AnsiString Constructor (double)

Pascal

```
constructor Create(src: double);
```

C++

```
__fastcall AnsiString(double src);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.9 AnsiString::AnsiString Constructor (int)

Pascal

```
constructor Create(src: Integer);
```

C++

```
__fastcall AnsiString(int src);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.10 AnsiString::AnsiString Constructor (long)

Pascal

```
constructor Create(: long);
```

C++

```
__fastcall AnsiString(long);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.11 AnsiString::AnsiString Constructor (short)

Pascal

```
constructor Create(: short);
```

C++

```
__fastcall AnsiString(short);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.12 AnsiString::AnsiString Constructor (unsigned __int64)

Pascal

```
constructor Create(: unsigned __int64);
```

C++

```
__fastcall AnsiString(unsigned __int64);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.13 AnsiString::AnsiString Constructor (unsigned int)

Pascal

```
constructor Create(: unsigned int);
```

C++

```
__fastcall AnsiString(unsigned int);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.14 AnsiString::AnsiString Constructor (unsigned long)

Pascal

```
constructor Create(: unsigned long);
```

C++

```
__fastcall AnsiString(unsigned long);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.15 AnsiString::AnsiString Constructor (unsigned short)

Pascal

```
constructor Create(: unsigned short);
```

C++

```
__fastcall AnsiString(unsigned short);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.3.16 AnsiString::AnsiString Constructor (wchar_t*)

Pascal

```
constructor Create(const src: wchar_t*);
```

C++

```
__fastcall AnsiString(const wchar_t* src);
```

Description

This is AnsiString, a member of class AnsiString.

158.1.1.4 AnsiString Structures

The structures of the AnsiString class are listed here.

Structures

	Name	Description
	StrRec (see page 22100)	This is record System::AnsiString::StrRec.

158.1.1.4.1 System::AnsiString::StrRec Structure

Pascal

```
StrRec = record
  allocSiz: Integer;
  refCnt: Integer;
  length: Integer;
end;
```

C++

```
struct StrRec {
  int allocSiz;
  int refCnt;
  int length;
};
```

File

dstring.h

Description

This is record System::AnsiString::StrRec.

158.1.1.5 AnsiString Enumerations

The enumerations of the AnsiString class are listed here.

Enumerations

	Name	Description
	TStringFloatFormat (see page 22101)	This is record System::AnsiString::TStringFloatFormat.
	TStringMbcsByteType (see page 22101)	This is record System::AnsiString::TStringMbcsByteType.

158.1.1.5.1 System::AnsiString::TStringFloatFormat Enumeration

Pascal

```
TStringFloatFormat = (
  sffGeneral,
  sffExponent,
  sffFixed,
  sffNumber,
  sffCurrency
);
```

C++

```
enum TStringFloatFormat {
  sffGeneral,
  sffExponent,
  sffFixed,
  sffNumber,
  sffCurrency
};
```

File

dstring.h

Description

This is record System::AnsiString::TStringFloatFormat.

158.1.1.5.2 System::AnsiString::TStringMbcsByteType Enumeration

Pascal

```
TStringMbcsByteType = (
  mbSingleByte,
  mbLeadByte,
```

```
    mbTrailByte
  );
```

C++

```
enum TStringMbcsByteType {
  mbSingleByte,
  mbLeadByte,
  mbTrailByte
};
```

File

dstring.h

Description

This is record System::AnsiString::TStringMbcsByteType.

158.1.1.6 AnsiString Methods

The methods of the AnsiString class are listed here.

Protected Methods

	Name	Description
	GetRec (see page 22112)	This is the overview for the GetRec method overload.
	ThrowIfOutOfRange (see page 22119)	This is ThrowIfOutOfRange, a member of class AnsiString.

Public Methods

	Name	Description
	AnsiCompare (see page 22103)	Compares the System::AnsiString::AnsiString (see page 22097) to another specified string (case-sensitively).
	AnsiCompareIC (see page 22104)	Compares the System::AnsiString::AnsiString (see page 22097) to another specified string (case insensitively).
	AnsiLastChar (see page 22104)	Returns a pointer to the last full character in the System::AnsiString::AnsiString (see page 22097).
	AnsiPos (see page 22104)	Returns the index at which the specified substring begins.
	ByteType (see page 22105)	Indicates the kind of byte that occupies a specified position in the System::AnsiString::AnsiString (see page 22097).
	c_str (see page 22105)	Returns the System::AnsiString::AnsiString (see page 22097) converted to null-terminated character array.
	cat_printf (see page 22106)	Appends to the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.
	cat_sprintf (see page 22106)	Appends the result of a given format string and its arguments to the end of the System::AnsiString::AnsiString (see page 22097).
	cat_vprintf (see page 22107)	Appends the result of a given format string and its arguments to the end of the System::AnsiString::AnsiString (see page 22097).
	CurrToStr (see page 22107)	Converts a currency value to its string representation.
	CurrToStrF (see page 22108)	Converts a currency value to its string representation using the indicated float format convention.
	data (see page 22108)	Returns a pointer to the underlying string System::AnsiString::data.
	Delete (see page 22108)	Removes a specified number of characters from the string.
	FloatToStrF (see page 22109)	Returns the string representation of a floating-point value.
	FmtLoadStr (see page 22110)	Formats output using a resourced format string.
	Format (see page 22110)	System::AnsiString::Formats a string assembled from an System::AnsiString::AnsiString (see page 22097), format, and a series of array arguments, args.
	FormatFloat (see page 22110)	Formats the floating-point value given by value using the format string given by format.
	Insert (see page 22112)	System::AnsiString::Inserts a specified string into the System::AnsiString::AnsiString (see page 22097).

	IntToHex (see page 22113)	Converts a number into a string containing the number's hexadecimal (base 16) representation.
	IsDelimiter (see page 22113)	Returns true if the specified character matches any character in the delimiters string.
	IsEmpty (see page 22113)	Returns true if the System::AnsiString::AnsiString (see page 22097) is empty.
	IsLeadByte (see page 22114)	Returns true if the specified byte is a lead byte.
	IsPathDelimiter (see page 22114)	Returns true if the specified character is '\'.
	IsTrailByte (see page 22114)	Returns true if the specified byte is of type mbTrailByte.
	LastDelimiter (see page 22115)	Returns the index of the rightmost character that matches any character in the delimiters string.
	Length (see page 22115)	Returns the length of the System::AnsiString::AnsiString (see page 22097).
	LoadStr (see page 22115)	This is the overview for the LoadStr method overload.
	LoadString (see page 22116)	Loads a string from the compiled resources of a specified module.
	LowerCase (see page 22116)	Returns a lower-case version of System::AnsiString::AnsiString (see page 22097).
	Pos (see page 22117)	Returns the index at which a specified substring begins.
	printf (see page 22117)	Sets the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.
	SetLength (see page 22117)	Changes the length of the System::AnsiString::AnsiString (see page 22097).
	sprintf (see page 22118)	Sets the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.
	StringOfChar (see page 22118)	Returns a string with the specified number of characters.
	SubString (see page 22118)	Returns a specified substring of the System::AnsiString::AnsiString (see page 22097).
	ToDouble (see page 22119)	Converts the string to a floating-point value.
	ToInt (see page 22119)	Converts a string to an integer, throwing an exception if the string is invalid.
	ToIntDef (see page 22120)	Converts the string to an integer, returning a default value if the string is invalid.
	Trim (see page 22120)	Returns a new System::AnsiString::AnsiString (see page 22097) without leading spaces, trailing spaces, or control characters.
	TrimLeft (see page 22120)	Returns a new System::AnsiString::AnsiString (see page 22097) without leading spaces or control characters.
	TrimRight (see page 22120)	Returns a new System::AnsiString::AnsiString (see page 22097) without trailing spaces or control characters.
	Unique (see page 22121)	Makes the System::AnsiString::AnsiString (see page 22097) unique.
	UpperCase (see page 22121)	Returns an upper-case version of this System::AnsiString::AnsiString (see page 22097).
	vprintf (see page 22121)	Sets the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.
	WideChar (see page 22122)	Converts the System::AnsiString::AnsiString (see page 22097) to a wide-character array.
	WideCharBufSize (see page 22122)	Returns the size of the buffer required by the WideChar (see page 22122) function.

158.1.1.6.1 AnsiString::AnsiCompare Method

Compares the System::AnsiString::AnsiString (see page 22097) to another specified string (case-sensitively).

Pascal

```
function AnsiCompare(const rhs: AnsiString&): Integer;
```

C++

```
__fastcall int AnsiCompare(const AnsiString& rhs) const;
```

Description

Compares this System::AnsiString::AnsiString (see page 22097) to rhs, with case sensitivity. The compare operation is controlled by the current Windows locale and is not necessarily the same as using the System::AnsiString::AnsiString (see page 22097) comparison operators. System::AnsiString::AnsiCompare is based on a locale-specific collating order. The return value is shown below:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

158.1.1.6.2 AnsiString::AnsiCompareIC Method

Compares the System::AnsiString::AnsiString (see page 22097) to another specified string (case insensitively).

Pascal

```
function AnsiCompareIC(const rhs: AnsiString&): Integer;
```

C++

```
__fastcall int AnsiCompareIC(const AnsiString& rhs) const;
```

Description

System::AnsiString::AnsiCompareIC compares this System::AnsiString::AnsiString (see page 22097) to rhs, without case sensitivity. The compare operation is controlled by the current Windows locale. The return value is shown below:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

158.1.1.6.3 AnsiString::AnsiLastChar Method

Returns a pointer to the last full character in the System::AnsiString::AnsiString (see page 22097).

Pascal

```
function AnsiLastChar: char*;
```

C++

```
__fastcall char* AnsiLastChar() const;
```

Description

Returns a pointer to the last full character in the System::AnsiString::AnsiString (see page 22097). This function supports multibyte characters.

See Also

System::AnsiString::ByteType (see page 22105)

158.1.1.6.4 AnsiString::AnsiPos Method

Returns the index at which the specified substring begins.

Pascal

```
function AnsiPos(const subStr: AnsiString&): Integer;
```

C++

```
__fastcall int AnsiPos(const AnsiString& subStr) const;
```

Description

Returns the index in the System::AnsiString::AnsiString (see page 22097) at which the substring subStr begins, where 1 is the first character in the string, 2 is the second character, and so on. If the substring is not contained in the System::AnsiString::AnsiString (see page 22097), Pos (see page 22117) returns 0. This member function is the same as Pos (see page 22117) but supports multibyte character strings.

Note: See ByteType (see page 22105) for more information about multibyte characters.

See Also

System::AnsiString::ByteType (see page 22105)

158.1.1.6.5 AnsiString::ByteType Method

Indicates the kind of byte that occupies a specified position in the System::AnsiString::AnsiString (see page 22097).

Pascal

```
function ByteType(index: Integer): TStringMbcsByteType;
```

C++

```
__fastcall TStringMbcsByteType ByteType(int index) const;
```

Description

System::AnsiString::ByteType indicates what kind of byte exists at the byte indicated by index (counting from 0) in the System::AnsiString::AnsiString (see page 22097). These are the possible return values.

Constant	Meaning
mbSingleByte	Single byte character.
mbLeadByte	Lead byte of a multi-byte character.
mbTrailByte	Trailing byte of a multi-byte character.

Some locales, including all Western locales, do not use multi-byte characters. Under those locales, System::AnsiString::ByteType always returns mbSingleByte.

158.1.1.6.6 AnsiString::c_str Method

Returns the System::AnsiString::AnsiString (see page 22097) converted to null-terminated character array.

Pascal

```
function c_str: char*;
```

C++

```
__fastcall char* c_str() const;
```

Description

c_System::AnsiString::c_str returns a pointer a null-terminated character array containing the same characters as the System::AnsiString::AnsiString (see page 22097). If the System::AnsiString::AnsiString (see page 22097) is unassigned, c_System::AnsiString::c_str returns an empty System::AnsiString::c_string (“”).

Usually, the value returned by c_System::AnsiString::c_str points to the internal character array referenced by the data (see page 22108) property. This pointer is valid until the System::AnsiString::c_string is next modified (for example when the SetLength (see page 22117) method is called or the System::AnsiString::AnsiString (see page 22097) goes out of scope). However, if the internal array is NULL, c_System::AnsiString::c_str returns a pointer to a System::AnsiString::c_string literal.

The c_System::AnsiString::c_str method is intended primarily for reading the value of the System::AnsiString::AnsiString (see page 22097). To modify the System::AnsiString::c_string's value, use the [] operator or System::AnsiString::AnsiString (see page 22097) methods such as Insert (see page 22112) and Delete (see page 22108).

158.1.1.6.7 AnsiString::cat_printf Method

Appends to the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.

Pascal

```
function cat_printf(const format: char*; : ...): Integer; cdecl;
```

C++

```
__cdecl int cat_printf(const char* format, ...);
```

Description

Use cat_System::AnsiString::cat_printf to modify the value of the System::AnsiString::AnsiString (see page 22097) by appending the result of using a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter. This method returns the number of bytes appended to the System::AnsiString::AnsiString (see page 22097).

See Also

System::AnsiString::Format (see page 22110)

System::AnsiString::cat_sprintf (see page 22106)

System::AnsiString::cat_printf

System::AnsiString::cat_vprintf (see page 22107)

158.1.1.6.8 AnsiString::cat_sprintf Method

Appends the result of a given format string and its arguments to the end of the System::AnsiString::AnsiString (see page 22097).

Pascal

```
function cat_sprintf(const format: char*; : ...): AnsiString&; cdecl;
```

C++

```
__cdecl AnsiString& cat_sprintf(const char* format, ...);
```

Description

Use cat_System::AnsiString::cat_sprintf to append to the value of the System::AnsiString::AnsiString (see page 22097) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter.

For example, the following code

```
AnsiString Salutation = "Mr."
AnsiString s = "";
s.cat_sprintf("Dear %s ", Salutation);
s.cat_sprintf("%s,", "Smith");
```

results in an System::AnsiString::AnsiString (see page 22097) with the value

```
Dear Mr. Smith,
```

This method returns a reference to the System::AnsiString::AnsiString (see page 22097) (*this) with the resulting value.

See Also

System::AnsiString::Format (see page 22110)

System::AnsiString::cat_sprintf

System::AnsiString::cat_printf (see page 22106)

System::AnsiString::cat_vprintf (see page 22107)

158.1.1.6.9 AnsiString::cat_vprintf Method

Appends the result of a given format string and its arguments to the end of the System::AnsiString::AnsiString (see page 22097).

Pascal

```
function cat_vprintf(const format: char*; : va_list): Integer; cdecl;
```

C++

```
__cdecl int cat_vprintf(const char* format, va_list);
```

Description

Use cat_System::AnsiString::cat_vprintf to append to the value of the System::AnsiString::AnsiString (see page 22097) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as a variable argument list that was created using va_start.

This method returns the number of bytes appended to the System::AnsiString::AnsiString (see page 22097).

See Also

System::AnsiString::Format (see page 22110)

System::AnsiString::cat_vprintf

System::AnsiString::cat_printf (see page 22106)

System::AnsiString::cat_sprintf (see page 22106)

arg

start

158.1.1.6.10 AnsiString::CurrToStr Method

Converts a currency value to its string representation.

Pascal

```
function CurrToStr(value: Currency): String; static;
```

C++

```
static __fastcall AnsiString CurrToStr(Currency value);
```

Description

System::AnsiString::CurrToStr converts the currency value given by value to its string representation. The conversion using the sffGeneral floating-point conversion rules. For further details, see System::AnsiString::CurrToStrF (see page 22108).

See Also

System::AnsiString::CurrToStrF (see page 22108)

158.1.1.6.11 AnsiString::CurrToStrF Method

Converts a currency value to its string representation using the indicated float format convention.

Pascal

```
function CurrToStrF(value: Currency; format: TStringFloatFormat; digits: Integer): String;
static;
```

C++

```
static __fastcall AnsiString CurrToStrF(Currency value, TStringFloatFormat format, int digits);
```

Description

System::AnsiString::CurrToStrF converts the currency value given by value to its string representation using the indicated float format convention. A call to System::AnsiString::CurrToStrF corresponds to a call to FloatToStrF (see page 22109) with an implied precision of 19 digits.

158.1.1.6.12 AnsiString::data Method

Returns a pointer to the underlying string System::AnsiString::data.

Pascal

```
function data: const void*;
```

C++

```
__fastcall const void* data() const;
```

Description

System::AnsiString::data() returns a pointer a null-terminated character array that the System::AnsiString::AnsiString (see page 22097) uses to store its value. This is the same value as the one returned by the c_str (see page 22105)() method, except that System::AnsiString::data() returns a NULL pointer when the value is an empty string.

Note: Because System::AnsiString::data() returns NULL instead of an empty string, it is useful for C++ functions that expect either a valid (non-empty) char* or NULL:

```
AnsiString x;
ShellExecute(0, static_cast<const char*>(x.data()), "File.txt", NULL, NULL, SW_SHOW);
```

See Also

System::AnsiString::c_str (see page 22105)

158.1.1.6.13 AnsiString::Delete Method

Removes a specified number of characters from the string.

Pascal

```
function Delete(index: Integer; count: Integer): AnsiString&;
```

C++

```
__fastcall AnsiString& Delete(int index, int count);
```

Description

System::AnsiString::Delete modifies the System::AnsiString::AnsiString (see page 22097) to remove count characters from the string beginning with the character at index, where 1 is the index of the first character. It returns the resulting modified string

(*this).

If index is larger than the length of the System::AnsiString::AnsiString (see page 22097) or less than 1, no characters are deleted.

If count specifies more characters than remain starting at the index, System::AnsiString::Delete removes the rest of the string. If count is less than 0, no characters are deleted.

158.1.1.6.14 AnsiString::FloatToStrF Method

Returns the string representation of a floating-point value.

Pascal

```
function FloatToStrF(value: long double; format: TStringFloatFormat; precision: Integer;
digits: Integer): String; static;
```

C++

```
static __fastcall AnsiString FloatToStrF(long double value, TStringFloatFormat format, int
precision, int digits);
```

Description

The format parameter controls the format of the resulting string. The precision parameter specifies the precision of the given value. It should be 7 or less for values of type float, 15 or less for values of type double, and 18 or less for values of type Extended. The meaning of the digits parameter depends on the particular format selected.

The possible values of the format parameter, and the meaning of each, are described below.

Value	Meaning
sffGeneral	General number format. The value is converted to the shortest possible decimal string using fixed or scientific format. Trailing zeros are removed from the resulting string, and a decimal point appears only if necessary. The resulting string uses fixed point format if the number of digits to the left of the decimal point in the value is less than or equal to the specified precision, and if the value is greater than or equal to 0.00001. Otherwise the resulting string uses scientific format, and the digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffExponent	Scientific format. The value is converted to a string of the form "-d.ddd...E+dddd". The resulting string starts with a minus sign if the number is negative, and one digit always precedes the decimal point. The total number of digits in the resulting string (including the one before the decimal point) is given by the precision parameter. The "E" exponent character in the resulting string is always followed by a plus or minus sign and up to four digits. The digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).
sffFixed	Fixed point format. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative, and at least one digit always precedes the decimal point. The number of digits after the decimal point is given by the digits parameter--it must be between 0 and 18. If the number of digits to the left of the decimal point is greater than the specified precision, the resulting value will use scientific format.
sffNumber	Number format. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The sffNumber format corresponds to the sffFixed format, except that the resulting string contains thousand separators.
sffCurrency	Currency (see page 22145) format. The value is converted to a string that represents a currency amount. The conversion is controlled by the CurrencyString, CurrencyFormat, NegCurrFormat, ThousandSeparator, and DecimalSeparator global variables, all of which are initialized from the Currency (see page 22145) Format (see page 22110) in the International section of the Windows Control Panels. The number of digits after the decimal point is given by the Digits parameter--it must be between 0 and 18.

For all formats, the actual characters used as decimal and thousand separators are obtained from the DecimalSeparator and ThousandSeparator global variables.

If the given value is a NAN (not-a-number), the resulting string is 'NAN'. If the given value is positive infinity, the resulting string is 'INF'. If the given value is negative infinity, the resulting string is '-INF'.

158.1.1.6.15 AnsiString::FmtLoadStr Method

Formats output using a resourced format string.

Pascal

```
function FmtLoadStr(ident: Integer; const args: TVarRec *; size: Integer): String; static;
```

C++

```
static __fastcall AnsiString FmtLoadStr(int ident, const TVarRec * args, int size);
```

Description

System::AnsiString::FmtLoadStr loads a string from a program's resource string table and uses that string, plus the args array, as a parameter to Format (see page 22110). Ident is the string resource ID of the desired format string.

See Also

System::AnsiString::LoadString (see page 22116)

System::AnsiString::LoadStr (see page 22115)

158.1.1.6.16 AnsiString::Format Method

System::AnsiString::Formats a string assembled from an System::AnsiString::AnsiString (see page 22097), format, and a series of array arguments, args.

Pascal

```
function Format(const format: AnsiString&; const args: TVarRec *; size: Integer): String;
static;
```

C++

```
static __fastcall AnsiString Format(const AnsiString& format, const TVarRec * args, int size);
```

Description

Use System::AnsiString::Format to obtain an System::AnsiString::AnsiString (see page 22097) whose value is the result of applying an array of arguments (args) to a given a format string (format). The last parameter (size) is the index of the last element in args (one less than the number of arguments).

Note that System::AnsiString::Format is a static method. The returned value is a newly allocated System::AnsiString::AnsiString (see page 22097), even if the method is called from an existing System::AnsiString::AnsiString (see page 22097) instance.

For information on how System::AnsiString::Format assembles a final string from its format string and arguments, see System::AnsiString::Format Strings.

See Also

System::AnsiString::printf (see page 22117)

System::AnsiString::sprintf (see page 22118)

158.1.1.6.17 AnsiString::FormatFloat Method

Formats the floating-point value given by value using the format string given by format.

Pascal

```
function FormatFloat(const format: AnsiString&; const value: long double&): String; static;
```

C++

```
static __fastcall AnsiString FormatFloat(const AnsiString& format, const long double& value);
```

Description

The following format specifiers are supported in the format string:

Specifier	Represents
0	Digit place holder. If the value being formatted has a digit in the position where the '0' appears in the format string, then that digit is copied to the output string. Otherwise, a '0' is stored in that position in the output string.
#	Digit placeholder. If the value being formatted has a digit in the position where the '#' appears in the format string, then that digit is copied to the output string. Otherwise, nothing is stored in that position in the output string.
.	Decimal point. The first dot character ('.') in the format string determines the location of the decimal separator in the formatted value; any additional dot characters are ignored. The actual character used as the decimal separator in the output string is determined by the DecimalSeparator global variable, whose default value is specified in the Number Format (see page 22110) of the International section in the Windows Control Panel.
,	Thousand separator. If the format string contains one or more comma characters (','), the output will have thousand separators inserted between each group of three digits to the left of the decimal point. The placement and number of comma characters in the format string does not affect the output, except to indicate that thousand separators are wanted. The actual character used as the thousand separator in the output is determined by the ThousandSeparator global variable, whose default value is specified in the Number Format (see page 22110) of the International section in the Windows Control Panel.
E+	Scientific notation. If any of the strings 'E+', 'E-', 'e+', or 'e-' are contained in the format string, the number is formatted using scientific notation. A group of up to four '0' characters can immediately follow the 'E+', 'E-', 'e+', or 'e-' to determine the minimum number of digits in the exponent. The 'E+' and 'e+' formats cause a plus sign to be output for positive exponents and a minus sign to be output for negative exponents. The 'E-' and 'e-' formats output a sign character only for negative exponents.
'xx'/"xx"	Characters enclosed in single or double quotes are output as-is, and do not affect formatting.
;	Separates sections for positive, negative, and zero numbers in the format string.

The locations of the leftmost '0' before the decimal point in the format string and the rightmost '0' after the decimal point in the format string determine the range of digits that are always present in the output string.

The number being formatted is always rounded to as many decimal places as there are digit placeholders ('0' or '#') to the right of the decimal point. If the format string contains no decimal point, the value being formatted is rounded to the nearest whole number.

If the number being formatted has more digits to the left of the decimal separator than there are digit placeholders to the left of the '.' character in the format string, the extra digits are output before the first digit placeholder.

To allow different formats for positive, negative, and zero values, the format string can contain from one to three sections separated by semicolons.

One section: The format string applies to all values.

Two sections: The first section applies to positive values and zeros, and the second section applies to negative values.

Three sections: The first section applies to positive values, the second applies to negative values, and the third applies to zeros.

If no formatting is specified for positive values, positive values are formatted using general floating-point formatting with 15 significant digits, corresponding to a call to FloatToStrF (see page 22109) with the sffGeneral format. General floating-point formatting is also used if the value has more than 18 digits to the left of the decimal point and the format string does not specify scientific notation.

The following table shows some sample formats and the results produced when the formats are applied to different values:

Format (see page 22110) string-1234-12340.50

Format (see page 22110) string-	1234	-1234	0.5	0
1234	-1234	0.5	0	
0	1234	-1234	1	
0.00	1234.00	-1234.00	0.50	
#	1234	-1234	.5	
#,##0.00	1,234.00	-1,234.00	0.50	
#,##0.00;(#,##0.00)	1,234.00	(1,234.00)	0.50	
#,##0.00;;Zero	1,234.00	-1,234.00	0.50	
0.000E+00	1.234E+03	-1.234E+03	5.000E-01	
#.###E-0	1.234E3	-1.234E3	5E-1	

158.1.1.6.18 GetRec Method

This is the overview for the GetRec method overload.

Overload List

	Name	Description
	AnsiString::GetRec () (see page 22112)	This is GetRec, a member of class AnsiString.
	AnsiString::GetRec () (see page 22112)	This is GetRec, a member of class AnsiString.

158.1.1.6.18.1 AnsiString::GetRec Method ()

Pascal

```
function GetRec: StrRec &;
```

C++

```
StrRec & GetRec();
```

Description

This is GetRec, a member of class AnsiString.

158.1.1.6.18.2 AnsiString::GetRec Method ()

Pascal

```
function GetRec: const StrRec &;
```

C++

```
const StrRec & GetRec() const;
```

Description

This is GetRec, a member of class AnsiString.

158.1.1.6.19 AnsiString::Insert Method

System::AnsiString::Inserts a specified string into the System::AnsiString::AnsiString (see page 22097).

Pascal

```
function Insert(const str: AnsiString&; index: Integer): AnsiString&;
```

C++

```
__fastcall AnsiString& Insert(const AnsiString& str, int index);
```

Description

System::AnsiString::Insert inserts the string str into this System::AnsiString::AnsiString (see page 22097) beginning at the position index, where 1 is the first position in the string. It returns the resulting modified string (*this).

If index is less than 1, it is mapped to a 1. If it is past the end of the string, it is set to Length (see page 22115)(), turning the operation into an append.

If the str parameter is an empty string, System::AnsiString::Insert does nothing.

System::AnsiString::Insert throws an EOutOfMemory exception if the method is unable to allocate enough memory to accommodate the new, longer, string.

Note: The index parameter specifies the character, not the byte, when working with a multi-byte character system.

158.1.1.6.20 AnsiString::IntToHex Method

Converts a number into a string containing the number's hexadecimal (base 16) representation.

Pascal

```
function IntToHex(value: Integer; digits: Integer): String; static;
```

C++

```
static __fastcall AnsiString IntToHex(int value, int digits);
```

Description

Value is the number to convert. Digits indicates the minimum number of hexadecimal digits.

158.1.1.6.21 AnsiString::IsDelimiter Method

Returns true if the specified character matches any character in the delimiters string.

Pascal

```
function IsDelimiter(const delimiters: AnsiString&; index: Integer): bool;
```

C++

```
__fastcall bool IsDelimiter(const AnsiString& delimiters, int index) const;
```

Description

System::AnsiString::IsDelimiter returns true if the byte indicated by index (counting from 0) is a single-byte character contained in delimiters. If the byte is part of a multi-byte character or not in delimiters, System::AnsiString::IsDelimiter returns false.

158.1.1.6.22 AnsiString::IsEmpty Method

Returns true if the System::AnsiString::AnsiString (see page 22097) is empty.

Pascal

```
function IsEmpty: bool;
```

C++

```
__fastcall bool IsEmpty() const;
```

Description

System::AnsiString::IsEmpty returns true if this System::AnsiString::AnsiString (see page 22097) is empty, false otherwise.

158.1.1.6.23 AnsiString::IsLeadByte Method

Returns true if the specified byte is a lead byte.

Pascal

```
function IsLeadByte(index: Integer): bool;
```

C++

```
__fastcall bool IsLeadByte(int index) const;
```

Description

System::AnsiString::IsLeadByte returns true if the byte indicated by index (counting from 0) is the lead byte in a multi-byte character. If the byte is a trailing byte, or not part of a multi-byte character, System::AnsiString::IsLeadByte returns false.

158.1.1.6.24 AnsiString::IsPathDelimiter Method

Returns true if the specified character is '\'.

Pascal

```
function IsPathDelimiter(index: Integer): bool;
```

C++

```
__fastcall bool IsPathDelimiter(int index) const;
```

Description

System::AnsiString::IsPathDelimiter returns true if the byte indicated by index (counting from 0) is a single-byte character containing the path delimiter ('\' on Windows, '/' on Linux).

See Also

System::AnsiString::ByteType (see page 22105)

158.1.1.6.25 AnsiString::IsTrailByte Method

Returns true if the specified byte is of type mbTrailByte.

Pascal

```
function IsTrailByte(index: Integer): bool;
```

C++

```
__fastcall bool IsTrailByte(int index) const;
```

Description

System::AnsiString::IsTrailByte returns true if the byte indicated by index (counting from 0) is the trailing byte in a multi-byte character. If the byte is a lead byte, or not part of a multi-byte character, System::AnsiString::IsTrailByte returns false.

158.1.1.6.26 AnsiString::LastDelimiter Method

Returns the index of the rightmost character that matches any character in the delimiters string.

Pascal

```
function LastDelimiter(const delimiters: AnsiString&): Integer;
```

C++

```
__fastcall int LastDelimiter(const AnsiString& delimiters) const;
```

Description

System::AnsiString::LastDelimiter returns the byte index in this System::AnsiString::AnsiString (see page 22097) of the rightmost whole character that matches any character in delimiters except NULL The System::AnsiString::AnsiString (see page 22097) may contain multibyte characters; delimiters must contain only single byte non-NULL characters.

See Also

System::AnsiString::ByteType (see page 22105)

158.1.1.6.27 AnsiString::Length Method

Returns the length of the System::AnsiString::AnsiString (see page 22097).

Pascal

```
function Length: Integer;
```

C++

```
__fastcall int Length() const;
```

Description

System::AnsiString::Length returns the number of bytes in this System::AnsiString::AnsiString (see page 22097).

158.1.1.6.28 LoadStr Method

This is the overview for the LoadStr method overload.

Overload List

	Name	Description
	AnsiString::LoadStr (HINSTANCE, int) (see page 22115)	Loads a string from the compiled resources of a specified module.
	AnsiString::LoadStr (int) (see page 22115)	Loads a string from the compiled resources of a specified module.

158.1.1.6.28.1 AnsiString::LoadStr Method (HINSTANCE, int)

Loads a string from the compiled resources of a specified module.

Pascal

```
function LoadStr(ident: Integer): String; static;
function LoadStr(hInstance: HINSTANCE; ident: Integer): String; static;
```

C++

```
static __fastcall AnsiString LoadStr(int ident);
```

```
static __fastcall AnsiString LoadStr(HINSTANCE hInstance, int ident);
```

Description

System::AnsiString::LoadStr loads a specified string resource.

ident is the resource identifier of the string.

hInstance is the instance handle of the module that contains the string resource. If hInstance is not given, System::AnsiString::LoadStr loads the string from the current module (executable or shared library)

If the string resource does not exist, System::AnsiString::LoadStr returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

See Also

System::AnsiString::LoadString (see page 22116)

System::AnsiString::FmtLoadStr (see page 22110)

158.1.1.6.29 AnsiString::LoadString Method

Loads a string from the compiled resources of a specified module.

Pascal

```
function LoadString(hInstance: HINSTANCE; ident: Integer): AnsiString&;
```

C++

```
__fastcall AnsiString& LoadString(HINSTANCE hInstance, int ident);
```

Description

System::AnsiString::LoadString loads a specified string resource.

ident is the resource identifier of the string.

hInstance is the instance handle of the module that contains the string resource.

If the string resource does not exist, System::AnsiString::LoadString returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

See Also

System::AnsiString::LoadStr (see page 22115)

System::AnsiString::FmtLoadStr (see page 22110)

158.1.1.6.30 AnsiString::LowerCase Method

Returns a lower-case version of System::AnsiString::AnsiString (see page 22097).

Pascal

```
function LowerCase: String;
```

C++

```
__fastcall AnsiString LowerCase() const;
```

Description

System::AnsiString::LowerCase returns a new System::AnsiString::AnsiString (see page 22097) that contains all characters in this string, converted to lower case. The conversion uses the current locale . The original System::AnsiString::AnsiString (see

page 22097) remains unchanged.

158.1.1.6.31 AnsiString::Pos Method

Returns the index at which a specified substring begins.

Pascal

```
function Pos(const subStr: AnsiString&): Integer;
```

C++

```
__fastcall int Pos(const AnsiString& subStr) const;
```

Description

System::AnsiString::Pos returns the index in the System::AnsiString::AnsiString (see page 22097) at which the substring subStr begins, where 1 is the index of the first character, 2 is the index of the second character, and so on. If the substring is not contained in the System::AnsiString::AnsiString (see page 22097), System::AnsiString::Pos returns 0.

158.1.1.6.32 AnsiString::printf Method

Sets the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.

Pascal

```
function printf(const format: char*; : ...): Integer; cdecl;
```

C++

```
__cdecl int printf(const char* format, ...);
```

Description

Use System::AnsiString::printf to set the value of the System::AnsiString::AnsiString (see page 22097) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter. This method returns the length of the final formatted string.

See Also

System::AnsiString::Format (see page 22110)

System::AnsiString::sprintf (see page 22118)

System::AnsiString::cat_printf (see page 22106)

System::AnsiString::vprintf (see page 22121)

158.1.1.6.33 AnsiString::SetLength Method

Changes the length of the System::AnsiString::AnsiString (see page 22097).

Pascal

```
function SetLength(newLength: Integer): AnsiString&;
```

C++

```
__fastcall AnsiString& SetLength(int newLength);
```

Description

System::AnsiString::SetLength changes the string's length to newLength, truncating if necessary.

System::AnsiString::SetLength reallocates the underlying array of characters that stores the value of the

System::AnsiString::AnsiString (see page 22097). Existing characters in the string are preserved, but the content of newly allocated space is undefined. If there is not enough memory available to reallocate the System::AnsiString::AnsiString (see page 22097), an EOutOfMemory exception is thrown. Following a call to System::AnsiString::SetLength, the System::AnsiString::AnsiString (see page 22097) is guaranteed not to be a shared reference.

System::AnsiString::SetLength returns the modified System::AnsiString::AnsiString (see page 22097) object (*this)

158.1.1.6.34 AnsiString::sprintf Method

Sets the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.

Pascal

```
function sprintf(const format: char*; : ...): AnsiString&; cdecl;
```

C++

```
__cdecl AnsiString& sprintf(const char* format, ...);
```

Description

Use System::AnsiString::sprintf to set to the value of the System::AnsiString::AnsiString (see page 22097) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as additional parameters following the format parameter.

This method returns a reference to the System::AnsiString::AnsiString (see page 22097) (*this) with the resulting value.

See Also

System::AnsiString::Format (see page 22110)

System::AnsiString::cat_sprintf (see page 22106)

System::AnsiString::printf (see page 22117)

System::AnsiString::vprintf (see page 22121)

158.1.1.6.35 AnsiString::StringOfChar Method

Returns a string with the specified number of characters.

Pascal

```
function StringOfChar(ch: char; count: Integer): String; static;
```

C++

```
static __fastcall AnsiString StringOfChar(char ch, int count);
```

Description

System::AnsiString::StringOfChar returns a string containing count characters with the character value given by ch. For example,

System::AnsiString::AnsiString (see page 22097) s = System::AnsiString::AnsiString::System::AnsiString::StringOfChar('A', 10);

sets s to the string "AAAAAAAAAA".

158.1.1.6.36 AnsiString::SubString Method

Returns a specified substring of the System::AnsiString::AnsiString (see page 22097).

Pascal

```
function SubString(index: Integer; count: Integer): String;
```

C++

```
__fastcall AnsiString SubString(int index, int count) const;
```

Description

System::AnsiString::SubString returns a new System::AnsiString::AnsiString (see page 22097) that is a substring of this System::AnsiString::AnsiString (see page 22097). The substring contains count characters beginning at index.

158.1.1.6.37 AnsiString::ThrowIfOutOfRange Method

Pascal

```
procedure ThrowIfOutOfRange(idx: Integer); cdecl;
```

C++

```
__cdecl void ThrowIfOutOfRange(int idx) const;
```

Description

This is ThrowIfOutOfRange, a member of class AnsiString.

158.1.1.6.38 AnsiString::ToDouble Method

Converts the string to a floating-point value.

Pascal

```
function ToDouble: double;
```

C++

```
__fastcall double ToDouble() const;
```

Description

System::AnsiString::ToDouble converts the string to a floating-point value. The string must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional 'E' or 'e' followed by a signed integer. Leading and trailing blanks in the string are ignored. The DecimalSeparator global variable defines the character that must be used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If the string doesn't contain a valid value, an EConvertError exception is thrown.

158.1.1.6.39 AnsiString::ToInt Method

Converts a string to an integer, throwing an exception if the string is invalid.

Pascal

```
function ToInt: Integer;
```

C++

```
__fastcall int ToInt() const;
```

Description

System::AnsiString::ToInt converts the given string to an integer value and returns the integer. If the string doesn't contain a valid value, an EConvertError exception is thrown.

See Also

System::AnsiString::ToIntDef (see page 22120)

158.1.1.6.40 AnsiString::ToIntDef Method

Converts the string to an integer, returning a default value if the string is invalid.

Pascal

```
function ToIntDef(defaultValue: Integer): Integer;
```

C++

```
__fastcall int ToIntDef(int defaultValue) const;
```

Description

System::AnsiString::ToIntDef converts the given string to an integer value and returns the integer. If the string doesn't contain a valid value, the value given by defaultValue is returned.

See Also

System::AnsiString::ToInt (see page 22119)

158.1.1.6.41 AnsiString::Trim Method

Returns a new System::AnsiString::AnsiString (see page 22097) without leading spaces, trailing spaces, or control characters.

Pascal

```
function Trim: String;
```

C++

```
__fastcall AnsiString Trim() const;
```

Description

System::AnsiString::Trim returns a new System::AnsiString::AnsiString (see page 22097) removing leading and trailing spaces and control characters. Use System::AnsiString::Trim to remove blank space before and after the first printing character.

158.1.1.6.42 AnsiString::TrimLeft Method

Returns a new System::AnsiString::AnsiString (see page 22097) without leading spaces or control characters.

Pascal

```
function TrimLeft: String;
```

C++

```
__fastcall AnsiString TrimLeft() const;
```

Description

System::AnsiString::TrimLeft returns a new System::AnsiString::AnsiString (see page 22097) removing leading spaces and control characters. Use System::AnsiString::TrimLeft to remove blank space before the first printing character.

158.1.1.6.43 AnsiString::TrimRight Method

Returns a new System::AnsiString::AnsiString (see page 22097) without trailing spaces or control characters.

Pascal

```
function TrimRight: String;
```

C++

```
__fastcall AnsiString TrimRight() const;
```

Description

System::AnsiString::TrimRight returns a new System::AnsiString::AnsiString (see page 22097) removing trailing spaces and control characters. Use the System::AnsiString::TrimRight function to remove blank space after the first printing character.

158.1.1.6.44 AnsiString::Unique Method

Makes the System::AnsiString::AnsiString (see page 22097) unique.

Pascal

```
function Unique: AnsiString&;
```

C++

```
__fastcall AnsiString& Unique();
```

Description

Use this function to make a string unique (refcnt == 1). System::AnsiString::Unique sets the reference count on the string for the System::AnsiString::AnsiString (see page 22097) object to 1 so that it is the only object referencing that string.

158.1.1.6.45 AnsiString::UpperCase Method

Returns an upper-case version of this System::AnsiString::AnsiString (see page 22097).

Pascal

```
function UpperCase: String;
```

C++

```
__fastcall AnsiString UpperCase() const;
```

Description

System::AnsiString::UpperCase returns a new System::AnsiString::AnsiString (see page 22097) that contains all characters in this string, converted to upper case. The conversion uses the current locale . The original System::AnsiString::AnsiString (see page 22097) remains unchanged.

158.1.1.6.46 AnsiString::vprintf Method

Sets the value of the System::AnsiString::AnsiString (see page 22097) given a format string and its arguments.

Pascal

```
function vprintf(const format: char*; : va_list): Integer; cdecl;
```

C++

```
__cdecl int vprintf(const char* format, va_list);
```

Description

Use System::AnsiString::vprintf to set to the value of the System::AnsiString::AnsiString (see page 22097) given a standard C++ format specifier. Pass the values to any arguments in the format specifier as a variable argument list that was created using va_start.

This method returns the length of the final formatted string.

See Also

System::AnsiString::Format (see page 22110)

System::AnsiString::sprintf (see page 22118)

System::AnsiString::printf (see page 22117)

System::AnsiString::cat_vprintf (see page 22107)

arg

start

158.1.1.6.47 AnsiString::WideChar Method

Converts the System::AnsiString::AnsiString (see page 22097) to a wide-character array.

Pascal

```
function WideChar(var dest: wchar_t; destSize: Integer): wchar_t*;
```

C++

```
__fastcall wchar_t* WideChar(wchar_t* dest, int destSize) const;
```

Description

System::AnsiString::WideChar converts the System::AnsiString::AnsiString (see page 22097) to an array of wide characters, and returns the resulting wide-character array.

dest is a buffer the caller allocates to hold the return value. Use the System::AnsiString::WideCharBufSize (see page 22122) method to determine the size needed to hold the entire string value.

destSize is the size, in bytes, of dest.

System::AnsiString::WideChar returns a pointer to the wide-character array that is written to dest.

See Also

System::AnsiString::WideCharBufSize (see page 22122)

158.1.1.6.48 AnsiString::WideCharBufSize Method

Returns the size of the buffer required by the WideChar (see page 22122) function.

Pascal

```
function WideCharBufSize: Integer;
```

C++

```
__fastcall int WideCharBufSize() const;
```

Description

System::AnsiString::WideCharBufSize returns an integer value indicating the size of the buffer required by the WideChar (see page 22122) method in order to convert this string.

See Also

System::AnsiString::WideChar (see page 22122)

158.1.1.7 AnsiString Operators

The operators of the AnsiString class are listed here.

Public Operators

	Name	Description
	!= (see page 22123)	Compares two strings.
	[] (see page 22123)	This is the overview for the [] operator overload.
	+ (see page 22124)	Concatenates two System::AnsiString::AnsiString (see page 22097) values.
	+= (see page 22124)	Append (see page 22415) an System::AnsiString::AnsiString (see page 22097).
	< (see page 22124)	Compares two strings.
	<= (see page 22125)	Compares two strings.
	= (see page 22125)	Assigns the string rhs to this System::AnsiString::AnsiString (see page 22097).
	== (see page 22126)	Compares the System::AnsiString::AnsiString (see page 22097) with a specified string, returning true if they are the same.
	> (see page 22126)	Compares two strings.
	>= (see page 22126)	Compares two strings.

158.1.1.7.1 AnsiString::!= Operator

Compares two strings.

Pascal

```
operator !=(const rhs: AnsiString&);
```

C++

```
__fastcall bool operator !=(const AnsiString& rhs) const;
```

Description

Returns true if the strings are not the same, false otherwise.

Note: This System::AnsiString (see page 22093)::!= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 22103) or AnsiCompareIC (see page 22104) methods.

See Also

System::AnsiString::AnsiCompare (see page 22103)

System::AnsiString::AnsiCompareIC (see page 22104)

158.1.1.7.2 [] Operator

This is the overview for the [] operator overload.

Overload List

	Name	Description
	AnsiString::[] (int) (see page 22123)	Returns the character at a specified index in the string.
	AnsiString::[] (int) (see page 22123)	Returns the character at a specified index in the string.

158.1.1.7.2.1 AnsiString::[] Operator (int)

Returns the character at a specified index in the string.

Pascal

```
operator [](const idx: Integer);
operator [](const idx: Integer);
```

C++

```
__fastcall char operator [](const int idx) const;
__fastcall char& operator [](const int idx);
```

Description

This System::AnsiString (see page 22093)::[] returns the byte in the string at index value idx. The System::AnsiString (see page 22093)::[] assumes a base index of 1.

Note: If the string contains multi-byte characters, the System::AnsiString (see page 22093)::[] may return a byte value that represents the wrong character and/or a partial character. For character-level access, use the SubString (see page 22118) method.

See Also

System::AnsiString::substring

158.1.1.7.3 AnsiString::+ Operator

Concatenates two System::AnsiString::AnsiString (see page 22097) values.

Pascal

```
operator +(const rhs: AnsiString&);
```

C++

```
__fastcall AnsiString operator +(const AnsiString& rhs) const;
```

Description

The friend function returns an System::AnsiString::AnsiString (see page 22097) that is the concatenation of strings lhs and rhs.

The method returns an System::AnsiString::AnsiString (see page 22097) that is the concatenation of this System::AnsiString::AnsiString (see page 22097) and rhs.

158.1.1.7.4 AnsiString::+= Operator

Append (see page 22415) an System::AnsiString::AnsiString (see page 22097).

Pascal

```
operator +=(const rhs: AnsiString&);
```

C++

```
__fastcall AnsiString& operator +=(const AnsiString& rhs);
```

Description

The System::AnsiString (see page 22093)::+= concatenates this System::AnsiString::AnsiString (see page 22097) and rhs, assigning the result to this System::AnsiString::AnsiString (see page 22097).

The System::AnsiString (see page 22093)::+=() is not supported on a property with getter/setter functions.

158.1.1.7.5 AnsiString::< Operator

Compares two strings.

Pascal

```
operator <(const rhs: AnsiString&);
```

C++

```
__fastcall bool operator <(const AnsiString& rhs) const;
```

Description

Returns true if this System::AnsiString::AnsiString (see page 22097) is less than rhs, false otherwise.

Note: This System::AnsiString (see page 22093)::< performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 22103) or AnsiCompareIC (see page 22104) methods.

See Also

System::AnsiString::AnsiCompare (see page 22103)

System::AnsiString::AnsiCompareIC (see page 22104)

158.1.1.7.6 AnsiString::<= Operator

Compares two strings.

Pascal

```
operator <=(const rhs: AnsiString&);
```

C++

```
__fastcall bool operator <=(const AnsiString& rhs) const;
```

Description

Returns true if this System::AnsiString::AnsiString (see page 22097) is less than or equal to rhs, false otherwise.

Note: This System::AnsiString (see page 22093)::<= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 22103) or AnsiCompareIC (see page 22104) methods.

See Also

System::AnsiString::AnsiCompare (see page 22103)

System::AnsiString::AnsiCompareIC (see page 22104)

158.1.1.7.7 AnsiString::= Operator

Assigns the string rhs to this System::AnsiString::AnsiString (see page 22097).

Pascal

```
operator =(const rhs: AnsiString&);
```

C++

```
__fastcall AnsiString& operator =(const AnsiString& rhs);
```

Description

Use this System::AnsiString (see page 22093)::= to assign the value of the System::AnsiString::AnsiString (see page 22097) from another System::AnsiString::AnsiString (see page 22097).

158.1.1.7.8 AnsiString::== Operator

Compares the System::AnsiString::AnsiString (see page 22097) with a specified string, returning true if they are the same.

Pascal

```
operator ==(const rhs: AnsiString&);
```

C++

```
__fastcall bool operator ==(const AnsiString& rhs) const;
```

Description

Returns true if this System::AnsiString::AnsiString (see page 22097) is the same as rhs, false otherwise.

Note: This System::AnsiString (see page 22093)::== performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 22103) or AnsiCompareIC (see page 22104) methods.

See Also

System::AnsiString::AnsiCompare (see page 22103)

System::AnsiString::AnsiCompareIC (see page 22104)

158.1.1.7.9 AnsiString::> Operator

Compares two strings.

Pascal

```
operator >(const rhs: AnsiString&);
```

C++

```
__fastcall bool operator >(const AnsiString& rhs) const;
```

Description

Returns true if this System::AnsiString::AnsiString (see page 22097) is greater than rhs, false otherwise.

Note: This System::AnsiString (see page 22093)::> performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 22103) or AnsiCompareIC (see page 22104) methods.

See Also

System::AnsiString::AnsiCompare (see page 22103)

System::AnsiString::AnsiCompareIC (see page 22104)

158.1.1.7.10 AnsiString::>= Operator

Compares two strings.

Pascal

```
operator >=(const rhs: AnsiString&);
```

C++

```
__fastcall bool operator >=(const AnsiString& rhs) const;
```

Description

Returns true if this System::AnsiString::AnsiString (see page 22097) is greater than or equal to rhs, false otherwise.

Note: This System::AnsiString (see page 22093)::>= performs a simple byte-level numeric comparison. For locale support, or to ignore case, use the AnsiCompare (see page 22103) or AnsiCompareIC (see page 22104) methods.

See Also

System::AnsiString::AnsiCompare (see page 22103)

System::AnsiString::AnsiCompareIC (see page 22104)

158.1.1.8 AnsiString Friends

The friends of the AnsiString class are listed here.

Public Friends

Name	Description
AnsiString __fastcall operator +(const char*, const AnsiString& rhs) (see page 22127)	This is friend AnsiString __fastcall operator +(const char*, const AnsiString& rhs).

158.1.1.8.1 friend AnsiString __fastcall operator +(const char*, const AnsiString& rhs) Friend

Pascal

```
AnsiString __fastcall operator +(const char*, const AnsiString& rhs)
```

C++

```
friend AnsiString __fastcall operator +(const char*, const AnsiString& rhs);
```

Description

This is friend AnsiString __fastcall operator +(const char*, const AnsiString& rhs).

158.1.2 AutoCmd Class

System::AutoCmd represents a command that can be executed by an Automation interface wrapped by a Variant (see page 22307) class.

Class Hierarchy

System::AutoCmd

Pascal

```
AutoCmd = class;
```

C++

```
class AutoCmd;
```

File

sysvari.h

Description

The System::AutoCmd class is a friend class to Variant (see page 22307). It represents a single method on an Automation interface that is assigned as the value of a Variant (see page 22307).

Do not use instances of System::AutoCmd, which includes pure virtual methods. Instead, use the System::AutoCmd descendant

that represents the type of the desired method. These descendants are

PropertyGet (see page 22233), for methods that return a property value.

PropertySet (see page 22236), for methods that set a property value.

Procedure (see page 22230), for methods that do not return a value.

Function (see page 22184), for methods that do return a value.

Each System::AutoCmd instance is assigned a name, which is the same as the name of the corresponding method on the interface. In addition, it can be assigned parameters that correspond to the parameters of the method. These parameters can be stored by position or by name.

Once you have assigned parameter values to the System::AutoCmd object, you can execute it using the Variant::Exec method.

See Also

System::Variant (see page 22307)

PropertyGet

PropertySet

System::Function (see page 22184)

System::Procedure (see page 22230)

158.1.2.1 AutoCmd Members

The following tables list the members exposed by AutoCmd.

Protected Data Members

	Name	Description
	Name (see page 22130)	This is Name, a member of class AutoCmd.
	NamedParmNames (see page 22130)	This is NamedParmNames, a member of class AutoCmd.
	NamedParms (see page 22130)	This is NamedParms, a member of class AutoCmd.
	NamedParmTypes (see page 22131)	This is NamedParmTypes, a member of class AutoCmd.
	Parms (see page 22131)	This is Parms, a member of class AutoCmd.
	ParmTypes (see page 22131)	This is ParmTypes, a member of class AutoCmd.

Protected Methods

	Name	Description
	AddElement (see page 22132)	This is AddElement, a member of class AutoCmd.

Public Methods

	Name	Description
	~AutoCmd (see page 22129)	Frees an System::AutoCmd::AutoCmd (see page 22129) object.
	AutoCmd (see page 22129)	This is the overview for the AutoCmd constructor overload.
	Clear (see page 22132)	System::AutoCmd::Clears any assigned parameters and blanks the name of the associated method.
	ClearArgs (see page 22132)	Clears any assigned parameters.
	ClearName (see page 22133)	Blanks the name of the associated method.
	GetArgCount (see page 22133)	Returns the number of positional arguments that have been assigned.
	GetArgType (see page 22134)	Returns the type of a parameter value.
A	GetCallType (see page 22134)	Indicates the type of the interface method represented by the System::AutoCmd::AutoCmd (see page 22129) object.
	GetName (see page 22134)	Returns the name of the interface method this System::AutoCmd::AutoCmd (see page 22129) object represents.

	GetNamedArgCount (see page 22135)	Returns the number of named arguments that have been assigned.
	GetNamedArgType (see page 22135)	Returns the type of a named parameter value.
	GetNamedParm (see page 22136)	Returns the value of a named parameter.
	GetNamedParmName (see page 22136)	Returns the named of a named parameter value.
	GetParm (see page 22137)	Returns the value of a positional parameter.
	RequestResult (see page 22137)	Indicates whether the method represented by the System::AutoCmd::AutoCmd (see page 22129) object has a return value.
	SetName (see page 22138)	Sets the name of the method the System::AutoCmd::AutoCmd (see page 22129) object represents.

Public Operators

	Name	Description
	<< (see page 22138)	This is the overview for the << operator overload.

158.1.2.2 AutoCmd::~AutoCmd Destructor

Frees an System::AutoCmd::AutoCmd (see page 22129) object.

Pascal

```
destructor Destroy;
```

C++

```
~AutoCmd();
```

Description

System::AutoCmd (see page 22127)::~AutoCmd (see page 22127) is the destructor for System::AutoCmd::AutoCmd (see page 22129).

158.1.2.3 AutoCmd Constructor

This is the overview for the AutoCmd constructor overload.

Overload List

	Name	Description
	AutoCmd::AutoCmd (AutoCmd&) (see page 22129)	System::AutoCmd::Creates an instance of System::AutoCmd::AutoCmd (see page 22127) for a specified method.
	AutoCmd::AutoCmd (String&) (see page 22129)	System::AutoCmd::Creates an instance of System::AutoCmd::AutoCmd (see page 22127) for a specified method.

158.1.2.3.1 AutoCmd::AutoCmd Constructor (AutoCmd&)

System::AutoCmd::Creates an instance of System::AutoCmd::AutoCmd (see page 22127) for a specified method.

Pascal

```
constructor Create(const name: String&);
constructor Create(const src: AutoCmd&);
```

C++

```
AutoCmd(const String& name);
AutoCmd(const AutoCmd& src);
```

Description

System::AutoCmd::AutoCmd (see page 22127) has two constructors: a version that takes the name of the method it represents, and a copy constructor. When creating a new System::AutoCmd::AutoCmd (see page 22127) object for a method, the name parameter must be the same as the name of the method as it appears in the interface declaration.

158.1.2.4 AutoCmd Data Members

The data members of the AutoCmd class are listed here.

Protected Data Members

	Name	Description
	Name (see page 22130)	This is Name, a member of class AutoCmd.
	NamedParmNames (see page 22130)	This is NamedParmNames, a member of class AutoCmd.
	NamedParms (see page 22130)	This is NamedParms, a member of class AutoCmd.
	NamedParmTypes (see page 22131)	This is NamedParmTypes, a member of class AutoCmd.
	Parms (see page 22131)	This is Parms, a member of class AutoCmd.
	ParmTypes (see page 22131)	This is ParmTypes, a member of class AutoCmd.

158.1.2.4.1 AutoCmd::Name Data Member

Pascal

```
Name: String;
```

C++

```
String Name;
```

Description

This is Name, a member of class AutoCmd.

158.1.2.4.2 AutoCmd::NamedParmNames Data Member

Pascal

```
NamedParmNames: Variant;
```

C++

```
Variant NamedParmNames;
```

Description

This is NamedParmNames, a member of class AutoCmd.

158.1.2.4.3 AutoCmd::NamedParms Data Member

Pascal

```
NamedParms: Variant;
```

C++

```
Variant NamedParms;
```

Description

This is NamedParms, a member of class AutoCmd.

158.1.2.4.4 AutoCmd::NamedParmTypes Data Member

Pascal

```
NamedParmTypes: Variant;
```

C++

```
Variant NamedParmTypes;
```

Description

This is NamedParmTypes, a member of class AutoCmd.

158.1.2.4.5 AutoCmd::Parms Data Member

Pascal

```
Parms: Variant;
```

C++

```
Variant Parms;
```

Description

This is Parms, a member of class AutoCmd.

158.1.2.4.6 AutoCmd::ParmTypes Data Member

Pascal

```
ParmTypes: Variant;
```

C++

```
Variant ParmTypes;
```

Description

This is ParmTypes, a member of class AutoCmd.

158.1.2.5 AutoCmd Methods

The methods of the AutoCmd class are listed here.

Protected Methods

	Name	Description
	AddElement (see page 22132)	This is AddElement, a member of class AutoCmd.

Public Methods

	Name	Description
	Clear (see page 22132)	System::AutoCmd::Clears any assigned parameters and blanks the name of the associated method.
	ClearArgs (see page 22132)	Clears any assigned parameters.
	ClearName (see page 22133)	Blanks the name of the associated method.
	GetArgCount (see page 22133)	Returns the number of positional arguments that have been assigned.
	GetArgType (see page 22134)	Returns the type of a parameter value.
	GetCallType (see page 22134)	Indicates the type of the interface method represented by the System::AutoCmd::AutoCmd (see page 22129) object.

	GetName (see page 22134)	Returns the name of the interface method this System::AutoCmd::AutoCmd (see page 22129) object represents.
	GetNamedArgCount (see page 22135)	Returns the number of named arguments that have been assigned.
	GetNamedArgType (see page 22135)	Returns the type of a named parameter value.
	GetNamedParm (see page 22136)	Returns the value of a named parameter.
	GetNamedParmName (see page 22136)	Returns the named of a named parameter value.
	GetParm (see page 22137)	Returns the value of a positional parameter.
	RequestResult (see page 22137)	Indicates whether the method represented by the System::AutoCmd::AutoCmd (see page 22129) object has a return value.
	SetName (see page 22138)	Sets the name of the method the System::AutoCmd::AutoCmd (see page 22129) object represents.

158.1.2.5.1 AutoCmd::AddElement Method

Pascal

```
procedure AddElement;
```

C++

```
void AddElement();
```

Description

This is AddElement, a member of class AutoCmd.

158.1.2.5.2 AutoCmd::Clear Method

System::AutoCmd::Clears any assigned parameters and blanks the name of the associated method.

Pascal

```
function Clear: AutoCmd&;
```

C++

```
AutoCmd& Clear();
```

Description

Call System::AutoCmd::Clear to remove the System::AutoCmd::AutoCmd (see page 22129) object's association with an Automation interface method. System::AutoCmd::Clear replaces the method name with an empty string, and frees all arguments that have been assigned. After a call to System::AutoCmd::Clear, the System::AutoCmd::AutoCmd (see page 22129) object can't be executed until a new method name is assigned (using SetName (see page 22138)) and, if necessary, new parameters assigned (using the << operator).

See Also

System::AutoCmd::ClearName (see page 22133)

System::AutoCmd::ClearArgs (see page 22132)

158.1.2.5.3 AutoCmd::ClearArgs Method

Clears any assigned parameters.

Pascal

```
function ClearArgs: AutoCmd&;
```

C++

```
AutoCmd& ClearArgs();
```

Description

Call System::AutoCmd::ClearArgs to remove all assigned parameter values (both named parameter values and values that were supplied by position). Once the existing values have been removed, new parameter values can be assigned using the << operator.

See Also

System::AutoCmd::ClearName (see page 22133)

System::AutoCmd::Clear (see page 22132)

158.1.2.5.4 AutoCmd::ClearName Method

Blanks the name of the associated method.

Pascal

```
function ClearName: AutoCmd&;
```

C++

```
AutoCmd& ClearName();
```

Description

Call System::AutoCmd::ClearName to disassociate the System::AutoCmd::AutoCmd (see page 22129) object from the Automation interface method it represents. System::AutoCmd::ClearName replaces the method name with an empty string, but does not free any parameter values that have been assigned. After a call to System::AutoCmd::ClearName, the System::AutoCmd::AutoCmd (see page 22129) object can't be executed until a new method name is assigned using the SetName (see page 22138) method.

See Also

System::AutoCmd::Clear (see page 22132)

System::AutoCmd::ClearArgs (see page 22132)

158.1.2.5.5 AutoCmd::GetArgCount Method

Returns the number of positional arguments that have been assigned.

Pascal

```
function GetArgCount: Byte;
```

C++

```
Byte GetArgCount() const;
```

Description

Call System::AutoCmd::GetArgCount to determine the number of parameter values that have been assigned using the << operator. The values themselves can be retrieved using the GetParm (see page 22137) method.

See Also

System::AutoCmd::operator_streaming

System::AutoCmd::GetNamedArgCount (see page 22135)

System::AutoCmd::GetParm (see page 22137)

158.1.2.5.6 AutoCmd::GetArgType Method

Returns the type of a parameter value.

Pascal

```
function GetArgType(const idx: Byte): Integer;
```

C++

```
int GetArgType(const Byte idx) const;
```

Description

Call System::AutoCmd::GetArgType to determine the type of an argument that was assigned using the << operator.

The idx parameter is the index of the value in the System::AutoCmd::AutoCmd (see page 22129) object's parameter list, where 0 is the index of the first argument. Use the GetArgCount (see page 22133) method to obtain an upper limit of possible values.

See Also

System::AutoCmd::operator_streaming

System::AutoCmd::GetNamedArgType (see page 22135)

System::AutoCmd::GetParm (see page 22137)

System::AutoCmd::GetArgCount (see page 22133)

158.1.2.5.7 AutoCmd::GetCallType Method

Indicates the type of the interface method represented by the System::AutoCmd::AutoCmd (see page 22129) object.

Pascal

```
function GetCallType: Byte; virtual; abstract;
```

C++

```
virtual Byte GetCallType() const = 0;
```

Description

Call System::AutoCmd::GetCallType to determine the type of flag needed to call the method represented by System::AutoCmd::AutoCmd (see page 22129) using the IDispatch::Invoke method of the Automation interface. System::AutoCmd::GetCallType returns DISPATCH_PROPERTYGET if the System::AutoCmd::AutoCmd (see page 22129) object represents a property getter, DISPATCH_PROPERTYSET if it represents a property setter, and DISPATCH_METHOD if it represents any other method type.

System::AutoCmd::GetCallType is declared as a pure virtual method. Descendant classes, which represent specific types of interface methods, override this method to return the appropriate value.

158.1.2.5.8 AutoCmd::GetName Method

Returns the name of the interface method this System::AutoCmd::AutoCmd (see page 22129) object represents.

Pascal

```
function GetName: String;
```

C++

```
String GetName() const;
```

Description

Call System::AutoCmd::GetName to determine the method on an Automation interface to invoke when executing the System::AutoCmd::AutoCmd (see page 22129) object. This is the name of the method, rather than its dispatch id.

Typically, the System::AutoCmd::AutoCmd (see page 22129) constructor specifies the name of the method, although this can be changed using the SetName (see page 22138) method.

See Also

System::AutoCmd::SetName (see page 22138)

System::AutoCmd::AutoCmd (see page 22127)

158.1.2.5.9 AutoCmd::GetNamedArgCount Method

Returns the number of named arguments that have been assigned.

Pascal

```
function GetNamedArgCount: Byte;
```

C++

```
Byte GetNamedArgCount() const;
```

Description

Call System::AutoCmd::GetNamedArgCount to determine the number of named parameter values that have been assigned using the << operator. The values themselves can be retrieved using the GetNamedParm (see page 22136) method, and the corresponding names using the GetNamedParmName (see page 22136) method.

See Also

System::AutoCmd::operator_streaming

System::AutoCmd::GetArgCount (see page 22133)

System::AutoCmd::GetNamedParm (see page 22136)

System::AutoCmd::GetNamedParmName (see page 22136)

System::AutoCmd::GetNamedArgType (see page 22135)

158.1.2.5.10 AutoCmd::GetNamedArgType Method

Returns the type of a named parameter value.

Pascal

```
function GetNamedArgType(const idx: Byte): Integer;
```

C++

```
int GetNamedArgType(const Byte idx) const;
```

Description

Call System::AutoCmd::GetNamedArgType to determine the type of an argument that was assigned using the << operator.

The idx parameter is the index of the value in the System::AutoCmd::AutoCmd (see page 22129) object's named parameter list, where 0 is the index of the first argument. Use the GetNamedArgCount (see page 22135) method to obtain an upper limit of possible values.

See Also

System::AutoCmd::operator_streaming

System::AutoCmd::GetArgType (see page 22134)

System::AutoCmd::GetNamedParm (see page 22136)

System::AutoCmd::GetnamedArgCount

System::AutoCmd::GetNamedParmName (see page 22136)

158.1.2.5.11 AutoCmd::GetNamedParm Method

Returns the value of a named parameter.

Pascal

```
function GetNamedParm(const idx: Byte): Variant&;
```

C++

```
Variant& GetNamedParm(const Byte idx);
```

Description

Call System::AutoCmd::GetNamedParm to determine the value of named parameter that was assigned using the << operator. The value is returned as a Variant (see page 22307) object. Its underlying type can be obtained using the GetNamedArgType (see page 22135) method.

The idx parameter is the index of the value in the System::AutoCmd::AutoCmd (see page 22129) object's named parameter list, where 0 is the index of the first argument. Use the GetNamedArgCount (see page 22135) method to obtain an upper limit of possible values.

See Also

System::AutoCmd::operator_streaming

System::AutoCmd::GetNamedArgCount (see page 22135)

System::AutoCmd::GetNamedArgType (see page 22135)

System::AutoCmd::GetNamedParmName (see page 22136)

System::Variant (see page 22307)

158.1.2.5.12 AutoCmd::GetNamedParmName Method

Returns the named of a named parameter value.

Pascal

```
function GetNamedParmName(const idx: Byte): String;
```

C++

```
String GetNamedParmName(const Byte idx) const;
```

Description

Call System::AutoCmd::GetNamedParmName to determine the name of an argument that was assigned using the << operator.

The idx parameter is the index of the value in the System::AutoCmd::AutoCmd (see page 22129) object's named parameter list, where 0 is the index of the first argument. Use the GetNamedArgCount (see page 22135) method to obtain an upper limit of possible values.

See Also

System::AutoCmd::operator_streaming

System::AutoCmd::GetNamedArgType (see page 22135)

System::AutoCmd::GetNamedParm (see page 22136)

System::AutoCmd::GetNamedArgCount (see page 22135)

158.1.2.5.13 AutoCmd::GetParm Method

Returns the value of a positional parameter.

Pascal

```
function GetParm(const idx: Byte): Variant&;
```

C++

```
Variant& GetParm(const Byte idx);
```

Description

Call System::AutoCmd::GetParm to determine the value of positional parameter that was assigned using the << operator. The value is returned as a Variant (see page 22307) object. Its underlying type can be obtained using the GetArgType (see page 22134) method.

The idx parameter is the index of the value in the System::AutoCmd::AutoCmd (see page 22129) object's parameter list, where 0 is the index of the first argument. Use the GetArgCount (see page 22133) method to obtain an upper limit of possible values.

See Also

System::AutoCmd::operator_streaming

System::AutoCmd::GetArgCount (see page 22133)

System::AutoCmd::GetArgType (see page 22134)

System::Variant (see page 22307)

158.1.2.5.14 AutoCmd::RequestResult Method

Indicates whether the method represented by the System::AutoCmd::AutoCmd (see page 22129) object has a return value.

Pascal

```
function RequestResult: bool; virtual; abstract;
```

C++

```
virtual bool RequestResult() const = 0;
```

Description

Call System::AutoCmd::RequestResult to determine whether there is a return value after executing the System::AutoCmd::AutoCmd (see page 22129) object using the Variant::Exec method.

System::AutoCmd::AutoCmd (see page 22129) declares System::AutoCmd::RequestResult as a pure virtual method. Descendant classes specialized to different call types return a value depending on what type of method they represent.

See Also

System::AutoCmd::GetCallType (see page 22134)

System::Variant::Exec (see page 22320)

158.1.2.5.15 AutoCmd::SetName Method

Sets the name of the method the System::AutoCmd::AutoCmd (see page 22129) object represents.

Pascal

```
function SetName(const name: String&): AutoCmd&;
```

C++

```
AutoCmd& SetName(const String& name);
```

Description

Use System::AutoCmd::SetName to associate the System::AutoCmd::AutoCmd (see page 22129) object with a specific method on an Automation interface. The name parameter is the name of the interface method.

Typically, the System::AutoCmd::AutoCmd (see page 22129) constructor specifies the name of the method. Use System::AutoCmd::SetName to change the method that the object represents.

See Also

System::AutoCmd::ClearName (see page 22133)

System::AutoCmd::GetName (see page 22134)

System::AutoCmd::AutoCmd (see page 22127)

158.1.2.6 AutoCmd Operators

The operators of the AutoCmd class are listed here.

Public Operators

	Name	Description
	<< (see page 22138)	This is the overview for the << operator overload.

158.1.2.6.1 << Operator

This is the overview for the << operator overload.

Overload List

	Name	Description
	AutoCmd::<< (AnsiString&) (see page 22139)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (AnsiString*) (see page 22139)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (bool) (see page 22142)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (Byte) (see page 22139)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (Byte*) (see page 22140)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (Currency) (see page 22140)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (Currency*) (see page 22140)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (double) (see page 22143)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (double*) (see page 22143)	This is <<, a member of class AutoCmd.

	AutoCmd::<< (float) (see page 22143)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (float*) (see page 22143)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (IDispatch*) (see page 22140)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (IInterface*) (see page 22141)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (int) (see page 22143)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (int*) (see page 22144)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (IUnknown*) (see page 22141)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (NamedParm&) (see page 22141)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (short) (see page 22144)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (short*) (see page 22144)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (TDateTime) (see page 22141)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (TDateTime*) (see page 22141)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (Variant&) (see page 22142)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (Variant*) (see page 22142)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (wchar_t*) (see page 22144)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (wchar_t**) (see page 22144)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (WordBool) (see page 22142)	This is <<, a member of class AutoCmd.
	AutoCmd::<< (WordBool*) (see page 22142)	This is <<, a member of class AutoCmd.

158.1.2.6.1.1 AutoCmd::<< Operator (AnsiString&)

Pascal

```
operator <<(const arg: AnsiString&);
```

C++

```
AutoCmd& operator <<(const AnsiString& arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.2 AutoCmd::<< Operator (AnsiString*)

Pascal

```
operator <<(var arg: String);
```

C++

```
AutoCmd& operator <<(AnsiString* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.3 AutoCmd::<< Operator (Byte)

Pascal

```
operator <<(const arg: Byte);
```

C++

```
AutoCmd& operator <<(const Byte arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.4 AutoCmd::<< Operator (Byte*)

Pascal

```
operator <<(var arg: Byte);
```

C++

```
AutoCmd& operator <<(Byte* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.5 AutoCmd::<< Operator (Currency)

Pascal

```
operator <<(const arg: Currency);
```

C++

```
AutoCmd& operator <<(const Currency arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.6 AutoCmd::<< Operator (Currency*)

Pascal

```
operator <<(var arg: Currency);
```

C++

```
AutoCmd& operator <<(Currency* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.7 AutoCmd::<< Operator (IDispatch*)

Pascal

```
operator <<(var arg: IDispatch);
```

C++

```
AutoCmd& operator <<(IDispatch* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.8 AutoCmd::<< Operator (IInterface*)

Pascal

```
operator <<(var arg: IInterface);
```

C++

```
AutoCmd& operator <<(IInterface* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.9 AutoCmd::<< Operator (IUnknown*)

Pascal

```
operator <<(var arg: IUnknown);
```

C++

```
AutoCmd& operator <<(IUnknown* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.10 AutoCmd::<< Operator (NamedParm&)

Pascal

```
operator <<(const np: NamedParm&);
```

C++

```
AutoCmd& operator <<(const NamedParm& np);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.11 AutoCmd::<< Operator (TDateTime)

Pascal

```
operator <<(const arg: TDateTime);
```

C++

```
AutoCmd& operator <<(const TDateTime arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.12 AutoCmd::<< Operator (TDateTime*)

Pascal

```
operator <<(var arg: TDateTime);
```

C++

```
AutoCmd& operator <<(TDateTime* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.13 AutoCmd::<< Operator (Variant&)

Pascal

```
operator <<(const arg: Variant&);
```

C++

```
AutoCmd& operator <<(const Variant& arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.14 AutoCmd::<< Operator (Variant*)

Pascal

```
operator <<(var arg: Variant);
```

C++

```
AutoCmd& operator <<(Variant* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.15 AutoCmd::<< Operator (WordBool)

Pascal

```
operator <<(const arg: WordBool);
```

C++

```
AutoCmd& operator <<(const WordBool arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.16 AutoCmd::<< Operator (WordBool*)

Pascal

```
operator <<(var arg: WordBool);
```

C++

```
AutoCmd& operator <<(WordBool* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.17 AutoCmd::<< Operator (bool)

Pascal

```
operator <<(const arg: bool);
```

C++

```
AutoCmd& operator <<(const bool arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.18 AutoCmd::<< Operator (double)

Pascal

```
operator <<(const arg: double);
```

C++

```
AutoCmd& operator <<(const double arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.19 AutoCmd::<< Operator (double*)

Pascal

```
operator <<(var arg: double);
```

C++

```
AutoCmd& operator <<(double* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.20 AutoCmd::<< Operator (float)

Pascal

```
operator <<(const arg: float);
```

C++

```
AutoCmd& operator <<(const float arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.21 AutoCmd::<< Operator (float*)

Pascal

```
operator <<(var arg: float);
```

C++

```
AutoCmd& operator <<(float* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.22 AutoCmd::<< Operator (int)

Pascal

```
operator <<(const arg: Integer);
```

C++

```
AutoCmd& operator <<(const int arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.23 AutoCmd::<< Operator (int*)

Pascal

```
operator <<(var arg: Integer);
```

C++

```
AutoCmd& operator <<(int* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.24 AutoCmd::<< Operator (short)

Pascal

```
operator <<(const arg: short);
```

C++

```
AutoCmd& operator <<(const short arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.25 AutoCmd::<< Operator (short*)

Pascal

```
operator <<(var arg: short);
```

C++

```
AutoCmd& operator <<(short* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.26 AutoCmd::<< Operator (wchar_t*)

Pascal

```
operator <<(var arg: wchar_t);
```

C++

```
AutoCmd& operator <<(wchar_t* arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.2.6.1.27 AutoCmd::<< Operator (wchar_t**)

Pascal

```
operator <<(var arg: wchar_t*);
```

C++

```
AutoCmd& operator <<(wchar_t** arg);
```

Description

This is <<, a member of class AutoCmd.

158.1.3 Currency Class

System::Currency is the C++ implementation of the Delphi System::Currency data type.

Class Hierarchy

Pascal

```
Currency = class(CurrencyBase);
```

C++

```
class Currency : public CurrencyBase;
```

File

syscurr.h

Description

System::Currency is a C++ class that implements a Delphi intrinsic type, also called System::Currency. Use System::Currency to hold monetary values.

Note: A System::Currency object is implemented as a 64-bit signed integer. Avoid operations that might cause integer overflow.

Note: Use only the operators defined by System::Currency. The compiler ignores any operators you overload yourself. Use the System::Currency constructors to create System::Currency objects from pointers to other System::Currency objects, and also from numeric and string values..

Note: To utilize the C++ streaming operators (<< and >>) with System::Currency, you must use #include <iostream> before #include <syscurr.h>. This occurs automatically if you include vcl.h, clx.h, or System.hpp. The following stream operators are defined:

```
ostream& operator << (ostream& os, const Currency& arg);
istream& operator >> (istream& is, Currency& arg);
```

System::CurrencyComp

System::CurrencyCurrencyBase

158.1.3.1 Currency Members

The following tables list the members exposed by Currency.

Public Data Members

	Name	Description
	Val (see page 22166)	This is Val, a member of class CurrencyBase.

Public Friends

Name	Description
Currency __fastcall operator -(double lhs, const Currency& rhs) (see page 22164)	This is friend Currency __fastcall operator -(double lhs, const Currency& rhs).
Currency __fastcall operator -(int lhs, const Currency& rhs) (see page 22164)	This is friend Currency __fastcall operator -(int lhs, const Currency& rhs).
Currency __fastcall operator *(double lhs, const Currency& rhs) (see page 22164)	This is friend Currency __fastcall operator *(double lhs, const Currency& rhs).
Currency __fastcall operator *(int lhs, const Currency& rhs) (see page 22164)	This is friend Currency __fastcall operator *(int lhs, const Currency& rhs).
Currency __fastcall operator /(double lhs, const Currency& rhs) (see page 22165)	This is friend Currency __fastcall operator /(double lhs, const Currency& rhs).
Currency __fastcall operator /(int lhs, const Currency& rhs) (see page 22165)	This is friend Currency __fastcall operator /(int lhs, const Currency& rhs).
Currency __fastcall operator +(double lhs, const Currency& rhs) (see page 22165)	This is friend Currency __fastcall operator +(double lhs, const Currency& rhs).
Currency __fastcall operator +(int lhs, const Currency& rhs) (see page 22165)	This is friend Currency __fastcall operator +(int lhs, const Currency& rhs).

Public Methods

	Name	Description
	Currency (see page 22147)	This is the overview for the Currency constructor overload.

Public Operators

	Name	Description
	- (see page 22148)	This is the overview for the - operator overload.
	-- (see page 22150)	This is the overview for the -- operator overload.
	! (see page 22150)	Returns a new System::Currency::Currency (see page 22147) object that is the logical negation of this System::Currency::Currency (see page 22147) object.
	!= (see page 22151)	This is the overview for the != operator overload.
	% (see page 22151)	Returns a new System::Currency::Currency (see page 22147) object with the value that is the remainder of this System::Currency::Currency (see page 22147) object divided by a specified integer.
	%= (see page 22152)	Assigns this System::Currency::Currency (see page 22147) object the remainder of its initial value divided by integer rhs.
	* (see page 22152)	This is the overview for the * operator overload.
	*= (see page 22153)	Assigns this System::Currency::Currency (see page 22147) object the result of its initial value multiplied by the value of System::Currency::Currency (see page 22147) object rhs.
	/ (see page 22153)	This is the overview for the / operator overload.
	/= (see page 22154)	Assigns this System::Currency::Currency (see page 22147) object the result of its initial value divided by the value of System::Currency::Currency (see page 22147) object rhs.
	+ (see page 22155)	This is the overview for the + operator overload.
	++ (see page 22156)	This is the overview for the ++ operator overload.
	+= (see page 22156)	Increments the value of this System::Currency::Currency (see page 22147) object by the value of rhs.
	< (see page 22157)	This is the overview for the < operator overload.
	<= (see page 22158)	This is the overview for the <= operator overload.
	-= (see page 22159)	Decrements the value of this System::Currency::Currency (see page 22147) object by the value of rhs.
	= (see page 22158)	This is the overview for the = operator overload.
	== (see page 22160)	This is the overview for the == operator overload.
	> (see page 22160)	This is the overview for the > operator overload.
	>= (see page 22161)	This is the overview for the >= operator overload.
	AnsiString (see page 22162)	Converts the System::Currency::Currency (see page 22147) object to an AnsiString that displays its value.
	double (see page 22162)	Converts the System::Currency::Currency (see page 22147) object to a double value.
	int (see page 22163)	Converts the System::Currency::Currency (see page 22147) object to an integer value

158.1.3.2 Currency Constructor

This is the overview for the Currency constructor overload.

Overload List

	Name	Description
	Currency::Currency () (see page 22147)	Creates and initializes a System::Currency::Currency (see page 22145) object.
	Currency::Currency (AnsiString&) (see page 22147)	Creates and initializes a System::Currency::Currency (see page 22145) object.
	Currency::Currency (Currency&) (see page 22147)	Creates and initializes a System::Currency::Currency (see page 22145) object.
	Currency::Currency (CurrencyBase&) (see page 22147)	Creates and initializes a System::Currency::Currency (see page 22145) object.
	Currency::Currency (double) (see page 22147)	Creates and initializes a System::Currency::Currency (see page 22145) object.
	Currency::Currency (int) (see page 22147)	Creates and initializes a System::Currency::Currency (see page 22145) object.

158.1.3.2.1 Currency::Currency Constructor ()

Creates and initializes a System::Currency::Currency (see page 22145) object.

Pascal

```
constructor Create;
constructor Create(val: double);
constructor Create(val: Integer);
constructor Create(const src: CurrencyBase&);
constructor Create(const src: Currency&);
constructor Create(const src: AnsiString&);
```

C++

```
__fastcall Currency();
__fastcall Currency(double val);
__fastcall Currency(int val);
__fastcall Currency(const CurrencyBase& src);
__fastcall Currency(const Currency& src);
__fastcall Currency(const AnsiString& src);
```

Description

Use System::Currency::Currency (see page 22145) to instantiate a System::Currency::Currency (see page 22145) object.

When called with no parameters, the resulting object has a value of 0.

When called with a System::Currency::Currency (see page 22145) object as the src parameter, the resulting object is a copy of src (the copy constructor).

When called with a System::Currency::CurrencyBase (see page 22166) object as the src parameter, the resulting object has the same value as the src parameter. System::Currency::CurrencyBase (see page 22166) is the base class for the System::Currency::Currency (see page 22145) type. It has a single member, a public Val (see page 22543) field that represents the value of the object.

When called with an AnsiString (see page 22162) object as the src parameter, the value of the resulting object is the parsed

value of the AnsiString (see page 22162). The AnsiString (see page 22162) must represent a numeric value within the range valid for System::Currency::Currency (see page 22145) (-922337203685477.5808 to 922337203685477.5807).

When called with a double (see page 22162) or integer as the val parameter, the value of the resulting object is the value of the val parameter.

158.1.3.3 Currency Operators

The operators of the Currency class are listed here.

Public Operators

	Name	Description
	- (see page 22148)	This is the overview for the - operator overload.
	-- (see page 22150)	This is the overview for the -- operator overload.
	! (see page 22150)	Returns a new System::Currency::Currency (see page 22147) object that is the logical negation of this System::Currency::Currency (see page 22147) object.
	!= (see page 22151)	This is the overview for the != operator overload.
	% (see page 22151)	Returns a new System::Currency::Currency (see page 22147) object with the value that is the remainder of this System::Currency::Currency (see page 22147) object divided by a specified integer.
	%= (see page 22152)	Assigns this System::Currency::Currency (see page 22147) object the remainder of its initial value divided by integer rhs.
	* (see page 22152)	This is the overview for the * operator overload.
	*= (see page 22153)	Assigns this System::Currency::Currency (see page 22147) object the result of its initial value multiplied by the value of System::Currency::Currency (see page 22147) object rhs.
	/ (see page 22153)	This is the overview for the / operator overload.
	/= (see page 22154)	Assigns this System::Currency::Currency (see page 22147) object the result of its initial value divided by the value of System::Currency::Currency (see page 22147) object rhs.
	+ (see page 22155)	This is the overview for the + operator overload.
	++ (see page 22156)	This is the overview for the ++ operator overload.
	+= (see page 22156)	Increments the value of this System::Currency::Currency (see page 22147) object by the value of rhs.
	< (see page 22157)	This is the overview for the < operator overload.
	<= (see page 22158)	This is the overview for the <= operator overload.
	= (see page 22158)	This is the overview for the = operator overload.
	-= (see page 22159)	Decrements the value of this System::Currency::Currency (see page 22147) object by the value of rhs.
	== (see page 22160)	This is the overview for the == operator overload.
	> (see page 22160)	This is the overview for the > operator overload.
	>= (see page 22161)	This is the overview for the >= operator overload.
	AnsiString (see page 22162)	Converts the System::Currency::Currency (see page 22147) object to an AnsiString that displays its value.
	double (see page 22162)	Converts the System::Currency::Currency (see page 22147) object to a double value.
	int (see page 22163)	Converts the System::Currency::Currency (see page 22147) object to an integer value

158.1.3.3.1 - Operator

This is the overview for the - operator overload.

Overload List

	Name	Description
	Currency::- () (see page 22149)	This is -, a member of class Currency.
	Currency::- (Currency&) (see page 22149)	This is -, a member of class Currency.
	Currency::- (double) (see page 22149)	This is -, a member of class Currency.
	Currency::- (int) (see page 22149)	This is -, a member of class Currency.

158.1.3.3.1.1 Currency::- Operator ()

Pascal

```
operator -;
```

C++

```
__fastcall Currency operator -() const;
```

Description

This is -, a member of class Currency.

158.1.3.3.1.2 Currency::- Operator (Currency&)

Pascal

```
operator -(const rhs: Currency&);
```

C++

```
__fastcall Currency operator -(const Currency& rhs) const;
```

Description

This is -, a member of class Currency.

158.1.3.3.1.3 Currency::- Operator (double)

Pascal

```
operator -(rhs: double);
```

C++

```
__fastcall Currency operator -(double rhs) const;
```

Description

This is -, a member of class Currency.

158.1.3.3.1.4 Currency::- Operator (int)

Pascal

```
operator -(rhs: Integer);
```

C++

```
__fastcall Currency operator -(int rhs) const;
```

Description

This is -, a member of class Currency.

158.1.3.3.2 -- Operator

This is the overview for the -- operator overload.

Overload List

	Name	Description
	Currency::-- () (see page 22150)	Decrements the value of the System::Currency::Currency (see page 22147) object by a specified integer value.
	Currency::-- (int) (see page 22150)	Decrements the value of the System::Currency::Currency (see page 22147) object by a specified integer value.

158.1.3.3.2.1 Currency::-- Operator ()

Decrements the value of the System::Currency::Currency (see page 22147) object by a specified integer value.

Pascal

```
operator --;
operator --(: Integer);
```

C++

```
Currency& operator --();
Currency operator --(int);
```

Description

Use the unary System::Currency (see page 22145)::-- to decrement the value of the System::Currency::Currency (see page 22147) object by 1.

Use the binary System::Currency (see page 22145)::-- to decrement the value by the integer specified as an operand.

See Also

System::Currency::++ (see page 22156)

System::Currency::-= (see page 22159)

System::Currency::operator_minus_binary

158.1.3.3.3 Currency::! Operator

Returns a new System::Currency::Currency (see page 22147) object that is the logical negation of this System::Currency::Currency (see page 22147) object.

Pascal

```
operator !;
```

C++

```
__fastcall Currency operator !() const;
```

Description

If the value of the System::Currency::Currency (see page 22147) object is nonzero, the System::Currency (see page 22145)::! returns 0. If the value of the System::Currency::Currency (see page 22147) object is 0, the System::Currency (see page 22145)::! returns 1.

See Also

System::Currency::!= (see page 22151)

System::Currency::operator_minus_unary

158.1.3.3.4 != Operator

This is the overview for the != operator overload.

Overload List

	Name	Description
	Currency::!= (Currency&) (see page 22151)	Tests for inequality between the System::Currency::Currency (see page 22147) object's value and a specified value.
	Currency::!= (double) (see page 22151)	Tests for inequality between the System::Currency::Currency (see page 22147) object's value and a specified value.
	Currency::!= (int) (see page 22151)	Tests for inequality between the System::Currency::Currency (see page 22147) object's value and a specified value.

158.1.3.3.4.1 Currency::!= Operator (Currency&)

Tests for inequality between the System::Currency::Currency (see page 22147) object's value and a specified value.

Pascal

```
operator !=(const rhs: Currency&);
operator !=(rhs: Integer);
operator !=(rhs: double);
```

C++

```
__fastcall bool operator !=(const Currency& rhs) const;
__fastcall bool operator !=(int rhs) const;
__fastcall bool operator !=(double rhs) const;
```

Description

The System::Currency (see page 22145)::!= compares the value of the System::Currency::Currency (see page 22147) object with the value specified by the rhs operand. If the values differ, the System::Currency (see page 22145)::!= returns true. If the values are the same, the System::Currency (see page 22145)::!= returns false.

See Also

System::Currency::= (see page 22159)

System::Currency::> (see page 22161)

System::Currency::>= (see page 22161)

System::Currency::< (see page 22157)

System::Currency::<= (see page 22158)

158.1.3.3.5 Currency::% Operator

Returns a new System::Currency::Currency (see page 22147) object with the value that is the remainder of this System::Currency::Currency (see page 22147) object divided by a specified integer.

Pascal

```
operator %(rhs: Integer);
```

C++

```
__fastcall Currency operator %(int rhs) const;
```

Description

Use the System::Currency (see page 22145)::% to obtain the remainder from dividing the value of this System::Currency::Currency (see page 22147) object by the integer specified by the rhs operand.

See Also

System::Currency::%= (see page 22152)

System::Currency::/ (see page 22154)

158.1.3.3.6 Currency::%= Operator

Assigns this System::Currency::Currency (see page 22147) object the remainder of its initial value divided by integer rhs.

Pascal

```
operator %=(rhs: Integer);
```

C++

```
__fastcall Currency& operator %=(int rhs);
```

Description

Use the System::Currency (see page 22145)::%= to obtain the remainder from dividing this System::Currency::Currency (see page 22147) object's value by the Value of the System::Currency::Currency (see page 22147) object specified by rhs.

See Also

System::Currency::= (see page 22159)

System::Currency::/= (see page 22154)

System::Currency::% (see page 22151)

158.1.3.3.7 * Operator

This is the overview for the * operator overload.

Overload List

	Name	Description
	Currency::* (Currency&) (see page 22152)	Multiplies the value of the System::Currency::Currency (see page 22147) object by a specified value.
	Currency::* (double) (see page 22152)	Multiplies the value of the System::Currency::Currency (see page 22147) object by a specified value.
	Currency::* (int) (see page 22152)	Multiplies the value of the System::Currency::Currency (see page 22147) object by a specified value.

158.1.3.3.7.1 Currency::* Operator (Currency&)

Multiplies the value of the System::Currency::Currency (see page 22147) object by a specified value.

Pascal

```
operator *(const rhs: Currency&);
operator *(rhs: Integer);
operator *(rhs: double);
```

C++

```
__fastcall Currency operator *(const Currency& rhs) const;
__fastcall Currency operator *(int rhs) const;
__fastcall Currency operator *(double rhs) const;
```

Description

Use the System::Currency (see page 22145)::* to multiply the value of the System::Currency::Currency (see page 22147) object by the value specified by the rhs operand.

Note that there are two related friend System::Currency (see page 22145)::*s:

```
friend Currency __fastcall operator *(int lhs, const Currency& rhs);
```

multiples the values of integer lhs and System::Currency::Currency (see page 22147) object rhs and returns a new System::Currency::Currency (see page 22147) object with the resulting value.

```
friend Currency __fastcall operator *(double lhs, const Currency& rhs);
```

multiples the values of double (see page 22162) lhs and System::Currency::Currency (see page 22147) object rhs and returns a new System::Currency::Currency (see page 22147) object with the resulting value.

See Also

System::Currency::*= (see page 22153)

System::Currency::/ (see page 22154)

158.1.3.3.8 Currency::*= Operator

Assigns this System::Currency::Currency (see page 22147) object the result of its initial value multiplied by the value of System::Currency::Currency (see page 22147) object rhs.

Pascal

```
operator *=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator *=(const Currency& rhs);
```

Description

Use the System::Currency (see page 22145)::*= to multiply this System::Currency::Currency (see page 22147) object's value by the Value of the System::Currency::Currency (see page 22147) object specified by rhs.

See Also

System::Currency::= (see page 22159)

System::Currency::/= (see page 22154)

System::Currency::* (see page 22152)

158.1.3.3.9 / Operator

This is the overview for the / operator overload.

Overload List

	Name	Description
	Currency::/ (Currency&) (see page 22154)	Divides the value of the System::Currency::Currency (see page 22147) object by a specified value.
	Currency::/ (double) (see page 22154)	Divides the value of the System::Currency::Currency (see page 22147) object by a specified value.
	Currency::/ (int) (see page 22154)	Divides the value of the System::Currency::Currency (see page 22147) object by a specified value.

158.1.3.3.9.1 Currency::/ Operator (Currency&)

Divides the value of the System::Currency::Currency (see page 22147) object by a specified value.

Pascal

```
operator /(const rhs: Currency&);
operator /(rhs: Integer);
operator /(rhs: double);
```

C++

```
__fastcall Currency operator /(const Currency& rhs) const;
__fastcall Currency operator /(int rhs) const;
__fastcall Currency operator /(double rhs) const;
```

Description

Use the System::Currency (see page 22145)::/ to divide the value of the System::Currency::Currency (see page 22147) object by the value specified by the rhs operand.

Note that there are two related friend System::Currency::operator_slashs:

```
friend Currency __fastcall operator /(int lhs, const Currency& rhs);
```

divides the value of int (see page 22163) lhs by the value of System::Currency::Currency (see page 22147) object rhs and returns a new System::Currency::Currency (see page 22147) object with the resulting value.

```
friend Currency __fastcalloperator /(double lhs, const Currency& rhs);
```

divides the value of double (see page 22162) lhs by the value of System::Currency::Currency (see page 22147) object rhs and returns a System::Currency::Currency (see page 22147) object with the resulting value.

See Also

System::Currency::/= (see page 22154)

System::Currency::* (see page 22152)

System::Currency::% (see page 22151)

158.1.3.3.10 Currency::/= Operator

Assigns this System::Currency::Currency (see page 22147) object the result of its initial value divided by the value of System::Currency::Currency (see page 22147) object rhs.

Pascal

```
operator /=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator /=(const Currency& rhs);
```

Description

Use the System::Currency (see page 22145)::/= to divide this System::Currency::Currency (see page 22147) object's value by the Value of the System::Currency::Currency (see page 22147) object specified by rhs.

See Also

System::Currency::= (see page 22159)

System::Currency::*= (see page 22153)

System::Currency::/ (see page 22154)

158.1.3.3.11 + Operator

This is the overview for the + operator overload.

Overload List

	Name	Description
	Currency::+ (Currency&) (see page 22155)	Adds a specified value to the System::Currency::Currency (see page 22147) object.
	Currency::+ (double) (see page 22155)	Adds a specified value to the System::Currency::Currency (see page 22147) object.
	Currency::+ (int) (see page 22155)	Adds a specified value to the System::Currency::Currency (see page 22147) object.

158.1.3.3.11.1 Currency::+ Operator (Currency&)

Adds a specified value to the System::Currency::Currency (see page 22147) object.

Pascal

```
operator +(const rhs: Currency&);
operator +(rhs: Integer);
operator +(rhs: double);
```

C++

```
__fastcall Currency operator +(const Currency& rhs) const;
__fastcall Currency operator +(int rhs) const;
__fastcall Currency operator +(double rhs) const;
```

Description

Use the System::Currency (see page 22145)::+ to add the value specified by the rhs operand to the System::Currency::Currency (see page 22147) object. If the rhs operand is another System::Currency::Currency (see page 22147) object, the System::Currency (see page 22145)::+ adds its value to the System::Currency::Currency (see page 22147) object. If it is an integer or double (see page 22162) value, the System::Currency (see page 22145)::+ adds that value to the value of the System::Currency::Currency (see page 22147) object.

Note that there are two related friend System::Currency (see page 22145)::+s:

```
friend Currency __fastcall operator +(int lhs, const Currency& rhs);
```

returns a new System::Currency::Currency (see page 22147) object that is the sum of int (see page 22163) lhs and System::Currency::Currency (see page 22147) object rhs.

```
friend Currency __fastcall operator +(double lhs, const Currency& rhs);
```

returns a new System::Currency::Currency (see page 22147) object that is the sum of double (see page 22162) lhs and

System::Currency::Currency (see page 22147) object rhs.

See Also

System::Currency::+= (see page 22156)

System::Currency::++ (see page 22156)

System::Currency::operator_minus_binary

158.1.3.3.12 ++ Operator

This is the overview for the ++ operator overload.

Overload List

	Name	Description
	Currency::++ () (see page 22156)	Increments the value of the System::Currency::Currency (see page 22147) object by a specified integer value.
	Currency::++ (int) (see page 22156)	Increments the value of the System::Currency::Currency (see page 22147) object by a specified integer value.

158.1.3.3.12.1 Currency::++ Operator ()

Increments the value of the System::Currency::Currency (see page 22147) object by a specified integer value.

Pascal

```
operator ++;
operator ++(: Integer);
```

C++

```
Currency& operator ++();
Currency operator ++(int);
```

Description

Use the unary System::Currency (see page 22145)::++ to increment the value of the System::Currency::Currency (see page 22147) object by 1.

Use the binary System::Currency (see page 22145)::++ to increment the value by the integer specified as an operand.

See Also

System::Currency::-- (see page 22150)

System::Currency::+= (see page 22156)

System::Currency::+ (see page 22155)

158.1.3.3.13 Currency::+= Operator

Increments the value of this System::Currency::Currency (see page 22147) object by the value of rhs.

Pascal

```
operator +=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator +=(const Currency& rhs);
```

Description

Use the System::Currency (see page 22145)::+= to add the value of another System::Currency::Currency (see page 22147) object to this one.

See Also

System::Currency::= (see page 22159)

System::Currency::-= (see page 22159)

System::Currency::+ (see page 22155)

System::Currency::++ (see page 22156)

158.1.3.3.14 < Operator

This is the overview for the < operator overload.

Overload List

	Name	Description
	Currency::< (Currency&) (see page 22157)	Tests whether this System::Currency::Currency (see page 22147) value is less than a specified value.
	Currency::< (double) (see page 22157)	Tests whether this System::Currency::Currency (see page 22147) value is less than a specified value.
	Currency::< (int) (see page 22157)	Tests whether this System::Currency::Currency (see page 22147) value is less than a specified value.

158.1.3.3.14.1 Currency::< Operator (Currency&)

Tests whether this System::Currency::Currency (see page 22147) value is less than a specified value.

Pascal

```
operator <(const rhs: Currency&);
operator <(rhs: Integer);
operator <(rhs: double);
```

C++

```
__fastcall bool operator <(const Currency& rhs) const;
__fastcall bool operator <(int rhs) const;
__fastcall bool operator <(double rhs) const;
```

Description

The < System::Currency (see page 22145)::< compares the value of the System::Currency::Currency (see page 22147) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 22147) object has the lesser value, false otherwise.

See Also

System::Currency::!= (see page 22151)

System::Currency::> (see page 22161)

System::Currency::>= (see page 22161)

System::Currency::== (see page 22160)

System::Currency::<= (see page 22158)

158.1.3.3.15 <= Operator

This is the overview for the <= operator overload.

Overload List

	Name	Description
	Currency::<= (Currency&) (see page 22158)	Tests whether this System::Currency::Currency (see page 22147) value is less than or equal to a specified value.
	Currency::<= (double) (see page 22158)	Tests whether this System::Currency::Currency (see page 22147) value is less than or equal to a specified value.
	Currency::<= (int) (see page 22158)	Tests whether this System::Currency::Currency (see page 22147) value is less than or equal to a specified value.

158.1.3.3.15.1 Currency::<= Operator (Currency&)

Tests whether this System::Currency::Currency (see page 22147) value is less than or equal to a specified value.

Pascal

```
operator <=(const rhs: Currency&);
operator <=(rhs: Integer);
operator <=(rhs: double);
```

C++

```
__fastcall bool operator <=(const Currency& rhs) const;
__fastcall bool operator <=(int rhs) const;
__fastcall bool operator <=(double rhs) const;
```

Description

The <= System::Currency (see page 22145)::<= compares the value of the System::Currency::Currency (see page 22147) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 22147) object has a value less than or equal to that of rhs, false otherwise.

See Also

System::Currency::!= (see page 22151)

System::Currency::> (see page 22161)

System::Currency::>= (see page 22161)

System::Currency::< (see page 22157)

System::Currency::== (see page 22160)

158.1.3.3.16 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	Currency::= (Currency&) (see page 22159)	Assigns the value of the System::Currency::Currency (see page 22147) object.

	Currency::= (CurrencyBase&) (see page 22159)	Assigns the value of the System::Currency::Currency (see page 22147) object.
	Currency::= (double) (see page 22159)	Assigns the value of the System::Currency::Currency (see page 22147) object.
	Currency::= (int) (see page 22159)	Assigns the value of the System::Currency::Currency (see page 22147) object.

158.1.3.3.16.1 Currency::= Operator (Currency&)

Assigns the value of the System::Currency::Currency (see page 22147) object.

Pascal

```
operator =(rhs: double);
operator =(rhs: Integer);
operator =(const rhs: CurrencyBase&);
operator =(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator =(double rhs);
__fastcall Currency& operator =(int rhs);
__fastcall Currency& operator =(const CurrencyBase& rhs);
__fastcall Currency& operator =(const Currency& rhs);
```

Description

The assignment System::Currency (see page 22145)::= assigns the value of the rhs operand to the System::Currency::Currency (see page 22147) object. The assignment System::Currency (see page 22145)::= can take

a double (see page 22162) or integer value, which is assigned to the System::Currency::Currency (see page 22147) object.

a System::Currency::CurrencyBase (see page 22166) or System::Currency::Currency (see page 22147) object, whose value is assigned to the System::Currency::Currency (see page 22147) object.

158.1.3.3.17 Currency::-= Operator

Decrements the value of this System::Currency::Currency (see page 22147) object by the value of rhs.

Pascal

```
operator -=(const rhs: Currency&);
```

C++

```
__fastcall Currency& operator -=(const Currency& rhs);
```

Description

Use the System::Currency (see page 22145)::-= to subtract the value of another System::Currency::Currency (see page 22147) object from this one.

See Also

System::Currency::= (see page 22159)

System::Currency::+= (see page 22156)

System::Currency::operator_minus_binary

System::Currency::-- (see page 22150)

158.1.3.3.18 == Operator

This is the overview for the == operator overload.

Overload List

	Name	Description
	Currency::== (Currency&) (see page 22160)	Tests for equality between the System::Currency::Currency (see page 22147) object's value and a specified value.
	Currency::== (double) (see page 22160)	Tests for equality between the System::Currency::Currency (see page 22147) object's value and a specified value.
	Currency::== (int) (see page 22160)	Tests for equality between the System::Currency::Currency (see page 22147) object's value and a specified value.

158.1.3.3.18.1 Currency::== Operator (Currency&)

Tests for equality between the System::Currency::Currency (see page 22147) object's value and a specified value.

Pascal

```
operator ==(const rhs: Currency&);
operator ==(rhs: Integer);
operator ==(rhs: double);
```

C++

```
__fastcall bool operator ==(const Currency& rhs) const;
__fastcall bool operator ==(int rhs) const;
__fastcall bool operator ==(double rhs) const;
```

Description

The == System::Currency (see page 22145)::== compares the value of the System::Currency::Currency (see page 22147) object with the value specified by the rhs operand. If the two values are the same, the System::Currency (see page 22145)::== returns true. If the values differ, the System::Currency (see page 22145)::== returns false.

See Also

System::Currency::!= (see page 22151)

System::Currency::> (see page 22161)

System::Currency::>= (see page 22161)

System::Currency::< (see page 22157)

System::Currency::<= (see page 22158)

158.1.3.3.19 > Operator

This is the overview for the > operator overload.

Overload List

	Name	Description
	Currency::> (Currency&) (see page 22161)	Tests whether this System::Currency::Currency (see page 22147) value is greater than a specified value.

	Currency::> (double) (see page 22161)	Tests whether this System::Currency::Currency (see page 22147) value is greater than a specified value.
	Currency::> (int) (see page 22161)	Tests whether this System::Currency::Currency (see page 22147) value is greater than a specified value.

158.1.3.3.19.1 Currency::> Operator (Currency&)

Tests whether this System::Currency::Currency (see page 22147) value is greater than a specified value.

Pascal

```
operator >(const rhs: Currency&);
operator >(rhs: Integer);
operator >(rhs: double);
```

C++

```
__fastcall bool operator >(const Currency& rhs) const;
__fastcall bool operator >(int rhs) const;
__fastcall bool operator >(double rhs) const;
```

Description

The System::Currency (see page 22145)::> compares the value of the System::Currency::Currency (see page 22147) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 22147) object has a greater value than rhs, false otherwise.

See Also

System::Currency::!= (see page 22151)

System::Currency::== (see page 22160)

System::Currency::>= (see page 22161)

System::Currency::< (see page 22157)

System::Currency::<= (see page 22158)

158.1.3.3.20 >= Operator

This is the overview for the >= operator overload.

Overload List

	Name	Description
	Currency::>= (Currency&) (see page 22161)	Tests whether this System::Currency::Currency (see page 22147) value is greater than or equal to a specified value.
	Currency::>= (double) (see page 22161)	Tests whether this System::Currency::Currency (see page 22147) value is greater than or equal to a specified value.
	Currency::>= (int) (see page 22161)	Tests whether this System::Currency::Currency (see page 22147) value is greater than or equal to a specified value.

158.1.3.3.20.1 Currency::>= Operator (Currency&)

Tests whether this System::Currency::Currency (see page 22147) value is greater than or equal to a specified value.

Pascal

```
operator >=(const rhs: Currency&);
operator >=(rhs: Integer);
operator >=(rhs: double);
```

C++

```
__fastcall bool operator >=(const Currency& rhs) const;
__fastcall bool operator >=(int rhs) const;
__fastcall bool operator >=(double rhs) const;
```

Description

The >= System::Currency (see page 22145)::>= compares the value of the System::Currency::Currency (see page 22147) object with the value specified by the rhs operand. It returns true if this System::Currency::Currency (see page 22147) object's value is greater than or equal to the value of rhs, false otherwise.

See Also

System::Currency::!= (see page 22151)

System::Currency::> (see page 22161)

System::Currency::== (see page 22160)

System::Currency::< (see page 22157)

System::Currency::<= (see page 22158)

158.1.3.3.21 Currency::AnsiString Operator

Converts the System::Currency::Currency (see page 22147) object to an AnsiString that displays its value.

Pascal

```
operator AnsiString;
```

C++

```
__fastcall operator AnsiString() const;
```

Description

AnsiString is a conversion System::Currency::AnsiString that converts the currency value into its string representation. The conversion uses the ffGeneral floating point conversion rules. For further details, see the description of the CurrToStrF and FloatToStrF methods of the AnsiString class.

See Also

System::Currency::CurrToStrF

System::Currency::FloatToStrF

System::Currency::int (see page 22163)

System::Currency::double (see page 22162)

158.1.3.3.22 Currency::double Operator

Converts the System::Currency::Currency (see page 22147) object to a double value.

Pascal

```
operator double;
```

C++

```
__fastcall operator double() const;
```

Description

double is a conversion System::Currency::double that converts a System::Currency::Currency (see page 22147) object to a double.

See Also

System::Currency::int (see page 22163)

System::Currency::AnsiString (see page 22162)

158.1.3.3.23 Currency::int Operator

Converts the System::Currency::Currency (see page 22147) object to an integer value

Pascal

```
operator int;
```

C++

```
__fastcall operator int() const;
```

Description

int is a conversion System::Currency::int that converts a System::Currency::Currency (see page 22147) object to an int.

See Also

System::Currency::double (see page 22162)

System::Currency::AnsiString (see page 22162)

158.1.3.4 Currency Friends

The friends of the Currency class are listed here.

Public Friends

Name	Description
Currency __fastcall operator -(double lhs, const Currency& rhs) (see page 22164)	This is friend Currency __fastcall operator -(double lhs, const Currency& rhs).
Currency __fastcall operator -(int lhs, const Currency& rhs) (see page 22164)	This is friend Currency __fastcall operator -(int lhs, const Currency& rhs).
Currency __fastcall operator *(double lhs, const Currency& rhs) (see page 22164)	This is friend Currency __fastcall operator *(double lhs, const Currency& rhs).
Currency __fastcall operator *(int lhs, const Currency& rhs) (see page 22164)	This is friend Currency __fastcall operator *(int lhs, const Currency& rhs).
Currency __fastcall operator /(double lhs, const Currency& rhs) (see page 22165)	This is friend Currency __fastcall operator /(double lhs, const Currency& rhs).
Currency __fastcall operator /(int lhs, const Currency& rhs) (see page 22165)	This is friend Currency __fastcall operator /(int lhs, const Currency& rhs).
Currency __fastcall operator +(double lhs, const Currency& rhs) (see page 22165)	This is friend Currency __fastcall operator +(double lhs, const Currency& rhs).
Currency __fastcall operator +(int lhs, const Currency& rhs) (see page 22165)	This is friend Currency __fastcall operator +(int lhs, const Currency& rhs).

158.1.3.4.1 friend Currency __fastcall operator -(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator -(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator -(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator -(double lhs, const Currency& rhs).

158.1.3.4.2 friend Currency __fastcall operator -(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator -(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator -(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator -(int lhs, const Currency& rhs).

158.1.3.4.3 friend Currency __fastcall operator *(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator *(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator *(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator *(double lhs, const Currency& rhs).

158.1.3.4.4 friend Currency __fastcall operator *(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator *(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator *(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator *(int lhs, const Currency& rhs).

158.1.3.4.5 friend Currency __fastcall operator /(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator /(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator /(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator /(double lhs, const Currency& rhs).

158.1.3.4.6 friend Currency __fastcall operator /(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator /(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator /(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator /(int lhs, const Currency& rhs).

158.1.3.4.7 friend Currency __fastcall operator +(double lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator +(double lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator +(double lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator +(double lhs, const Currency& rhs).

158.1.3.4.8 friend Currency __fastcall operator +(int lhs, const Currency& rhs) Friend

Pascal

```
Currency __fastcall operator +(int lhs, const Currency& rhs)
```

C++

```
friend Currency __fastcall operator +(int lhs, const Currency& rhs);
```

Description

This is friend Currency __fastcall operator +(int lhs, const Currency& rhs).

158.1.4 CurrencyBase Class

Class Hierarchy

System::CurrencyBase

Pascal

```
CurrencyBase = class;
```

C++

```
class CurrencyBase;
```

File

syscurr.h

Description

This is class System::CurrencyBase.

158.1.4.1 CurrencyBase Members

The following tables list the members exposed by CurrencyBase.

Public Data Members

	Name	Description
	Val (see page 22166)	This is Val, a member of class CurrencyBase.

158.1.4.2 CurrencyBase Data Members

The data members of the CurrencyBase class are listed here.

Public Data Members

	Name	Description
	Val (see page 22166)	This is Val, a member of class CurrencyBase.

158.1.4.2.1 CurrencyBase::Val Data Member

Pascal

```
Val: __int64;
```

C++

```
__int64 Val;
```

Description

This is Val, a member of class CurrencyBase.

158.1.5 DelphiInterface Template

System::DelphiInterface is a C++ implementation of the Delphi interface.

Class Hierarchy

System::DelphiInterface

Pascal

```
DelphiInterface = class;
```

C++

```
template <class T>
class DelphiInterface;
```

File

systobj.h

Description

A Delphi interface is an abstract collection of properties, methods, and events with no implementation. It resembles a C++ class with only pure virtual methods. However a Delphi interface type supports built-in reference counting.

System::DelphiInterface is a C++ template that defines types compatible with Delphi interfaces, System::DelphiInterface defines reference counting logic in its initialization constructor, copy constructor, assignment operator, and destructor.

Note: Other operators that provide access to the underlying interface pointer do not handle reference counting. You may need to explicitly call AddRef or Release (see page 22169) to ensure proper reference counting.

System::DelphiInterface is a template:

```
template <class T> class RTL_DELPHIRETURN DelphiInterface;
```

where the T parameter is an underlying interface class or COM interface. In the object framework, the resulting System::DelphiInterface class is usually given a name such as _di_IUnknown, where IUnknown (see page 22586) is the name of the corresponding interface. Such interfaces are documented under the interface name (such as IFormDesigner).

158.1.5.1 DelphiInterface Members

The following tables list the members exposed by DelphiInterface.

Public Methods

	Name	Description
	~DelphiInterface (see page 22168)	Frees an instance of System::DelphiInterface::DelphiInterface (see page 22168).
	DelphiInterface (see page 22168)	This is the overview for the DelphiInterface constructor overload.
	Release (see page 22169)	This is Release, a member of class DelphiInterface.

Public Operators

	Name	Description
	! (see page 22170)	Indicates whether the System::DelphiInterface::DelphiInterface (see page 22168) object represents a NULL interface.
	& (see page 22170)	Returns a pointer to the underlying interface pointer.
	* (see page 22170)	Returns the underlying interface pointer.
	= (see page 22170)	This is the overview for the = operator overload.
	-> (see page 22171)	Provides access to the properties and methods on the underlying interface.
	T* (see page 22171)	This is T*, a member of class DelphiInterface.

158.1.5.2 DelphiInterface::~DelphiInterface Destructor

Frees an instance of System::DelphiInterface::DelphiInterface (see page 22168).

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~DelphiInterface<T>();
```

Description

Before freeing the System::DelphiInterface::DelphiInterface (see page 22168) instance, System::DelphiInterface (see page 22167)::~DelphiInterface (see page 22167) calls the Release (see page 22169) method of the underlying interface.

158.1.5.3 DelphiInterface Constructor

This is the overview for the DelphiInterface constructor overload.

Overload List

	Name	Description
	DelphiInterface::DelphiInterface () (see page 22168)	Creates an instance of System::DelphiInterface::DelphiInterface (see page 22167).
	DelphiInterface::DelphiInterface (DelphiInterface<ANOTHERINTF> &) (see page 22168)	Creates an instance of System::DelphiInterface::DelphiInterface (see page 22167).
	DelphiInterface::DelphiInterface (DelphiInterface<T> &) (see page 22168)	Creates an instance of System::DelphiInterface::DelphiInterface (see page 22167).
	DelphiInterface::DelphiInterface (T*) (see page 22168)	Creates an instance of System::DelphiInterface::DelphiInterface (see page 22167).

158.1.5.3.1 DelphiInterface::DelphiInterface Constructor ()

Creates an instance of System::DelphiInterface::DelphiInterface (see page 22167).

Pascal

```
constructor Create;
constructor Create(const rhs: DelphiInterface<ANOTHERINTF> &);
constructor Create(const rhs: DelphiInterface<T> &);
constructor Create(var rhs: T);
```

C++

```
__fastcall DelphiInterface<T>();
template <class ANOTHERINTF> __fastcall DelphiInterface<T>(const DelphiInterface<ANOTHERINTF>
& rhs);
__fastcall DelphiInterface<T>(const DelphiInterface<T> & rhs);
__fastcall DelphiInterface<T>(T* rhs);
```

Description

The System::DelphiInterface::DelphiInterface (see page 22167) constructor is overloaded to create a System::DelphiInterface::DelphiInterface (see page 22167) in one of three ways:

When used with no parameters, System::DelphiInterface::DelphiInterface (see page 22167) creates a NULL interface.

When used with another System::DelphiInterface::DelphiInterface (see page 22167) object (the copy constructor), System::DelphiInterface::DelphiInterface (see page 22167) creates a new copy of the interface specified by rhs, incrementing the reference count of the underlying interface.

When used with an interface pointer of the underlying type, System::DelphiInterface::DelphiInterface (see page 22167) wraps the underlying interface specified by rhs and increments its reference count.

158.1.5.4 DelphiInterface Methods

The methods of the DelphiInterface class are listed here.

Public Methods

	Name	Description
	Release (see page 22169)	This is Release, a member of class DelphiInterface.

158.1.5.4.1 DelphiInterface::Release Method

Pascal

```
function Release: Integer;
```

C++

```
int Release();
```

Description

This is Release, a member of class DelphiInterface.

158.1.5.5 DelphiInterface Operators

The operators of the DelphiInterface class are listed here.

Public Operators

	Name	Description
	! (see page 22170)	Indicates whether the System::DelphiInterface::DelphiInterface (see page 22168) object represents a NULL interface.
	& (see page 22170)	Returns a pointer to the underlying interface pointer.
	* (see page 22170)	Returns the underlying interface pointer.
	= (see page 22170)	This is the overview for the = operator overload.
	-> (see page 22171)	Provides access to the properties and methods on the underlying interface.
	T* (see page 22171)	This is T*, a member of class DelphiInterface.

158.1.5.5.1 DelphiInterface::! Operator

Indicates whether the System::DelphiInterface::DelphiInterface (see page 22168) object represents a NULL interface.

Pascal

```
operator !;
```

C++

```
bool operator !() const;
```

Description

The ! System::DelphiInterface (see page 22167)::! returns true if the System::DelphiInterface::DelphiInterface (see page 22168) object represents a NULL interface, and false otherwise.

158.1.5.5.2 DelphiInterface::& Operator

Returns a pointer to the underlying interface pointer.

Pascal

```
operator &;
```

C++

```
__fastcall T** operator &();
```

Description

Use the & System::DelphiInterface (see page 22167)::& to access the underlying interface pointer. Care should be used with this System::DelphiInterface (see page 22167)::&, because it provides no reference counting support. For example, when using this System::DelphiInterface (see page 22167)::& to programmatically replace the underlying interface, you must first call Release (see page 22169) to decrement the reference count of the current interface and, depending on whether you are using this as an additional interface reference, you may need to increment the reference count on the interface being added.

158.1.5.5.3 DelphiInterface::* Operator

Returns the underlying interface pointer.

Pascal

```
operator *;
```

C++

```
__fastcall T& operator *();
```

Description

Use the & System::DelphiInterface (see page 22167)::* to access the underlying interface pointer. Care should be used with this System::DelphiInterface (see page 22167)::*, because it provides no reference counting support. For example, you may need to increment the reference count on the returned value.

158.1.5.5.4 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	DelphiInterface::= (DelphiInterface<ANOTHERINTF> &) (see page 22171)	Assigns a value to the System::DelphiInterface::DelphiInterface (see page 22168).
	DelphiInterface::= (DelphiInterface<T> &) (see page 22171)	Assigns a value to the System::DelphiInterface::DelphiInterface (see page 22168).
	DelphiInterface::= (T *) (see page 22171)	Assigns a value to the System::DelphiInterface::DelphiInterface (see page 22168).

158.1.5.5.4.1 DelphiInterface::= Operator (DelphiInterface<ANOTHERINTF> &)

Assigns a value to the System::DelphiInterface::DelphiInterface (see page 22168).

Pascal

```
operator =(var rhs: DelphiInterface<ANOTHERINTF>);
operator =(var rhs: DelphiInterface<T>);
operator =(var rhs: T);
```

C++

```
template <class ANOTHERINTF> __fastcall DelphiInterface<T>& operator
=(DelphiInterface<ANOTHERINTF> & rhs);
__fastcall DelphiInterface<T>& operator =(DelphiInterface<T> & rhs);
__fastcall DelphiInterface<T>& operator =(T * rhs);
```

Description

The assignment System::DelphiInterface (see page 22167)::= assigns a value to the underlying interface from an interface pointer of the underlying type or from another System::DelphiInterface::DelphiInterface (see page 22168) object that wraps the same interface type.

This System::DelphiInterface (see page 22167)::= manages all reference counting issues. That is, it decrements the reference count on the current interface (if any) before making the assignment and increments the reference count on the newly assigned interface (if any).

158.1.5.5.5 DelphiInterface::-> Operator

Provides access to the properties and methods on the underlying interface.

Pascal

```
operator ->;
```

C++

```
__fastcall T* operator ->() const;
```

Description

Use the System::DelphiInterface (see page 22167)::-> to access the properties and methods of the underlying interface. If the underlying interface is a dual interface, the System::DelphiInterface (see page 22167)::-> makes a vtable call.

158.1.5.5.6 DelphiInterface::T* Operator

Pascal

```
operator T*;
```

C++

```
__fastcall operator T*() const;
```

Description

This is T*, a member of class DelphiInterface.

158.1.6 DynamicArray Template

System::DynamicArray is the C++ analog for the Delphi dynamic array type.

Class Hierarchy

Pascal

```
DynamicArray = class;
```

C++

```
template <class T>
class DynamicArray;
```

File

sysdyn.h

Description

A Dynamic Array is a resizable collection implemented as an array. The System::DynamicArray template is a C++ implementation of Delphi Dynamic Array types. The System::DynamicArray template uses a binary layout compatible with the Delphi Dynamic Array implementation.

```
template <class T> class DELPHIRETURN DynamicArray;
```

You must specify one template parameter:

Parameter	Usage
type	the type of the elements

Length (see page 22181) of dynamic arrays

The size of a System::DynamicArray can be set or obtained from the Length (see page 22181) property:

//C++ example

```
DynamicArray<int> arrayOfInt;
arrayOfInt.Length = 10;
cout << "ArrayLength: " << arrayOfInt.Length << endl;
```

To free a System::DynamicArray, assign it a Length (see page 22181) of zero.

Accessing data

Access elements of a Dynamic Array via the subscript [] operator:

//C++ example

```
void InitArray(DynamicArray<char> &c_array)
{
  c_array[0] = 'A';
  c_array[1] = 'B';
```

```
  cout << "Third char is: " << c_array[2];
}
```

Bounds of dynamic arrays

The Low (see page 22182) and High (see page 22181) properties of System::DynamicArrays return the low and high bounds of the array respectively.

//C++ example

```
int TotalArray(const DynamicArray<int>& arrayOfInt)
{
int total=0;
for (int i=arrayOfInt.Low; i<=arrayOfInt.High; i++)
    total += arrayOfInt[i];
return total;
}
```

Note: The Low (see page 22182) property always returns 0. The High (see page 22181) property returns Length (see page 22181)-1. So you may also traverse a dynamic array via the following construct:

for (int i=0; i<arrayOfInt. Length (see page 22181); i++)

Assigning, comparing and copying dynamic arrays

Dynamic Arrays are reference counted. When a System::DynamicArray is assigned to another, only the reference is assigned (and the reference count adjusted), the content of the source is not copied. Similarly, when two Dynamic Arrays are compared, only the references are compared, not the contents. To copy the contents of a System::DynamicArray, you must use the Copy (see page 22176) (or CopyRange (see page 22177)) methods.

//C++ example

```
void foo(DynamicArray<int> &i_array)
{
  DynamicArray<int> temp = i_array;
  assert(temp == i_array); // temp and i_array point to same chunk
                           // of data..
  i_array[0] = 20;
  assert(temp[0] == 20); // Temp 'sees' changes to i_array..
  temp = i_array.Copy(); // Temp gets its own copy of data
  temp[0] = 10;
  assert(temp[0] != i_array[0]); // Above assignment did not
                                 // modify i_array.
}
```

Multidimensional dynamic arrays

Dynamic arrays can be multidimensional. Multidimensional dynamic arrays don't have to be rectangular. The Length (see page 22181) property can be used to set each dimension. The following example illustrates.

//C++ example

```
typedef DynamicArray< DynamicArray < AnsiString > > T2DStringArray;
void foo(T2DStringArray &s_array)
{
  SetLength(s_array, 10);
for (int i=0; i<s_array.Length; i++)
  { // Set lengths of second dimensions.(NOTE: non-rectangular)
    SetLength(s_array[i], i+1);
for (int j=0; j<s_array[i].Length; j++)
    /* */ s_array[i][j] = itoa(i*10+j);
  }
}
```

C++ & Delphi System::DynamicArrays

A dynamic array declared in C++ code can be used in Delphi code and vice versa. The following examples illustrate passing a

one-dimensional and two-dimensional array between C++ and Delphi.

C++ System::DynamicArray Example

Delphi System::DynamicArray Example

158.1.6.1 DynamicArray Members

The following tables list the members exposed by DynamicArray.

Protected Methods

	Name	Description
	AllocData (see page 22176)	This is AllocData, a member of class DynamicArray.
	DecRefCount (see page 22177)	This is DecRefCount, a member of class DynamicArray.
	FreeData (see page 22178)	This is FreeData, a member of class DynamicArray.
	IncRefCount (see page 22178)	This is IncRefCount, a member of class DynamicArray.
	SetData (see page 22179)	This is SetData, a member of class DynamicArray.

Public Methods

	Name	Description
	~DynamicArray (see page 22174)	Frees a DynamicArray (see page 22172) object.
	Copy (see page 22176)	This is the overview for the Copy method overload.
	CopyRange (see page 22176)	This is the overview for the CopyRange method overload.
	DimCount (see page 22177)	This is DimCount, a member of class DynamicArray.
	DynamicArray (see page 22175)	This is the overview for the DynamicArray constructor overload.
	get_high (see page 22178)	This is get_high, a member of class DynamicArray.
	get_length (see page 22178)	This is get_length, a member of class DynamicArray.
	get_low (see page 22178)	This is get_low, a member of class DynamicArray.
	set_length (see page 22179)	This is set_length, a member of class DynamicArray.

Public Operators

	Name	Description
	[] (see page 22179)	This is the overview for the [] operator overload.
	= (see page 22180)	Assigns data from another Dynamic Array.
	== (see page 22180)	Compares two Dynamic Arrays for equality.

Public Properties

	Name	Description
R	High (see page 22181)	Indicates the high bounds of the array.
	Length (see page 22181)	Represents the number of elements in the DynamicArray (see page 22172).
R	Low (see page 22182)	Indicates the low bound of a dynamic array.

158.1.6.2 DynamicArray::~DynamicArray Destructor

Frees a DynamicArray (see page 22172) object.

Pascal

```
destructor Destroy;
```

C++

```
~DynamicArray();
```

Description

Don't call the dynamic array destructor. To free a dynamically allocated DynamicArray (see page 22172), assign it a Length (

see page 22181) of zero. (DynamicArray (see page 22172) instances on the stack are freed when they go out of scope).

158.1.6.3 DynamicArray Constructor

This is the overview for the DynamicArray constructor overload.

Overload List

	Name	Description
	DynamicArray::DynamicArray () (see page 22175)	Creates and initializes a System::DynamicArray::DynamicArray (see page 22172) object.
	DynamicArray::DynamicArray (DynamicArray<T>&) (see page 22175)	Creates and initializes a System::DynamicArray::DynamicArray (see page 22172) object.

158.1.6.3.1 DynamicArray::DynamicArray Constructor ()

Creates and initializes a System::DynamicArray::DynamicArray (see page 22172) object.

Pascal

```
constructor Create;
constructor Create(const src: DynamicArray<T>&);
```

C++

```
DynamicArray();
DynamicArray(const DynamicArray<T>& src);
```

Description

When called with no parameters, the constructor creates an empty dynamic array. Otherwise, it copies another System::DynamicArray::DynamicArray (see page 22172).

158.1.6.4 DynamicArray Methods

The methods of the DynamicArray class are listed here.

Protected Methods

	Name	Description
	AllocData (see page 22176)	This is AllocData, a member of class DynamicArray.
	DecRefCount (see page 22177)	This is DecRefCount, a member of class DynamicArray.
	FreeData (see page 22178)	This is FreeData, a member of class DynamicArray.
	IncRefCount (see page 22178)	This is IncRefCount, a member of class DynamicArray.
	SetData (see page 22179)	This is SetData, a member of class DynamicArray.

Public Methods

	Name	Description
	Copy (see page 22176)	This is the overview for the Copy method overload.
	CopyRange (see page 22176)	This is the overview for the CopyRange method overload.
	DimCount (see page 22177)	This is DimCount, a member of class DynamicArray.
	get_high (see page 22178)	This is get_high, a member of class DynamicArray.
	get_length (see page 22178)	This is get_length, a member of class DynamicArray.
	get_low (see page 22178)	This is get_low, a member of class DynamicArray.

	set_length (see page 22179)	This is set_length, a member of class DynamicArray.

158.1.6.4.1 DynamicArray::AllocData Method

Pascal

```
function AllocData(count: Integer): T*; static;
```

C++

```
static T* AllocData(int count);
```

Description

This is AllocData, a member of class DynamicArray.

158.1.6.4.2 Copy Method

This is the overview for the Copy method overload.

Overload List

	Name	Description
	DynamicArray::Copy () (see page 22176)	Copies the contents of a DynamicArray (see page 22172) to the specified DynamicArray (see page 22172).
	DynamicArray::Copy (DynamicArray<T> &) (see page 22176)	Copies the contents of a DynamicArray (see page 22172) to the specified DynamicArray (see page 22172).

158.1.6.4.2.1 DynamicArray::Copy Method ()

Copies the contents of a DynamicArray (see page 22172) to the specified DynamicArray (see page 22172).

Pascal

```
function Copy: DynamicArray<T>;
procedure Copy(var dst: DynamicArray<T>);
```

C++

```
DynamicArray<T> Copy() const;
void Copy(DynamicArray<T> & dst) const;
```

Description

Use System::DynamicArray::Copy to make a copy of a dynamic array. Dynamic arrays are reference counted. Therefore assigning one to another simply copies the reference, not the data. The System::DynamicArray::Copy method, on the other hand, makes a separate copy of the dynamic array. The original contents of the destination array are discarded.

The following code copies the contents of i_array into temp; temp and i_array must be of the same DynamicArray (see page 22172) type.

```
temp = i_array.Copy();
```

See Also

CopyRange

158.1.6.4.3 CopyRange Method

This is the overview for the CopyRange method overload.

Overload List

	Name	Description
	DynamicArray::CopyRange (DynamicArray<T> &, int, int) (see page 22177)	Copies a range of the contents of a DynamicArray (see page 22172) within a specified range.
	DynamicArray::CopyRange (int, int) (see page 22177)	Copies a range of the contents of a DynamicArray (see page 22172) within a specified range.

158.1.6.4.3.1 DynamicArray::CopyRange Method (DynamicArray<T> &, int, int)

Copies a range of the contents of a DynamicArray (see page 22172) within a specified range.

Pascal

```
function CopyRange(startIndex: Integer; count: Integer): DynamicArray<T>;
procedure CopyRange(var dst: DynamicArray<T>; startIndex: Integer; count: Integer);
```

C++

```
DynamicArray<T> CopyRange(int startIndex, int count) const;
void CopyRange(DynamicArray<T> & dst, int startIndex, int count) const;
```

Description

Use the System::DynamicArray::CopyRange method to copy a subrange of a dynamic array. The System::DynamicArray::CopyRange method is similar to the Copy (see page 22176) method except that you can specify the startIndex and the number of items to copy from the source object. The size of the destination array will be truncated or expanded to accommodate what has been copied.

newArray = array.System::DynamicArray::CopyRange(3, 5);

See Also

Copy

158.1.6.4.4 DynamicArray::DecRefCount Method

Pascal

```
procedure DecRefCount;
```

C++

```
void DecRefCount();
```

Description

This is DecRefCount, a member of class DynamicArray.

158.1.6.4.5 DynamicArray::DimCount Method

Pascal

```
function DimCount: Integer; static;
```

C++

```
static int DimCount();
```

Description

This is DimCount, a member of class DynamicArray.

158.1.6.4.6 DynamicArray::FreeData Method

Pascal

```
procedure FreeData;
```

C++

```
void FreeData();
```

Description

This is FreeData, a member of class DynamicArray.

158.1.6.4.7 DynamicArray::get_high Method

Pascal

```
function get_high: Integer;
```

C++

```
int get_high() const;
```

Description

This is get_high, a member of class DynamicArray.

158.1.6.4.8 DynamicArray::get_length Method

Pascal

```
function get_length: Integer;
```

C++

```
int get_length() const;
```

Description

This is get_length, a member of class DynamicArray.

158.1.6.4.9 DynamicArray::get_low Method

Pascal

```
function get_low: Integer;
```

C++

```
int get_low() const;
```

Description

This is get_low, a member of class DynamicArray.

158.1.6.4.10 DynamicArray::IncRefCount Method

Pascal

```
procedure IncRefCount;
```

C++

```
void IncRefCount();
```

Description

This is IncRefCount, a member of class DynamicArray.

158.1.6.4.11 DynamicArray::set_length Method

Pascal

```
procedure set_length(l: Integer);
```

C++

```
void set_length(int l);
```

Description

This is set_length, a member of class DynamicArray.

158.1.6.4.12 DynamicArray::SetData Method

Pascal

```
procedure SetData(var t: T);
```

C++

```
void SetData(T* t);
```

Description

This is SetData, a member of class DynamicArray.

158.1.6.5 DynamicArray Operators

The operators of the DynamicArray class are listed here.

Public Operators

	Name	Description
	[] (see page 22179)	This is the overview for the [] operator overload.
	= (see page 22180)	Assigns data from another Dynamic Array.
	== (see page 22180)	Compares two Dynamic Arrays for equality.

158.1.6.5.1 [] Operator

This is the overview for the [] operator overload.

Overload List

	Name	Description
	DynamicArray::[] (int) (see page 22179)	Provides access to the data held by the dynamic array.
	DynamicArray::[] (int) (see page 22179)	Provides access to the data held by the dynamic array.

158.1.6.5.1.1 DynamicArray::[] Operator (int)

Provides access to the data held by the dynamic array.

Pascal

```
operator [](index: Integer);
operator [](index: Integer);
```

C++

```
T& operator [](int index);
T operator [](int index) const;
```

Description

The const version of the System::DynamicArray (see page 22172)::[] returns a copy of the data at the specified subscript. The non-const version returns a reference to the data, allowing you to modify the data.

cout << i_array[0]=10;

158.1.6.5.2 DynamicArray::= Operator

Assigns data from another Dynamic Array.

Pascal

```
operator =(const src: DynamicArray<T>&);
```

C++

```
DynamicArray& operator =(const DynamicArray<T>& src);
```

Description

Dynamic Arrays are reference counted. When a DynamicArray (see page 22172) is assigned to another, only the reference is assigned (and the reference count adjusted), the contents of the source are not copied. Similarly, when two Dynamic Arrays are compared, only the references are compared, not the contents. To create a separate copy of the contents of a DynamicArray (see page 22172), use the Copy (see page 22176) (or CopyRange (see page 22177)) method.

See Also

Copy

158.1.6.5.3 DynamicArray::== Operator

Compares two Dynamic Arrays for equality.

Pascal

```
operator ==(const other: DynamicArray<T> &);
```

C++

```
bool operator ==(const DynamicArray<T> & other) const;
```

Description

The == System::DynamicArray (see page 22172)::== determines whether two dynamic arrays refer to the same memory. It does not compare the contents of the arrays.

158.1.6.6 DynamicArray Properties

The properties of the DynamicArray class are listed here.

Public Properties

	Name	Description
R	High (see page 22181)	Indicates the high bounds of the array.
	Length (see page 22181)	Represents the number of elements in the DynamicArray (see page 22172).
R	Low (see page 22182)	Indicates the low bound of a dynamic array.

158.1.6.6.1 DynamicArray::High Property

Indicates the high bounds of the array.

Pascal

```
property High: Integer;
```

C++

```
__property int High;
```

Description

Reading the High property returns Length (see page 22181)-1.

The following function returns the sum of the contents of an integer type DynamicArray (see page 22172).

int TotalArray(const DynamicArray (see page 22172)<int>& arrayOfInt)

```
{
int total=0;
for (int i=arrayOfInt.Low; i<=arrayOfInt.High; i++)
    total += arrayOfInt[i];
return total;
}
```

See Also

Length

Low

158.1.6.6.2 DynamicArray::Length Property

Represents the number of elements in the DynamicArray (see page 22172).

Pascal

```
property Length: Integer;
```

C++

```
__property int Length;
```

Description

Use the Length property to set or get the length of the dynamic array. The following code sets the length of a DynamicArray (see page 22172) to 10.

DynamicArray (see page 22172)<int> arrayOfInt;

```
arrayOfInt.Length = 10;
cout << "ArrayLength: " << arrayOfInt.Length << endl;
```

SetLength (see page 22522)(arrayOfInt, 10);

To free a dynamic array, simply set its Length to 0:

arrayOfInt.Length = 0;

See Also

High

158.1.6.6.3 DynamicArray::Low Property

Indicates the low bound of a dynamic array.

Pascal

```
property Low: Integer;
```

C++

```
__property int Low;
```

Description

The Low property always returns 0. The following function returns the sum of the contents of an integer type DynamicArray (see page 22172).

int TotalArray(const DynamicArray (see page 22172)<int>& arrayOfInt)

```
{
int total=0;
for (int i=arrayOfInt.Low; i<=arrayOfInt.High; i++)
    total += arrayOfInt[i];
return total;
}
```

High

158.1.7 DynArrayException Class

Class Hierarchy

System::DynArrayException

Pascal

```
DynArrayException = class;
```

C++

```
class DynArrayException;
```

File

sysdyn.h

Description

This is class System::DynArrayException.

158.1.8 DynArrayNullData Class

Class Hierarchy

Pascal

```
DynArrayNullData = class(DynArrayException);
```

C++

```
class DynArrayNullData : public DynArrayException;
```

File

sysdyn.h

Description

This is class System::DynArrayNullData.

158.1.9 DynArrayOutOfRange Class

Class Hierarchy

Pascal

```
DynArrayOutOfRange = class(DynArrayException);
```

C++

```
class DynArrayOutOfRange : public DynArrayException;
```

File

sysdyn.h

Description

This is class System::DynArrayOutOfRange.

158.1.9.1 DynArrayOutOfRange Members

The following tables list the members exposed by DynArrayOutOfRange.

Public Data Members

	Name	Description
	m_Count (see page 22184)	This is m_Count, a member of class DynArrayOutOfRange.
	m_Index (see page 22184)	This is m_Index, a member of class DynArrayOutOfRange.

Public Methods

	Name	Description
	DynArrayOutOfRange (see page 22184)	This is DynArrayOutOfRange, a member of class DynArrayOutOfRange.

158.1.9.2 DynArrayOutOfRange::DynArrayOutOfRange Constructor

Pascal

```
constructor Create(index: Integer; count: Integer);
```

C++

```
DynArrayOutOfRange(int index, int count);
```

Description

This is DynArrayOutOfRange, a member of class DynArrayOutOfRange.

158.1.9.3 DynArrayOutOfRange Data Members

The data members of the DynArrayOutOfRange class are listed here.

Public Data Members

	Name	Description
	m_Count (see page 22184)	This is m_Count, a member of class DynArrayOutOfRange.
	m_Index (see page 22184)	This is m_Index, a member of class DynArrayOutOfRange.

158.1.9.3.1 DynArrayOutOfRange::m_Count Data Member

Pascal

```
m_Count: Integer;
```

C++

```
int m_Count;
```

Description

This is m_Count, a member of class DynArrayOutOfRange.

158.1.9.3.2 DynArrayOutOfRange::m_Index Data Member

Pascal

```
m_Index: Integer;
```

C++

```
int m_Index;
```

Description

This is m_Index, a member of class DynArrayOutOfRange.

158.1.10 Function Class

System::Function represents a method on an Automation interface that returns a value.

Class Hierarchy

Pascal

```
Function = class(AutoCmd);
```

C++

```
class Function : public AutoCmd;
```

File

sysvari.h

Description

The System::Function class represents a single method on an Automation interface that is assigned as the value of a Variant (see page 22307). It can be executed using the Variant (see page 22307)'s Exec method.

Each System::Function instance is assigned a name, which is the same as the name of the corresponding method on the interface. In addition, it can be assigned parameters that correspond to the parameters of the method. These parameters can be stored by position or by name.

See Also

System::Variant (see page 22307)

System::Procedure (see page 22230)

PropertyGet

PropertySet

158.1.10.1 Function Members

The following tables list the members exposed by Function.

Protected Data Members

	Name	Description
	Name (see page 22130)	This is Name, a member of class AutoCmd.
	NamedParmNames (see page 22130)	This is NamedParmNames, a member of class AutoCmd.
	NamedParms (see page 22130)	This is NamedParms, a member of class AutoCmd.
	NamedParmTypes (see page 22131)	This is NamedParmTypes, a member of class AutoCmd.
	Parms (see page 22131)	This is Parms, a member of class AutoCmd.
	ParmTypes (see page 22131)	This is ParmTypes, a member of class AutoCmd.

Protected Methods

	Name	Description
	AddElement (see page 22132)	This is AddElement, a member of class AutoCmd.

Public Methods

	Name	Description
	~AutoCmd (see page 22129)	Frees an System::AutoCmd::AutoCmd (see page 22129) object.
	AutoCmd (see page 22129)	This is the overview for the AutoCmd constructor overload.
	Clear (see page 22132)	System::AutoCmd::Clears any assigned parameters and blanks the name of the associated method.
	ClearArgs (see page 22132)	Clears any assigned parameters.
	ClearName (see page 22133)	Blanks the name of the associated method.
	Function (see page 22186)	This is the overview for the Function constructor overload.
	GetArgCount (see page 22133)	Returns the number of positional arguments that have been assigned.
	GetArgType (see page 22134)	Returns the type of a parameter value.

	GetCallType (see page 22187)	Indicates the type of the interface method represented by the System::Function::Function (see page 22186) object.
	GetName (see page 22134)	Returns the name of the interface method this System::AutoCmd::AutoCmd (see page 22129) object represents.
	GetNamedArgCount (see page 22135)	Returns the number of named arguments that have been assigned.
	GetNamedArgType (see page 22135)	Returns the type of a named parameter value.
	GetNamedParm (see page 22136)	Returns the value of a named parameter.
	GetNamedParmName (see page 22136)	Returns the named of a named parameter value.
	GetParm (see page 22137)	Returns the value of a positional parameter.
	RequestResult (see page 22187)	Indicates that the interface method returns a value.
	SetName (see page 22138)	Sets the name of the method the System::AutoCmd::AutoCmd (see page 22129) object represents.

Public Operators

	Name	Description
	<< (see page 22138)	This is the overview for the << operator overload.

158.1.10.2 Function Constructor

This is the overview for the Function constructor overload.

Overload List

	Name	Description
	Function::Function (AutoCmd&) (see page 22186)	Creates an instance of System::Function::Create for a specified method.
	Function::Function (String&) (see page 22186)	Creates an instance of System::Function::Create for a specified method.

158.1.10.2.1 Function::Function Constructor (AutoCmd&)

Creates an instance of System::Function::Create for a specified method.

Pascal

```
constructor Create(const name: String&);
constructor Create(const src: AutoCmd&);
```

C++

```
Function(const String& name);
Function(const AutoCmd& src);
```

Description

System::Function::Create has two constructors: a version that takes the name of the method it represents, and a copy constructor. When creating a new System::Function::Create object for a method, the name parameter must be the same as the name of the method as it appears in the interface declaration.

158.1.10.3 Function Methods

The methods of the Function class are listed here.

Public Methods

	Name	Description
	GetCallType (see page 22187)	Indicates the type of the interface method represented by the System::Function::Function (see page 22186) object.
	RequestResult (see page 22187)	Indicates that the interface method returns a value.

158.1.10.3.1 Function::GetCallType Method

Indicates the type of the interface method represented by the System::Function::Function (see page 22186) object.

Pascal

```
function GetCallType: Byte;
```

C++

```
Byte GetCallType() const;
```

Description

Call System::Function::GetCallType to determine the type of flag needed to call the method represented by System::Function::Function (see page 22186) using the IDispatch::Invoke method of the Automation interface. System::Function::GetCallType returns DISPATCH_METHOD, indicating a method that is not a property access method.

158.1.10.3.2 Function::RequestResult Method

Indicates that the interface method returns a value.

Pascal

```
function RequestResult: bool;
```

C++

```
bool RequestResult() const;
```

Description

System::Function::RequestResult always returns true, indicating that there is a return value after executing the System::Function::Function (see page 22186) object using the Variant::Exec method.

See Also

System::Function::GetCallType (see page 22187)

System::Variant::Exec (see page 22320)

158.1.11 NamedParm Class

NamedParm represents a named parameter assigned to a TAutoCmd descendant.

Class Hierarchy

System::NamedParm

Pascal

```
NamedParm = class;
```

C++

```
class NamedParm;
```

File

sysvari.h

Description

The NamedParm class represents a named parameter that can be assigned as an argument to one of the AutoCmd (see page 22127) descendants (PropertyGet (see page 22233), PropertySet (see page 22236), Procedure (see page 22230), or Function (see page 22184)).

NamedParm overloads the constructor to let you assign a variety of types as the value of the parameter. It also defines methods for retrieving the name, value, or type of the parameter.

See Also

PropertyGet

System::Function (see page 22184)

System::Procedure (see page 22230)

PropertySet

System::AutoCmd (see page 22127)

158.1.11.1 NamedParm Members

The following tables list the members exposed by NamedParm.

Protected Data Members

	Name	Description
	Name (see page 22191)	This is Name, a member of class NamedParm.
	Parm (see page 22191)	This is Parm, a member of class NamedParm.
	Type (see page 22192)	This is Type, a member of class NamedParm.

Protected Methods

	Name	Description
	AddElement (see page 22192)	This is AddElement, a member of class NamedParm.

Public Methods

	Name	Description
	GetParm (see page 22192)	Returns the value of the parameter.
	GetParmName (see page 22193)	Returns the name of the parameter.
	GetType (see page 22193)	Returns the type of the parameter's value.
	NamedParm (see page 22188)	This is the overview for the NamedParm constructor overload.

158.1.11.2 NamedParm Constructor

This is the overview for the NamedParm constructor overload.

Overload List

	Name	Description
	NamedParm::NamedParm (String&, AnsiString&) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, bool) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, Byte) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, Byte*) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, char*) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, Currency) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, Currency*) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, double) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, double*) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, float) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, float*) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, IDispatch* const) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, IInterface* const) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, int) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, int*) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, IUnknown* const) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, short) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, short*) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, String*) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, TDateTime) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, TDateTime*) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, Variant&) (see page 22190)	Creates an instance of Create for a specified method.

	NamedParm::NamedParm (String&, Variant*) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, wchar_t*) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, wchar_t**) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, WordBool) (see page 22190)	Creates an instance of Create for a specified method.
	NamedParm::NamedParm (String&, WordBool*) (see page 22190)	Creates an instance of Create for a specified method.

158.1.11.2.1 NamedParm::NamedParm Constructor (String&, AnsiString&)

Creates an instance of Create for a specified method.

Pascal

```
constructor Create(const name: String&; const arg: Variant&);
constructor Create(const name: String&; const arg: short);
constructor Create(const name: String&; const arg: Integer);
constructor Create(const name: String&; const arg: float);
constructor Create(const name: String&; const arg: double);
constructor Create(const name: String&; const arg: Currency);
constructor Create(const name: String&; const arg: TDateTime);
constructor Create(const name: String&; const arg: bool);
constructor Create(const name: String&; const arg: WordBool);
constructor Create(const name: String&; const arg: Byte);
constructor Create(const name: String&; const arg: AnsiString&);
constructor Create(const name: String&; const arg: char*);
constructor Create(const name: String&; var arg: wchar_t);
constructor Create(const name: String&; arg: IDispatch* const);
constructor Create(const name: String&; arg: IUnknown* const);
constructor Create(const name: String&; arg: IInterface* const);
constructor Create(const name: String&; var arg: Variant);
constructor Create(const name: String&; var arg: short);
constructor Create(const name: String&; var arg: Integer);
constructor Create(const name: String&; var arg: float);
constructor Create(const name: String&; var arg: double);
constructor Create(const name: String&; var arg: Currency);
constructor Create(const name: String&; var arg: TDateTime);
constructor Create(const name: String&; var arg: WordBool);
constructor Create(const name: String&; var arg: Byte);
constructor Create(const name: String&; var arg: wchar_t*);
constructor Create(const name: String&; var arg: String);
```

C++

```
NamedParm(const String& name, const Variant& arg);
NamedParm(const String& name, const short arg);
NamedParm(const String& name, const int arg);
NamedParm(const String& name, const float arg);
NamedParm(const String& name, const double arg);
NamedParm(const String& name, const Currency arg);
NamedParm(const String& name, const TDateTime arg);
NamedParm(const String& name, const bool arg);
NamedParm(const String& name, const WordBool arg);
NamedParm(const String& name, const Byte arg);
NamedParm(const String& name, const AnsiString& arg);
NamedParm(const String& name, const char* arg);
NamedParm(const String& name, wchar_t* arg);
NamedParm(const String& name, IDispatch* const arg);
```

```
NamedParm(const String& name, IUnknown* const arg);
NamedParm(const String& name, IInterface* const arg);
NamedParm(const String& name, Variant* arg);
NamedParm(const String& name, short* arg);
NamedParm(const String& name, int* arg);
NamedParm(const String& name, float* arg);
NamedParm(const String& name, double* arg);
NamedParm(const String& name, Currency* arg);
NamedParm(const String& name, TDateTime* arg);
NamedParm(const String& name, WordBool* arg);
NamedParm(const String& name, Byte* arg);
NamedParm(const String& name, wchar_t** arg);
NamedParm(const String& name, String* arg);
```

Description

Pass the Create constructor two arguments: the name of the parameter it represents (name), and the value to assign to that parameter (arg).

158.1.11.3 NamedParm Data Members

The data members of the NamedParm class are listed here.

Protected Data Members

	Name	Description
	Name (see page 22191)	This is Name, a member of class NamedParm.
	Parm (see page 22191)	This is Parm, a member of class NamedParm.
	Type (see page 22192)	This is Type, a member of class NamedParm.

158.1.11.3.1 NamedParm::Name Data Member

Pascal

```
Name: String;
```

C++

```
String Name;
```

Description

This is Name, a member of class NamedParm.

158.1.11.3.2 NamedParm::Parm Data Member

Pascal

```
Parm: Variant;
```

C++

```
Variant Parm;
```

Description

This is Parm, a member of class NamedParm.

158.1.11.3.3 NamedParm::Type Data Member

Pascal

```
Type: Integer;
```

C++

```
int Type;
```

Description

This is Type, a member of class NamedParm.

158.1.11.4 NamedParm Methods

The methods of the NamedParm class are listed here.

Protected Methods

	Name	Description
	AddElement (see page 22192)	This is AddElement, a member of class NamedParm.

Public Methods

	Name	Description
	GetParm (see page 22192)	Returns the value of the parameter.
	GetParmName (see page 22193)	Returns the name of the parameter.
	GetType (see page 22193)	Returns the type of the parameter's value.

158.1.11.4.1 NamedParm::AddElement Method

Pascal

```
procedure AddElement;
```

C++

```
void AddElement();
```

Description

This is AddElement, a member of class NamedParm.

158.1.11.4.2 NamedParm::GetParm Method

Returns the value of the parameter.

Pascal

```
function GetParm: Variant;
```

C++

```
Variant GetParm() const;
```

Description

Call GetParm to obtain the value that was assigned to the named parameter by the constructor. The value is always returned as a Variant (see page 22307). To determine the underlying type of this value, use the GetType (see page 22193) method.

See Also

namedParm

GetType

158.1.11.4.3 NamedParm::GetParmName Method

Returns the name of the parameter.

Pascal

```
function GetParmName: String;
```

C++

```
String GetParmName() const;
```

Description

GetParmName returns the name that was assigned to the parameter by the constructor.

See Also

GetParm

NamedParm

158.1.11.4.4 NamedParm::GetType Method

Returns the type of the parameter's value.

Pascal

```
function GetType: Integer;
```

C++

```
int GetType() const;
```

Description

Call GetType to determine the type of the parameter's value. GetType returns one of the constants declared in the System (see page 22079) unit to represent the types of Variant (see page 22307) values. As such, it returns the value you would obtain by calling VarType on the Variant (see page 22307) returned by GetParm (see page 22192).

Note: A list of the possible return values is included in the topic for VarType.

See Also

GetParm

158.1.12 OleVariant Template

System::OleVariant is a C++ implementation of the Delphi intrinsic type System::OleVariant.

Class Hierarchy

Pascal

```
OleVariant = class(Variant);
```

C++

```
template <class P1, class P2, class P3, class P4, class P5, class P6, class P7, class P8,
```

```
class P9, class P10>
class OleVariant : protected Variant;
```

File

sysvari.h

Description

System::OleVariant is a special descendant of the Variant (see page 22307) class that is used to represent COM interfaces or data that is passed over a COM interface. System::OleVariant inherits from Variant (see page 22307) as a protected class so that it can prevent operations on AnsiString (see page 22093) objects, which are not compatible with COM.

The syntax for using System::OleVariant is the same as that for using the Variant (see page 22307) class. Like the Variant (see page 22307) class, System::OleVariant has the following characteristics:

System::OleVariants can contain integer values, real values, string values, boolean values, date-and-time values, and Automation objects. In addition, System::OleVariants can contain arrays of varying size and dimension with elements of any of these types.

The special System::OleVariant value Unassigned is used to indicate that a System::OleVariant has not yet been assigned a value, and the special System::OleVariant value Null is used to indicate unknown or missing data.

A System::OleVariant can be combined with other System::OleVariants and it can be constructed from any of the following data types. The compiler automatically performs the necessary type conversions.

shortWordBool

intByte

floatVariant

doubleWideString

Currencywchar_t*

TDateTimeOle2::IDispatch (see page 22394)*

boolOle2::IUnknown (see page 22586)*

When an System::OleVariant contains an Automation object, the System::OleVariant can be used to get and set properties of the object, and to invoke methods on the object.

System::OleVariant variables are always initialized to be Unassigned when they are first created. This is true whether a System::OleVariant variable is global, local, or part of a structure such as an array.

Note that while System::OleVariants offer great flexibility, they also consume more memory than regular variables, and operations on System::OleVariants are substantially slower than operations on statically typed values.

Note: Use only the operators declared within System::OleVariant. The compiler will ignore any operators you overload yourself.

Note: For binary operators, if one operand is of type System::OleVariant, the other operand is automatically converted to type System::OleVariant.

See Also

System::Variant (see page 22307)

TVariantT

158.1.12.1 OleVariant Members

The following tables list the members exposed by OleVariant.

Public Friends

Name	Description
class AutoCmd (see page 22375)	This is friend class AutoCmd.

Public Methods

	Name	Description
	~OleVariant (see page 22197)	Frees an instance of System::OleVariant::OleVariant (see page 22200).
	~Variant (see page 22311)	Frees a System::Variant::Variant (see page 22314) object.
	ArrayDimCount (see page 22317)	Returns the number of dimensions of the given variant.
	ArrayHighBound (see page 22317)	Returns the high bound of the given dimension in the given variant array.
	ArrayLock (see page 22317)	Locks the given variant array and returns a pointer to the data stored in the array.
	ArrayLowBound (see page 22318)	Returns the low bound of the given dimension in the given variant array.
	ArrayRedim (see page 22318)	Resizes the given variant array by changing the high bound of the rightmost dimension to the given value.
	ArrayUnlock (see page 22318)	Unlocks a variant array that was previously locked by ArrayLock (see page 22317).
	Assign (see page 22318)	This is Assign, a member of class Variant.
	AsType (see page 22319)	Casts a System::Variant::Variant (see page 22314) object to the type specified by the argument VarType.
	ChangeType (see page 22319)	Changes the data type of a System::Variant::Variant (see page 22314) object once it has been instantiated.
	Clear (see page 22319)	System::Variant::Clears the value of the System::Variant::Variant (see page 22314).
	CreateObject (see page 22320)	Creates an OLE Automation object with the programmatic identifier specified by ProgID and returns it as a System::Variant::Variant (see page 22314).
	Empty (see page 22320)	This is Empty, a member of class Variant.
	Exec (see page 22320)	System::Variant::Executes an OLE procedure, function, or a property Get or Set method.
	GetActiveObject (see page 22321)	Retrieves a reference to an IDispatch (see page 22394) interface of a currently running, registered OLE Automation object, and returns it as a System::Variant::Variant (see page 22314).
	GetBaseVariant (see page 22321)	Returns the Variant (see page 22307) that is assigned as the value of this Variant (see page 22307) when Type (see page 22341) is varVariant (see page 22690).
	GetElement (see page 22322)	This is the overview for the GetElement method overload.
	GetError (see page 22322)	Converts the System::Variant::Variant (see page 22314) to a varError (see page 22684) type and returns the integer value.
	IsArray (see page 22323)	Queries the VType of the base class TVarData (see page 22571) for the varArray (see page 22679) bit.
	IsEmpty (see page 22323)	Queries the VType of the base class TVarData (see page 22571).
	IsNull (see page 22323)	Queries the VType of the base class TVarData (see page 22571) for the varNull (see page 22686) bit.
	NoParam (see page 22324)	This is NoParam, a member of class Variant.
	OleFunction (see page 22324)	This is the overview for the OleFunction method overload.
	OleProcedure (see page 22330)	This is the overview for the OleProcedure method overload.
	OlePropertyGet (see page 22336)	This is the overview for the OlePropertyGet method overload.
	OlePropertySet (see page 22338)	This is the overview for the OlePropertySet method overload.
	OleVariant (see page 22198)	This is the overview for the OleVariant constructor overload.
	PutElement (see page 22340)	This is the overview for the PutElement method overload.
	Sanitized (see page 22340)	This is Sanitized, a member of class Variant.
	SetError (see page 22341)	Converts the System::Variant::Variant (see page 22314) to a varError (see page 22684) type and assigns the integer err as the value of the varError (see page 22684).
	Type (see page 22341)	This is Type, a member of class Variant.

	Variant (see page 22312)	This is the overview for the Variant constructor overload.

Public Operators

	Name	Description
	- (see page 22343)	This is the overview for the - operator overload.
	! (see page 22344)	Returns a new System::Variant::Variant (see page 22314) that is the logical negation of this System::Variant::Variant (see page 22314).
	!= (see page 22209)	This is the overview for the != operator overload.
	!= (see page 22344)	This is the overview for the != operator overload.
	% (see page 22345)	This is the overview for the % operator overload.
	%= (see page 22346)	Returns this System::Variant::Variant (see page 22314) as the remainder from dividing its original value and the System::Variant::Variant (see page 22314) specified by rhs.
	& (see page 22346)	This is the overview for the & operator overload.
	&= (see page 22347)	Returns this System::Variant::Variant (see page 22314) after performing a bitwise and operation.
	* (see page 22347)	This is the overview for the * operator overload.
	*= (see page 22348)	Multiplies this System::Variant::Variant (see page 22314) by the System::Variant::Variant (see page 22314) specified by rhs.
	/ (see page 22348)	This is the overview for the / operator overload.
	/= (see page 22349)	Divides this System::Variant::Variant (see page 22314) by the System::Variant::Variant (see page 22314) rhs.
	^ (see page 22349)	This is the overview for the ^ operator overload.
	^= (see page 22350)	Returns this System::Variant::Variant (see page 22314) after performing a bitwise xor operation.
	__int64 (see page 22350)	This is __int64, a member of class Variant.
	| (see page 22351)	This is the overview for the | operator overload.
	|= (see page 22351)	Returns this System::Variant::Variant (see page 22314) after performing a bitwise or operation.
	+ (see page 22352)	This is the overview for the + operator overload.
	+= (see page 22352)	Adds the System::Variant::Variant (see page 22314) specified by rhs to this System::Variant::Variant (see page 22314) object.
	< (see page 22210)	This is the overview for the < operator overload.
	< (see page 22353)	This is the overview for the < operator overload.
	<< (see page 22353)	This is the overview for the << operator overload.
	<<= (see page 22354)	Performs a bitwise shl (left shift) operation on this System::Variant::Variant (see page 22314).
	<= (see page 22211)	This is the overview for the <= operator overload.
	<= (see page 22355)	This is the overview for the <= operator overload.
	-= (see page 22361)	Subtracts the System::Variant::Variant (see page 22314) specified by rhs from this System::Variant::Variant (see page 22314) object.
	= (see page 22211)	This is the overview for the = operator overload.
	= (see page 22355)	This is the overview for the = operator overload.
	== (see page 22214)	This is the overview for the == operator overload.
	== (see page 22361)	This is the overview for the == operator overload.
	> (see page 22214)	This is the overview for the > operator overload.
	> (see page 22362)	This is the overview for the > operator overload.
	>= (see page 22215)	This is the overview for the >= operator overload.
	>= (see page 22363)	This is the overview for the >= operator overload.
	>> (see page 22363)	This is the overview for the >> operator overload.
	>>= (see page 22365)	Performs a bitwise shr (right shift) operation on this System::Variant::Variant (see page 22314).
	AnsiString (see page 22365)	Converts the System::Variant::Variant (see page 22314) to an AnsiString object.
	bool (see page 22365)	Converts the System::Variant::Variant (see page 22314) to a boolean value.
	char (see page 22365)	This is char, a member of class Variant.
	Currency (see page 22366)	Converts the System::Variant::Variant (see page 22314) to a Currency object.
	CURRENCY (see page 22366)	This is CURRENCY, a member of class Variant.

	Currency* (see page 22366)	This is Currency*, a member of class Variant.
	DECIMAL (see page 22366)	This is DECIMAL, a member of class Variant.
	double (see page 22367)	Converts the System::Variant::Variant (see page 22314) to a double value.
	double* (see page 22367)	This is double*, a member of class Variant.
	float (see page 22367)	Converts the System::Variant::Variant (see page 22314) to a float value.
	float* (see page 22368)	This is float*, a member of class Variant.
	IDispatch* (see page 22368)	This is IDispatch*, a member of class Variant.
	IInterface* (see page 22368)	This is IInterface*, a member of class Variant.
	int (see page 22368)	Converts the System::Variant::Variant (see page 22314) to an integer value.
	int* (see page 22369)	This is int*, a member of class Variant.
	IUnknown* (see page 22369)	This is IUnknown*, a member of class Variant.
	long (see page 22369)	This is long, a member of class Variant.
	long* (see page 22369)	This is long*, a member of class Variant.
	LPSAFEARRAY (see page 22369)	This is LPSAFEARRAY, a member of class Variant.
	short (see page 22370)	Converts the System::Variant::Variant (see page 22314) to a short value.
	short* (see page 22370)	This is short*, a member of class Variant.
	signed char (see page 22370)	This is signed char, a member of class Variant.
	signed char* (see page 22370)	This is signed char*, a member of class Variant.
	TDateTime (see page 22371)	Converts the System::Variant::Variant (see page 22314) to a TDateTime object.
	TDateTime* (see page 22371)	This is TDateTime*, a member of class Variant.
	TVariant (see page 22371)	This is TVariant, a member of class Variant.
	TVariant* (see page 22371)	This is TVariant*, a member of class Variant.
	unsigned char (see page 22372)	This is unsigned char, a member of class Variant.
	unsigned char* (see page 22372)	This is unsigned char*, a member of class Variant.
	unsigned int (see page 22372)	This is unsigned int, a member of class Variant.
	unsigned int* (see page 22372)	This is unsigned int*, a member of class Variant.
	unsigned long (see page 22373)	This is unsigned long, a member of class Variant.
	unsigned long* (see page 22373)	This is unsigned long*, a member of class Variant.
	unsigned short (see page 22373)	This is unsigned short, a member of class Variant.
	unsigned short* (see page 22373)	This is unsigned short*, a member of class Variant.
	VARIANT (see page 22373)	This is VARIANT, a member of class Variant.
	VARIANT* (see page 22374)	This is VARIANT*, a member of class Variant.
	wchar_t* (see page 22374)	Converts the System::Variant::Variant (see page 22314) to the specified type and sets the varByRef (see page 22680) bit, meaning that the variant contains a reference as opposed to a value.
	wchar_t** (see page 22374)	This is wchar_t**, a member of class Variant.
	WideString (see page 22374)	This is WideString, a member of class Variant.

158.1.12.2 OleVariant::~OleVariant Destructor

Frees an instance of System::OleVariant::OleVariant (see page 22200).

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~OleVariant();
```

Description

~System::OleVariant::OleVariant (see page 22200) is the destructor for System::OleVariant::OleVariant (see page 22200).

158.1.12.3 OleVariant Constructor

This is the overview for the OleVariant constructor overload.

Overload List

	Name	Description
	OleVariant::OleVariant () (see page 22200)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (__int64) (see page 22204)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (__int64*) (see page 22204)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (AnsiString&) (see page 22200)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (bool) (see page 22204)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (char) (see page 22204)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (char*) (see page 22204)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (Currency) (see page 22200)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (CURRENCY&) (see page 22200)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (Currency*) (see page 22201)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (CURRENCY*) (see page 22200)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (double) (see page 22205)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (double*) (see page 22205)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (float) (see page 22205)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (float*) (see page 22205)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (IDispatch* const) (see page 22201)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (IInterface* const) (see page 22201)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (int) (see page 22206)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (int*) (see page 22206)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (int*, int, Word) (see page 22206)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (IUnknown* const) (see page 22201)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (long*) (see page 22206)	This is OleVariant, a member of class OleVariant.

	OleVariant::OleVariant (OleVariant&) (see page 22202)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (OleVariant*, int) (see page 22202)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (short) (see page 22206)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (short*) (see page 22207)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (signed char*) (see page 22207)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (TDateTime) (see page 22202)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (TDateTime*) (see page 22202)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (TVariant&) (see page 22202)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned char) (see page 22207)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned char*) (see page 22207)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned int) (see page 22208)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned int*) (see page 22208)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned long*) (see page 22208)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned short) (see page 22208)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (unsigned short*) (see page 22208)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (Variant&) (see page 22203)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (VARIANT&) (see page 22203)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (VARIANT*) (see page 22203)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (wchar_t* const, bool) (see page 22209)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (wchar_t**) (see page 22209)	This is OleVariant, a member of class OleVariant.
	OleVariant::OleVariant (WideString&) (see page 22203)	This is OleVariant, a member of class OleVariant.

158.1.12.3.1 OleVariant::OleVariant Constructor ()

Pascal

```
constructor Create;
```

C++

```
__fastcall OleVariant();
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.2 OleVariant::OleVariant Constructor (AnsiString&)

Pascal

```
constructor Create(const src: AnsiString&);
```

C++

```
__fastcall OleVariant(const AnsiString& src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.3 OleVariant::OleVariant Constructor (CURRENCY&)

Pascal

```
constructor Create(const src: CURRENCY&);
```

C++

```
__fastcall OleVariant(const CURRENCY& src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.4 OleVariant::OleVariant Constructor (CURRENCY*)

Pascal

```
constructor Create(var src: CURRENCY);
```

C++

```
__fastcall OleVariant(CURRENCY* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.5 OleVariant::OleVariant Constructor (Currency)

Pascal

```
constructor Create(const src: Currency);
```

C++

```
__fastcall OleVariant(const Currency src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.6 OleVariant::OleVariant Constructor (Currency*)

Pascal

```
constructor Create(var src: Currency);
```

C++

```
__fastcall OleVariant(Currency* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.7 OleVariant::OleVariant Constructor (IDispatch* const)

Pascal

```
constructor Create(src: IDispatch* const);
```

C++

```
__fastcall OleVariant(IDispatch* const src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.8 OleVariant::OleVariant Constructor (IInterface* const)

Pascal

```
constructor Create(src: IInterface* const);
```

C++

```
__fastcall OleVariant(IInterface* const src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.9 OleVariant::OleVariant Constructor (IUnknown* const)

Pascal

```
constructor Create(src: IUnknown* const);
```

C++

```
__fastcall OleVariant(IUnknown* const src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.10 OleVariant::OleVariant Constructor (OleVariant&)

Pascal

```
constructor Create(const src: OleVariant&);
```

C++

```
__fastcall OleVariant(const OleVariant& src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.11 OleVariant::OleVariant Constructor (OleVariant*, int)

Pascal

```
constructor Create(const values: OleVariant*; const valuesSize: Integer);
```

C++

```
__fastcall OleVariant(const OleVariant* values, const int valuesSize);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.12 OleVariant::OleVariant Constructor (TDateTime)

Pascal

```
constructor Create(const src: TDateTime);
```

C++

```
__fastcall OleVariant(const TDateTime src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.13 OleVariant::OleVariant Constructor (TDateTime*)

Pascal

```
constructor Create(var src: TDateTime);
```

C++

```
__fastcall OleVariant(TDateTime* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.14 OleVariant::OleVariant Constructor (TVariant&)

Pascal

```
constructor Create(const src: TVariant&);
```

C++

```
__fastcall OleVariant(const TVariant& src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.15 OleVariant::OleVariant Constructor (VARIANT&)

Pascal

```
constructor Create(const src: VARIANT&);
```

C++

```
__fastcall OleVariant(const VARIANT& src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.16 OleVariant::OleVariant Constructor (VARIANT*)

Pascal

```
constructor Create(var src: VARIANT);
```

C++

```
__fastcall OleVariant(VARIANT* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.17 OleVariant::OleVariant Constructor (Variant&)

Pascal

```
constructor Create(const src: Variant&);
```

C++

```
__fastcall OleVariant(const Variant& src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.18 OleVariant::OleVariant Constructor (WideString&)

Pascal

```
constructor Create(const src: WideString&);
```

C++

```
__fastcall OleVariant(const WideString& src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.19 OleVariant::OleVariant Constructor (__int64)

Pascal

```
constructor Create(const src: __int64);
```

C++

```
__fastcall OleVariant(const __int64 src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.20 OleVariant::OleVariant Constructor (__int64*)

Pascal

```
constructor Create(var src: __int64);
```

C++

```
__fastcall OleVariant(__int64* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.21 OleVariant::OleVariant Constructor (bool)

Pascal

```
constructor Create(const src: bool);
```

C++

```
__fastcall OleVariant(const bool src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.22 OleVariant::OleVariant Constructor (char)

Pascal

```
constructor Create(const src: char);
```

C++

```
__fastcall OleVariant(const char src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.23 OleVariant::OleVariant Constructor (char*)

Pascal

```
constructor Create(const src: char*);
```

C++

```
__fastcall OleVariant(const char* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.24 OleVariant::OleVariant Constructor (double)

Pascal

```
constructor Create(const src: double);
```

C++

```
__fastcall OleVariant(const double src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.25 OleVariant::OleVariant Constructor (double*)

Pascal

```
constructor Create(var src: double);
```

C++

```
__fastcall OleVariant(double* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.26 OleVariant::OleVariant Constructor (float)

Pascal

```
constructor Create(const src: float);
```

C++

```
__fastcall OleVariant(const float src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.27 OleVariant::OleVariant Constructor (float*)

Pascal

```
constructor Create(var src: float);
```

C++

```
__fastcall OleVariant(float* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.28 OleVariant::OleVariant Constructor (int)

Pascal

```
constructor Create(const src: Integer);
```

C++

```
__fastcall OleVariant(const int src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.29 OleVariant::OleVariant Constructor (int*)

Pascal

```
constructor Create(var src: Integer);
```

C++

```
__fastcall OleVariant(int* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.30 OleVariant::OleVariant Constructor (int*, int, Word)

Pascal

```
constructor Create(const bounds: int*; const boundsSize: Integer; varType: Word);
```

C++

```
__fastcall OleVariant(const int* bounds, const int boundsSize, Word varType);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.31 OleVariant::OleVariant Constructor (long*)

Pascal

```
constructor Create(var src: long);
```

C++

```
__fastcall OleVariant(long* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.32 OleVariant::OleVariant Constructor (short)

Pascal

```
constructor Create(const src: short);
```

C++

```
__fastcall OleVariant(const short src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.33 OleVariant::OleVariant Constructor (short*)

Pascal

```
constructor Create(var src: short);
```

C++

```
__fastcall OleVariant(short* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.34 OleVariant::OleVariant Constructor (signed char*)

Pascal

```
constructor Create(var src: signed char);
```

C++

```
__fastcall OleVariant(signed char* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.35 OleVariant::OleVariant Constructor (unsigned char)

Pascal

```
constructor Create(const src: unsigned char);
```

C++

```
__fastcall OleVariant(const unsigned char src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.36 OleVariant::OleVariant Constructor (unsigned char*)

Pascal

```
constructor Create(var src: unsigned char);
```

C++

```
__fastcall OleVariant(unsigned char* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.37 OleVariant::OleVariant Constructor (unsigned int)

Pascal

```
constructor Create(const src: unsigned int);
```

C++

```
__fastcall OleVariant(const unsigned int src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.38 OleVariant::OleVariant Constructor (unsigned int*)

Pascal

```
constructor Create(var src: unsigned int);
```

C++

```
__fastcall OleVariant(unsigned int* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.39 OleVariant::OleVariant Constructor (unsigned long*)

Pascal

```
constructor Create(var src: unsigned long);
```

C++

```
__fastcall OleVariant(unsigned long* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.40 OleVariant::OleVariant Constructor (unsigned short)

Pascal

```
constructor Create(const src: unsigned short);
```

C++

```
__fastcall OleVariant(const unsigned short src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.41 OleVariant::OleVariant Constructor (unsigned short*)

Pascal

```
constructor Create(var src: unsigned short);
```

C++

```
__fastcall OleVariant(unsigned short* src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.42 OleVariant::OleVariant Constructor (wchar_t* const, bool)

Pascal

```
constructor Create(src: wchar_t* const; isBSTR: bool = true);
```

C++

```
__fastcall OleVariant(wchar_t* const src, bool isBSTR = true);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.3.43 OleVariant::OleVariant Constructor (wchar_t**)

Pascal

```
constructor Create(var src: wchar_t*);
```

C++

```
__fastcall OleVariant(wchar_t** src);
```

Description

This is OleVariant, a member of class OleVariant.

158.1.12.4 OleVariant Operators

The operators of the OleVariant class are listed here.

Public Operators

	Name	Description
	!= (see page 22209)	This is the overview for the != operator overload.
	< (see page 22210)	This is the overview for the < operator overload.
	<= (see page 22211)	This is the overview for the <= operator overload.
	= (see page 22211)	This is the overview for the = operator overload.
	== (see page 22214)	This is the overview for the == operator overload.
	> (see page 22214)	This is the overview for the > operator overload.
	>= (see page 22215)	This is the overview for the >= operator overload.

158.1.12.4.1 != Operator

This is the overview for the != operator overload.

Overload List

	Name	Description
	OleVariant::!= (char*) (see page 22210)	This is !=, a member of class OleVariant.
	OleVariant::!= (OleVariant&) (see page 22210)	This is !=, a member of class OleVariant.

158.1.12.4.1.1 OleVariant::!= Operator (OleVariant&)

Pascal

```
operator !=(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator !=(const OleVariant& rhs) const;
```

Description

This is !=, a member of class OleVariant.

158.1.12.4.1.2 OleVariant::!= Operator (char*)

Pascal

```
operator !=(const rhs: char*);
```

C++

```
__fastcall bool operator !=(const char* rhs) const;
```

Description

This is !=, a member of class OleVariant.

158.1.12.4.2 < Operator

This is the overview for the < operator overload.

Overload List

	Name	Description
	OleVariant::< (char*) (see page 22210)	This is <, a member of class OleVariant.
	OleVariant::< (OleVariant&) (see page 22210)	This is <, a member of class OleVariant.

158.1.12.4.2.1 OleVariant::< Operator (OleVariant&)

Pascal

```
operator <(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator <(const OleVariant& rhs) const;
```

Description

This is <, a member of class OleVariant.

158.1.12.4.2.2 OleVariant::< Operator (char*)

Pascal

```
operator <(const rhs: char*);
```

C++

```
__fastcall bool operator <(const char* rhs) const;
```

Description

This is <, a member of class OleVariant.

158.1.12.4.3 <= Operator

This is the overview for the <= operator overload.

Overload List

	Name	Description
	OleVariant::<= (char*) (see page 22211)	This is <=, a member of class OleVariant.
	OleVariant::<= (OleVariant&) (see page 22211)	This is <=, a member of class OleVariant.

158.1.12.4.3.1 OleVariant::<= Operator (OleVariant&)

Pascal

```
operator <=(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator <=(const OleVariant& rhs) const;
```

Description

This is <=, a member of class OleVariant.

158.1.12.4.3.2 OleVariant::<= Operator (char*)

Pascal

```
operator <=(const rhs: char*);
```

C++

```
__fastcall bool operator <=(const char* rhs) const;
```

Description

This is <=, a member of class OleVariant.

158.1.12.4.4 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	OleVariant::= (__int64) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (AnsiString&) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (bool) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (char) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (char*) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (Currency&) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).

	OleVariant::= (CURRENCY&) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (Currency*) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (CURRENCY*) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (double) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (double*) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (float) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (IDispatch*) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (int) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (IUnknown*) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (long) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (OleVariant&) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (SAFEARRAY**) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (short) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (signed char) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (TDateTime&) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (TDateTime*) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (unsigned char) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (unsigned int) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (unsigned long) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (unsigned short) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (Variant&) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (VARIANT&) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).
	OleVariant::= (VARIANT*) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).

	OleVariant::= (WideString&) (see page 22213)	Copies a value into the System::OleVariant::OleVariant (see page 22200).

158.1.12.4.4.1 OleVariant::= Operator (AnsiString&)

Copies a value into the System::OleVariant::OleVariant (see page 22200).

Pascal

```
operator =(const rhs: OleVariant&);
operator =(const rhs: Variant&);
operator =(var rhs: VARIANT);
operator =(const rhs: AnsiString&);
operator =(const rhs: char*);
operator =(const rhs: WideString&);
operator =(const rhs: bool);
operator =(const rhs: char);
operator =(const rhs: signed char);
operator =(const rhs: unsigned char);
operator =(const rhs: short);
operator =(const rhs: unsigned short);
operator =(const rhs: Integer);
operator =(const rhs: unsigned int);
operator =(const rhs: long);
operator =(const rhs: unsigned long);
operator =(const rhs: float);
operator =(const rhs: double);
operator =(const rhs: __int64);
operator =(const rhs: CURRENCY&);
operator =(const rhs: TDateTime&);
operator =(const rhs: Currency&);
operator =(var rhs: double);
operator =(var rhs: TDateTime);
operator =(var rhs: Currency);
operator =(var rhs: IDispatch);
operator =(var rhs: IUnknown);
operator =(var src: CURRENCY);
operator =(var src: SAFEARRAY*);
operator =(var src: VARIANT);
```

C++

```
__fastcall OleVariant& operator =(const OleVariant& rhs);
__fastcall OleVariant& operator =(const Variant& rhs);
__fastcall OleVariant& operator =(VARIANT& rhs);
__fastcall OleVariant& operator =(const AnsiString& rhs);
__fastcall OleVariant& operator =(const char* rhs);
__fastcall OleVariant& operator =(const WideString& rhs);
__fastcall OleVariant& operator =(const bool rhs);
__fastcall OleVariant& operator =(const char rhs);
__fastcall OleVariant& operator =(const signed char rhs);
__fastcall OleVariant& operator =(const unsigned char rhs);
__fastcall OleVariant& operator =(const short rhs);
__fastcall OleVariant& operator =(const unsigned short rhs);
__fastcall OleVariant& operator =(const int rhs);
__fastcall OleVariant& operator =(const unsigned int rhs);
__fastcall OleVariant& operator =(const long rhs);
__fastcall OleVariant& operator =(const unsigned long rhs);
__fastcall OleVariant& operator =(const float rhs);
__fastcall OleVariant& operator =(const double rhs);
__fastcall OleVariant& operator =(const __int64 rhs);
__fastcall OleVariant& operator =(const CURRENCY& rhs);
__fastcall OleVariant& operator =(const TDateTime& rhs);
__fastcall OleVariant& operator =(const Currency& rhs);
__fastcall OleVariant& operator =(double* rhs);
```

```
__fastcall OleVariant& operator =(TDateTime* rhs);
__fastcall OleVariant& operator =(Currency* rhs);
__fastcall OleVariant& operator =(IDispatch* rhs);
__fastcall OleVariant& operator =(IUnknown* rhs);
__fastcall OleVariant& operator =(CURRENCY* src);
__fastcall OleVariant& operator =(SAFEARRAY** src);
__fastcall OleVariant& operator =(VARIANT* src);
```

Description

The assignment operator converts the value of rhs, as appropriate, and assigns it to the System::OleVariant::OleVariant (see page 22200). If it is not possible to perform the conversion, an EVariantError exception is thrown.

158.1.12.4.5 == Operator

This is the overview for the == operator overload.

Overload List

	Name	Description
	OleVariant::== (char*) (see page 22214)	This is ==, a member of class OleVariant.
	OleVariant::== (OleVariant&) (see page 22214)	This is ==, a member of class OleVariant.

158.1.12.4.5.1 OleVariant::== Operator (OleVariant&)

Pascal

```
operator ==(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator ==(const OleVariant& rhs) const;
```

Description

This is ==, a member of class OleVariant.

158.1.12.4.5.2 OleVariant::== Operator (char*)

Pascal

```
operator ==(const rhs: char*);
```

C++

```
__fastcall bool operator ==(const char* rhs) const;
```

Description

This is ==, a member of class OleVariant.

158.1.12.4.6 > Operator

This is the overview for the > operator overload.

Overload List

	Name	Description
	OleVariant::> (char*) (see page 22215)	This is >, a member of class OleVariant.
	OleVariant::> (OleVariant&) (see page 22215)	This is >, a member of class OleVariant.

158.1.12.4.6.1 OleVariant::> Operator (OleVariant&)

Pascal

```
operator >(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator >(const OleVariant& rhs) const;
```

Description

This is >, a member of class OleVariant.

158.1.12.4.6.2 OleVariant::> Operator (char*)

Pascal

```
operator >(const rhs: char*);
```

C++

```
__fastcall bool operator >(const char* rhs) const;
```

Description

This is >, a member of class OleVariant.

158.1.12.4.7 >= Operator

This is the overview for the >= operator overload.

Overload List

	Name	Description
	OleVariant::>= (char*) (see page 22215)	This is >=, a member of class OleVariant.
	OleVariant::>= (OleVariant&) (see page 22215)	This is >=, a member of class OleVariant.

158.1.12.4.7.1 OleVariant::>= Operator (OleVariant&)

Pascal

```
operator >=(const rhs: OleVariant&);
```

C++

```
__fastcall bool operator >=(const OleVariant& rhs) const;
```

Description

This is >=, a member of class OleVariant.

158.1.12.4.7.2 OleVariant::>= Operator (char*)

Pascal

```
operator >=(const rhs: char*);
```

C++

```
__fastcall bool operator >=(const char* rhs) const;
```

Description

This is >=, a member of class OleVariant.

158.1.13 OpenArray Template

Class Hierarchy

System::OpenArray

Pascal

```
OpenArray = class;
```

C++

```
template <class T>
class OpenArray;
```

File

sysopen.h

Description

This is class System::OpenArray.

158.1.13.1 OpenArray Members

The following tables list the members exposed by OpenArray.

Public Methods

	Name	Description
	~OpenArray (see page 22216)	This is ~OpenArray, a member of class OpenArray.
	GetHigh (see page 22223)	This is GetHigh, a member of class OpenArray.
	OpenArray (see page 22216)	This is the overview for the OpenArray constructor overload.

Public Operators

	Name	Description
	= (see page 22223)	This is =, a member of class OpenArray.
	T* (see page 22223)	This is T*, a member of class OpenArray.

158.1.13.2 OpenArray::~OpenArray Destructor

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~OpenArray();
```

Description

This is ~OpenArray, a member of class OpenArray.

158.1.13.3 OpenArray Constructor

This is the overview for the OpenArray constructor overload.

Overload List

	Name	Description
	OpenArray::OpenArray (OpenArray&) (see page 22217)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T) (see page 22218)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T) (see page 22218)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T) (see page 22218)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T) (see page 22218)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T) (see page 22219)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T) (see page 22219)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T) (see page 22219)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T) (see page 22219)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T, T) (see page 22219)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T, T, T) (see page 22220)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T, T, T, T) (see page 22220)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T, T, T, T, T) (see page 22220)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22220)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22221)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22221)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22221)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22222)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22222)	This is OpenArray, a member of class OpenArray.
	OpenArray::OpenArray (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22222)	This is OpenArray, a member of class OpenArray.

158.1.13.3.1 OpenArray::OpenArray Constructor (OpenArray&)

Pascal

```
constructor Create(const src: OpenArray&);
```

C++

```
__fastcall OpenArray(const OpenArray& src);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.2 OpenArray::OpenArray Constructor (T)

Pascal

```
constructor Create(arg0: T);
```

C++

```
__fastcall OpenArray(T arg0);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.3 OpenArray::OpenArray Constructor (T, T)

Pascal

```
constructor Create(arg0: T; arg1: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.4 OpenArray::OpenArray Constructor (T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.5 OpenArray::OpenArray Constructor (T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.6 OpenArray::OpenArray Constructor (T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.7 OpenArray::OpenArray Constructor (T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.8 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.9 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.10 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T arg8);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.11 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T arg8, T
arg9);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.12 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T arg8, T
arg9, T arg10);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.13 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T arg8, T
arg9, T arg10, T arg11);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.14 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
```

```
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T arg8, T
arg9, T arg10, T arg11, T arg12);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.15 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T arg8, T
arg9, T arg10, T arg11, T arg12, T arg13);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.16 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T; arg14: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T arg8, T
arg9, T arg10, T arg11, T arg12, T arg13, T arg14);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.17 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T; arg14: T; arg15: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T arg8, T
arg9, T arg10, T arg11, T arg12, T arg13, T arg14, T arg15);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.18 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T; arg14: T; arg15: T; arg16: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T arg8, T
arg9, T arg10, T arg11, T arg12, T arg13, T arg14, T arg15, T arg16);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.19 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T; arg14: T; arg15: T; arg16: T; arg17:
T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T arg8, T
arg9, T arg10, T arg11, T arg12, T arg13, T arg14, T arg15, T arg16, T arg17);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.3.20 OpenArray::OpenArray Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T; arg14: T; arg15: T; arg16: T; arg17:
T; arg18: T);
```

C++

```
__fastcall OpenArray(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T arg8, T
arg9, T arg10, T arg11, T arg12, T arg13, T arg14, T arg15, T arg16, T arg17, T arg18);
```

Description

This is OpenArray, a member of class OpenArray.

158.1.13.4 OpenArray Methods

The methods of the OpenArray class are listed here.

Public Methods

	Name	Description
	GetHigh (see page 22223)	This is GetHigh, a member of class OpenArray.

158.1.13.4.1 OpenArray::GetHigh Method

Pascal

```
function GetHigh: Integer;
```

C++

```
__fastcall int GetHigh();
```

Description

This is GetHigh, a member of class OpenArray.

158.1.13.5 OpenArray Operators

The operators of the OpenArray class are listed here.

Public Operators

	Name	Description
	= (see page 22223)	This is =, a member of class OpenArray.
	T* (see page 22223)	This is T*, a member of class OpenArray.

158.1.13.5.1 OpenArray::= Operator

Pascal

```
operator =(const rhs: OpenArray&);
```

C++

```
__fastcall OpenArray& operator =(const OpenArray& rhs);
```

Description

This is =, a member of class OpenArray.

158.1.13.5.2 OpenArray::T* Operator

Pascal

```
operator T*;
```

C++

```
__fastcall operator T*();
```

Description

This is T*, a member of class OpenArray.

158.1.14 OpenArrayCount Template

Class Hierarchy

System::OpenArrayCount

Pascal

```
OpenArrayCount = class;
```

C++

```
template <class T>
class OpenArrayCount;
```

File

sysopen.h

Description

This is class System::OpenArrayCount.

158.1.14.1 OpenArrayCount Members

The following tables list the members exposed by OpenArrayCount.

Public Methods

	Name	Description
	GetHigh (see page 22230)	This is GetHigh, a member of class OpenArrayCount.
	OpenArrayCount (see page 22224)	This is the overview for the OpenArrayCount constructor overload.

158.1.14.2 OpenArrayCount Constructor

This is the overview for the OpenArrayCount constructor overload.

Overload List

	Name	Description
	OpenArrayCount::OpenArrayCount (T) (see page 22225)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T) (see page 22225)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T) (see page 22225)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T) (see page 22226)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T) (see page 22226)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T) (see page 22226)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T) (see page 22226)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T) (see page 22227)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T, T) (see page 22227)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T, T, T) (see page 22227)	This is OpenArrayCount, a member of class OpenArrayCount.

	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T, T, T, T) (see page 22227)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T, T, T, T, T) (see page 22228)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22228)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22228)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22228)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22229)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22229)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22229)	This is OpenArrayCount, a member of class OpenArrayCount.
	OpenArrayCount::OpenArrayCount (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T) (see page 22230)	This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.1 OpenArrayCount::OpenArrayCount Constructor (T)

Pascal

```
constructor Create(arg0: T);
```

C++

```
__fastcall OpenArrayCount(T arg0);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.2 OpenArrayCount::OpenArrayCount Constructor (T, T)

Pascal

```
constructor Create(arg0: T; arg1: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.3 OpenArrayCount::OpenArrayCount Constructor (T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.4 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.5 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.6 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.7 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.8 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.9 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T
arg8);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.10 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T
arg8, T arg9);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.11 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T
arg8, T arg9, T arg10);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.12 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T
arg8, T arg9, T arg10, T arg11);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.13 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T
arg8, T arg9, T arg10, T arg11, T arg12);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.14 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T
arg8, T arg9, T arg10, T arg11, T arg12, T arg13);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.15 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
```

```
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T; arg14: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T
arg8, T arg9, T arg10, T arg11, T arg12, T arg13, T arg14);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.16 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T; arg14: T; arg15: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T
arg8, T arg9, T arg10, T arg11, T arg12, T arg13, T arg14, T arg15);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.17 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T; arg14: T; arg15: T; arg16: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T
arg8, T arg9, T arg10, T arg11, T arg12, T arg13, T arg14, T arg15, T arg16);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.18 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T; arg14: T; arg15: T; arg16: T; arg17:
T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T
arg8, T arg9, T arg10, T arg11, T arg12, T arg13, T arg14, T arg15, T arg16, T arg17);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.2.19 OpenArrayCount::OpenArrayCount Constructor (T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T, T)

Pascal

```
constructor Create(arg0: T; arg1: T; arg2: T; arg3: T; arg4: T; arg5: T; arg6: T; arg7: T;
arg8: T; arg9: T; arg10: T; arg11: T; arg12: T; arg13: T; arg14: T; arg15: T; arg16: T; arg17:
T; arg18: T);
```

C++

```
__fastcall OpenArrayCount(T arg0, T arg1, T arg2, T arg3, T arg4, T arg5, T arg6, T arg7, T
arg8, T arg9, T arg10, T arg11, T arg12, T arg13, T arg14, T arg15, T arg16, T arg17, T arg18);
```

Description

This is OpenArrayCount, a member of class OpenArrayCount.

158.1.14.3 OpenArrayCount Methods

The methods of the OpenArrayCount class are listed here.

Public Methods

	Name	Description
	GetHigh (see page 22230)	This is GetHigh, a member of class OpenArrayCount.

158.1.14.3.1 OpenArrayCount::GetHigh Method

Pascal

```
function GetHigh: Integer;
```

C++

```
__fastcall int GetHigh();
```

Description

This is GetHigh, a member of class OpenArrayCount.

158.1.15 Procedure Class

System::Procedure represents a method on an Automation interface that does not return a value.

Class Hierarchy

Pascal

```
Procedure = class(AutoCmd);
```

C++

```
class Procedure : public AutoCmd;
```

File

sysvari.h

Description

The System::Procedure class represents a single method on an Automation interface that is assigned as the value of a Variant (see page 22307). It can be executed using the Variant (see page 22307)'s Exec method.

Each System::Procedure instance is assigned a name, which is the same as the name of the corresponding method on the interface. In addition, it can be assigned parameters that correspond to the parameters of the method. These parameters can be stored by position or by name.

See Also

System::Variant (see page 22307)

System::Function (see page 22184)

PropertyGet

PropertySet

158.1.15.1 Procedure Members

The following tables list the members exposed by Procedure.

Protected Data Members

	Name	Description
	Name (see page 22130)	This is Name, a member of class AutoCmd.
	NamedParmNames (see page 22130)	This is NamedParmNames, a member of class AutoCmd.
	NamedParms (see page 22130)	This is NamedParms, a member of class AutoCmd.
	NamedParmTypes (see page 22131)	This is NamedParmTypes, a member of class AutoCmd.
	Parms (see page 22131)	This is Parms, a member of class AutoCmd.
	ParmTypes (see page 22131)	This is ParmTypes, a member of class AutoCmd.

Protected Methods

	Name	Description
	AddElement (see page 22132)	This is AddElement, a member of class AutoCmd.

Public Methods

	Name	Description
	~AutoCmd (see page 22129)	Frees an System::AutoCmd::AutoCmd (see page 22129) object.
	AutoCmd (see page 22129)	This is the overview for the AutoCmd constructor overload.
	Clear (see page 22132)	System::AutoCmd::Clears any assigned parameters and blanks the name of the associated method.
	ClearArgs (see page 22132)	Clears any assigned parameters.
	ClearName (see page 22133)	Blanks the name of the associated method.
	GetArgCount (see page 22133)	Returns the number of positional arguments that have been assigned.
	GetArgType (see page 22134)	Returns the type of a parameter value.
	GetCallType (see page 22232)	Indicates the type of the interface method represented by the System::Procedure::Procedure (see page 22232) object.
	GetName (see page 22134)	Returns the name of the interface method this System::AutoCmd::AutoCmd (see page 22129) object represents.
	GetNamedArgCount (see page 22135)	Returns the number of named arguments that have been assigned.
	GetNamedArgType (see page 22135)	Returns the type of a named parameter value.
	GetNamedParm (see page 22136)	Returns the value of a named parameter.
	GetNamedParmName (see page 22136)	Returns the named of a named parameter value.
	GetParm (see page 22137)	Returns the value of a positional parameter.
	Procedure (see page 22232)	This is the overview for the Procedure constructor overload.
	RequestResult (see page 22233)	Indicates that the interface method does not return a value.

	SetName (see page 22138)	Sets the name of the method the System::AutoCmd::AutoCmd (see page 22129) object represents.

Public Operators

	Name	Description
	<< (see page 22138)	This is the overview for the << operator overload.

158.1.15.2 Procedure Constructor

This is the overview for the Procedure constructor overload.

Overload List

	Name	Description
	Procedure::Procedure (AutoCmd&) (see page 22232)	Creates an instance of System::Procedure::Create for a specified method.
	Procedure::Procedure (String&) (see page 22232)	Creates an instance of System::Procedure::Create for a specified method.

158.1.15.2.1 Procedure::Procedure Constructor (AutoCmd&)

Creates an instance of System::Procedure::Create for a specified method.

Pascal

```
constructor Create(const name: String&);
constructor Create(const src: AutoCmd&);
```

C++

```
Procedure(const String& name);
Procedure(const AutoCmd& src);
```

Description

System::Procedure::Create has two constructors: a version that takes the name of the method it represents, and a copy constructor. When creating a new System::Procedure::Create object for a method, the name parameter must be the same as the name of the method as it appears in the interface declaration.

158.1.15.3 Procedure Methods

The methods of the Procedure class are listed here.

Public Methods

	Name	Description
	GetCallType (see page 22232)	Indicates the type of the interface method represented by the System::Procedure::Procedure (see page 22232) object.
	RequestResult (see page 22233)	Indicates that the interface method does not return a value.

158.1.15.3.1 Procedure::GetCallType Method

Indicates the type of the interface method represented by the System::Procedure::Procedure (see page 22232) object.

Pascal

```
function GetCallType: Byte;
```

C++

```
Byte GetCallType() const;
```

Description

Call System::Procedure::GetCallType to determine the type of flag needed to call the method represented by System::Procedure::Procedure (see page 22232) using the IDispatch::Invoke method of the Automation interface. System::Procedure::GetCallType returns DISPATCH_METHOD, indicating a method that is not a property access method.

158.1.15.3.2 Procedure::RequestResult Method

Indicates that the interface method does not return a value.

Pascal

```
function RequestResult: bool;
```

C++

```
bool RequestResult() const;
```

Description

System::Procedure::RequestResult always returns false, indicating that there is no return value after executing the System::Procedure::Procedure (see page 22232) object using the Variant::Exec method.

See Also

System::Procedure::GetCallType (see page 22232)

System::Variant::Exec (see page 22320)

158.1.16 PropertyGet Class

PropertyGet represents a property access method on an Automation interface.

Class Hierarchy

Pascal

```
PropertyGet = class(AutoCmd);
```

C++

```
class PropertyGet : public AutoCmd;
```

File

sysvari.h

Description

The PropertyGet class represents a single method on an Automation interface that returns the value of a property. The interface is assigned as the value of a Variant (see page 22307). The PropertyGet object can be executed using the Variant (see page 22307)'s Exec method.

Each PropertyGet instance is assigned a name, which is the same as the name of the corresponding method on the interface. In addition, it can be assigned parameters that correspond to the parameters of the method. These parameters can be stored by position or by name.

System::Variant (see page 22307)

System::Function (see page 22184)

System::Procedure (see page 22230)

PropertySet

158.1.16.1 PropertyGet Members

The following tables list the members exposed by PropertyGet.

Protected Data Members

	Name	Description
	Name (see page 22130)	This is Name, a member of class AutoCmd.
	NamedParmNames (see page 22130)	This is NamedParmNames, a member of class AutoCmd.
	NamedParms (see page 22130)	This is NamedParms, a member of class AutoCmd.
	NamedParmTypes (see page 22131)	This is NamedParmTypes, a member of class AutoCmd.
	Parms (see page 22131)	This is Parms, a member of class AutoCmd.
	ParmTypes (see page 22131)	This is ParmTypes, a member of class AutoCmd.

Protected Methods

	Name	Description
	AddElement (see page 22132)	This is AddElement, a member of class AutoCmd.

Public Methods

	Name	Description
	~AutoCmd (see page 22129)	Frees an System::AutoCmd::AutoCmd (see page 22129) object.
	AutoCmd (see page 22129)	This is the overview for the AutoCmd constructor overload.
	Clear (see page 22132)	System::AutoCmd::Clears any assigned parameters and blanks the name of the associated method.
	ClearArgs (see page 22132)	Clears any assigned parameters.
	ClearName (see page 22133)	Blanks the name of the associated method.
	GetArgCount (see page 22133)	Returns the number of positional arguments that have been assigned.
	GetArgType (see page 22134)	Returns the type of a parameter value.
	GetCallType (see page 22235)	Indicates the type of the interface method represented by the PropertyGet (see page 22233) object.
	GetName (see page 22134)	Returns the name of the interface method this System::AutoCmd::AutoCmd (see page 22129) object represents.
	GetNamedArgCount (see page 22135)	Returns the number of named arguments that have been assigned.
	GetNamedArgType (see page 22135)	Returns the type of a named parameter value.
	GetNamedParm (see page 22136)	Returns the value of a named parameter.
	GetNamedParmName (see page 22136)	Returns the named of a named parameter value.
	GetParm (see page 22137)	Returns the value of a positional parameter.
	PropertyGet (see page 22235)	This is the overview for the PropertyGet constructor overload.
	RequestResult (see page 22236)	Indicates that the interface method returns a value.
	SetName (see page 22138)	Sets the name of the method the System::AutoCmd::AutoCmd (see page 22129) object represents.

Public Operators

	Name	Description
	<< (see page 22138)	This is the overview for the << operator overload.

158.1.16.2 PropertyGet Constructor

This is the overview for the PropertyGet constructor overload.

Overload List

	Name	Description
	PropertyGet::PropertyGet (AutoCmd&) (see page 22235)	This is PropertyGet, a member of class PropertyGet.
	PropertyGet::PropertyGet (String&) (see page 22235)	This is PropertyGet, a member of class PropertyGet.

158.1.16.2.1 PropertyGet::PropertyGet Constructor (AutoCmd&)

Pascal

```
constructor Create(const src: AutoCmd&);
```

C++

```
PropertyGet(const AutoCmd& src);
```

Description

This is PropertyGet, a member of class PropertyGet.

158.1.16.2.2 PropertyGet::PropertyGet Constructor (String&)

Pascal

```
constructor Create(const name: String&);
```

C++

```
PropertyGet(const String& name);
```

Description

This is PropertyGet, a member of class PropertyGet.

158.1.16.3 PropertyGet Methods

The methods of the PropertyGet class are listed here.

Public Methods

	Name	Description
	GetCallType (see page 22235)	Indicates the type of the interface method represented by the PropertyGet (see page 22233) object.
	RequestResult (see page 22236)	Indicates that the interface method returns a value.

158.1.16.3.1 PropertyGet::GetCallType Method

Indicates the type of the interface method represented by the PropertyGet (see page 22233) object.

Pascal

```
function GetCallType: Byte;
```

C++

```
Byte GetCallType() const;
```

Description

Call GetCallType to determine the type of flag needed to call the method represented by PropertyGet (see page 22233) using the IDispatch::Invoke method of the Automation interface. GetCallType returns DISPATCH_PROPERTYGET, indicating a method that returns the value of a property.

158.1.16.3.2 PropertyGet::RequestResult Method

Indicates that the interface method returns a value.

Pascal

```
function RequestResult: bool;
```

C++

```
bool RequestResult() const;
```

Description

RequestResult always returns true, indicating that there is a return value (the property value) after executing the PropertyGet (see page 22233) object using the Variant::Exec method.

See Also

GetCallType

System::Variant::Exec (see page 22320)

158.1.17 PropertySet Class

PropertySet represents a property access method on an Automation interface.

Class Hierarchy

Pascal

```
PropertySet = class(AutoCmd);
```

C++

```
class PropertySet : public AutoCmd;
```

File

sysvari.h

Description

The PropertySet class represents a single method on an Automation interface that sets the value of a property. The interface is assigned as the value of a Variant (see page 22307). The PropertySet object can be executed using the Variant (see page 22307)'s Exec method.

Each PropertySet instance is assigned a name, which is the same as the name of the corresponding method on the interface. In addition, it can be assigned parameters that correspond to the parameters of the method. These parameters can be stored by position or by name.

System::Variant (see page 22307)

System::Function (see page 22184)

System::Procedure (see page 22230)

PropertySet

158.1.17.1 PropertySet Members

The following tables list the members exposed by PropertySet.

Protected Data Members

	Name	Description
	Name (see page 22130)	This is Name, a member of class AutoCmd.
	NamedParmNames (see page 22130)	This is NamedParmNames, a member of class AutoCmd.
	NamedParms (see page 22130)	This is NamedParms, a member of class AutoCmd.
	NamedParmTypes (see page 22131)	This is NamedParmTypes, a member of class AutoCmd.
	Parms (see page 22131)	This is Parms, a member of class AutoCmd.
	ParmTypes (see page 22131)	This is ParmTypes, a member of class AutoCmd.

Protected Methods

	Name	Description
	AddElement (see page 22132)	This is AddElement, a member of class AutoCmd.

Public Methods

	Name	Description
	~AutoCmd (see page 22129)	Frees an System::AutoCmd::AutoCmd (see page 22129) object.
	AutoCmd (see page 22129)	This is the overview for the AutoCmd constructor overload.
	Clear (see page 22132)	System::AutoCmd::Clears any assigned parameters and blanks the name of the associated method.
	ClearArgs (see page 22132)	Clears any assigned parameters.
	ClearName (see page 22133)	Blanks the name of the associated method.
	GetArgCount (see page 22133)	Returns the number of positional arguments that have been assigned.
	GetArgType (see page 22134)	Returns the type of a parameter value.
	GetCallType (see page 22238)	Indicates the type of the interface method represented by the PropertySet (see page 22236) object.
	GetName (see page 22134)	Returns the name of the interface method this System::AutoCmd::AutoCmd (see page 22129) object represents.
	GetNamedArgCount (see page 22135)	Returns the number of named arguments that have been assigned.
	GetNamedArgType (see page 22135)	Returns the type of a named parameter value.
	GetNamedParm (see page 22136)	Returns the value of a named parameter.
	GetNamedParmName (see page 22136)	Returns the named of a named parameter value.
	GetParm (see page 22137)	Returns the value of a positional parameter.
	PropertySet (see page 22238)	This is the overview for the PropertySet constructor overload.
	RequestResult (see page 22239)	Indicates that the interface method does not return a value.
	SetName (see page 22138)	Sets the name of the method the System::AutoCmd::AutoCmd (see page 22129) object represents.

Public Operators

	Name	Description
	<< (see page 22138)	This is the overview for the << operator overload.

158.1.17.2 PropertySet Constructor

This is the overview for the PropertySet constructor overload.

Overload List

	Name	Description
	PropertySet::PropertySet (AutoCmd&) (see page 22238)	This is PropertySet, a member of class PropertySet.
	PropertySet::PropertySet (String&) (see page 22238)	This is PropertySet, a member of class PropertySet.

158.1.17.2.1 PropertySet::PropertySet Constructor (AutoCmd&)

Pascal

```
constructor Create(const src: AutoCmd&);
```

C++

```
PropertySet(const AutoCmd& src);
```

Description

This is PropertySet, a member of class PropertySet.

158.1.17.2.2 PropertySet::PropertySet Constructor (String&)

Pascal

```
constructor Create(const name: String&);
```

C++

```
PropertySet(const String& name);
```

Description

This is PropertySet, a member of class PropertySet.

158.1.17.3 PropertySet Methods

The methods of the PropertySet class are listed here.

Public Methods

	Name	Description
	GetCallType (see page 22238)	Indicates the type of the interface method represented by the PropertySet (see page 22236) object.
	RequestResult (see page 22239)	Indicates that the interface method does not return a value.

158.1.17.3.1 PropertySet::GetCallType Method

Indicates the type of the interface method represented by the PropertySet (see page 22236) object.

Pascal

```
function GetCallType: Byte;
```

C++

```
Byte GetCallType() const;
```

Description

Call GetCallType to determine the type of flag needed to call the method represented by PropertySet (see page 22236) using the IDispatch::Invoke method of the Automation interface. GetCallType returns DISPATCH_PROPERTYPUT, indicating a method that sets the value of a property.

158.1.17.3.2 PropertySet::RequestResult Method

Indicates that the interface method does not return a value.

Pascal

```
function RequestResult: bool;
```

C++

```
bool RequestResult() const;
```

Description

RequestResult always returns false, indicating that there is no return value after executing the PropertySet (see page 22236) object using the Variant::Exec method.

See Also

GetCallType

System::Variant::Exec (see page 22320)

158.1.18 SmallString Template

Class Hierarchy

Pascal

```
SmallString = class(SmallStringBase<sz>);
```

C++

```
template <unsigned char sz>
class SmallString : private SmallStringBase<sz>;
```

File

dstring.h

Description

This is class System::SmallString.

158.1.18.1 SmallString Members

The following tables list the members exposed by SmallString.

Public Methods

	Name	Description
	SmallString (see page 22240)	This is the overview for the SmallString constructor overload.

Public Operators

	Name	Description
	[] (see page 22241)	This is [], a member of class SmallString.
	= (see page 22241)	This is =, a member of class SmallString.
	AnsiString (see page 22242)	This is AnsiString, a member of class SmallString.

158.1.18.2 SmallString Constructor

This is the overview for the SmallString constructor overload.

Overload List

	Name	Description
	SmallString::SmallString () (see page 22240)	This is SmallString, a member of class SmallString.
	SmallString::SmallString (AnsiString&) (see page 22240)	This is SmallString, a member of class SmallString.
	SmallString::SmallString (char*) (see page 22241)	This is SmallString, a member of class SmallString.
	SmallString::SmallString (SmallString&) (see page 22241)	This is SmallString, a member of class SmallString.

158.1.18.2.1 SmallString::SmallString Constructor ()

Pascal

```
constructor Create;
```

C++

```
__fastcall SmallString();
```

Description

This is SmallString, a member of class SmallString.

158.1.18.2.2 SmallString::SmallString Constructor (AnsiString&)

Pascal

```
constructor Create(const src: AnsiString&);
```

C++

```
__fastcall SmallString(const AnsiString& src);
```

Description

This is SmallString, a member of class SmallString.

158.1.18.2.3 SmallString::SmallString Constructor (SmallString&)

Pascal

```
constructor Create(const src: SmallString&);
```

C++

```
__fastcall SmallString(const SmallString& src);
```

Description

This is SmallString, a member of class SmallString.

158.1.18.2.4 SmallString::SmallString Constructor (char*)

Pascal

```
constructor Create(const src: char*);
```

C++

```
__fastcall SmallString(const char* src);
```

Description

This is SmallString, a member of class SmallString.

158.1.18.3 SmallString Operators

The operators of the SmallString class are listed here.

Public Operators

	Name	Description
	[] (see page 22241)	This is [], a member of class SmallString.
	= (see page 22241)	This is =, a member of class SmallString.
	AnsiString (see page 22242)	This is AnsiString, a member of class SmallString.

158.1.18.3.1 SmallString::[] Operator

Pascal

```
operator [](const idx: unsigned char);
```

C++

```
__fastcall char& operator [](const unsigned char idx);
```

Description

This is [], a member of class SmallString.

158.1.18.3.2 SmallString::= Operator

Pascal

```
operator =(const rhs: SmallString&);
```

C++

```
__fastcall SmallString& operator =(const SmallString& rhs);
```

Description

This is =, a member of class SmallString.

158.1.18.3.3 SmallString::AnsiString Operator

Pascal

```
operator AnsiString;
```

C++

```
__fastcall operator AnsiString() const;
```

Description

This is AnsiString, a member of class SmallString.

158.1.19 SmallStringBase Template

Class Hierarchy

System::SmallStringBase

Pascal

```
SmallStringBase = class;
```

C++

```
template <unsigned char sz>
class SmallStringBase;
```

File

dstring.h

Description

This is class System::SmallStringBase.

158.1.19.1 SmallStringBase Members

The following tables list the members exposed by SmallStringBase.

Protected Data Members

	Name	Description
	Data (see page 22243)	This is Data, a member of class SmallStringBase.
	Len (see page 22243)	This is Len, a member of class SmallStringBase.

158.1.19.2 SmallStringBase Data Members

The data members of the SmallStringBase class are listed here.

Protected Data Members

	Name	Description
	Data (see page 22243)	This is Data, a member of class SmallStringBase.
	Len (see page 22243)	This is Len, a member of class SmallStringBase.

158.1.19.2.1 SmallStringBase::Data Data Member

Pascal

```
[sz] Data: char;
```

C++

```
char Data[sz];
```

Description

This is Data, a member of class SmallStringBase.

158.1.19.2.2 SmallStringBase::Len Data Member

Pascal

```
Len: unsigned char;
```

C++

```
unsigned char Len;
```

Description

This is Len, a member of class SmallStringBase.

158.1.20 sPointer Template

Class Hierarchy

Pascal

```
sPointer = class;
```

C++

```
template <typename T>
class sPointer;
```

File

sysdyn.h

Description

This is class System::sPointer.

158.1.20.1 sPointer Members

The following tables list the members exposed by sPointer.

Public Methods

	Name	Description
	~sPointer (see page 22244)	This is ~sPointer, a member of class sPointer.
	sPointer (see page 22244)	This is the overview for the sPointer constructor overload.

Public Operators

	Name	Description
	& (see page 22245)	This is &, a member of class sPointer.
	-> (see page 22245)	This is ->, a member of class sPointer.

158.1.20.2 sPointer::~sPointer Destructor

Pascal

```
destructor Destroy;
```

C++

```
~sPointer();
```

Description

This is ~sPointer, a member of class sPointer.

158.1.20.3 sPointer Constructor

This is the overview for the sPointer constructor overload.

Overload List

	Name	Description
	sPointer::sPointer () (see page 22244)	This is sPointer, a member of class sPointer.
	sPointer::sPointer (T*) (see page 22244)	This is sPointer, a member of class sPointer.

158.1.20.3.1 sPointer::sPointer Constructor ()

Pascal

```
constructor Create;
```

C++

```
sPointer();
```

Description

This is sPointer, a member of class sPointer.

158.1.20.3.2 sPointer::sPointer Constructor (T*)

Pascal

```
constructor Create(var p: T);
```

C++

```
sPointer(T* p);
```

Description

This is sPointer, a member of class sPointer.

158.1.20.4 sPointer Operators

The operators of the sPointer class are listed here.

Public Operators

	Name	Description
	& (see page 22245)	This is &, a member of class sPointer.
	-> (see page 22245)	This is ->, a member of class sPointer.

158.1.20.4.1 sPointer::& Operator

Pascal

```
operator &;
```

C++

```
T* operator &();
```

Description

This is &, a member of class sPointer.

158.1.20.4.2 sPointer::-> Operator

Pascal

```
operator ->;
```

C++

```
T* operator ->();
```

Description

This is ->, a member of class sPointer.

158.1.21 StaticArray Structure

Pascal

```
StaticArray = record
  [size] data: T;
end;
```

C++

```
template <typename T, int size>
struct StaticArray {
  T data[size];
};
```

File

sysdyn.h

Description

This is class System::StaticArray.

158.1.21.1 StaticArray Members

The following tables list the members exposed by StaticArray.

Public Data Members

	Name	Description
	data (see page 22246)	This is data, a member of class StaticArray.

Public Operators

	Name	Description
	[] (see page 22246)	This is the overview for the [] operator overload.
	const T* (see page 22247)	This is const T*, a member of class StaticArray.
	T* (see page 22247)	This is T*, a member of class StaticArray.

158.1.21.2 StaticArray Data Members

The data members of the StaticArray class are listed here.

Public Data Members

	Name	Description
	data (see page 22246)	This is data, a member of class StaticArray.

158.1.21.2.1 StaticArray::data Data Member

Pascal

```
[size] data: T;
```

C++

```
T data[size];
```

Description

This is data, a member of class StaticArray.

158.1.21.3 StaticArray Operators

The operators of the StaticArray class are listed here.

Public Operators

	Name	Description
	[] (see page 22246)	This is the overview for the [] operator overload.
	const T* (see page 22247)	This is const T*, a member of class StaticArray.
	T* (see page 22247)	This is T*, a member of class StaticArray.

158.1.21.3.1 [] Operator

This is the overview for the [] operator overload.

Overload List

	Name	Description
	StaticArray::[] (int) (see page 22247)	This is [], a member of class StaticArray.
	StaticArray::[] (int) (see page 22247)	This is [], a member of class StaticArray.

158.1.21.3.1.1 StaticArray::[] Operator (int)

Pascal

```
operator [](index: Integer);
```

C++

```
T& operator [](int index);
```

Description

This is [], a member of class StaticArray.

158.1.21.3.1.2 StaticArray::[] Operator (int)

Pascal

```
operator [](index: Integer);
```

C++

```
const T& operator [](int index) const;
```

Description

This is [], a member of class StaticArray.

158.1.21.3.2 StaticArray::const T* Operator

Pascal

```
operator const T*;
```

C++

```
operator const T*() const;
```

Description

This is const T*, a member of class StaticArray.

158.1.21.3.3 StaticArray::T* Operator

Pascal

```
operator T*;
```

C++

```
operator T*();
```

Description

This is T*, a member of class StaticArray.

158.1.22 TAggregatedObject Class

System::TAggregatedObject provides the functionality for an inner object of an aggregate by implementing the IInterface (see page 22396) methods to delegate to the controlling IInterface (see page 22396).

Class Hierarchy

Pascal

```
TAggregatedObject = class(TObject);
```

C++

```
class TAggregatedObject : public TObject;
```

File

System.pas

Description

An aggregated object is an object composed of several interfaced objects. Each object implements its own behavior and interfaces, but all of the objects share the same reference count, which is that of the controller object. In the container pattern, the controller is the container object.

System::TAggregatedObject does not itself support any interfaces. However, as is typical of an aggregate, it does implement the methods of IInterface (see page 22396), which are used by the objects that descend from it. System::TAggregatedObject, therefore, serves as a base for classes that implement interfaces for creating objects that are part of an aggregate.

System::TAggregatedObject is used as a base for classes that create contained objects and connecting objects. Using System::TAggregatedObject ensures that calls to the IInterface (see page 22396) methods delegate to the controlling IInterface (see page 22396) of the aggregate.

The controlling IInterface (see page 22396) is specified in the constructor for System::TAggregatedObject and is indicated by the System::TAggregatedObject::Controller (see page 22251) property.

158.1.22.1 TAggregatedObject Members

The following tables list the members exposed by TAggregatedObject.

Protected Methods

	Name	Description
	_AddRef (see page 22250)	This is _AddRef, a member of class TAggregatedObject.
	_Release (see page 22250)	This is _Release, a member of class TAggregatedObject.
	QueryInterface (see page 22250)	This is QueryInterface, a member of class TAggregatedObject.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22249)	Instantiates an aggregated object.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	Controller (see page 22251)	Provides access to the controlling interface of the aggregate.

158.1.22.2 TAggregatedObject::Create Constructor

Instantiates an aggregated object.

Pascal

```
constructor Create(const Controller: IInterface);
```

C++

```
Create(const IInterface Controller);
```

Description

Call System::TAggregatedObject::Create to instantiate an aggregated object at runtime.

System::TAggregatedObject::Create allocates memory for an aggregated object and sets the System::TAggregatedObject::Controller (see page 22251) property to the System::TAggregatedObject::Controller (see page 22251) parameter passed to it. The System::TAggregatedObject::Controller (see page 22251) is the controlling interface of the

aggregate. All other interfaces implemented in the aggregate delegate IInterface (see page 22396) method calls to this System::TAggregatedObject::Controller (see page 22251).

See Also

System::TAggregatedObject::Controller (see page 22251)

158.1.22.3 TAggregatedObject Methods

The methods of the TAggregatedObject class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 22250)	This is _AddRef, a member of class TAggregatedObject.
	_Release (see page 22250)	This is _Release, a member of class TAggregatedObject.
	QueryInterface (see page 22250)	This is QueryInterface, a member of class TAggregatedObject.

158.1.22.3.1 TAggregatedObject::_AddRef Method

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__stdcall Integer _AddRef();
```

Description

This is _AddRef, a member of class TAggregatedObject.

158.1.22.3.2 TAggregatedObject::_Release Method

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__stdcall Integer _Release();
```

Description

This is _Release, a member of class TAggregatedObject.

158.1.22.3.3 TAggregatedObject::QueryInterface Method

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__stdcall HResult QueryInterface(const TGUID IID, out  Obj);
```

Description

This is QueryInterface, a member of class TAggregatedObject.

158.1.22.4 TAggregatedObject Properties

The properties of the TAggregatedObject class are listed here.

Public Properties

	Name	Description
R	Controller (see page 22251)	Provides access to the controlling interface of the aggregate.

158.1.22.4.1 TAggregatedObject::Controller Property

Provides access to the controlling interface of the aggregate.

Pascal

```
property Controller: IInterface;
```

C++

```
__property IInterface Controller;
```

Description

System::TAggregatedObject::Controller is the interface reference of the aggregate. System::TAggregatedObject::TAggregatedObject (see page 22248) is used as part of an aggregate that has a single controlling IInterface (see page 22396). The IInterface (see page 22396) methods that are implemented in aggregated objects are delegated to the System::TAggregatedObject::Controller.

When the aggregated object is created, its constructor is passed a controlling IInterface (see page 22396). System::TAggregatedObject::Controller is initialized to this IInterface (see page 22396) in the constructor.

System::TAggregatedObject::Create (see page 22249)

158.1.23 TClassHelperBase Class

Class Hierarchy

Pascal

```
TClassHelperBase = class(TInterfacedObject, IInterface);
```

C++

```
class TClassHelperBase : public TInterfacedObject, public IInterface;
```

File

System

Description

This is class System.TClassHelperBase.

158.1.23.1 TClassHelperBase Members

The following tables list the members exposed by TClassHelperBase.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Fields

	Name	Description
	FInstance (see page 22253)	This is FInstance, a member of class TClassHelperBase.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Create (see page 22253)	This is _Create, a member of class TClassHelperBase.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.

	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.

158.1.23.2 TClassHelperBase._Create Constructor

Pascal

```
constructor _Create(Instance: TObject);
```

C++

```
__fastcall TClassHelperBase(TObject * Instance);
```

Description

This is _Create, a member of class TClassHelperBase.

158.1.23.3 TClassHelperBase Fields

The fields of the TClassHelperBase class are listed here.

Protected Fields

	Name	Description
	FInstance (see page 22253)	This is FInstance, a member of class TClassHelperBase.

158.1.23.3.1 TClassHelperBase.FInstance Field

Pascal

```
FInstance: TObject;
```

C++

```
TObject * FInstance;
```

Description

This is FInstance, a member of class TClassHelperBase.

158.1.24 TContainedObject Class

System::TContainedObject implements the IInterface (see page 22396) interface as an inner object in an aggregate.

Class Hierarchy

Pascal

```
TContainedObject = class(TAggregatedObject, IInterface);
```

C++

```
class TContainedObject : public TAggregatedObject, public IInterface;
```

File

System.pas

Description

System::TContainedObject can be used as a base for classes that create inner, or contained, objects of an aggregate. In Delphi, use TComObject or its descendants to instantiate an outer object that supports aggregation.

- The following implementation rules apply to aggregatable (inner or contained) objects, and are supported by System::TContainedObject:
- When an object of its type is created, the creation succeeds only for a requested interface of type IInterface (see page 22396).
- The IInterface (see page 22396) methods _AddRef (see page 22250) and _Release (see page 22250) delegate to the controlling IInterface (see page 22396).
- QueryInterface (see page 22255) is implemented in System::TContainedObject only for interfaces implemented in the contained object.
- The reference count on the inner object is incremented in the containing object.

Note: In Delphi, System::TContainedObject is used as a base class for a connection point that must be an inner object in an aggregate.

Note: An aggregated object is an object that is composed of several interfaced objects. Each object implements its own behavior and interfaces, but all of the objects share the same reference count, which is that of the controller object. In the container pattern, the controller is the container object.

158.1.24.1 TContainedObject Members

The following tables list the members exposed by TContainedObject.

Protected Methods

	Name	Description
	_AddRef (see page 22250)	This is _AddRef, a member of class TAggregatedObject.
	_Release (see page 22250)	This is _Release, a member of class TAggregatedObject.
V	QueryInterface (see page 22255)	Returns a reference to a specified interface if the object supports that interface.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.

V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22249)	Instantiates an aggregated object.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	Controller (see page 22251)	Provides access to the controlling interface of the aggregate.

158.1.24.2 TContainedObject Methods

The methods of the TContainedObject class are listed here.

Protected Methods

	Name	Description
V	QueryInterface (see page 22255)	Returns a reference to a specified interface if the object supports that interface.

158.1.24.2.1 TContainedObject::QueryInterface Method

Returns a reference to a specified interface if the object supports that interface.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; virtual; stdcall;
```

C++

```
virtual __stdcall HResult QueryInterface(const TGUID IID, out  Obj);
```

Description

QueryInterface checks whether the object that implements this interface supports the interface specified by IID. If so, QueryInterface

increments the reference count.

sets the Obj parameter so that it points to an instance of the specified interface.

returns 0 to indicate success.

If the object does not support the interface, QueryInterface returns a nonzero error code such as E_NoInterface.

_AddRef (see page 22397)

158.1.25 TDateTime Class

System::TDateTime is the C++ analog for the Delphi System::TDateTime data type.

Class Hierarchy

Pascal

```
TDateTime = class(TDateTimeBase);
```

C++

```
class TDateTime : public TDateTimeBase;
```

File

systdate.h

Description

System::TDateTime implements the Delphi System::TDateTime data type and the date/time runtime library routines that use the System::TDateTime data type.

The System::TDateTime class inherits a val data member declared as a double (see page 22274) that holds the date-time value. The integral part of a System::TDateTime value is the number of days that have passed since 12/30/1899. The fractional part of a System::TDateTime value is the time of day.

Following are some examples of System::TDateTime values and their corresponding dates and times:

0 12/30/1899 12:00 am

2.75 1/1/1900 6:00 pm

-1.25 12/29/1899 6:00 am

35065 1/1/1996 12:00 am

To find the fractional number of days between two dates, simply subtract the two values, unless one of the System::TDateTime values is negative. Similarly, to increment a date and time value by a certain fractional number of days, add the fractional number to the date and time value if the System::TDateTime value is positive.

When working with negative System::TDateTime values, computations must handle time portion separately. The fractional part reflects the fraction of a 24-hour day without regard to the sign of the System::TDateTime value. For example, 6:00 am on

12/29/1899 is –1.25, not –1 + 0.25, which would be –0.75. There are no System::TDateTime values between –1 and 0.

Note: Use only the operators declared by System::TDateTime. The compiler ignores any operators you overload yourself.

Warning: It is not possible to use System::TDateTime as a base class for inheriting. To add functionality to System::TDateTime, you must write a wrapper class.

Note: To utilize the C++ streaming operators (<< and >>) with Currency (see page 22145), you must use #include <iostream> before #include <systdate.h>. This occurs automatically if you include vcl.h, clx.h, or System.hpp. The following stream operators are defined:

ostream& operator << (ostream& os, const System::TDateTime& arg);

istream& operator >> (istream& is, System::TDateTime& arg);

158.1.25.1 TDateTime Members

The following tables list the members exposed by TDateTime.

Enumerations

	Name	Description
	TDateTimeFlag (see page 22260)	This is record System::TDateTime::TDateTimeFlag.

Public Data Members

	Name	Description
	Val (see page 22275)	This is Val, a member of class TDateTimeBase.

Public Methods

	Name	Description
	CurrentDate (see page 22261)	Returns the current date as a System::TDateTime::TDateTime (see page 22259) value.
	CurrentDateTime (see page 22261)	Returns the current date and time as a System::TDateTime::TDateTime (see page 22259) value.
	CurrentTime (see page 22262)	Returns the current time as a System::TDateTime::TDateTime (see page 22259) value.
	DateString (see page 22262)	Converts the date of the System::TDateTime::TDateTime (see page 22259) value to a string.
	DateTimeString (see page 22262)	Converts the System::TDateTime::TDateTime (see page 22259) value to a string.
	DayOfWeek (see page 22263)	Returns the day of the week of the date portion of the System::TDateTime::TDateTime (see page 22259)
	DecodeDate (see page 22263)	Separates the System::TDateTime::TDateTime (see page 22259) value into year, month, and day values and stores these values in the year, month, and day parameters, respectively.
	DecodeTime (see page 22263)	Separates the System::TDateTime::TDateTime (see page 22259) value into hour, minute, second, and millisecond values and stores these values in the hour, min, sec, and msec parameters, respectively.
	FileDate (see page 22264)	Converts the date/time value to an OS date/time stamp.
	FileDateToDateTime (see page 22264)	Converts an OS timestamp value to System::TDateTime::TDateTime (see page 22259) value.
	FormatString (see page 22265)	Formats the System::TDateTime::TDateTime (see page 22259) object using the format given by format.
	TDateTime (see page 22258)	This is the overview for the TDateTime constructor overload.
	TimeString (see page 22266)	Converts the System::TDateTime::TDateTime (see page 22259) object to an AnsiString (see page 22273).

Public Operators

	Name	Description
	- (see page 22267)	This is the overview for the - operator overload.
	-- (see page 22268)	This is the overview for the -- operator overload.
	!= (see page 22268)	Compares two System::TDateTime::TDateTime (see page 22259) objects for inequality.
	+ (see page 22268)	This is the overview for the + operator overload.
	++ (see page 22269)	This is the overview for the ++ operator overload.
	+= (see page 22270)	This is the overview for the += operator overload.
	< (see page 22270)	Tests whether this System::TDateTime::TDateTime (see page 22259) value is less than another specified System::TDateTime::TDateTime (see page 22259) value.
	<= (see page 22271)	Tests whether this System::TDateTime::TDateTime (see page 22259) value is less than or equal to another specified System::TDateTime::TDateTime (see page 22259) value.
	= (see page 22271)	This is the overview for the = operator overload.
	-= (see page 22272)	This is the overview for the -= operator overload.
	== (see page 22273)	Compares two System::TDateTime::TDateTime (see page 22259) objects for equality.
	> (see page 22273)	Tests whether this System::TDateTime::TDateTime (see page 22259) value is greater than another specified System::TDateTime::TDateTime (see page 22259) value.
	>= (see page 22273)	Tests whether this System::TDateTime::TDateTime (see page 22259) value is greater than or equal to another specified System::TDateTime::TDateTime (see page 22259) value.
	AnsiString (see page 22273)	Converts the System::TDateTime::TDateTime (see page 22259) object to an AnsiString.
	double (see page 22274)	Converts the System::TDateTime::TDateTime (see page 22259) object to a double value.
	int (see page 22274)	Converts the System::TDateTime::TDateTime (see page 22259) object to an integer value.

158.1.25.2 TDateTime Constructor

This is the overview for the TDateTime constructor overload.

Overload List

	Name	Description
	TDateTime::TDateTime () (see page 22259)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 22256).
	TDateTime::TDateTime (AnsiString&, TDateTimeFlag) (see page 22259)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 22256).
	TDateTime::TDateTime (double) (see page 22259)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 22256).
	TDateTime::TDateTime (int) (see page 22259)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 22256).
	TDateTime::TDateTime (TDateTime&) (see page 22259)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 22256).
	TDateTime::TDateTime (TDateTimeBase&) (see page 22259)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 22256).
	TDateTime::TDateTime (unsigned short, unsigned short, unsigned short) (see page 22259)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 22256).

	TDateTime::TDateTime (unsigned short, unsigned short, unsigned short, unsigned short) (see page 22259)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 22256).
	TDateTime::TDateTime (unsigned short, unsigned short, unsigned short, unsigned short, unsigned short, unsigned short, unsigned short) (see page 22259)	Creates and initializes an instance of System::TDateTime::TDateTime (see page 22256).

158.1.25.2.1 TDateTime::TDateTime Constructor ()

Creates and initializes an instance of System::TDateTime::TDateTime (see page 22256).

Pascal

```
constructor Create;
constructor Create(const src: TDateTimeBase&);
constructor Create(const src: TDateTime&);
constructor Create(const src: double);
constructor Create(const src: Integer);
constructor Create(const src: AnsiString&; flag: TDateTimeFlag = DateTime);
constructor Create(year: unsigned short; month: unsigned short; day: unsigned short);
constructor Create(hour: unsigned short; min: unsigned short; sec: unsigned short; msec:
unsigned short);
constructor Create(year: unsigned short; month: unsigned short; day: unsigned short; hour:
unsigned short; min: unsigned short; sec: unsigned short; msec: unsigned short);
```

C++

```
__fastcall TDateTime();
__fastcall TDateTime(const TDateTimeBase& src);
__fastcall TDateTime(const TDateTime& src);
__fastcall TDateTime(const double src);
__fastcall TDateTime(const int src);
__fastcall TDateTime(const AnsiString& src, TDateTimeFlag flag = DateTime);
__fastcall TDateTime(unsigned short year, unsigned short month, unsigned short day);
__fastcall TDateTime(unsigned short hour, unsigned short min, unsigned short sec, unsigned
short msec);
__fastcall TDateTime(unsigned short year, unsigned short month, unsigned short day, unsigned
short hour, unsigned short min, unsigned short sec, unsigned short msec);
```

Description

Use System::TDateTime::TDateTime (see page 22256) to instantiate a System::TDateTime::TDateTime (see page 22256) object.

When called with no arguments, the resulting System::TDateTime::TDateTime (see page 22256) object has a Val (see page 22543) data member of zero. This date and time corresponds to 12/30/1899 12:00 am.

When called with a System::TDateTime::TDateTime (see page 22256) object as the src parameter, the resulting object is a copy of src (the copy constructor).

When called with a System::TDateTime::TDateTimeBase (see page 22275) object as the src parameter, the resulting object has the same value as the src parameter. System::TDateTime::TDateTimeBase (see page 22275) is the base class for the System::TDateTime::TDateTime (see page 22256) type. It has a single member, a public Val (see page 22543) field that represents the value of the object.

When called with a double (see page 22274) or integer as the src parameter, the resulting object has the same value as the src parameter. The integral part of src is the number of days that have passed since 12/30/1899. The fractional part is the time of day, represented as a fraction of 24 hours.

When called with an AnsiString (see page 22273) as the src parameter and a System::TDateTime::TDateTimeFlag (see

page 22260) as the flag parameter, the resulting object's value is converted from the AnsiString (see page 22273). The flag parameter indicates whether the string contains a date, a time, or both. The default for the flag is DateTime.

When called with three unsigned shorts (as the year, month, and day parameters), the resulting object's value is assembled from the specified year, month, and day, with a time portion of 0 (midnight). The year must be between 1 and 9999. Valid month values are 1 through 12. Valid day values are 1 through 28, 29, 30, or 31, depending on the month value. For example, the possible day values for month 2 (February) are 1 through 28 or 1 through 29, depending on whether or not the year value specifies a leap year.

When called with four unsigned shorts (as the hour, min, sec, and msec parameters), the resulting object's value represents a time based on the specified number of hours, minutes, seconds, and milliseconds past midnight. The date portion of the resulting value is 0 (12/30/1899). The hour must be between 0 and 23, the minute must be between 0 and 59, the second must be between 0 and 59, and the millisecond must be between 0 and 999.

Note: When the constructor calls for a conversion that can't be performed (an AnsiString (see page 22273) that does not represent a date or time, or invalid year, month, day, hour, min, sec, or msec value), an EConvertError exception is thrown.

158.1.25.3 TDateTime Enumerations

The enumerations of the TDateTime class are listed here.

Enumerations

	Name	Description
	TDateTimeFlag (see page 22260)	This is record System::TDateTime::TDateTimeFlag.

158.1.25.3.1 System::TDateTime::TDateTimeFlag Enumeration

Pascal

```
TDateTimeFlag = (
  Date,
  Time,
  DateTime
);
```

C++

```
enum TDateTimeFlag {
  Date,
  Time,
  DateTime
};
```

File

systdate.h

Description

This is record System::TDateTime::TDateTimeFlag.

158.1.25.4 TDateTime Methods

The methods of the TDateTime class are listed here.

Public Methods

	Name	Description
	CurrentDate (see page 22261)	Returns the current date as a System::TDateTime::TDateTime (see page 22259) value.
	CurrentDateTime (see page 22261)	Returns the current date and time as a System::TDateTime::TDateTime (see page 22259) value.
	CurrentTime (see page 22262)	Returns the current time as a System::TDateTime::TDateTime (see page 22259) value.
	DateString (see page 22262)	Converts the date of the System::TDateTime::TDateTime (see page 22259) value to a string.
	DateTimeString (see page 22262)	Converts the System::TDateTime::TDateTime (see page 22259) value to a string.
	DayOfWeek (see page 22263)	Returns the day of the week of the date portion of the System::TDateTime::TDateTime (see page 22259)
	DecodeDate (see page 22263)	Separates the System::TDateTime::TDateTime (see page 22259) value into year, month, and day values and stores these values in the year, month, and day parameters, respectively.
	DecodeTime (see page 22263)	Separates the System::TDateTime::TDateTime (see page 22259) value into hour, minute, second, and millisecond values and stores these values in the hour, min, sec, and msec parameters, respectively.
	FileDate (see page 22264)	Converts the date/time value to an OS date/time stamp.
	FileDateToDateTime (see page 22264)	Converts an OS timestamp value to System::TDateTime::TDateTime (see page 22259) value.
	FormatString (see page 22265)	Formats the System::TDateTime::TDateTime (see page 22259) object using the format given by format.
	TimeString (see page 22266)	Converts the System::TDateTime::TDateTime (see page 22259) object to an AnsiString (see page 22273).

158.1.25.4.1 TDateTime::CurrentDate Method

Returns the current date as a System::TDateTime::TDateTime (see page 22259) value.

Pascal

```
function CurrentDate: TDateTime; static;
```

C++

```
static __fastcall TDateTime CurrentDate();
```

Description

System::TDateTime::CurrentDate retrieves the current date and returns it as a new System::TDateTime::TDateTime (see page 22259) object with a 0 time value.

See Also

System::TDateTime::CurrentDateTime (see page 22261)

System::TDateTime::CurrentTime (see page 22262)

158.1.25.4.2 TDateTime::CurrentDateTime Method

Returns the current date and time as a System::TDateTime::TDateTime (see page 22259) value.

Pascal

```
function CurrentDateTime: TDateTime; static;
```

C++

```
static __fastcall TDateTime CurrentDateTime();
```

Description

System::TDateTime::CurrentDateTime retrieves the current date and time, and returns it as a new System::TDateTime::TDateTime (see page 22259) object.

See Also

System::TDateTime::CurrentTime (see page 22262)

System::TDateTime::CurrentDate (see page 22261)

158.1.25.4.3 TDateTime::CurrentTime Method

Returns the current time as a System::TDateTime::TDateTime (see page 22259) value.

Pascal

```
function CurrentTime: TDateTime; static;
```

C++

```
static __fastcall TDateTime CurrentTime();
```

Description

System::TDateTime::CurrentTime retrieves the current time and returns it as a new System::TDateTime::TDateTime (see page 22259) object with a 0 date value.

See Also

System::TDateTime::CurrentDateTime (see page 22261)

System::TDateTime::CurrentDate (see page 22261)

158.1.25.4.4 TDateTime::DateString Method

Converts the date of the System::TDateTime::TDateTime (see page 22259) value to a string.

Pascal

```
function DateString: String;
```

C++

```
__fastcall AnsiString DateString() const;
```

Description

System::TDateTime::DateString returns the value of the System::TDateTime::TDateTime (see page 22259) object as an AnsiString (see page 22273). The conversion uses the format specified by the ShortDateFormat global variable.

See Also

System::TDateTime::DateTimeString (see page 22262)

System::TDateTime::TimeString (see page 22266)

variables

158.1.25.4.5 TDateTime::DateTimeString Method

Converts the System::TDateTime::TDateTime (see page 22259) value to a string.

Pascal

```
function DateTimeString: String;
```

C++

```
__fastcall AnsiString DateTimeString() const;
```

Description

System::TDateTime::DateTimeString returns an AnsiString (see page 22273) object containing the date and time value (the Val (see page 22543) data member) of the System::TDateTime::TDateTime (see page 22259) object to a string. System::TDateTime::DateTimeString converts the System::TDateTime::TDateTime (see page 22259) value using the format given by the ShortDateFormat global variable, followed by the time using the format given by the LongTimeFormat global variable. The time is not displayed if the fractional part of the DateTime value is zero.

See Also

System::TDateTime::DateString (see page 22262)

System::TDateTime::TimeString (see page 22266)

variables

158.1.25.4.6 TDateTime::DayOfWeek Method

Returns the day of the week of the date portion of the System::TDateTime::TDateTime (see page 22259)

Pascal

```
function DayOfWeek: Integer;
```

C++

```
__fastcall int DayOfWeek() const;
```

Description

System::TDateTime::DayOfWeek returns an integer between 1 and 7. Sunday is treated as the first day of the week and Saturday as the seventh.

158.1.25.4.7 TDateTime::DecodeDate Method

Separates the System::TDateTime::TDateTime (see page 22259) value into year, month, and day values and stores these values in the year, month, and day parameters, respectively.

Pascal

```
procedure DecodeDate(var year: unsigned short; var month: unsigned short; var day: unsigned
short);
```

C++

```
__fastcall void DecodeDate(unsigned short* year, unsigned short* month, unsigned short* day)
const;
```

Description

Use System::TDateTime::DecodeDate() when you need to access the year, month, or day of a System::TDateTime::TDateTime (see page 22259) object's date portion.

158.1.25.4.8 TDateTime::DecodeTime Method

Separates the System::TDateTime::TDateTime (see page 22259) value into hour, minute, second, and millisecond values and

stores these values in the hour, min, sec, and msec parameters, respectively.

Pascal

```
procedure DecodeTime(var hour: unsigned short; var min: unsigned short; var sec: unsigned
short; var msec: unsigned short);
```

C++

```
__fastcall void DecodeTime(unsigned short* hour, unsigned short* min, unsigned short* sec,
unsigned short* msec) const;
```

Description

Use System::TDateTime::DecodeTime() to access the hour, minute, second, or millisecond values of the System::TDateTime::TDateTime (see page 22259) object's time portion.

158.1.25.4.9 TDateTime::FileDate Method

Converts the date/time value to an OS date/time stamp.

Pascal

```
function FileDate: Integer;
```

C++

```
__fastcall int FileDate() const;
```

Description

Use System::TDateTime::FileDate to convert a System::TDateTime::TDateTime (see page 22259) value to an OS date/time stamp. For example, use System::TDateTime::FileDate to convert a System::TDateTime::TDateTime (see page 22259) value to a format that can be used as the Age parameter of FileSetDate. You may also need to use System::TDateTime::FileDate to convert a System::TDateTime::TDateTime (see page 22259) so that it is compatible with the Time field of the TSearchRec structure used by the FindFirst and FindNext functions.

See Also

System::TDateTime::FileDateToDateTime (see page 22264)

FileSetDate (see page 22878)

TSearchRec (see page 23005)

158.1.25.4.10 TDateTime::FileDateToDateTime Method

Converts an OS timestamp value to System::TDateTime::TDateTime (see page 22259) value.

Pascal

```
function FileDateToDateTime(fileDate: Integer): TDateTime; static;
```

C++

```
static __fastcall TDateTime FileDateToDateTime(int fileDate);
```

Description

A timestamp is a signed 32-bit integer, used by the OS to record information such as the date and time a file was modified. The precise format of a timestamp depends on the OS. Use System::TDateTime::FileDateToDateTime to convert a timestamp to a System::TDateTime::TDateTime (see page 22259) value.

For example, use System::TDateTime::FileDateToDateTime to convert the file timestamp returned by FileGetDate or FileAge. You may also need to use System::TDateTime::FileDateToDateTime to convert the Time field of the TSearchRec struct used by the FindFirst and FindNext functions.

See Also

FileGetDate (see page 22866)

FileAge (see page 22850)

TSearchRec (see page 23005)

158.1.25.4.11 TDateTime::FormatString Method

Formats the System::TDateTime::TDateTime (see page 22259) object using the format given by format.

Pascal

```
function FormatString(const format: AnsiString&): String;
```

C++

```
__fastcall AnsiString FormatString(const AnsiString& format) const;
```

Description

The following format specifiers are supported:

Specifier	Displays
c	Displays the date using the format given by the ShortDateFormat global variable, followed by the time using the format given by the LongTimeFormat global variable. The time is not displayed if the fractional part of the DateTime value is zero.
d	Displays the day as a number without a leading zero (1-31).
dd	Displays the day as a number with a leading zero (01-31).
ddd	Displays the day as an abbreviation (Sun-Sat) using the strings given by the ShortDayNames global variable.
dddd	Displays the day as a full name (Sunday-Saturday) using the strings given by the LongDayNames global variable.
ddddd	Displays the date using the format given by the ShortDateFormat global variable.
dddddd	Displays the date using the format given by the LongDateFormat global variable.
m	Displays the month as a number without a leading zero (1-12). If the m specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mm	Displays the month as a number with a leading zero (01-12). If the mm specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mmm	Displays the month as an abbreviation (Jan-Dec (see page 22441)) using the strings given by the ShortMonthNames global variable.
mmmm	Displays the month as a full name (January-December) using the strings given by the LongMonthNames global variable.
yy	Displays the year as a two-digit number (00-99).
yyyy	Displays the year as a four-digit number (0000-9999).
h	Displays the hour without a leading zero (0-23).
hh	Displays the hour with a leading zero (00-23).
n	Displays the minute without a leading zero (0-59).
nn	Displays the minute with a leading zero (00-59).
s	Displays the second without a leading zero (0-59).
ss	Displays the second with a leading zero (00-59).
t	Displays the time using the format given by the ShortTimeFormat global variable.

tt	Displays the time using the format given by the LongTimeFormat global variable.
am/pm	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'am' for any hour before noon, and 'pm' for any hour after noon. The am/pm specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
a/p	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'a' for any hour before noon, and 'p' for any hour after noon. The a/p specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
ampm	Uses the 12-hour clock for the preceding h or hh specifier, and displays the contents of the TimeAMString global variable for any hour before noon, and the contents of the TimePMString global variable for any hour after noon.
/	Displays the date separator character given by the DateSeparator global variable.
:	Displays the time separator character given by the TimeSeparator global variable.
'xx'/"xx"	Characters enclosed in single or double (see page 22274) quotes are displayed as is, and do not affect formatting.

If the string given by the format parameter is empty, the System::TDateTime::TDateTime (see page 22259) value is formatted as if a c format specifier had been given.

158.1.25.4.12 TDateTime::TimeString Method

Converts the System::TDateTime::TDateTime (see page 22259) object to an AnsiString (see page 22273).

Pascal

```
function TimeString: String;
```

C++

```
__fastcall AnsiString TimeString() const;
```

Description

System::TDateTime::TimeString returns an AnsiString (see page 22273) object containing the time value (the fractional portion of the Val (see page 22543) data member) of the System::TDateTime::TDateTime (see page 22259) object to a string. The conversion uses the format specified by the LongTimeFormat variable. Change the format of how the string is displayed by changing the value of one or more of the date/time formatting variables.

See Also

System::TDateTime::DateString (see page 22262)

System::TDateTime::DateTimeString (see page 22262)

variables

158.1.25.5 TDateTime Operators

The operators of the TDateTime class are listed here.

Public Operators

	Name	Description
	- (see page 22267)	This is the overview for the - operator overload.
	-- (see page 22268)	This is the overview for the -- operator overload.
	!= (see page 22268)	Compares two System::TDateTime::TDateTime (see page 22259) objects for inequality.
	+ (see page 22268)	This is the overview for the + operator overload.
	++ (see page 22269)	This is the overview for the ++ operator overload.
	+= (see page 22270)	This is the overview for the += operator overload.

	< (see page 22270)	Tests whether this System::TDateTime::TDateTime (see page 22259) value is less than another specified System::TDateTime::TDateTime (see page 22259) value.
	<= (see page 22271)	Tests whether this System::TDateTime::TDateTime (see page 22259) value is less than or equal to another specified System::TDateTime::TDateTime (see page 22259) value.
	= (see page 22271)	This is the overview for the = operator overload.
	-= (see page 22272)	This is the overview for the -= operator overload.
	== (see page 22273)	Compares two System::TDateTime::TDateTime (see page 22259) objects for equality.
	> (see page 22273)	Tests whether this System::TDateTime::TDateTime (see page 22259) value is greater than another specified System::TDateTime::TDateTime (see page 22259) value.
	>= (see page 22273)	Tests whether this System::TDateTime::TDateTime (see page 22259) value is greater than or equal to another specified System::TDateTime::TDateTime (see page 22259) value.
	AnsiString (see page 22273)	Converts the System::TDateTime::TDateTime (see page 22259) object to an AnsiString.
	double (see page 22274)	Converts the System::TDateTime::TDateTime (see page 22259) object to a double value.
	int (see page 22274)	Converts the System::TDateTime::TDateTime (see page 22259) object to an integer value.

158.1.25.5.1 - Operator

This is the overview for the - operator overload.

Overload List

	Name	Description
	TDateTime::- (double) (see page 22267)	Subtracts a specified value from the System::TDateTime::TDateTime (see page 22259) object.
	TDateTime::- (int) (see page 22267)	Subtracts a specified value from the System::TDateTime::TDateTime (see page 22259) object.
	TDateTime::- (TDateTime&) (see page 22267)	Subtracts a specified value from the System::TDateTime::TDateTime (see page 22259) object.
	TDateTime::- (TDateTimeBase&) (see page 22267)	Subtracts a specified value from the System::TDateTime::TDateTime (see page 22259) object.

158.1.25.5.1.1 TDateTime::- Operator (TDateTime&)

Subtracts a specified value from the System::TDateTime::TDateTime (see page 22259) object.

Pascal

```
operator -(const rhs: TDateTimeBase&);
operator -(const rhs: TDateTime&);
operator -(const rhs: double);
operator -(const rhs: Integer);
```

C++

```
__fastcall TDateTime operator -(const TDateTimeBase& rhs) const;
__fastcall TDateTime operator -(const TDateTime& rhs) const;
__fastcall TDateTime operator -(const double rhs) const;
__fastcall TDateTime operator -(const int rhs) const;
```

Description

Use the System::TDateTime (see page 22256)::- to subtract the value specified by the rhs operand from the System::TDateTime::TDateTime (see page 22259) object. The rhs operand represents the number of days (including

fractional days) to subtract.

158.1.25.5.2 -- Operator

This is the overview for the -- operator overload.

Overload List

	Name	Description
	TDateTime::-- () (see page 22268)	Decrements the value of the System::TDateTime::TDateTime (see page 22259) object by a specified number of days.
	TDateTime::-- (int) (see page 22268)	Decrements the value of the System::TDateTime::TDateTime (see page 22259) object by a specified number of days.

158.1.25.5.2.1 TDateTime::-- Operator ()

Decrements the value of the System::TDateTime::TDateTime (see page 22259) object by a specified number of days.

Pascal

```
operator --;
operator --(: Integer);
```

C++

```
TDateTime& operator --();
TDateTime operator --(int);
```

Description

Use the unary System::TDateTime::operator_MinusMinus to decrement the value of the System::TDateTime::TDateTime (see page 22259) object by 1 day.

Use the binary System::TDateTime::operator_MinusMinus to decrement the value by the number of days specified by the integer operand.

158.1.25.5.3 TDateTime::!= Operator

Compares two System::TDateTime::TDateTime (see page 22259) objects for inequality.

Pascal

```
operator !=(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator !=(const TDateTime& rhs) const;
```

Description

The != System::TDateTime (see page 22256)::!= returns true if the two objects do not have the same value, false otherwise.

158.1.25.5.4 + Operator

This is the overview for the + operator overload.

Overload List

	Name	Description
	TDateTime::+ (double) (see page 22269)	Adds a specified value to the System::TDateTime::TDateTime (see page 22259) object.
	TDateTime::+ (int) (see page 22269)	Adds a specified value to the System::TDateTime::TDateTime (see page 22259) object.
	TDateTime::+ (TDateTime&) (see page 22269)	Adds a specified value to the System::TDateTime::TDateTime (see page 22259) object.
	TDateTime::+ (TDateTimeBase&) (see page 22269)	Adds a specified value to the System::TDateTime::TDateTime (see page 22259) object.

158.1.25.5.4.1 TDateTime::+ Operator (TDateTime&)

Adds a specified value to the System::TDateTime::TDateTime (see page 22259) object.

Pascal

```
operator +(const rhs: TDateTimeBase&);
operator +(const rhs: TDateTime&);
operator +(const rhs: double);
operator +(const rhs: Integer);
```

C++

```
__fastcall TDateTime operator +(const TDateTimeBase& rhs) const;
__fastcall TDateTime operator +(const TDateTime& rhs) const;
__fastcall TDateTime operator +(const double rhs) const;
__fastcall TDateTime operator +(const int rhs) const;
```

Description

Use the + System::TDateTime (see page 22256)::+ to add the value specified by the rhs operand to the System::TDateTime::TDateTime (see page 22259) object. The rhs operand represents the number of days (including fractional days) to add.

158.1.25.5.5 ++ Operator

This is the overview for the ++ operator overload.

Overload List

	Name	Description
	TDateTime::++ () (see page 22269)	Increments the value of the System::TDateTime::TDateTime (see page 22259) object by a specified number of days.
	TDateTime::++ (int) (see page 22269)	Increments the value of the System::TDateTime::TDateTime (see page 22259) object by a specified number of days.

158.1.25.5.5.1 TDateTime::++ Operator ()

Increments the value of the System::TDateTime::TDateTime (see page 22259) object by a specified number of days.

Pascal

```
operator ++;
operator ++(: Integer);
```

C++

```
TDateTime& operator ++();
TDateTime operator ++(int);
```

Description

Use the unary ++ System::TDateTime (see page 22256)::+Plus to increment the value of the System::TDateTime::TDateTime (see page 22259) object by 1 day.

Use the binary ++ System::TDateTime (see page 22256)::+Plus to increment the value by the number of days specified by the integer operand.

158.1.25.5.6 += Operator

This is the overview for the += operator overload.

Overload List

	Name	Description
	TDateTime::+= (double) (see page 22270)	Increments the value of this System::TDateTime::TDateTime (see page 22259) object by a specified value.
	TDateTime::+= (int) (see page 22270)	Increments the value of this System::TDateTime::TDateTime (see page 22259) object by a specified value.
	TDateTime::+= (TDateTime&) (see page 22270)	Increments the value of this System::TDateTime::TDateTime (see page 22259) object by a specified value.
	TDateTime::+= (TDateTimeBase&) (see page 22270)	Increments the value of this System::TDateTime::TDateTime (see page 22259) object by a specified value.

158.1.25.5.6.1 TDateTime::+= Operator (TDateTime&)

Increments the value of this System::TDateTime::TDateTime (see page 22259) object by a specified value.

Pascal

```
operator +=(const rhs: TDateTimeBase&);
operator +=(const rhs: TDateTime&);
operator +=(const rhs: double);
operator +=(const rhs: Integer);
```

C++

```
__fastcall TDateTime& operator +=(const TDateTimeBase& rhs);
__fastcall TDateTime& operator +=(const TDateTime& rhs);
__fastcall TDateTime& operator +=(const double rhs);
__fastcall TDateTime& operator +=(const int rhs);
```

Description

Use the += System::TDateTime (see page 22256)::+= to add to the value specified by rhs to this System::TDateTime::TDateTime (see page 22259) value. The rhs operand represents the number of days (including fractional days) to add.

158.1.25.5.7 TDateTime::< Operator

Tests whether this System::TDateTime::TDateTime (see page 22259) value is less than another specified System::TDateTime::TDateTime (see page 22259) value.

Pascal

```
operator <(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator <(const TDateTime& rhs) const;
```

Description

The < System::TDateTime (see page 22256)::< returns true if this System::TDateTime::TDateTime (see page 22259) object has a value (Val (see page 22543) data member) less than that of the object specified by rhs, and false otherwise.

158.1.25.5.8 TDateTime::<= Operator

Tests whether this System::TDateTime::TDateTime (see page 22259) value is less than or equal to another specified System::TDateTime::TDateTime (see page 22259) value.

Pascal

```
operator <=(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator <=(const TDateTime& rhs) const;
```

Description

The <= System::TDateTime (see page 22256)::<= returns true if this System::TDateTime::TDateTime (see page 22259) object has a value (Val (see page 22543) data member) less than or equal to that of the object specified by rhs, and false otherwise.

158.1.25.5.9 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	TDateTime::= (double) (see page 22271)	Assigns the value of the System::TDateTime::TDateTime (see page 22259) object.
	TDateTime::= (int) (see page 22271)	Assigns the value of the System::TDateTime::TDateTime (see page 22259) object.
	TDateTime::= (TDateTime&) (see page 22271)	Assigns the value of the System::TDateTime::TDateTime (see page 22259) object.
	TDateTime::= (TDateTimeBase&) (see page 22271)	Assigns the value of the System::TDateTime::TDateTime (see page 22259) object.

158.1.25.5.9.1 TDateTime::= Operator (TDateTime&)

Assigns the value of the System::TDateTime::TDateTime (see page 22259) object.

Pascal

```
operator =(const rhs: TDateTimeBase&);
operator =(const rhs: TDateTime&);
operator =(const rhs: double);
operator =(const rhs: Integer);
```

C++

```
__fastcall TDateTime& operator =(const TDateTimeBase& rhs);
__fastcall TDateTime& operator =(const TDateTime& rhs);
__fastcall TDateTime& operator =(const double rhs);
__fastcall TDateTime& operator =(const int rhs);
```

Description

The assignment System::TDateTime (see page 22256)::= assigns the value of the rhs operand to the System::TDateTime::TDateTime (see page 22259) object. The assignment System::TDateTime (see page 22256)::= can take

a double (see page 22274) or integer value, which is assigned to the System::TDateTime::TDateTime (see page 22259) object such that the integral part of rhs is the number of days that have passed since 12/30/1899 and the fractional part is the time of day, represented as a fraction of 24 hours.

a System::TDateTime::TDateTimeBase (see page 22275) or System::TDateTime::TDateTime (see page 22259) object, whose value is assigned to the System::TDateTime::TDateTime (see page 22259) object. (Note that System::TDateTime::TDateTimeBase (see page 22275) is the base class for the System::TDateTime::TDateTime (see page 22259) class. It has a single member, a public Val (see page 22543) field that represents the value of the object).

158.1.25.5.10 -= Operator

This is the overview for the -= operator overload.

Overload List

	Name	Description
	TDateTime::-= (double) (see page 22272)	Decrements the value of this System::TDateTime::TDateTime (see page 22259) object by a specified value.
	TDateTime::-= (int) (see page 22272)	Decrements the value of this System::TDateTime::TDateTime (see page 22259) object by a specified value.
	TDateTime::-= (TDateTime&) (see page 22272)	Decrements the value of this System::TDateTime::TDateTime (see page 22259) object by a specified value.
	TDateTime::-= (TDateTimeBase&) (see page 22272)	Decrements the value of this System::TDateTime::TDateTime (see page 22259) object by a specified value.

158.1.25.5.10.1 TDateTime::-= Operator (TDateTime&)

Decrements the value of this System::TDateTime::TDateTime (see page 22259) object by a specified value.

Pascal

```
operator -=(const rhs: TDateTimeBase&);
operator -=(const rhs: TDateTime&);
operator -=(const rhs: double);
operator -=(const rhs: Integer);
```

C++

```
__fastcall TDateTime& operator -=(const TDateTimeBase& rhs);
__fastcall TDateTime& operator -=(const TDateTime& rhs);
__fastcall TDateTime& operator -=(const double rhs);
__fastcall TDateTime& operator -=(const int rhs);
```

Description

Use the -= System::TDateTime (see page 22256)::-= to subtract the value specified by rhs from this

System::TDateTime::TDateTime (see page 22259) value. The rhs operand represents the number of days (including fractional days) to subtract.

158.1.25.5.11 TDateTime::== Operator

Compares two System::TDateTime::TDateTime (see page 22259) objects for equality.

Pascal

```
operator ==(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator ==(const TDateTime& rhs) const;
```

Description

The == System::TDateTime (see page 22256)::== returns true if the two objects have the same value, false otherwise.

158.1.25.5.12 TDateTime::> Operator

Tests whether this System::TDateTime::TDateTime (see page 22259) value is greater than another specified System::TDateTime::TDateTime (see page 22259) value.

Pascal

```
operator >(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator >(const TDateTime& rhs) const;
```

Description

The > System::TDateTime (see page 22256)::> returns true if this System::TDateTime::TDateTime (see page 22259) object has a value (Val (see page 22543) data member) greater than that of the object specified by rhs, and false otherwise.

158.1.25.5.13 TDateTime::>= Operator

Tests whether this System::TDateTime::TDateTime (see page 22259) value is greater than or equal to another specified System::TDateTime::TDateTime (see page 22259) value.

Pascal

```
operator >=(const rhs: TDateTime&);
```

C++

```
__fastcall bool operator >=(const TDateTime& rhs) const;
```

Description

The >= System::TDateTime (see page 22256)::>= returns true if this System::TDateTime::TDateTime (see page 22259) object has a value (Val (see page 22543) data member) greater than or equal to that of the object specified by rhs, and false otherwise.

158.1.25.5.14 TDateTime::AnsiString Operator

Converts the System::TDateTime::TDateTime (see page 22259) object to an AnsiString.

Pascal

```
operator AnsiString;
```

C++

```
__fastcall operator AnsiString() const;
```

Description

The AnsiString conversion System::TDateTime::AnsiString returns an AnsiString object that is the string conversion of this System::TDateTime::TDateTime (see page 22259) object. The conversion uses the format specified by the LongTimeFormat global variable of the System::TDateTime::TDateTime (see page 22259) formatting variables. Change the format of the string display by changing the values of some of the date and time variables.

See Also

System::TDateTime::DateTimeString (see page 22262)

variables

158.1.25.5.15 TDateTime::double Operator

Converts the System::TDateTime::TDateTime (see page 22259) object to a double value.

Pascal

```
operator double;
```

C++

```
__fastcall operator double() const;
```

Description

The double conversion System::TDateTime::double returns a double that represents this System::TDateTime::TDateTime (see page 22259) object. The integral part of the double is the number of days that have passed since 12/30/1899. The fractional part is the time of day, represented as a fraction of 24 hours.

See Also

System::TDateTime::TDateTime (see page 22259)

158.1.25.5.16 TDateTime::int Operator

Converts the System::TDateTime::TDateTime (see page 22259) object to an integer value.

Pascal

```
operator int;
```

C++

```
__fastcall operator int() const;
```

Description

The int conversion System::TDateTime::int returns an int that is the integer conversion of the date portion of this System::TDateTime::TDateTime (see page 22259) object. The resulting integer is the number of days that have passed since 12/30/1899.

System::TDateTime::TDateTime (see page 22259)

158.1.26 TDateTimeBase Class

Class Hierarchy

System::TDateTimeBase

Pascal

```
TDateTimeBase = class;
```

C++

```
class TDateTimeBase;
```

File

systdate.h

Description

This is class System::TDateTimeBase.

158.1.26.1 TDateTimeBase Members

The following tables list the members exposed by TDateTimeBase.

Public Data Members

	Name	Description
	Val (see page 22275)	This is Val, a member of class TDateTimeBase.

158.1.26.2 TDateTimeBase Data Members

The data members of the TDateTimeBase class are listed here.

Public Data Members

	Name	Description
	Val (see page 22275)	This is Val, a member of class TDateTimeBase.

158.1.26.2.1 TDateTimeBase::Val Data Member

Pascal

```
Val: double;
```

C++

```
double Val;
```

Description

This is Val, a member of class TDateTimeBase.

158.1.27 TInterfacedObject Class

System::TInterfacedObject is a base for simple classes that need a basic IInterface (see page 22396) implementation.

Class Hierarchy

Pascal

```
TInterfacedObject = class(TObject, IInterface);
```

C++

```
class TInterfacedObject : public TObject, public IInterface;
```

File

System.pas

Description

System::TInterfacedObject is a thread-safe base class for Delphi classes that support interfaces. System::TInterfacedObject provides basic reference-counting functionality that makes its descendant classes useful in both Delphi and C++ code.

Note: In Delphi, variables declared to be of type System::TInterfacedObject have dynamic-binding, meaning that an instance of a descendant class can be assigned to that variable at runtime. This is because System::TInterfacedObject implements System::TInterfacedObject::QueryInterface (see page 22280), which is called at runtime to query whether the instantiated object supports the requested interface. If it does, then the descendant object is successfully assigned to the variable. Without System::TInterfacedObject::QueryInterface (see page 22280) support, such an assignment would produce a compile-time error.

Note: In Delphi, a descendant of System::TInterfacedObject does not have a class factories or a CLSID. Thus it cannot be instantiated except by calling a constructor.

Note: System::TInterfacedObject does not implement the methods of the C++ version of IUnknown (see page 22586) or IInterface (see page 22396). This is not a problem when using C++ wrappers for System::TInterfacedObject descendants that are written in Delphi. However, if you are creating C++ descendants of System::TInterfacedObject, you must provide your own implementation of IUnknown (see page 22586). For information on how to do this, see Creating classes that support IUnknown (see page 22586) (supplied with C++ products only).

158.1.27.1 TInterfacedObject Members

The following tables list the members exposed by TInterfacedObject.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.

158.1.27.2 TInterfacedObject Data Members

The data members of the TInterfacedObject class are listed here.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

158.1.27.2.1 TInterfacedObject::FRefCount Data Member

Pascal

```
FRefCount: Integer;
```

C++

```
Integer FRefCount;
```

Description

This is FRefCount, a member of class TInterfacedObject.

158.1.27.3 TInterfacedObject Methods

The methods of the TInterfacedObject class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.

158.1.27.3.1 TInterfacedObject::_AddRef Method

Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__stdcall Integer _AddRef();
```

Description

Do not call the protected System::TInterfacedObject::_AddRef method directly. System::TInterfacedObject::_AddRef is called through the interface to indicate that another object is using the interfaced object's interface pointer. When the other object is through with the interface, it calls System::TInterfacedObject::_Release (see page 22279) through the same interface. This allows the interfaced object to free itself when it is no longer used (when the reference count goes to zero).

System::TInterfacedObject::_AddRef increments the System::TInterfacedObject::RefCount (see page 22281) property.

See Also

System::TInterfacedObject::RefCount (see page 22281)

System::TInterfacedObject::_Release (see page 22279)

158.1.27.3.2 TInterfacedObject::_Release Method

Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__stdcall Integer _Release();
```

Description

Do not call the protected _System::TInterfacedObject::_Release method directly. _System::TInterfacedObject::_Release is called through the IInterface (see page 22396) interface to indicate that another object is through with the interfaced object's interface pointer. This allows the interfaced object to free itself when it is no longer used (when the reference count goes to zero).

_System::TInterfacedObject::_Release decrements the System::TInterfacedObject::RefCount (see page 22281) property.

See Also

System::TInterfacedObject::RefCount (see page 22281)

System::TInterfacedObject::_AddRef (see page 22278)

System::TInterfacedObject::BeforeDestruction (see page 22279)

158.1.27.3.3 TInterfacedObject::AfterConstruction Method

Responds after the last constructor executes.

Pascal

```
procedure AfterConstruction; virtual; override;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

System::TInterfacedObject::AfterConstruction is called automatically after the object's last constructor has executed. Do not call it explicitly in your applications.

When an instance of System::TInterfacedObject::TInterfacedObject (see page 22276) is allocated, System::TInterfacedObject::RefCount (see page 22281) is incremented to prevent its destruction while processing the constructor. System::TInterfacedObject::AfterConstruction decrements that System::TInterfacedObject::RefCount (see page 22281) to re-establish the correct reference count after all constructors have executed.

See Also

System::TInterfacedObject::BeforeDestruction (see page 22279)

System::TInterfacedObject::NewInstance (see page 22280)

System::TInterfacedObject::RefCount (see page 22281)

158.1.27.3.4 TInterfacedObject::BeforeDestruction Method

Checks that the reference count is zero before allowing the interfaced object to be destroyed.

Pascal

```
procedure BeforeDestruction; virtual; override;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

System::TInterfacedObject::BeforeDestruction is called automatically immediately before the interfaced object's destructor. It checks that the reference count is zero, and, if it is not, raises an exception.

See Also

System::TInterfacedObject::RefCount (see page 22281)

System::TObject::free

158.1.27.3.5 TInterfacedObject::NewInstance Method

Allocates memory for each instance of an interfaced object.

Pascal

```
class function NewInstance: TObject; override;
```

C++

```
TObject NewInstance();
```

Description

All constructors call System::TInterfacedObject::NewInstance automatically. System::TInterfacedObject::NewInstance calls System::TObject::InstanceSize (see page 22306) to determine how much memory to allocate from the heap to contain a particular instance. Do not call System::TInterfacedObject::NewInstance directly.

System::TInterfacedObject::TInterfacedObject (see page 22276) overrides System::TInterfacedObject::NewInstance to increment the reference count when a new instance is created. This prevents any constructor from accidentally deleting the instance due to a System::TInterfacedObject::RefCount (see page 22281) of zero. The System::TInterfacedObject::AfterConstruction (see page 22279) method decrements the value of System::TInterfacedObject::RefCount (see page 22281) after all constructors have executed.

See Also

System::TInterfacedObject::RefCount (see page 22281)

System::TObject::NewInstance (see page 22306)

System::TObject::InstanceSize (see page 22306)

System::TInterfacedObject::AfterConstruction (see page 22279)

158.1.27.3.6 TInterfacedObject::QueryInterface Method

Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__stdcall HResult QueryInterface(const TGUID IID, out  Obj);
```

Description

Do not call the protected System::TInterfacedObject::QueryInterface method directly. System::TInterfacedObject::QueryInterface is called through IInterface (see page 22396) to obtain an interface pointer for the interface identified by the IID parameter. If the object supports the requested interface, it is returned in the Obj parameter and System::TInterfacedObject::QueryInterface returns S_OK (see page 22677). If the object does not support the interface, System::TInterfacedObject::QueryInterface returns E_NOINTERFACE (see page 22663).

If System::TInterfacedObject::QueryInterface successfully returns an interface pointer, it automatically increments the reference count.

See Also

System::TInterfacedObject::_AddRef (see page 22278)

158.1.27.4 TInterfacedObject Properties

The properties of the TInterfacedObject class are listed here.

Public Properties

	Name	Description
R	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.

158.1.27.4.1 TInterfacedObject::RefCount Property

Indicates the number of interface pointers currently dependent upon the object.

Pascal

```
property RefCount: Integer;
```

C++

```
__property Integer RefCount;
```

Description

System::TInterfacedObject::RefCount defines the lifetime of the object. When System::TInterfacedObject::RefCount is zero, the object is destroyed.

System::TInterfacedObject::RefCount is incremented by calls to the _AddRef (see page 22278) method and decremented by the _Release (see page 22279) method.

Note: If the destructor is called on a System::TInterfacedObject::TInterfacedObject (see page 22276) descendant that is not fully constructed (an exception was raised in the constructor), then System::TInterfacedObject::RefCount will have a value of 1. Otherwise, System::TInterfacedObject::RefCount will be zero.

158.1.28 TMetaClass Class

System::TMetaClass is the C++ representation of the Delphi class-reference type.

Class Hierarchy

System::TMetaClass

Pascal

```
TMetaClass = class;
```

C++

```
class TMetaClass;
```

File

systobj.h

Description

System::TMetaClass allows operations to be performed directly on classes. This contrasts with class types, which can be instantiated as objects and which allow operations to be performed on those instances. The System::TMetaClass for a given class can be acquired by using the __classid keyword extension.

A variable of type System::TMetaClass can be NULL, which indicates that the variable does not currently reference a class.

Every class inherits a method function called ClassType, which returns a reference to the class of an object. The type of the value returned by ClassType is TClass (see page 22611) (System::TMetaClass*), which is a pointer to a System::TMetaClass.

The methods of System::TMetaClass correspond to the static methods of TObject (see page 22285). They have the same functionality but differ in parameters. Whereas the TObject (see page 22285) methods take a TClass (see page 22611) (System::TMetaClass*) as the first parameter, this parameter is implicit in the System::TMetaClass methods.

C++ Examples:

```
/*
The following example allows users to type the name of a
graphics class into an edit control and when a button is
pressed, the name of the default extension for that class is
displayed in another edit control.  In the form's OnCreate
event handler (or a similar place) you must register the
graphics classes so that GetClass can find them.
*/
TMetaClass *MetaClass;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClassFinder *myClassFinder = new TClassFinder(MetaClass, False);
  TGraphicClass mygraphclass = (TGraphicClass) (myClassFinder->GetClass(Edit2->Text));
//  TGraphicClass mygraphclass = (TGraphicClass) GetClass(Edit2->Text);
  Edit1->Text = GraphicExtension(mygraphclass);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  MetaClass = __classid(TIcon); // ico
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(Graphics::TBitmap); // bmp
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TMetafile); // emf
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TShape);  // nographic extension
  RegisterClasses(&MetaClass, 0);
  MetaClass = __classid(TImage); // nographic extension
  RegisterClasses(&MetaClass, 0);
}
```

TObject

158.1.28.1 TMetaClass Members

The following tables list the members exposed by TMetaClass.

Public Methods

	Name	Description
	ClassInfo (see page 22283)	This is ClassInfo, a member of class TMetaClass.
	ClassName (see page 22283)	This is ClassName, a member of class TMetaClass.
	ClassNameIs (see page 22284)	This is ClassNameIs, a member of class TMetaClass.
	ClassParent (see page 22284)	This is ClassParent, a member of class TMetaClass.
	InheritsFrom (see page 22284)	This is InheritsFrom, a member of class TMetaClass.
	InitInstance (see page 22284)	This is InitInstance, a member of class TMetaClass.
	InstanceSize (see page 22285)	This is InstanceSize, a member of class TMetaClass.
	MethodAddress (see page 22285)	This is MethodAddress, a member of class TMetaClass.
	MethodName (see page 22285)	This is MethodName, a member of class TMetaClass.

158.1.28.2 TMetaClass Methods

The methods of the TMetaClass class are listed here.

Public Methods

	Name	Description
	ClassInfo (see page 22283)	This is ClassInfo, a member of class TMetaClass.
	ClassName (see page 22283)	This is ClassName, a member of class TMetaClass.
	ClassNameIs (see page 22284)	This is ClassNameIs, a member of class TMetaClass.
	ClassParent (see page 22284)	This is ClassParent, a member of class TMetaClass.
	InheritsFrom (see page 22284)	This is InheritsFrom, a member of class TMetaClass.
	InitInstance (see page 22284)	This is InitInstance, a member of class TMetaClass.
	InstanceSize (see page 22285)	This is InstanceSize, a member of class TMetaClass.
	MethodAddress (see page 22285)	This is MethodAddress, a member of class TMetaClass.
	MethodName (see page 22285)	This is MethodName, a member of class TMetaClass.

158.1.28.2.1 TMetaClass::ClassInfo Method

Pascal

```
function ClassInfo: Pointer;
```

C++

```
__fastcall void * ClassInfo();
```

Description

This is ClassInfo, a member of class TMetaClass.

158.1.28.2.2 TMetaClass::ClassName Method

Pascal

```
function ClassName: ShortString;
```

C++

```
__fastcall ShortString ClassName();
```

Description

This is ClassName, a member of class TMetaClass.

158.1.28.2.3 TMetaClass::ClassNameIs Method

Pascal

```
function ClassNameIs(const string: AnsiString &): bool;
```

C++

```
__fastcall bool ClassNameIs(const AnsiString & string);
```

Description

This is ClassNameIs, a member of class TMetaClass.

158.1.28.2.4 TMetaClass::ClassParent Method

Pascal

```
function ClassParent: TClass;
```

C++

```
__fastcall TClass ClassParent();
```

Description

This is ClassParent, a member of class TMetaClass.

158.1.28.2.5 TMetaClass::InheritsFrom Method

Pascal

```
function InheritsFrom(aClass: TClass): bool;
```

C++

```
__fastcall bool InheritsFrom(TClass aClass);
```

Description

This is InheritsFrom, a member of class TMetaClass.

158.1.28.2.6 TMetaClass::InitInstance Method

Pascal

```
function InitInstance(var instance): TObject;
```

C++

```
__fastcall TObject * InitInstance(void * instance);
```

Description

This is InitInstance, a member of class TMetaClass.

158.1.28.2.7 TMetaClass::InstanceSize Method

Pascal

```
function InstanceSize: long;
```

C++

```
__fastcall long InstanceSize();
```

Description

This is InstanceSize, a member of class TMetaClass.

158.1.28.2.8 TMetaClass::MethodAddress Method

Pascal

```
function MethodAddress(const Name: ShortString &): Pointer;
```

C++

```
__fastcall void * MethodAddress(const ShortString & Name);
```

Description

This is MethodAddress, a member of class TMetaClass.

158.1.28.2.9 TMetaClass::MethodName Method

Pascal

```
function MethodName(var Address): ShortString;
```

C++

```
__fastcall ShortString MethodName(void * Address);
```

Description

This is MethodName, a member of class TMetaClass.

158.1.29 TObject Class

System::TObject is the ultimate ancestor of all objects and components.

Class Hierarchy

System::TObject

Pascal

```
TObject = class;
```

C++

```
class TObject;
```

File

System.pas

Description

System::TObject encapsulates fundamental behavior common to objects by introducing methods that

create, maintain and destroy instances of the object by allocating, initializing, and freeing required memory.

respond when object instances are created or destroyed.

return class-type and instance information on an object and runtime type information (RTTI) about its published properties.

support message handling.

support interfaces that the object implements.

Use System::TObject as an immediate base class when declaring simple objects that do not need to persist (are not saved and reloaded) and that do not need to be assigned to other objects.

Much of the capability of objects is established by methods that System::TObject introduces. Many of these methods are used internally by IDEs and are not intended for users to call directly. Others are overridden in descendant objects that have more complex behavior.

Although System::TObject is the based object of a component framework, not all objects are components. All component classes are descended from TComponent.

Note: System::TObject is never directly instantiated. Although it does not use programming language features that prevent instantiation, System::TObject is an abstract class.

VCL Overview

158.1.29.1 TObject Members

The following tables list the members exposed by TObject.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.

	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

158.1.29.2 TObject::Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create;
```

C++

```
Create();
```

Description

System::TObject::Create constructs an object. The purpose, size, and behavior of objects differ greatly. The System::TObject::Create constructor defined by System::TObject::TObject (see page 22285) allocates memory but does not initialize data.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

System::TObject::Destroy (see page 22287)

System::TObject::Free (see page 22300)

158.1.29.3 TObject::Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; virtual;
```

C++

```
virtual Destroy();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free (see page 22300) instead. Free (see page 22300) verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject (see page 22285) deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free (see page 22300) on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free (see page 22300) provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 22300)

158.1.29.4 TObject Methods

The methods of the TObject class are listed here.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

158.1.29.4.1 TObject::AfterConstruction Method

Responds after the last constructor has executed.

Pascal

```
procedure AfterConstruction; virtual;
```

C++

```
virtual __fastcall AfterConstruction();
```

Description

System::TObject::AfterConstruction is called automatically after the object's last constructor has executed. Do not call it explicitly in your applications.

The System::TObject::AfterConstruction method implemented in System::TObject::TObject (see page 22285) does nothing. Override this method when creating a class that takes some action after the object is created. For example, TCustomForm overrides System::TObject::AfterConstruction to generate an OnCreate event.

See Also

System::TObject::BeforeDestruction (see page 22289)

OnCreate (see page 13951)

System::TObject::Create (see page 22287)

158.1.29.4.2 TObject::BeforeDestruction Method

Responds before the first destructor executes.

Pascal

```
procedure BeforeDestruction; virtual;
```

C++

```
virtual __fastcall BeforeDestruction();
```

Description

System::TObject::BeforeDestruction is called automatically before the object's first destructor executes. Do not call it explicitly in your applications.

The System::TObject::BeforeDestruction method implemented in System::TObject::TObject (see page 22285) does nothing. Override this method when creating a class that takes some action before the object is destroyed. For example, TCustomForm overrides System::TObject::BeforeDestruction to generate an OnDestroy event.

Note: System::TObject::BeforeDestruction is not called when the object is destroyed before it is fully constructed. That is, if the object's constructor raises an exception, the destructor is called to dispose of the object, but System::TObject::BeforeDestruction is not called.

See Also

System::TObject::AfterConstruction (see page 22289)

OnDestroy (see page 13953)

System::TObject::Destroy (see page 22287)

158.1.29.4.3 TObject::ClassInfo Method

Returns a pointer to the runtime type information (RTTI) table for the object type.

Pascal

```
class function ClassInfo: Pointer;
```

C++

```
Pointer ClassInfo();
```

Description

System::TObject::ClassInfo provides access to the RTTI table for a given object type.

Note: The format of the RTTI table is subject to change. Applications should use the other RTTI methods provided by System::TObject::TObject (see page 22285); these provide easy, consistent access to RTTI data.

Note: Some classes do not provide runtime type information. For these classes, System::TObject::ClassInfo returns nil (Delphi) or NULL (C++). All classes descended from TPersistent do provide runtime type information.

Note: The Delphi compiler does not provide RTTI by default. Most classes implemented in Delphi that need to provide RTTI are descended from TPersistent. If your Delphi class needs RTTI but not the full functionality of TPersistent, compile the code with the $M switch.

Note: The C++ compiler provides RTTI by default. This feature can be disabled as project option and selectively re-enabled using the __rtti keyword.

System::TObject::InheritsFrom (see page 22305)

_typeinfo_Macro

158.1.29.4.4 TObject::ClassName Method

Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).

Pascal

```
class function ClassName: ShortString;
```

C++

```
ShortString ClassName();
```

Description

Use System::TObject::ClassName to obtain the class name from an object instance or class reference. This is useful for differentiating object instances that are assigned to a variable that has the type of an ancestor class.

Note: In C++ code, call System::TObject::ClassName as a method to obtain an object's class name. Use the global static function to obtain the class name from a metaclass object.

C++ Examples:

```
/*
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button's class and the names of its
parent classes are added to the list box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClass ClassRef;
  ListBox1->Clear();
  ClassRef = Sender->ClassType();
  while (ClassRef != NULL)
  {
    ListBox1->Items->Add(ClassName(ClassRef));
    ClassRef = ClassParent(ClassRef);
  };
}
/*
The list box contains the following strings after the user clicks the button:
    TButton
    TButtonControl
    TWinControl or TWinControl
    TControl
    TComponent
    TPersistent
    TObject
*/
/*
To run this example, add the example code to a new project.
The example code dynamically creates a TCoolbar and three
TCoolBand objects populated with a windowed control in each
TCoolBand.
*/
void AddBands(TCoolBar *CoolBar, TList *Objects)
{
  TControl *pCurrent;
  for (int i = 0; i < Objects->Count; i++)
  {
    pCurrent = (TControl *)Objects->Items[i];
    // only add windowed controls to the coolbar
    if (dynamic_cast<TWinControl *>(pCurrent) != NULL)
    {
      // Placing the control onto the CoolBar
      // causes the TCoolBar object to create a TCoolBand
      // and place the control within the band.
      pCurrent->Parent = CoolBar;   // This statement increments CoolBar->Bands->Count.
      // Get the reference of the TCoolBand just created and assign text.
      String S = pCurrent->ClassName(pCurrent->ClassType());
      CoolBar->Bands->Items[CoolBar->Bands->Count - 1]->Text = S;
```

```
      }
    }
  }

  void __fastcall TForm1::FormCreate(TObject *Sender)
  {
    TCoolBar *CoolBar = new TCoolBar(this);
    TList *List;
    CoolBar->Parent = this;
    CoolBar->Align = alTop;
    List = new TList();
    try
    {
      TControl *Control;
      Control = new TButton(CoolBar);
      List->Add(Control);
      Control = new TCheckBox(CoolBar);
      List->Add(Control);
      Control = new TEdit(CoolBar);
      List->Add(Control);
      AddBands(CoolBar, List);
    }
    catch (...)
    {
      ShowMessage("Some objects could not be added to Coolband");
    }
    delete List;
  }
```

Delphi Examples:

```
  {
  This example shows how to obtain the ancestry of a component
  using the ClassType and ClassParent properties. It uses a
  button and a list box on a form. When the user clicks the
  button, the name of the button's class and the names of its
  parent classes are added to the list box.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    ClassRef: TClass;
  begin
    ListBox1.Clear;
    ClassRef := Sender.ClassType;
    while ClassRef <> nil do
    begin
      ListBox1.Items.Add(ClassRef.ClassName);
      ClassRef := ClassRef.ClassParent;
    end;
  end;
  {
  The list box contains the following strings after the user clicks the button:
      TButton
      TButtonControl
      TWinControl or TWinControl
      TControl
      TComponent
      TPersistent
      TObject
  }
```

See Also

System::TObject::ClassNameIs (see page 22293)

System::TObject::ClassParent (see page 22293)

System::TObject::ClassType (see page 22295)

158.1.29.4.5 TObject::ClassNameIs Method

Determines whether an object is of a specific type.

Pascal

```
class function ClassNameIs(const Name: string): Boolean;
```

C++

```
Boolean ClassNameIs(const string Name);
```

Description

System::TObject::ClassNameIs determines whether an object instance or class reference has a class name that matches a specified string. This is useful to query objects across modules or shared libraries.

Note: In C++ code, call System::TObject::ClassNameIs as a method to compare an object's class name. Use the global static function to compare the class name from a metaclass object.

See Also

System::TObject::ClassName (see page 22290)

System::TObject::InheritsFrom (see page 22305)

158.1.29.4.6 TObject::ClassParent Method

Returns the type of the immediate ancestor of a class.

Pascal

```
class function ClassParent: TClass;
```

C++

```
TClass ClassParent();
```

Description

System::TObject::ClassParent returns the name of the parent class for an object instance or class reference. For System::TObject::TObject (see page 22285), System::TObject::ClassParent returns nil (Delphi) or NULL (C++).

Avoid using System::TObject::ClassParent in application code.

Note: In Delphi code, use the is or as operators instead of System::TObject::ClassParent.

Note: In C++ code, use a dynamic cast or the System::TObject::InheritsFrom (see page 22305) method instead of System::TObject::ClassParent.

C++ Examples:

```
/*
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button’s class and the names of its
parent classes are added to the list box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
```

```
{
  TClass ClassRef;
  ListBox1->Clear();
  ClassRef = Sender->ClassType();
  while (ClassRef != NULL)
  {
    ListBox1->Items->Add(ClassName(ClassRef));
    ClassRef = ClassParent(ClassRef);
  };
}
/*
The list box contains the following strings after the user clicks the button:
    TButton
    TButtonControl
    TWinControl or TWinControl
    TControl
    TComponent
    TPersistent
    TObject
*/
/*
For the following example, add a button, a status bar, and a
list box to the form. Set the SimplePanel property of the
status bar to true, using the object inspector. Also, populate
the OnMouseUp event handler for the list box.  The following
code fills a list box with the names of all components on the
form when the user clicks the button. References to the
components themselves are inserted along with the names. The
components are all inserted at the front of the list, so that
the last component added to the form is the first component
in the list.  When the user right-clicks the name of an
object in the list, the component’s coordinates are displayed
on the status bar. Note that because we are using the right-
click, the item need not be selected.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int i = 0; i < ComponentCount; i++)
    ListBox1->Items->InsertObject(0,
                                  Components[i]->Name,
                                  (TObject *)Components[i]);
}

void __fastcall TForm1::ListBox1MouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  if (Button == mbRight)
  {
    TClass ClassRef;
    int Index = ListBox1->ItemAtPos(Point(X,Y), true);
    // only components that are controls have a position
    // make sure the component is a control
    for (ClassRef = ListBox1->Items->Objects[Index]->ClassType();
         ClassRef != NULL;
         ClassRef = ClassRef->ClassParent())
      if (String(ClassRef->ClassName()) == "TControl")
      {
        TControl *TheObject = (TControl *)ListBox1->Items->Objects[Index];
        StatusBar1->SimpleText =
          TheObject->Name + " is at (" +
          IntToStr(TheObject->Left) + ", " +
          IntToStr(TheObject->Top) + ")";
         break;
      }
    if (ClassRef == NULL) // if it wasn't a control
      MessageBeep(0);
```

```
  }
}
```

Delphi Examples:

```
{
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button's class and the names of its
parent classes are added to the list box.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ClassRef: TClass;
begin
  ListBox1.Clear;
  ClassRef := Sender.ClassType;
  while ClassRef <> nil do
  begin
    ListBox1.Items.Add(ClassRef.ClassName);
    ClassRef := ClassRef.ClassParent;
  end;
end;
{
The list box contains the following strings after the user clicks the button:
    TButton
    TButtonControl
    TWinControl or TWinControl
    TControl
    TComponent
    TPersistent
    TObject
}
```

System::TObject::InheritsFrom (see page 22305)

158.1.29.4.7 TObject::ClassType Method

Returns the class reference for the object's class.

Pascal

```
function ClassType: TClass;
```

C++

```
__fastcall TClass ClassType();
```

Description

Note: System::TObject::ClassType dynamically determines the type of an object and returns its class reference, or metaclass.

Avoid using System::TObject::ClassType in application code.

Note: In Delphi code, use the is or as operators instead of System::TObject::ClassType.

Note: In C++ code, use a dynamic cast or the System::TObject::InheritsFrom (see page 22305) method instead of System::TObject::ClassType.

C++ Examples:

```
/*
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button's class and the names of its
parent classes are added to the list box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TClass ClassRef;
  ListBox1->Clear();
  ClassRef = Sender->ClassType();

The list box contains the following strings after the user clicks the button:
    TButton
    TButtonControl
    TWinControl or TWinControl
    TControl
    TComponent
    TPersistent
    TObject
*/
/*
For the following example, add a button, a status bar, and a
list box to the form. Set the SimplePanel property of the
status bar to true, using the object inspector. Also, populate
the OnMouseUp event handler for the list box.  The following
code fills a list box with the names of all components on the
form when the user clicks the button. References to the
components themselves are inserted along with the names. The
components are all inserted at the front of the list, so that
the last component added to the form is the first component
in the list.  When the user right-clicks the name of an
object in the list, the component's coordinates are displayed
on the status bar. Note that because we are using the right-
click, the item need not be selected.
*/

    }
    delete List;
  }
```

Delphi Examples:

```
{
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button's class and the names of its
parent classes are added to the list box.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ClassRef: TClass;
begin
  ListBox1.Clear;
  ClassRef := Sender.ClassType;
  while ClassRef <> nil do
  begin
    ListBox1.Items.Add(ClassRef.ClassName);
    ClassRef := ClassRef.ClassParent;
  end;
end;
{
The list box contains the following strings after the user clicks the button:
    TButton
    TButtonControl
    TWinControl or TWinControl
    TControl
    TComponent
    TPersistent
    TObject
}
```

158.1.29.4.8 TObject::CleanupInstance Method

Performs finalization on long strings, variants, and interface variables within a class.

Pascal

```
procedure CleanupInstance;
```

C++

```
__fastcall CleanupInstance();
```

Description

Do not call System::TObject::CleanupInstance directly. System::TObject::CleanupInstance is called automatically when the object instance is destroyed.

System::TObject::CleanupInstance releases all long strings and variants. It sets long strings to empty and variants to Unassigned.

See Also

System::TObject::Destroy (see page 22287)

System::TObject::Free (see page 22300)

delete

158.1.29.4.9 TObject::DefaultHandler Method

Provides the interface for a method that processes message records.

Pascal

```
procedure DefaultHandler(var Message); virtual;
```

C++

```
virtual DefaultHandler(var  Message);
```

Description

System::TObject::DefaultHandler is called by System::TObject::Dispatch (see page 22299) when it cannot find a method for a particular message. System::TObject::DefaultHandler provides message handling for all messages for which an object does not have specific handlers. Descendant classes that process messages override System::TObject::DefaultHandler according to the types of messages they handle.

Note: In a Delphi message-handling method, calling inherited results in a call to the ancestor's System::TObject::DefaultHandler method only if that ancestor does not specify a message method for the particular message being handled. Otherwise, calling inherited results in a call to the specific handler for that type of message.

See Also

System::TObject::Dispatch (see page 22299)

158.1.29.4.10 TObject::Dispatch Method

Calls message-handling methods for the object, based on the contents of the Message parameter.

Pascal

```
procedure Dispatch(var Message); virtual;
```

C++

```
virtual Dispatch(var  Message);
```

Description

Call System::TObject::Dispatch to automatically pass messages to the appropriate message handler.

System::TObject::Dispatch determines whether a message is in the list of message handlers declared for the object. If the object does not handle the message, System::TObject::Dispatch then examines the message-handler list of the ancestor class, and continues checking ancestors until it either finds a specific handler or runs out of ancestors, in which case it calls System::TObject::DefaultHandler (see page 22299).

The only assumption System::TObject::Dispatch makes about the data in Message is that the first two bytes contain a message ID—that is, an integer that determines which message handler System::TObject::Dispatch calls. Although any kind of data can be passed to System::TObject::Dispatch, most System::TObject::TObject (see page 22285) descendants expect a message record such as TMessage or a specific data structure type.

See Also

System::TObject::DefaultHandler (see page 22299)

TMessage

158.1.29.4.11 TObject::FieldAddress Method

Returns the address of a published object field.

Pascal

```
function FieldAddress(const Name: ShortString): Pointer;
```

C++

```
Pointer FieldAddress(const ShortString Name);
```

Description

System::TObject::FieldAddress is used internally by the component streaming system to access a specified published field of an object. System::TObject::FieldAddress returns a pointer to the field if it exists. If the object has no published field by that name, System::TObject::FieldAddress returns nil (Delphi) or NULL (C++).

Programs should access and manipulate fields by using properties instead of System::TObject::FieldAddress.

158.1.29.4.12 TObject::Free Method

Destroys an object and frees its associated memory, if necessary.

Pascal

```
procedure Free;
```

C++

```
__fastcall Free();
```

Description

Use System::TObject::Free to destroy an object. System::TObject::Free automatically calls the destructor if the object reference is not nil. Any object instantiated at runtime that does not have an owner should be destroyed by a call to System::TObject::Free so that it can be properly disposed of and its memory released. Unlike System::TObject::Destroy (see page 22287), System::TObject::Free is successful even if the object is nil; so if the object was never initialized, System::TObject::Free won't result in an error.

When you call System::TObject::Free for a component, it calls System::TObject::Free for all components that it owns—that is, all components in its component list. Since a form owns all the controls and other components that are created on it in design mode, those components are automatically freed when the form is freed. By default, all forms are owned by the Application object; when the application terminates, it frees the Application object, which frees all forms. For objects that are not components, or for components created with a nil owner, be sure to call System::TObject::Free after you are finished with them; otherwise the allocated memory will not be usable until after the application terminates.

Warning: Never explicitly free a component within one of its own event handlers or the event handler of a component it owns or contains. For example, don't free a button, or the form that owns the button, in its OnClick event handler.

To free a form, call its Release method, which destroys the form and releases the memory allocated for it after all its event handlers and those of the components it contains are through executing.

Note: In C++ code, do not use System::TObject::Free to destroy an object. Use the delete keyword.

C++ Examples:

```
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
```

```
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
}

158.1.29.4.13 TObject::FreeInstance Method

Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.

Pascal

```
procedure FreeInstance; virtual;
```

C++

```
virtual __fastcall FreeInstance();
```

Description

All destructors call System::TObject::FreeInstance automatically to deallocate memory that was allocated by overriding System::TObject::NewInstance (see page 22306).

Do not call System::TObject::FreeInstance directly. System::TObject::FreeInstance should be overridden if System::TObject::NewInstance (see page 22306) was overridden to change the way the object's instance data was allocated.

Like System::TObject::NewInstance (see page 22306), System::TObject::FreeInstance uses the value returned from System::TObject::InstanceSize (see page 22306) to deallocate the object's memory.

See Also

System::TObject::InstanceSize (see page 22306)

System::TObject::NewInstance (see page 22306)

158.1.29.4.14 TObject::GetInterface Method

Retrieves a specified interface.

Pascal

```
function GetInterface(const IID: TGUID; out Obj): Boolean;
```

C++

```
Boolean GetInterface(const TGUID IID, out  Obj);
```

Description

System::TObject::GetInterface retrieves the interface designated by a GUID or type name. The basic implementation of System::TObject::GetInterface uses the GUID specified in the IID parameter. If the specified interface is supported by the class, it is returned in the Obj parameter, and System::TObject::GetInterface has a return value of true. Otherwise Obj contains nil (Delphi) or NULL (C++), and System::TObject::GetInterface returns false.

Note: In Delphi code, IID can be an interface name. The compiler automatically translates this name into the corresponding GUID.

Note: In C++ code, use the templated version of System::TObject::GetInterface to obtain an interface from a DelphiInterface (see page 22167) object.

System::TObject::GetInterface is equivalent to the as operator (Delphi) and dynamic casts (C++), except that System::TObject::GetInterface does not raise an exception if the interface is not supported.

See Also

System::TInterfacedObject::QueryInterface (see page 22280)

158.1.29.4.15 TObject::GetInterfaceEntry Method

Returns the entry for a specific interface implemented in a class.

Pascal

```
class function GetInterfaceEntry(const IID: TGUID): PInterfaceEntry;
```

C++

```
PInterfaceEntry GetInterfaceEntry(const TGUID IID);
```

Description

System::TObject::GetInterfaceEntry returns the class entry for the interface specified by the IID parameter.

Note: In Delphi Code, IID can be an interface name. The compiler replaces this name with the actual GUID.

Note: COM objects can use System::TObject::GetInterfaceEntry to automate dispatch calls to a dual-IDispatch (see page 22394) interface.

158.1.29.4.16 TObject::GetInterfaceTable Method

Returns a pointer to a structure containing all of the interfaces implemented by a given class.

Pascal

```
class function GetInterfaceTable: PInterfaceTable;
```

C++

```
PInterfaceTable GetInterfaceTable();
```

Description

System::TObject::GetInterfaceTable returns the interface entries for the class. This list contains only interfaces implemented by this class, not its ancestors. To find the ancestor list, iteratively call System::TObject::ClassParent (see page 22293) and then call System::TObject::GetInterfaceTable on the value it returns. To find the entry for a specific interface, use the System::TObject::GetInterfaceEntry (see page 22304) method instead.

See Also

System::TObject::GetInterfaceEntry (see page 22304)

System::TObject::ClassParent (see page 22293)

158.1.29.4.17 TObject::InheritsFrom Method

Determines the relationship of two object types.

Pascal

```
class function InheritsFrom(AClass: TClass): Boolean;
```

C++

```
Boolean InheritsFrom(TClass AClass);
```

Description

Use System::TObject::InheritsFrom to determine if a particular class type or object is an instance of a class or one of its descendants. System::TObject::InheritsFrom returns true if the object type specified in the aClass parameter is an ancestor of the object type or the type of the object itself. Otherwise, it returns false.

Note: System::TObject::InheritsFrom is similar to the Delphi is operator, but applies to class references.

Note: In C++ code, a non-static version of System::TObject::InheritsFrom is provided. This call is useful in determining whether a descendant class method or property can be used, given a variable of a base class. For example, use System::TObject::InheritsFrom to determine whether the Sender parameter in an event handler is of a particular class type or one of its descendants.

See Also

System::TObject::ClassParent (see page 22293)

System::TObject::ClassNameIs (see page 22293)

158.1.29.4.18 TObject::InitInstance Method

Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.

Pascal

```
class function InitInstance(Instance: Pointer): TObject;
```

C++

```
TObject InitInstance(Pointer Instance);
```

Description

There should be no reason to call System::TObject::InitInstance directly. System::TObject::InitInstance is called by System::TObject::NewInstance (see page 22306) when an object is created. When overriding System::TObject::NewInstance (see page 22306), be sure to call System::TObject::InitInstance as the last statement.

System::TObject::InitInstance is not virtual, so you cannot override it: Instead, initialize any data for an object in the constructor.

See Also

System::TObject::Create (see page 22287)

System::TObject::NewInstance (see page 22306)

158.1.29.4.19 TObject::InstanceSize Method

Returns the size in bytes of each instance of the object type.

Pascal

```
class function InstanceSize: Longint;
```

C++

```
Longint InstanceSize();
```

Description

System::TObject::InstanceSize indicates how many bytes of memory are required for a class's instance data. System::TObject::InstanceSize is called from methods that allocate and deallocate memory. System::TObject::InstanceSize is not a virtual method, so it cannot be overridden. System::TObject::InstanceSize should be called only when implementing a custom version of System::TObject::NewInstance (see page 22306).

See Also

System::TObject::FreeInstance (see page 22303)

System::TObject::NewInstance (see page 22306)

158.1.29.4.20 TObject::MethodAddress Method

Pascal

```
class function MethodAddress(const Name: ShortString): Pointer;
```

C++

```
Pointer MethodAddress(const ShortString Name);
```

Description

This is MethodAddress, a member of class TObject.

158.1.29.4.21 TObject::MethodName Method

Pascal

```
class function MethodName(Address: Pointer): ShortString;
```

C++

```
ShortString MethodName(Pointer Address);
```

Description

This is MethodName, a member of class TObject.

158.1.29.4.22 TObject::NewInstance Method

Allocates memory for an instance of an object type and returns a pointer to that new instance.

Pascal

```
class function NewInstance: TObject; virtual;
```

C++

```
virtual TObject NewInstance();
```

Description

All constructors call System::TObject::NewInstance automatically. System::TObject::NewInstance calls System::TObject::InstanceSize (see page 22306) to determine how much memory to allocate from the heap to contain a particular instance. Do not call System::TObject::NewInstance directly.

Override System::TObject::NewInstance only for special memory allocation requirements. For example, when allocating a large number of identical objects that all need to be in memory at the same time, you could allocate a single block of memory for the entire group, then override System::TObject::NewInstance to use part of that larger block for each instance.

If you override System::TObject::NewInstance to allocate memory, you may need to override System::TObject::FreeInstance (see page 22303) to deallocate the memory.

Note: By default System::TObject::NewInstance calls System::TObject::InitInstance (see page 22305).

See Also

System::TObject::FreeInstance (see page 22303)

System::TObject::InstanceSize (see page 22306)

System::TObject::InitInstance (see page 22305)

158.1.29.4.23 TObject::SafeCallException Method

Handles exceptions in methods declared using the safecall calling convention.

Pascal

```
function SafeCallException(ExceptObject: TObject; ExceptAddr: Pointer): HResult; virtual;
```

C++

```
virtual HResult SafeCallException(TObject ExceptObject, Pointer ExceptAddr);
```

Description

System::TObject::SafeCallException handles exceptions in methods that use the safecall calling convention. Some classes that implement interfaces override this method to handle errors that might occur.

As implemented in System::TObject::TObject (see page 22285), System::TObject::SafeCallException simply returns E_UNEXPECTED (see page 22664). This is the appropriate response for classes that do no support interfaces

158.1.30 Variant Class

System::Variant is a C++ implementation of the Delphi intrinsic type System::Variant.

Class Hierarchy

Pascal

```
Variant = class(TVarData);
```

C++

```
class Variant : public TVarData;
```

File

sysvari.h

Description

The System::Variant type is capable of representing values that change type dynamically. Whereas a variable of any other type is statically bound to that type, a variable of the System::Variant type can assume values of differing types at run-time. The System::Variant type is most commonly used in situations where the actual type to be operated upon varies or is unknown at compile-time. While variants offer great flexibility, they also consume more memory than regular variables, and operations on variants are substantially slower than operations on statically typed values.

System::Variants (see page 23567) can contain various numeric, string, Boolean, and date-time values. If COM is available (Windows only) variants can also contain OLE Automation objects. Finally, variants can contain arrays of any of the above types. The special System::Variant value Unassigned is used to indicate that a variant has not yet been assigned a value, and the special variant value Null is used to indicate unknown or missing data.

A variant can be constructed from the following data types:

short (see page 22370)

int (see page 22368)

float (see page 22367)

double (see page 22367)

Currency (see page 22366)

TDateTime (see page 22371)

bool (see page 22365)

WordBool

Byte

AnsiString (see page 22365)&

char (see page 22365) *

wchar_t * const

Ole2::IDispatch (see page 22394)* const (Windows only)

Ole2::IUnknown (see page 22586)* const (Windows only)

Note: When a System::Variant contains an OLE Automation object, the variant can be used to get and set properties of the object, and to invoke methods on the object.

System::Variant variables are always initialized to be Unassigned when they are first created. This is true whether a variant variable is global, local, or part of a structure such as an array.

In C++ code, variant arrays are usually created using a System::Variant constructor in conjunction with the OPENARRAY macro:

```
Variant V(OPENARRAY(int,(0,HighVal,0,HighVal)),varInteger);
```

You can also use the VarArrayCreate function, but that function is designed for use in Delphi code, and makes for complex C++ code.

Note: Use only the operators declared within System::Variant. The compiler ignores any operators you overload yourself.

Note: For binary operators, if one operand is of type System::Variant, the other operand is automatically converted to type System::Variant.

158.1.30.1 Variant Members

The following tables list the members exposed by Variant.

Public Friends

Name	Description
class AutoCmd (see page 22375)	This is friend class AutoCmd.

Public Methods

	Name	Description
	~Variant (see page 22311)	Frees a System::Variant::Variant (see page 22314) object.
	ArrayDimCount (see page 22317)	Returns the number of dimensions of the given variant.
	ArrayHighBound (see page 22317)	Returns the high bound of the given dimension in the given variant array.
	ArrayLock (see page 22317)	Locks the given variant array and returns a pointer to the data stored in the array.
	ArrayLowBound (see page 22318)	Returns the low bound of the given dimension in the given variant array.
	ArrayRedim (see page 22318)	Resizes the given variant array by changing the high bound of the rightmost dimension to the given value.
	ArrayUnlock (see page 22318)	Unlocks a variant array that was previously locked by ArrayLock (see page 22317).
	Assign (see page 22318)	This is Assign, a member of class Variant.
	AsType (see page 22319)	Casts a System::Variant::Variant (see page 22314) object to the type specified by the argument VarType.
	ChangeType (see page 22319)	Changes the data type of a System::Variant::Variant (see page 22314) object once it has been instantiated.
	Clear (see page 22319)	System::Variant::Clears the value of the System::Variant::Variant (see page 22314).
	CreateObject (see page 22320)	Creates an OLE Automation object with the programmatic identifier specified by ProgID and returns it as a System::Variant::Variant (see page 22314).
	Empty (see page 22320)	This is Empty, a member of class Variant.
	Exec (see page 22320)	System::Variant::Executes an OLE procedure, function, or a property Get or Set method.
	GetActiveObject (see page 22321)	Retrieves a reference to an IDispatch (see page 22394) interface of a currently running, registered OLE Automation object, and returns it as a System::Variant::Variant (see page 22314).
	GetBaseVariant (see page 22321)	Returns the Variant (see page 22307) that is assigned as the value of this Variant (see page 22307) when Type (see page 22341) is varVariant (see page 22690).
	GetElement (see page 22322)	This is the overview for the GetElement method overload.
	GetError (see page 22322)	Converts the System::Variant::Variant (see page 22314) to a varError (see page 22684) type and returns the integer value.
	IsArray (see page 22323)	Queries the VType of the base class TVarData (see page 22571) for the varArray (see page 22679) bit.
	IsEmpty (see page 22323)	Queries the VType of the base class TVarData (see page 22571).
	IsNull (see page 22323)	Queries the VType of the base class TVarData (see page 22571) for the varNull (see page 22686) bit.

	NoParam (see page 22324)	This is NoParam, a member of class Variant.
	OleFunction (see page 22324)	This is the overview for the OleFunction method overload.
	OleProcedure (see page 22330)	This is the overview for the OleProcedure method overload.
	OlePropertyGet (see page 22336)	This is the overview for the OlePropertyGet method overload.
	OlePropertySet (see page 22338)	This is the overview for the OlePropertySet method overload.
	PutElement (see page 22340)	This is the overview for the PutElement method overload.
	Sanitized (see page 22340)	This is Sanitized, a member of class Variant.
	SetError (see page 22341)	Converts the System::Variant::Variant (see page 22314) to a varError (see page 22684) type and assigns the integer err as the value of the varError (see page 22684).
	Type (see page 22341)	This is Type, a member of class Variant.
	Variant (see page 22312)	This is the overview for the Variant constructor overload.

Public Operators

	Name	Description
	- (see page 22343)	This is the overview for the - operator overload.
	! (see page 22344)	Returns a new System::Variant::Variant (see page 22314) that is the logical negation of this System::Variant::Variant (see page 22314).
	!= (see page 22344)	This is the overview for the != operator overload.
	% (see page 22345)	This is the overview for the % operator overload.
	%= (see page 22346)	Returns this System::Variant::Variant (see page 22314) as the remainder from dividing its original value and the System::Variant::Variant (see page 22314) specified by rhs.
	& (see page 22346)	This is the overview for the & operator overload.
	&= (see page 22347)	Returns this System::Variant::Variant (see page 22314) after performing a bitwise and operation.
	* (see page 22347)	This is the overview for the * operator overload.
	*= (see page 22348)	Multiplies this System::Variant::Variant (see page 22314) by the System::Variant::Variant (see page 22314) specified by rhs.
	/ (see page 22348)	This is the overview for the / operator overload.
	/= (see page 22349)	Divides this System::Variant::Variant (see page 22314) by the System::Variant::Variant (see page 22314) rhs.
	^ (see page 22349)	This is the overview for the ^ operator overload.
	^= (see page 22350)	Returns this System::Variant::Variant (see page 22314) after performing a bitwise xor operation.
	__int64 (see page 22350)	This is __int64, a member of class Variant.
	| (see page 22351)	This is the overview for the | operator overload.
	|= (see page 22351)	Returns this System::Variant::Variant (see page 22314) after performing a bitwise or operation.
	+ (see page 22352)	This is the overview for the + operator overload.
	+= (see page 22352)	Adds the System::Variant::Variant (see page 22314) specified by rhs to this System::Variant::Variant (see page 22314) object.
	< (see page 22353)	This is the overview for the < operator overload.
	<< (see page 22353)	This is the overview for the << operator overload.
	<<= (see page 22354)	Performs a bitwise shl (left shift) operation on this System::Variant::Variant (see page 22314).
	<= (see page 22355)	This is the overview for the <= operator overload.
	-= (see page 22361)	Subtracts the System::Variant::Variant (see page 22314) specified by rhs from this System::Variant::Variant (see page 22314) object.
	= (see page 22355)	This is the overview for the = operator overload.
	== (see page 22361)	This is the overview for the == operator overload.
	> (see page 22362)	This is the overview for the > operator overload.
	>= (see page 22363)	This is the overview for the >= operator overload.
	>> (see page 22363)	This is the overview for the >> operator overload.
	>>= (see page 22365)	Performs a bitwise shr (right shift) operation on this System::Variant::Variant (see page 22314).
	AnsiString (see page 22365)	Converts the System::Variant::Variant (see page 22314) to an AnsiString object.
	bool (see page 22365)	Converts the System::Variant::Variant (see page 22314) to a boolean value.

	char (see page 22365)	This is char, a member of class Variant.
	Currency (see page 22366)	Converts the System::Variant::Variant (see page 22314) to a Currency object.
	CURRENCY (see page 22366)	This is CURRENCY, a member of class Variant.
	Currency* (see page 22366)	This is Currency*, a member of class Variant.
	DECIMAL (see page 22366)	This is DECIMAL, a member of class Variant.
	double (see page 22367)	Converts the System::Variant::Variant (see page 22314) to a double value.
	double* (see page 22367)	This is double*, a member of class Variant.
	float (see page 22367)	Converts the System::Variant::Variant (see page 22314) to a float value.
	float* (see page 22368)	This is float*, a member of class Variant.
	IDispatch* (see page 22368)	This is IDispatch*, a member of class Variant.
	IInterface* (see page 22368)	This is IInterface*, a member of class Variant.
	int (see page 22368)	Converts the System::Variant::Variant (see page 22314) to an integer value.
	int* (see page 22369)	This is int*, a member of class Variant.
	IUnknown* (see page 22369)	This is IUnknown*, a member of class Variant.
	long (see page 22369)	This is long, a member of class Variant.
	long* (see page 22369)	This is long*, a member of class Variant.
	LPSAFEARRAY (see page 22369)	This is LPSAFEARRAY, a member of class Variant.
	short (see page 22370)	Converts the System::Variant::Variant (see page 22314) to a short value.
	short* (see page 22370)	This is short*, a member of class Variant.
	signed char (see page 22370)	This is signed char, a member of class Variant.
	signed char* (see page 22370)	This is signed char*, a member of class Variant.
	TDateTime (see page 22371)	Converts the System::Variant::Variant (see page 22314) to a TDateTime object.
	TDateTime* (see page 22371)	This is TDateTime*, a member of class Variant.
	TVariant (see page 22371)	This is TVariant, a member of class Variant.
	TVariant* (see page 22371)	This is TVariant*, a member of class Variant.
	unsigned char (see page 22372)	This is unsigned char, a member of class Variant.
	unsigned char* (see page 22372)	This is unsigned char*, a member of class Variant.
	unsigned int (see page 22372)	This is unsigned int, a member of class Variant.
	unsigned int* (see page 22372)	This is unsigned int*, a member of class Variant.
	unsigned long (see page 22373)	This is unsigned long, a member of class Variant.
	unsigned long* (see page 22373)	This is unsigned long*, a member of class Variant.
	unsigned short (see page 22373)	This is unsigned short, a member of class Variant.
	unsigned short* (see page 22373)	This is unsigned short*, a member of class Variant.
	VARIANT (see page 22373)	This is VARIANT, a member of class Variant.
	VARIANT* (see page 22374)	This is VARIANT*, a member of class Variant.
	wchar_t* (see page 22374)	Converts the System::Variant::Variant (see page 22314) to the specified type and sets the varByRef (see page 22680) bit, meaning that the variant contains a reference as opposed to a value.
	wchar_t** (see page 22374)	This is wchar_t**, a member of class Variant.
	WideString (see page 22374)	This is WideString, a member of class Variant.

158.1.30.2 Variant::~Variant Destructor

Frees a System::Variant::Variant (see page 22314) object.

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~Variant();
```

Description

System::Variant::Destroy is the destructor for System::Variant::Variant (see page 22314).

158.1.30.3 Variant Constructor

This is the overview for the Variant constructor overload.

Overload List

	Name	Description
	Variant::Variant () (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (__int64) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (__int64*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (AnsiString&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (bool) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (char) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (char*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (Currency&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (CURRENCY&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (Currency*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (CURRENCY*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (DECIMAL&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (DECIMAL*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (double) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (double*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (float) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (float*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (IDispatch*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (IInterface*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (int) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (int*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (int*, int, Word) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (IUnknown*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (long) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (long double) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (long*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (SAFEARRAY&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (SAFEARRAY*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (SAFEARRAY**) (see page 22314)	Creates an instance of System::Variant::Create.

	Variant::Variant (short) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (short*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (signed char) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (signed char*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (System::DelphiInterface<IDispatch>&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (TDateTime&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (TDateTime*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (TVarData&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (TVariant&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (unsigned char) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (unsigned char*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (unsigned int) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (unsigned int*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (unsigned long) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (unsigned long*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (unsigned short) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (unsigned short*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (Variant&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (VARIANT&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (Variant*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (VARIANT*) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (Variant*, int) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (VariantError&) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (wchar_t**) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (wchar_t*, bool) (see page 22314)	Creates an instance of System::Variant::Create.
	Variant::Variant (WideString&) (see page 22314)	Creates an instance of System::Variant::Create.

158.1.30.3.1 Variant::Variant Constructor ()

Creates an instance of System::Variant::Create.

Pascal

```
constructor Create;
constructor Create(const src: Variant&);
constructor Create(const src: TVarData&);
constructor Create(const src: bool);
constructor Create(const src: char);
constructor Create(const src: signed char);
constructor Create(const src: unsigned char);
constructor Create(const src: short);
constructor Create(const src: unsigned short);
constructor Create(const src: Integer);
constructor Create(const src: unsigned int);
constructor Create(const src: long);
constructor Create(const src: unsigned long);
constructor Create(const src: float);
constructor Create(const src: double);
constructor Create(const src: long double);
constructor Create(const src: __int64);
constructor Create(const src: CURRENCY&);
constructor Create(const src: DECIMAL&);
constructor Create(const src: SAFEARRAY&);
constructor Create(const src: VARIANT&);
constructor Create(var src: SAFEARRAY);
constructor Create(var src: VARIANT);
constructor Create(const src: TVariant&);
constructor Create(const src: AnsiString&);
constructor Create(const src: Currency&);
constructor Create(const src: TDateTime&);
constructor Create(const src: VariantError&);
constructor Create(const src: WideString&);
constructor Create(const src: char*);
constructor Create(var src: wchar_t; makeCopy: bool = true);
constructor Create(var src: IUnknown);
constructor Create(var src: IInterface);
constructor Create(var src: IDispatch);
constructor Create(const src: System::DelphiInterface<IDispatch>&);
constructor Create(var src: signed char);
constructor Create(var src: unsigned char);
constructor Create(var src: short);
constructor Create(var src: unsigned short);
constructor Create(var src: Integer);
constructor Create(var src: unsigned int);
constructor Create(var src: long);
constructor Create(var src: unsigned long);
constructor Create(var src: float);
constructor Create(var src: double);
constructor Create(var src: __int64);
constructor Create(var src: CURRENCY);
constructor Create(var src: DECIMAL);
constructor Create(var src: SAFEARRAY*);
constructor Create(var src: wchar_t*);
constructor Create(var src: Currency);
constructor Create(var src: TDateTime);
constructor Create(var src: Variant);
constructor Create(const bounds: int*; const boundsSize: Integer; varType: Word);
constructor Create(const values: Variant*; const valuesSize: Integer);
```

C++

```
__fastcall Variant();
```

```
__fastcall Variant(const Variant& src);
__fastcall Variant(const TVarData& src);

__fastcall Variant(Currency* src);
__fastcall Variant(TDateTime* src);
__fastcall Variant(Variant* src);
__fastcall Variant(const int* bounds, const int boundsSize, Word varType);
__fastcall Variant(const Variant* values, const int valuesSize);
```

Description

The first System::Variant::Create constructor above creates a variant instance with the value Unassigned.

The second System::Variant::Create constructor creates a System::Variant::Create array with the bounds given by bounds and the element type given by varType. The bounds parameter must contain an even number of values, and each pair of values must specify the upper and lower bounds of one dimension of the array. The boundsSize parameter is the index of the last element in bounds. The element type of the array, given by the varType parameter, must be one of the TVarData (see page 22571) type codes, and cannot include the varArray (see page 22679) or varByRef (see page 22680) bits. The element type cannot be varString (see page 22688). To create an array of strings, use the varOleStr (see page 22686) type code. If the

element type is varSystem::Variant::Create, the elements of the array are themselves System::Variant::Creates and can, in turn, contain System::Variant::Create arrays.

The third System::Variant::Create constructor creates a one-dimensional System::Variant::Create array with the elements given by the values parameter. The low bound of the returned array is zero, the high bound is given by valuesSize (the index of the last value). The element type of the instantiated array is System::Variant::Create.

The remaining System::Variant::Create constructors create a System::Variant::Create with the same value as the src argument, converting src as appropriate. Constructors that declare src as a const parameter copy src into the variant's internal representation. Constructors that do not declare src as a const create a reference to src and set the variant's varByRef (see page 22680) bit.

158.1.30.4 Variant Methods

The methods of the Variant class are listed here.

Public Methods

	Name	Description
	ArrayDimCount (see page 22317)	Returns the number of dimensions of the given variant.
	ArrayHighBound (see page 22317)	Returns the high bound of the given dimension in the given variant array.
	ArrayLock (see page 22317)	Locks the given variant array and returns a pointer to the data stored in the array.
	ArrayLowBound (see page 22318)	Returns the low bound of the given dimension in the given variant array.
	ArrayRedim (see page 22318)	Resizes the given variant array by changing the high bound of the rightmost dimension to the given value.
	ArrayUnlock (see page 22318)	Unlocks a variant array that was previously locked by ArrayLock (see page 22317).
	Assign (see page 22318)	This is Assign, a member of class Variant.
	AsType (see page 22319)	Casts a System::Variant::Variant (see page 22314) object to the type specified by the argument VarType.
	ChangeType (see page 22319)	Changes the data type of a System::Variant::Variant (see page 22314) object once it has been instantiated.
	Clear (see page 22319)	System::Variant::Clears the value of the System::Variant::Variant (see page 22314).
	CreateObject (see page 22320)	Creates an OLE Automation object with the programmatic identifier specified by ProgID and returns it as a System::Variant::Variant (see page 22314).
	Empty (see page 22320)	This is Empty, a member of class Variant.
	Exec (see page 22320)	System::Variant::Executes an OLE procedure, function, or a property Get or Set method.
	GetActiveObject (see page 22321)	Retrieves a reference to an IDispatch (see page 22394) interface of a currently running, registered OLE Automation object, and returns it as a System::Variant::Variant (see page 22314).
	GetBaseVariant (see page 22321)	Returns the Variant (see page 22307) that is assigned as the value of this Variant (see page 22307) when Type (see page 22341) is varVariant (see page 22690).
	GetElement (see page 22322)	This is the overview for the GetElement method overload.
	GetError (see page 22322)	Converts the System::Variant::Variant (see page 22314) to a varError (see page 22684) type and returns the integer value.
	IsArray (see page 22323)	Queries the VType of the base class TVarData (see page 22571) for the varArray (see page 22679) bit.
	IsEmpty (see page 22323)	Queries the VType of the base class TVarData (see page 22571).
	IsNull (see page 22323)	Queries the VType of the base class TVarData (see page 22571) for the varNull (see page 22686) bit.
	NoParam (see page 22324)	This is NoParam, a member of class Variant.

	OleFunction (see page 22324)	This is the overview for the OleFunction method overload.
	OleProcedure (see page 22330)	This is the overview for the OleProcedure method overload.
	OlePropertyGet (see page 22336)	This is the overview for the OlePropertyGet method overload.
	OlePropertySet (see page 22338)	This is the overview for the OlePropertySet method overload.
	PutElement (see page 22340)	This is the overview for the PutElement method overload.
	Sanitized (see page 22340)	This is Sanitized, a member of class Variant.
	SetError (see page 22341)	Converts the System::Variant::Variant (see page 22314) to a varError (see page 22684) type and assigns the integer err as the value of the varError (see page 22684).
	Type (see page 22341)	This is Type, a member of class Variant.

158.1.30.4.1 Variant::ArrayDimCount Method

Returns the number of dimensions of the given variant.

Pascal

```
function ArrayDimCount: Integer;
```

C++

```
__fastcall int ArrayDimCount() const;
```

Description

The resulting value is zero if the given variant is not a System::Variant::Variant (see page 22314) array.

158.1.30.4.2 Variant::ArrayHighBound Method

Returns the high bound of the given dimension in the given variant array.

Pascal

```
function ArrayHighBound(const dim: Integer = 1): Integer;
```

C++

```
__fastcall int ArrayHighBound(const int dim = 1) const;
```

Description

The dim parameter should be 1 for the leftmost dimension, 2 for the second leftmost dimension, and so on. An ESystem::Variant::VariantError (see page 22375) exception is raised if the variant given by A is not an array, or if the dimension specified by dim does not exist.

158.1.30.4.3 Variant::ArrayLock Method

Locks the given variant array and returns a pointer to the data stored in the array.

Pascal

```
function ArrayLock: Pointer;
```

C++

```
__fastcall Pointer ArrayLock();
```

Description

While locked, a variant array can not be resized and any calls to ArrayRedim (see page 22318) will fail. Once locked, a variant array must later be unlocked using ArrayUnlock (see page 22318). An ESystem::Variant::VariantError (see page 22375) exception is raised if the variant given by A is not an array.

The pointer returned by System::Variant::ArrayLock points to an array of elements in which the leftmost dimension increases

first. In other words, the dimensions of the returned array pointer are reversed from the dimensions of the variant array.

Once it is verified that a variant array has the correct bounds and dimensions, System::Variant::ArrayLock can be used to gain direct access to the array data which results in much improved performance.

158.1.30.4.4 Variant::ArrayLowBound Method

Returns the low bound of the given dimension in the given variant array.

Pascal

```
function ArrayLowBound(const dim: Integer = 1): Integer;
```

C++

```
__fastcall int ArrayLowBound(const int dim = 1) const;
```

Description

The dim parameter should be 1 for the leftmost dimension, 2 for the second leftmost dimension, and so on. An ESystem::Variant::VariantError (see page 22375) exception is raised if the variant given by A is not an array, or if the dimension specified by dim does not exist.

158.1.30.4.5 Variant::ArrayRedim Method

Resizes the given variant array by changing the high bound of the rightmost dimension to the given value.

Pascal

```
procedure ArrayRedim(highBound: Integer);
```

C++

```
__fastcall void ArrayRedim(int highBound);
```

Description

Existing elements of the array are preserved, and new elements are set to zero or empty. An ESystem::Variant::VariantError (see page 22375) exception is raised if the variant given by A is not an array, or if there is not enough memory to resize the array.

158.1.30.4.6 Variant::ArrayUnlock Method

Unlocks a variant array that was previously locked by ArrayLock (see page 22317).

Pascal

```
procedure ArrayUnlock;
```

C++

```
__fastcall void ArrayUnlock();
```

Description

System::Variant::ArrayUnlock invalidates the pointer returned by a call to the ArrayLock (see page 22317) method. An ESystem::Variant::VariantError (see page 22375) exception is raised if the System::Variant::Variant (see page 22314) is not an array.

158.1.30.4.7 Variant::Assign Method

Pascal

```
function Assign(var src: wchar_t; makeCopy: bool): Variant&;
```

C++

```
__fastcall Variant& Assign(wchar_t* src, bool makeCopy);
```

Description

This is Assign, a member of class Variant.

158.1.30.4.8 Variant::AsType Method

Casts a System::Variant::Variant (see page 22314) object to the type specified by the argument VarType.

Pascal

```
function AsType(VarType: Integer): Variant;
```

C++

```
__fastcall Variant AsType(int VarType) const;
```

Description

System::Variant::AsType returns a new System::Variant::Variant (see page 22314) with the same value as this System::Variant::Variant (see page 22314) but with the type specified by VarType. After the call to System::Variant::AsType there are two System::Variant::Variant (see page 22314) objects of the same type.

158.1.30.4.9 Variant::ChangeType Method

Changes the data type of a System::Variant::Variant (see page 22314) object once it has been instantiated.

Pascal

```
function ChangeType(VarType: Integer): Variant&;
```

C++

```
__fastcall Variant& ChangeType(int VarType);
```

Description

System::Variant::ChangeType converts the System::Variant::Variant (see page 22314) to the type specified by VarType.

See Also

System::Variant::Type2

158.1.30.4.10 Variant::Clear Method

System::Variant::Clears the value of the System::Variant::Variant (see page 22314).

Pascal

```
procedure Clear;
```

C++

```
__fastcall void Clear();
```

Description

System::Variant::Clear assigns the value Unassigned to this System::Variant::Variant (see page 22314).

See Also

Unassigned (see page 23643)

158.1.30.4.11 Variant::CreateObject Method

Creates an OLE Automation object with the programmatic identifier specified by ProgID and returns it as a System::Variant::Variant (see page 22314).

Pascal

```
function CreateObject(const ProgID: String&): Variant; static;
```

C++

```
static __fastcall Variant CreateObject(const String& ProgID);
```

Description

System::Variant::CreateObject creates a single uninitialized object of the class associated with the ProgID specified by the ProgID parameter. System::Variant::CreateObject is used to create an object of a specified type when the ProgID is known, and when the object is on a local or in-proc server. Only objects that are not part of an aggregate are created using System::Variant::CreateObject.

System::Variant::CreateObject is called once to create each new single instance of a class. To create multiple instance of the same class, it is recommended to use a class factory.

System::Variant::CreateObject returns a reference to the identifier of the interface to be used to communicate with the object. For System::Variant::CreateObject, this interface is of type IDispatch (see page 22394).

If ProgID is invalid, System::Variant::CreateObject throws an EOleSysError exception.

158.1.30.4.12 Variant::Empty Method

Pascal

```
function Empty: Variant&; static;
```

C++

```
static Variant& Empty();
```

Description

This is Empty, a member of class Variant.

158.1.30.4.13 Variant::Exec Method

System::Variant::Executes an OLE procedure, function, or a property Get or Set method.

Pascal

```
function Exec(var cmd: AutoCmd; lcid: Integer = LOCALE_SYSTEM_DEFAULT): Variant;
```

C++

```
__fastcall Variant Exec(AutoCmd& cmd, Integer lcid = LOCALE_SYSTEM_DEFAULT) const;
```

Description

Use System::Variant::Exec to call Automation methods.

The cmd parameter is the wrapper class for the method on an interface that is assigned as the System::Variant::Variant (see page 22314)'s value. Use this parameter to identify the method you want to call and to assign any parameter values.

The lcid parameter is ignored by System::Variant::Variant (see page 22314). The locale identifier used to interpret parameters is always LOCALE_SYSTEM_DEFAULT.

See Also

System::Variant::OleFunction (see page 22326)

System::Variant::OleProcedure (see page 22332)

System::Variant::OlePropertyGet (see page 22337)

System::Variant::OlePropertySet (see page 22338)

158.1.30.4.14 Variant::GetActiveObject Method

Retrieves a reference to an IDispatch (see page 22394) interface of a currently running, registered OLE Automation object, and returns it as a System::Variant::Variant (see page 22314).

Pascal

```
function GetActiveObject(const ProgID: String&): Variant; static;
```

C++

```
static __fastcall Variant GetActiveObject(const String& ProgID);
```

Description

System::Variant::GetActiveObject returns a reference to the IDispatch (see page 22394) interface of the active object for the given class indicated by ProgID. ProgID is the programmatic ID for the class of the active object from the OLE registration database.

If either the class object or the IDispatch (see page 22394) interface is not successfully returned, an EOleSysError exception is thrown.

Tip: If the Automation object is not running or not registered, use the CreateObject (see page 22320) member of System::Variant::Variant (see page 22314) to run it.

See Also

System::Variant::CreateObject (see page 22320)

158.1.30.4.15 Variant::GetBaseVariant Method

Returns the Variant (see page 22307) that is assigned as the value of this Variant (see page 22307) when Type (see page 22341) is varVariant (see page 22690).

Pascal

```
function GetBaseVariant: Variant*;
```

C++

```
__fastcall Variant* GetBaseVariant();
```

Description

Call GetBaseVariant to remove a level of indirection by accessing a Variant (see page 22307) that has been assigned as the value of this Variant (see page 22307). Check the Type (see page 22341) method to ensure that the variant is of type var Variant (see page 22307) before calling GetBaseVariant.

See Also

System::Variant (see page 22307)

158.1.30.4.16 GetElement Method

This is the overview for the GetElement method overload.

Overload List

	Name	Description
	Variant::GetElement (int) (see page 22322)	Returns the value of a specified element in a System::Variant::Variant (see page 22314) array.
	Variant::GetElement (int, int) (see page 22322)	Returns the value of a specified element in a System::Variant::Variant (see page 22314) array.
	Variant::GetElement (int, int, int) (see page 22322)	Returns the value of a specified element in a System::Variant::Variant (see page 22314) array.
	Variant::GetElement (int, int, int, int) (see page 22322)	Returns the value of a specified element in a System::Variant::Variant (see page 22314) array.
	Variant::GetElement (int, int, int, int, int) (see page 22322)	Returns the value of a specified element in a System::Variant::Variant (see page 22314) array.

158.1.30.4.16.1 Variant::GetElement Method (int)

Returns the value of a specified element in a System::Variant::Variant (see page 22314) array.

Pascal

```
function GetElement(const i1: Integer): Variant;
function GetElement(const i1: Integer; const i2: Integer): Variant;
function GetElement(const i1: Integer; const i2: Integer; const i3: Integer): Variant;
function GetElement(const i1: Integer; const i2: Integer; const i3: Integer; const i4:
Integer): Variant;
function GetElement(const i1: Integer; const i2: Integer; const i3: Integer; const i4:
Integer; const i5: Integer): Variant;
```

C++

```
__fastcall Variant GetElement(const int i1) const;
__fastcall Variant GetElement(const int i1, const int i2) const;
__fastcall Variant GetElement(const int i1, const int i2, const int i3) const;
__fastcall Variant GetElement(const int i1, const int i2, const int i3, const int i4) const;
__fastcall Variant GetElement(const int i1, const int i2, const int i3, const int i4, const
int i5) const;
```

Description

Use System::Variant::GetElement to access one-dimensional or multi-dimensional System::Variant::Variant (see page 22314) arrays of up to 5 dimensions. The parameters specify the indexes of the desired element.

See Also

System::Variant::PutElement (see page 22340)

158.1.30.4.17 Variant::GetError Method

Converts the System::Variant::Variant (see page 22314) to a varError (see page 22684) type and returns the integer value.

Pascal

```
function GetError: HResult;
```

C++

```
__fastcall HResult GetError() const;
```

Description

See the base class TVarData (see page 22571) for more information about varError (see page 22684).

158.1.30.4.18 Variant::IsArray Method

Queries the VType of the base class TVarData (see page 22571) for the varArray (see page 22679) bit.

Pascal

```
function IsArray: bool;
```

C++

```
__fastcall bool IsArray() const;
```

Description

System::Variant::IsArray returns true if the given variant is an array, false otherwise.

See Also

TVarData (see page 22571)

158.1.30.4.19 Variant::IsEmpty Method

Queries the VType of the base class TVarData (see page 22571).

Pascal

```
function IsEmpty: bool;
```

C++

```
__fastcall bool IsEmpty() const;
```

Description

System::Variant::IsEmpty returns true if the System::Variant::Variant (see page 22314) type code is varEmpty (see page 22683), false otherwise.

See Also

TVarData (see page 22571)

158.1.30.4.20 Variant::IsNull Method

Queries the VType of the base class TVarData (see page 22571) for the varNull (see page 22686) bit.

Pascal

```
function IsNull: bool;
```

C++

```
__fastcall bool IsNull() const;
```

Description

System::Variant::IsNull returns true if the System::Variant::Variant (see page 22314) type code is varNull (see page 22686), false otherwise.

See Also

TVarData (see page 22571)

158.1.30.4.21 Variant::NoParam Method

Pascal

```
function NoParam: Variant&; static;
```

C++

```
static Variant& NoParam();
```

Description

This is NoParam, a member of class Variant.

158.1.30.4.22 OleFunction Method

This is the overview for the OleFunction method overload.

Overload List

	Name	Description
	Variant::OleFunction (String&, P1) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().

	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().

	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27, P28) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27, P28, P29) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27, P28, P29, P30) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27, P28, P29, P30, P31) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27, P28, P29, P30, P31, P32) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().
	Variant::OleFunction (String&, TAutoArgsBase*) (see page 22326)	Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().

158.1.30.4.22.1 Variant::OleFunction Method (String&, P1)

Provides an alternate syntax for OLE Automation calls to Exec (see page 22320)().

Description

System::Variant::OleFunction is a wrapper for calling Exec (see page 22320) for OLE Automation object functions. The System::Variant::Variant (see page 22314) object's value must be a COM interface.

name specifies the name of the function to call. Note that this parameter's value may be different for localized versions of the Automation server. As a result, it is a good idea to use a string resource for this value if the application is intended for multiple locales.

args is a TAutoArgsBase object that contains the parameter values. Typically, this is an instance of TAutoArgs. The args parameter can be omitted if the function has no parameters.

As an alternate syntax, there is a templatized version that can be called with up to 32 arguments, where the template parameters specify the types of each argument.

System::Variant::OleFunction returns the value returned by the COM object's function as a System::Variant::Variant (see page 22314).

Note: Do not use COM features in cross-platform applications. COM is only available under Windows.

158.1.30.4.23 OleProcedure Method

This is the overview for the OleProcedure method overload.

Overload List

	Name	Description
	Variant::OleProcedure (String&, P1) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().

	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().

	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27, P28) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27, P28, P29) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27, P28, P29, P30) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27, P28, P29, P30, P31) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10, P11, P12, P13, P14, P15, P16, P17, P18, P19, P20, P21, P22, P23, P24, P25, P26, P27, P28, P29, P30, P31, P32) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().
	Variant::OleProcedure (String&, TAutoArgsBase*) (see page 22332)	Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().

158.1.30.4.23.1 Variant::OleProcedure Method (String&, P1)

Provides alternative syntax to OLE Automation calls to Exec (see page 22320)().

```

Description

System::Variant::OleProcedure is a wrapper for calling Exec (see page 22320) for OLE procedures (functions that do not return a value). The System::Variant::Variant (see page 22314) object's value must be a COM interface.

name specifies the name of the procedure to call. Note that this parameter's value may be different for localized versions of the Automation server. As a result, it is a good idea to use a string resource for this value if the application is intended for multiple locales.

args is a TAutoArgsBase object that contains the parameter values. Typically, this is an instance of TAutoArgs. The args parameter can be omitted if the procedure has no parameters.

As an alternate syntax, there is a templatized version that can be called with up to 32 arguments, where the template parameters specify the types of each argument.

Note: Do not use COM features in cross-platform applications. COM is only available under Windows.

158.1.30.4.24 OlePropertyGet Method

This is the overview for the OlePropertyGet method overload.

Overload List

	Name	Description
	Variant::OlePropertyGet (String&, P1) (see page 22337)	Returns the value of a property on a COM interface.
	Variant::OlePropertyGet (String&, P1, P2) (see page 22337)	Returns the value of a property on a COM interface.
	Variant::OlePropertyGet (String&, P1, P2, P3) (see page 22337)	Returns the value of a property on a COM interface.
	Variant::OlePropertyGet (String&, P1, P2, P3, P4) (see page 22337)	Returns the value of a property on a COM interface.
	Variant::OlePropertyGet (String&, P1, P2, P3, P4, P5) (see page 22337)	Returns the value of a property on a COM interface.
	Variant::OlePropertyGet (String&, P1, P2, P3, P4, P5, P6) (see page 22337)	Returns the value of a property on a COM interface.
	Variant::OlePropertyGet (String&, P1, P2, P3, P4, P5, P6, P7) (see page 22337)	Returns the value of a property on a COM interface.

	Variant::OlePropertyGet (String&, P1, P2, P3, P4, P5, P6, P7, P8) (see page 22337)	Returns the value of a property on a COM interface.
	Variant::OlePropertyGet (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9) (see page 22337)	Returns the value of a property on a COM interface.
	Variant::OlePropertyGet (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10) (see page 22337)	Returns the value of a property on a COM interface.
	Variant::OlePropertyGet (String&, TAutoArgsBase*) (see page 22337)	Returns the value of a property on a COM interface.

158.1.30.4.24.1 Variant::OlePropertyGet Method (String&, P1)

Returns the value of a property on a COM interface.

Pascal

```
function OlePropertyGet(const name: String&; var args: TAutoArgsBase = 0): Variant;
function OlePropertyGet(const name: String&; p1: P1): Variant;

p5, P6 p6, P7 p7, P8 p8, P9 p9, P10 p10);
```

Description

System::Variant::OlePropertyGet is a wrapper for calling Exec (see page 22320)(). System::Variant::OlePropertyGet returns a property value on the interface that is the System::Variant::Variant (see page 22314) object's value.

name is the name of the property whose value is returned. Note that this parameter's value may be different for localized

versions of the Automation server. As a result, it is a good idea to use a string resource for this value if the application is intended for multiple locales.

args is a TAutoArgsBase object that contains the parameter values for the property's read access method. Typically, this is an instance of TAutoArgs. The args parameter can be omitted if the access method has no parameters.

As an alternate syntax, there is a templatized version that can be called with up to 10 arguments, where the template parameters specify the types of each argument.

Note: Do not use COM features in cross-platform applications. COM is only available under Windows.

158.1.30.4.25 OlePropertySet Method

This is the overview for the OlePropertySet method overload.

Overload List

	Name	Description
	Variant::OlePropertySet (String&, P1) (see page 22338)	Sets the value of a property on a COM interface.
	Variant::OlePropertySet (String&, P1, P2) (see page 22338)	Sets the value of a property on a COM interface.
	Variant::OlePropertySet (String&, P1, P2, P3) (see page 22338)	Sets the value of a property on a COM interface.
	Variant::OlePropertySet (String&, P1, P2, P3, P4) (see page 22338)	Sets the value of a property on a COM interface.
	Variant::OlePropertySet (String&, P1, P2, P3, P4, P5) (see page 22338)	Sets the value of a property on a COM interface.
	Variant::OlePropertySet (String&, P1, P2, P3, P4, P5, P6) (see page 22338)	Sets the value of a property on a COM interface.
	Variant::OlePropertySet (String&, P1, P2, P3, P4, P5, P6, P7) (see page 22338)	Sets the value of a property on a COM interface.
	Variant::OlePropertySet (String&, P1, P2, P3, P4, P5, P6, P7, P8) (see page 22338)	Sets the value of a property on a COM interface.
	Variant::OlePropertySet (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9) (see page 22338)	Sets the value of a property on a COM interface.
	Variant::OlePropertySet (String&, P1, P2, P3, P4, P5, P6, P7, P8, P9, P10) (see page 22338)	Sets the value of a property on a COM interface.
	Variant::OlePropertySet (String&, TAutoArgsBase&) (see page 22338)	Sets the value of a property on a COM interface.

158.1.30.4.25.1 Variant::OlePropertySet Method (String&, P1)

Sets the value of a property on a COM interface.

Pascal

```
procedure OlePropertySet(const name: String&; var args: TAutoArgsBase);
```

```
procedure OlePropertySet(const name: String&; p1: P1);
procedure OlePropertySet(const name: String&; p1: P1; p2: P2);

p7, P8 p8, P9 p9);
template <class P1, class P2, class P3, class P4, class P5, class P6, class P7, class P8,
class P9, class P10> void OlePropertySet(const String& name, P1 p1, P2 p2, P3 p3, P4 p4, P5
p5, P6 p6, P7 p7, P8 p8, P9 p9, P10 p10);
```

Description

System::Variant::OlePropertySet is a wrapper for calling Exec (see page 22320). You can use System::Variant::OlePropertySet to set the value of a property on an interface that is the System::Variant::Variant (see page 22314) object's value.

name is the name of the property whose value is set. Note that this parameter's value may be different for localized versions of the Automation server. As a result, it is a good idea to use a string resource for this value if the application is intended for multiple locales.

args is a TAutoArgsBase object that contains the parameter values of the property's write access method. Typically, this is an instance of TAutoArgs with one parameter (the value to set).

As an alternate syntax, there is a templatized version that can be called with up to 10 arguments, where the template parameters specify the types of each argument.

Note: Do not use COM features in cross-platform applications. COM is only available under Windows.

158.1.30.4.26 PutElement Method

This is the overview for the PutElement method overload.

Overload List

	Name	Description
	Variant::PutElement (Variant&, int) (see page 22340)	Assigns an element as the value of an entry in a System::Variant::Variant (see page 22314) array.
	Variant::PutElement (Variant&, int, int) (see page 22340)	Assigns an element as the value of an entry in a System::Variant::Variant (see page 22314) array.
	Variant::PutElement (Variant&, int, int, int) (see page 22340)	Assigns an element as the value of an entry in a System::Variant::Variant (see page 22314) array.
	Variant::PutElement (Variant&, int, int, int, int) (see page 22340)	Assigns an element as the value of an entry in a System::Variant::Variant (see page 22314) array.
	Variant::PutElement (Variant&, int, int, int, int, int) (see page 22340)	Assigns an element as the value of an entry in a System::Variant::Variant (see page 22314) array.

158.1.30.4.26.1 Variant::PutElement Method (Variant&, int)

Assigns an element as the value of an entry in a System::Variant::Variant (see page 22314) array.

Pascal

```
procedure PutElement(const data: Variant&; const i1: Integer);
procedure PutElement(const data: Variant&; const i1: Integer; const i2: Integer);
procedure PutElement(const data: Variant&; const i1: Integer; const i2: Integer; const i3:
Integer);
procedure PutElement(const data: Variant&; const i1: Integer; const i2: Integer; const i3:
Integer; const i4: Integer);
procedure PutElement(const data: Variant&; const i1: Integer; const i2: Integer; const i3:
Integer; const i4: Integer; const i5: Integer);
```

C++

```
__fastcall void PutElement(const Variant& data, const int i1);
__fastcall void PutElement(const Variant& data, const int i1, const int i2);
__fastcall void PutElement(const Variant& data, const int i1, const int i2, const int i3);
__fastcall void PutElement(const Variant& data, const int i1, const int i2, const int i3,
const int i4);
__fastcall void PutElement(const Variant& data, const int i1, const int i2, const int i3,
const int i4, const int i5);
```

Description

Use System::Variant::PutElement to access one-dimensional and multi-dimensional System::Variant::Variant (see page 22314) arrays of up to 5 dimensions. The data parameter is the value to assign. The remaining parameters provide indexes into the dimensions of the array.

See Also

System::Variant::GetElement (see page 22322)

158.1.30.4.27 Variant::Sanitized Method

Pascal

```
function Sanitized: Variant;
```

C++

```
__fastcall Variant Sanitized() const;
```

Description

This is Sanitized, a member of class Variant.

158.1.30.4.28 Variant::SetError Method

Converts the System::Variant::Variant (see page 22314) to a varError (see page 22684) type and assigns the integer err as the value of the varError (see page 22684).

Pascal

```
procedure SetError(const err: HResult);
```

C++

```
__fastcall void SetError(const HResult err);
```

Description

See the base class TVarData (see page 22571) for more information about varError (see page 22684).

See Also

TVarData (see page 22571)

158.1.30.4.29 Variant::Type Method

Pascal

```
function Type: Integer;
```

C++

```
__fastcall int Type() const;
```

Description

This is Type, a member of class Variant.

158.1.30.5 Variant Operators

The operators of the Variant class are listed here.

Public Operators

	Name	Description
	- (see page 22343)	This is the overview for the - operator overload.
	! (see page 22344)	Returns a new System::Variant::Variant (see page 22314) that is the logical negation of this System::Variant::Variant (see page 22314).
	!= (see page 22344)	This is the overview for the != operator overload.
	% (see page 22345)	This is the overview for the % operator overload.
	%= (see page 22346)	Returns this System::Variant::Variant (see page 22314) as the remainder from dividing its original value and the System::Variant::Variant (see page 22314) specified by rhs.
	& (see page 22346)	This is the overview for the & operator overload.
	&= (see page 22347)	Returns this System::Variant::Variant (see page 22314) after performing a bitwise and operation.
	* (see page 22347)	This is the overview for the * operator overload.

	*= (see page 22348)	Multiplies this System::Variant::Variant (see page 22314) by the System::Variant::Variant (see page 22314) specified by rhs.
	/ (see page 22348)	This is the overview for the / operator overload.
	/= (see page 22349)	Divides this System::Variant::Variant (see page 22314) by the System::Variant::Variant (see page 22314) rhs.
	^ (see page 22349)	This is the overview for the ^ operator overload.
	^= (see page 22350)	Returns this System::Variant::Variant (see page 22314) after performing a bitwise xor operation.
	__int64 (see page 22350)	This is __int64, a member of class Variant.
	| (see page 22351)	This is the overview for the | operator overload.
	|= (see page 22351)	Returns this System::Variant::Variant (see page 22314) after performing a bitwise or operation.
	+ (see page 22352)	This is the overview for the + operator overload.
	+= (see page 22352)	Adds the System::Variant::Variant (see page 22314) specified by rhs to this System::Variant::Variant (see page 22314) object.
	< (see page 22353)	This is the overview for the < operator overload.
	<< (see page 22353)	This is the overview for the << operator overload.
	<<= (see page 22354)	Performs a bitwise shl (left shift) operation on this System::Variant::Variant (see page 22314).
	<= (see page 22355)	This is the overview for the <= operator overload.
	= (see page 22355)	This is the overview for the = operator overload.
	-= (see page 22361)	Subtracts the System::Variant::Variant (see page 22314) specified by rhs from this System::Variant::Variant (see page 22314) object.
	== (see page 22361)	This is the overview for the == operator overload.
	> (see page 22362)	This is the overview for the > operator overload.
	>= (see page 22363)	This is the overview for the >= operator overload.
	>> (see page 22363)	This is the overview for the >> operator overload.
	>>= (see page 22365)	Performs a bitwise shr (right shift) operation on this System::Variant::Variant (see page 22314).
	AnsiString (see page 22365)	Converts the System::Variant::Variant (see page 22314) to an AnsiString object.
	bool (see page 22365)	Converts the System::Variant::Variant (see page 22314) to a boolean value.
	char (see page 22365)	This is char, a member of class Variant.
	Currency (see page 22366)	Converts the System::Variant::Variant (see page 22314) to a Currency object.
	CURRENCY (see page 22366)	This is CURRENCY, a member of class Variant.
	Currency* (see page 22366)	This is Currency*, a member of class Variant.
	DECIMAL (see page 22366)	This is DECIMAL, a member of class Variant.
	double (see page 22367)	Converts the System::Variant::Variant (see page 22314) to a double value.
	double* (see page 22367)	This is double*, a member of class Variant.
	float (see page 22367)	Converts the System::Variant::Variant (see page 22314) to a float value.
	float* (see page 22368)	This is float*, a member of class Variant.
	IDispatch* (see page 22368)	This is IDispatch*, a member of class Variant.
	IInterface* (see page 22368)	This is IInterface*, a member of class Variant.
	int (see page 22368)	Converts the System::Variant::Variant (see page 22314) to an integer value.
	int* (see page 22369)	This is int*, a member of class Variant.
	IUnknown* (see page 22369)	This is IUnknown*, a member of class Variant.
	long (see page 22369)	This is long, a member of class Variant.
	long* (see page 22369)	This is long*, a member of class Variant.
	LPSAFEARRAY (see page 22369)	This is LPSAFEARRAY, a member of class Variant.
	short (see page 22370)	Converts the System::Variant::Variant (see page 22314) to a short value.
	short* (see page 22370)	This is short*, a member of class Variant.
	signed char (see page 22370)	This is signed char, a member of class Variant.
	signed char* (see page 22370)	This is signed char*, a member of class Variant.
	TDateTime (see page 22371)	Converts the System::Variant::Variant (see page 22314) to a TDateTime object.
	TDateTime* (see page 22371)	This is TDateTime*, a member of class Variant.
	TVariant (see page 22371)	This is TVariant, a member of class Variant.

	TVariant* (see page 22371)	This is TVariant*, a member of class Variant.
	unsigned char (see page 22372)	This is unsigned char, a member of class Variant.
	unsigned char* (see page 22372)	This is unsigned char*, a member of class Variant.
	unsigned int (see page 22372)	This is unsigned int, a member of class Variant.
	unsigned int* (see page 22372)	This is unsigned int*, a member of class Variant.
	unsigned long (see page 22373)	This is unsigned long, a member of class Variant.
	unsigned long* (see page 22373)	This is unsigned long*, a member of class Variant.
	unsigned short (see page 22373)	This is unsigned short, a member of class Variant.
	unsigned short* (see page 22373)	This is unsigned short*, a member of class Variant.
	VARIANT (see page 22373)	This is VARIANT, a member of class Variant.
	VARIANT* (see page 22374)	This is VARIANT*, a member of class Variant.
	wchar_t* (see page 22374)	Converts the System::Variant::Variant (see page 22314) to the specified type and sets the varByRef (see page 22680) bit, meaning that the variant contains a reference as opposed to a value.
	wchar_t** (see page 22374)	This is wchar_t**, a member of class Variant.
	WideString (see page 22374)	This is WideString, a member of class Variant.

158.1.30.5.1 - Operator

This is the overview for the - operator overload.

Overload List

	Name	Description
	Variant::- (AnsiString&) (see page 22343)	This is -, a member of class Variant.
	Variant::- () (see page 22343)	This is -, a member of class Variant.
	Variant::- (double) (see page 22344)	This is -, a member of class Variant.
	Variant::- (int) (see page 22344)	This is -, a member of class Variant.
	Variant::- (Variant&) (see page 22344)	This is -, a member of class Variant.

158.1.30.5.1.1 Variant::- Operator ()

Pascal

```
operator -;
```

C++

```
__fastcall Variant operator -() const;
```

Description

This is -, a member of class Variant.

158.1.30.5.1.2 Variant::- Operator (AnsiString&)

Pascal

```
operator -(const rhs: AnsiString&);
```

C++

```
__fastcall Variant operator -(const AnsiString& rhs) const;
```

Description

This is -, a member of class Variant.

158.1.30.5.1.3 Variant::- Operator (Variant&)

Pascal

```
operator -(const rhs: Variant&);
```

C++

```
__fastcall Variant operator -(const Variant& rhs) const;
```

Description

This is -, a member of class Variant.

158.1.30.5.1.4 Variant::- Operator (double)

Pascal

```
operator -(rhs: double);
```

C++

```
__fastcall Variant operator -(double rhs) const;
```

Description

This is -, a member of class Variant.

158.1.30.5.1.5 Variant::- Operator (int)

Pascal

```
operator -(rhs: Integer);
```

C++

```
__fastcall Variant operator -(int rhs) const;
```

Description

This is -, a member of class Variant.

158.1.30.5.2 Variant::! Operator

Returns a new System::Variant::Variant (see page 22314) that is the logical negation of this System::Variant::Variant (see page 22314).

Pascal

```
operator !;
```

C++

```
__fastcall Variant operator !() const;
```

Description

The System::Variant (see page 22307)::! returns 0 if the System::Variant::Variant (see page 22314) has a nonzero value and 1 if the value of the System::Variant::Variant (see page 22314) is 0 or NULL.

158.1.30.5.3 != Operator

This is the overview for the != operator overload.

Overload List

	Name	Description
	Variant::!= (char*) (see page 22345)	Compares the System::Variant::Variant (see page 22314) with another value, testing for inequality.
	Variant::!= (double) (see page 22345)	Compares the System::Variant::Variant (see page 22314) with another value, testing for inequality.
	Variant::!= (int) (see page 22345)	Compares the System::Variant::Variant (see page 22314) with another value, testing for inequality.
	Variant::!= (TDateTime) (see page 22345)	Compares the System::Variant::Variant (see page 22314) with another value, testing for inequality.
	Variant::!= (Variant&) (see page 22345)	Compares the System::Variant::Variant (see page 22314) with another value, testing for inequality.

158.1.30.5.3.1 Variant::!= Operator (TDateTime)

Compares the System::Variant::Variant (see page 22314) with another value, testing for inequality.

Pascal

```
operator !=(const rhs: Variant&);
operator !=(const rhs: char*);
operator !=(rhs: Integer);
operator !=(rhs: double);
operator !=(rhs: TDateTime);
```

C++

```
__fastcall bool operator !=(const Variant& rhs) const;
__fastcall bool operator !=(const char* rhs) const;
__fastcall bool operator !=(int rhs) const;
__fastcall bool operator !=(double rhs) const;
__fastcall bool operator !=(TDateTime rhs) const;
```

Description

The != System::Variant (see page 22307)::!= returns true if the System::Variant::Variant (see page 22314)'s value is not the same as the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.4 % Operator

This is the overview for the % operator overload.

Overload List

	Name	Description
	Variant::% (AnsiString&) (see page 22346)	Returns the remainder from dividing the System::Variant::Variant (see page 22314)'s value by a specified value.
	Variant::% (double) (see page 22346)	Returns the remainder from dividing the System::Variant::Variant (see page 22314)'s value by a specified value.
	Variant::% (int) (see page 22346)	Returns the remainder from dividing the System::Variant::Variant (see page 22314)'s value by a specified value.

	Variant::% (Variant&) (see page 22346)	Returns the remainder from dividing the System::Variant::Variant (see page 22314)'s value by a specified value.

158.1.30.5.4.1 Variant::% Operator (AnsiString&)

Returns the remainder from dividing the System::Variant::Variant (see page 22314)'s value by a specified value.

Pascal

```
operator %(const rhs: Variant&);
operator %(const rhs: AnsiString&);
operator %(rhs: Integer);
operator %(rhs: double);
```

C++

```
__fastcall Variant operator %(const Variant& rhs) const;
__fastcall Variant operator %(const AnsiString& rhs) const;
__fastcall Variant operator %(int rhs) const;
__fastcall Variant operator %(double rhs) const;
```

Description

The System::Variant (see page 22307)::% returns a new System::Variant::Variant (see page 22314) that is the modulus of this System::Variant::Variant (see page 22314) and rhs.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.5 Variant::%= Operator

Returns this System::Variant::Variant (see page 22314) as the remainder from dividing its original value and the System::Variant::Variant (see page 22314) specified by rhs.

Pascal

```
operator %=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator %=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 23567) determine the meaning of this operation. If the System::Variant::Variants (see page 23567) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.6 & Operator

This is the overview for the & operator overload.

Overload List

	Name	Description
	Variant::& (AnsiString&) (see page 22347)	Performs a bitwise and operation with a specified value.
	Variant::& (double) (see page 22347)	Performs a bitwise and operation with a specified value.

	Variant::& (int) (see page 22347)	Performs a bitwise and operation with a specified value.
	Variant::& (Variant&) (see page 22347)	Performs a bitwise and operation with a specified value.

158.1.30.5.6.1 Variant::& Operator (AnsiString&)

Performs a bitwise and operation with a specified value.

Pascal

```
operator &(const rhs: Variant&);
operator &(const rhs: AnsiString&);
operator &(rhs: Integer);
operator &(rhs: double);
```

C++

```
__fastcall Variant operator &(const Variant& rhs) const;
__fastcall Variant operator &(const AnsiString& rhs) const;
__fastcall Variant operator &(int rhs) const;
__fastcall Variant operator &(double rhs) const;
```

Description

The System::Variant (see page 22307)::& returns a new System::Variant::Variant (see page 22314) that is the result of a bitwise and operation on this System::Variant::Variant (see page 22314) using rhs as the rvalue.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.7 Variant::&= Operator

Returns this System::Variant::Variant (see page 22314) after performing a bitwise and operation.

Pascal

```
operator &=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator &=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 23567) determine the meaning of this operation. If the System::Variant::Variants (see page 23567) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.8 * Operator

This is the overview for the * operator overload.

Overload List

	Name	Description
	Variant::* (AnsiString&) (see page 22348)	Multiplies the System::Variant::Variant (see page 22314)'s value by a specified value.
	Variant::* (double) (see page 22348)	Multiplies the System::Variant::Variant (see page 22314)'s value by a specified value.

	Variant::* (int) (see page 22348)	Multiplies the System::Variant::Variant (see page 22314)'s value by a specified value.
	Variant::* (Variant&) (see page 22348)	Multiplies the System::Variant::Variant (see page 22314)'s value by a specified value.

158.1.30.5.8.1 Variant::* Operator (AnsiString&)

Multiplies the System::Variant::Variant (see page 22314)'s value by a specified value.

Pascal

```
operator *(const rhs: Variant&);
operator *(const rhs: AnsiString&);
operator *(rhs: Integer);
operator *(rhs: double);
```

C++

```
__fastcall Variant operator *(const Variant& rhs) const;
__fastcall Variant operator *(const AnsiString& rhs) const;
__fastcall Variant operator *(int rhs) const;
__fastcall Variant operator *(double rhs) const;
```

Description

The System::Variant (see page 22307)::* returns a new System::Variant::Variant (see page 22314) that is the result of multiplying this System::Variant::Variant (see page 22314) with rhs.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.9 Variant::*= Operator

Multiplies this System::Variant::Variant (see page 22314) by the System::Variant::Variant (see page 22314) specified by rhs.

Pascal

```
operator *=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator *=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 23567) determine the meaning of this operation. If the System::Variant::Variants (see page 23567) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.10 / Operator

This is the overview for the / operator overload.

Overload List

	Name	Description
	Variant::/ (AnsiString&) (see page 22349)	Divides the System::Variant::Variant (see page 22314)'s value by a specified value.

	Variant::/ (double) (see page 22349)	Divides the System::Variant::Variant (see page 22314)'s value by a specified value.
	Variant::/ (int) (see page 22349)	Divides the System::Variant::Variant (see page 22314)'s value by a specified value.
	Variant::/ (Variant&) (see page 22349)	Divides the System::Variant::Variant (see page 22314)'s value by a specified value.

158.1.30.5.10.1 Variant::/ Operator (AnsiString&)

Divides the System::Variant::Variant (see page 22314)'s value by a specified value.

Pascal

```
operator /(const rhs: Variant&);
operator /(const rhs: AnsiString&);
operator /(rhs: Integer);
operator /(rhs: double);
```

C++

```
__fastcall Variant operator /(const Variant& rhs) const;
__fastcall Variant operator /(const AnsiString& rhs) const;
__fastcall Variant operator /(int rhs) const;
__fastcall Variant operator /(double rhs) const;
```

Description

The System::Variant (see page 22307)::/ returns a new System::Variant::Variant (see page 22314) that is the result of dividing this System::Variant::Variant (see page 22314) by rhs.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.11 Variant::/= Operator

Divides this System::Variant::Variant (see page 22314) by the System::Variant::Variant (see page 22314) rhs.

Pascal

```
operator /=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator /=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 23567) determine the meaning of this operation. If the System::Variant::Variants (see page 23567) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.12 ^ Operator

This is the overview for the ^ operator overload.

Overload List

	Name	Description
	Variant::^ (AnsiString&) (see page 22350)	Performs a bitwise xor operation with a specified value.
	Variant::^ (double) (see page 22350)	Performs a bitwise xor operation with a specified value.
	Variant::^ (int) (see page 22350)	Performs a bitwise xor operation with a specified value.
	Variant::^ (Variant&) (see page 22350)	Performs a bitwise xor operation with a specified value.

158.1.30.5.12.1 Variant::^ Operator (AnsiString&)

Performs a bitwise xor operation with a specified value.

Pascal

```
operator ^(const rhs: Variant&);
operator ^(const rhs: AnsiString&);
operator ^(rhs: Integer);
operator ^(rhs: double);
```

C++

```
__fastcall Variant operator ^(const Variant& rhs) const;
__fastcall Variant operator ^(const AnsiString& rhs) const;
__fastcall Variant operator ^(int rhs) const;
__fastcall Variant operator ^(double rhs) const;
```

Description

The ^ System::Variant (see page 22307)::^ returns a new System::Variant::Variant (see page 22314) that is the result of a bitwise xor operation on this System::Variant::Variant (see page 22314) using rhs as the rvalue.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.13 Variant::^= Operator

Returns this System::Variant::Variant (see page 22314) after performing a bitwise xor operation.

Pascal

```
operator ^=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator ^=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 23567) determine the meaning of this operation. If the System::Variant::Variants (see page 23567) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.14 Variant::__int64 Operator

Pascal

```
operator __int64;
```

C++

```
__fastcall operator __int64() const;
```

Description

This is __int64, a member of class Variant.

158.1.30.5.15 | Operator

This is the overview for the | operator overload.

Overload List

	Name	Description
	Variant::| (AnsiString&) (see page 22351)	Performs a bitwise or operation with a specified value.
	Variant::| (double) (see page 22351)	Performs a bitwise or operation with a specified value.
	Variant::| (int) (see page 22351)	Performs a bitwise or operation with a specified value.
	Variant::| (Variant&) (see page 22351)	Performs a bitwise or operation with a specified value.

158.1.30.5.15.1 Variant::| Operator (AnsiString&)

Performs a bitwise or operation with a specified value.

Pascal

```
operator |(const rhs: Variant&);
operator |(const rhs: AnsiString&);
operator |(rhs: Integer);
operator |(rhs: double);
```

C++

```
__fastcall Variant operator |(const Variant& rhs) const;
__fastcall Variant operator |(const AnsiString& rhs) const;
__fastcall Variant operator |(int rhs) const;
__fastcall Variant operator |(double rhs) const;
```

Description

The | System::Variant (see page 22307)::| returns a new System::Variant::Variant (see page 22314) that is the result of a bitwise or operation on this System::Variant::Variant (see page 22314) using rhs as the rvalue.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.16 Variant::|= Operator

Returns this System::Variant::Variant (see page 22314) after performing a bitwise or operation.

Pascal

```
operator |=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator |=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 23567) determine the meaning of this operation. If the

System::Variant::Variants (see page 23567) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.17 + Operator

This is the overview for the + operator overload.

Overload List

	Name	Description
	Variant::+ (double) (see page 22352)	Adds a specified value to the System::Variant::Variant (see page 22314).
	Variant::+ (int) (see page 22352)	Adds a specified value to the System::Variant::Variant (see page 22314).
	Variant::+ (Variant&) (see page 22352)	Adds a specified value to the System::Variant::Variant (see page 22314).

158.1.30.5.17.1 Variant::+ Operator (Variant&)

Adds a specified value to the System::Variant::Variant (see page 22314).

Pascal

```
operator +(const rhs: Variant&);
operator +(rhs: Integer);
operator +(rhs: double);
```

C++

```
__fastcall Variant operator +(const Variant& rhs) const;
__fastcall Variant operator +(int rhs) const;
__fastcall Variant operator +(double rhs) const;
```

Description

The + System::Variant (see page 22307)::+ returns a new System::Variant::Variant (see page 22314) that is the sum of this System::Variant::Variant (see page 22314) and rhs.

If the operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.18 Variant::+= Operator

Adds the System::Variant::Variant (see page 22314) specified by rhs to this System::Variant::Variant (see page 22314) object.

Pascal

```
operator +=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator +=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 23567) determine the meaning of this operation. If the System::Variant::Variants (see page 23567) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an

ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.19 < Operator

This is the overview for the < operator overload.

Overload List

	Name	Description
	Variant::< (char*) (see page 22353)	Tests whether the System::Variant::Variant (see page 22314)'s value is less than a specified value.
	Variant::< (double) (see page 22353)	Tests whether the System::Variant::Variant (see page 22314)'s value is less than a specified value.
	Variant::< (int) (see page 22353)	Tests whether the System::Variant::Variant (see page 22314)'s value is less than a specified value.
	Variant::< (TDateTime) (see page 22353)	Tests whether the System::Variant::Variant (see page 22314)'s value is less than a specified value.
	Variant::< (Variant&) (see page 22353)	Tests whether the System::Variant::Variant (see page 22314)'s value is less than a specified value.

158.1.30.5.19.1 Variant::< Operator (TDateTime)

Tests whether the System::Variant::Variant (see page 22314)'s value is less than a specified value.

Pascal

```
operator <(const rhs: Variant&);
operator <(const rhs: char*);
operator <(rhs: Integer);
operator <(rhs: double);
operator <(rhs: TDateTime);
```

C++

```
__fastcall bool operator <(const Variant& rhs) const;
__fastcall bool operator <(const char* rhs) const;
__fastcall bool operator <(int rhs) const;
__fastcall bool operator <(double rhs) const;
__fastcall bool operator <(TDateTime rhs) const;
```

Description

The < System::Variant (see page 22307)::< returns true if the System::Variant::Variant (see page 22314)'s value is less than the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.20 << Operator

This is the overview for the << operator overload.

Overload List

	Name	Description
	Variant::<< (AnsiString&) (see page 22354)	This is <<, a member of class Variant.
	Variant::<< (double) (see page 22354)	This is <<, a member of class Variant.
	Variant::<< (int) (see page 22354)	This is <<, a member of class Variant.

	Variant::<< (Variant&) (see page 22354)	This is <<, a member of class Variant.

158.1.30.5.20.1 Variant::<< Operator (AnsiString&)

Pascal

```
operator <<(const rhs: AnsiString&);
```

C++

```
__fastcall Variant operator <<(const AnsiString& rhs) const;
```

Description

This is <<, a member of class Variant.

158.1.30.5.20.2 Variant::<< Operator (Variant&)

Pascal

```
operator <<(const rhs: Variant&);
```

C++

```
__fastcall Variant operator <<(const Variant& rhs) const;
```

Description

This is <<, a member of class Variant.

158.1.30.5.20.3 Variant::<< Operator (double)

Pascal

```
operator <<(rhs: double);
```

C++

```
__fastcall Variant operator <<(double rhs) const;
```

Description

This is <<, a member of class Variant.

158.1.30.5.20.4 Variant::<< Operator (int)

Pascal

```
operator <<(rhs: Integer);
```

C++

```
__fastcall Variant operator <<(int rhs) const;
```

Description

This is <<, a member of class Variant.

158.1.30.5.21 Variant::<<= Operator

Performs a bitwise shl (left shift) operation on this System::Variant::Variant (see page 22314).

Pascal

```
operator <<=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator <<=(const Variant& rhs);
```

Description

If the System::Variant::Variants (see page 23567) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.22 <= Operator

This is the overview for the <= operator overload.

Overload List

	Name	Description
	Variant::<= (char*) (see page 22355)	Tests whether the System::Variant::Variant (see page 22314)'s value is less than or equal to a specified value.
	Variant::<= (double) (see page 22355)	Tests whether the System::Variant::Variant (see page 22314)'s value is less than or equal to a specified value.
	Variant::<= (int) (see page 22355)	Tests whether the System::Variant::Variant (see page 22314)'s value is less than or equal to a specified value.
	Variant::<= (TDateTime) (see page 22355)	Tests whether the System::Variant::Variant (see page 22314)'s value is less than or equal to a specified value.
	Variant::<= (Variant&) (see page 22355)	Tests whether the System::Variant::Variant (see page 22314)'s value is less than or equal to a specified value.

158.1.30.5.22.1 Variant::<= Operator (TDateTime)

Tests whether the System::Variant::Variant (see page 22314)'s value is less than or equal to a specified value.

Pascal

```
operator <=(const rhs: Variant&);
operator <=(const rhs: char*);
operator <=(rhs: Integer);
operator <=(rhs: double);
operator <=(rhs: TDateTime);
```

C++

```
__fastcall bool operator <=(const Variant& rhs) const;
__fastcall bool operator <=(const char* rhs) const;
__fastcall bool operator <=(int rhs) const;
__fastcall bool operator <=(double rhs) const;
__fastcall bool operator <=(TDateTime rhs) const;
```

Description

The <= System::Variant (see page 22307)::<= returns true if the System::Variant::Variant (see page 22314)'s value is less than or equal to the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.23 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	Variant::= (__int64) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (__int64*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (AnsiString&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (bool) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (char) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (char*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (Currency&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (CURRENCY&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (Currency*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (CURRENCY*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (DECIMAL&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (DECIMAL*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (double) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (double*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (float) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (float*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).

	Variant::= (IDispatch*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (IDispatch**) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (IInterface*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (IInterface**) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (int) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (int*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (IUnknown*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (IUnknown**) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (long) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (long*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (SAFEARRAY&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (SAFEARRAY*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (SAFEARRAY**) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (short) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (short*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (signed char) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (signed char*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).

	Variant::= (System::DelphiInterface<IDispatch>&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (TDateTime&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (TDateTime*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (TVariant&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (TVariant*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (unsigned char) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (unsigned char*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (unsigned int) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (unsigned int*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (unsigned long) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (unsigned long*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (unsigned short) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (unsigned short*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (Variant&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (VARIANT&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (Variant*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (VARIANT*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).

	Variant::= (VariantError&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (wchar_t*) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (wchar_t**) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).
	Variant::= (WideString&) (see page 22359)	Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).

158.1.30.5.23.1 Variant::= Operator (AnsiString&)

Copies the System::Variant::Variant (see page 22314) specified by rhs into this System::Variant::Variant (see page 22314).

Pascal

```
operator =(const rhs: Variant&);
operator =(const src: bool);
operator =(const src: char);
operator =(const src: signed char);
operator =(const src: unsigned char);
operator =(const src: short);
operator =(const src: unsigned short);
operator =(const src: Integer);

__fastcall Variant& operator =(IDispatch** src);
__fastcall Variant& operator =(Currency* src);
```

```
__fastcall Variant& operator =(TDateTime* src);
__fastcall Variant& operator =(Variant* src);
```

Description

The actual types of the System::Variant::Variants (see page 23567) determine the meaning of this operation. If the System::Variant::Variants (see page 23567) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.24 Variant::-= Operator

Subtracts the System::Variant::Variant (see page 22314) specified by rhs from this System::Variant::Variant (see page 22314) object.

Pascal

```
operator -=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator -=(const Variant& rhs);
```

Description

The actual types of the System::Variant::Variants (see page 23567) determine the meaning of this operation. If the System::Variant::Variants (see page 23567) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.25 == Operator

This is the overview for the == operator overload.

Overload List

	Name	Description
	Variant::== (AnsiString&) (see page 22361)	Compares the System::Variant::Variant (see page 22314) with another value, testing for equality.
	Variant::== (char*) (see page 22361)	Compares the System::Variant::Variant (see page 22314) with another value, testing for equality.
	Variant::== (double) (see page 22361)	Compares the System::Variant::Variant (see page 22314) with another value, testing for equality.
	Variant::== (int) (see page 22361)	Compares the System::Variant::Variant (see page 22314) with another value, testing for equality.
	Variant::== (TDateTime) (see page 22361)	Compares the System::Variant::Variant (see page 22314) with another value, testing for equality.
	Variant::== (Variant&) (see page 22361)	Compares the System::Variant::Variant (see page 22314) with another value, testing for equality.

158.1.30.5.25.1 Variant::== Operator (AnsiString&)

Compares the System::Variant::Variant (see page 22314) with another value, testing for equality.

Pascal

```
operator ==(const rhs: Variant&);
```

```
operator ==(const rhs: char*);
operator ==(rhs: Integer);
operator ==(const rhs: AnsiString&);
operator ==(rhs: double);
operator ==(rhs: TDateTime);
```

C++

```
__fastcall bool operator ==(const Variant& rhs) const;
__fastcall bool operator ==(const char* rhs) const;
__fastcall bool operator ==(int rhs) const;
__fastcall bool operator ==(const AnsiString& rhs) const;
__fastcall bool operator ==(double rhs) const;
__fastcall bool operator ==(TDateTime rhs) const;
```

Description

The == System::Variant (see page 22307)::== returns true if the System::Variant::Variant (see page 22314)'s value is the same as the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.26 > Operator

This is the overview for the > operator overload.

Overload List

	Name	Description
	Variant::> (char*) (see page 22362)	Tests whether the System::Variant::Variant (see page 22314)'s value is greater than a specified value.
	Variant::> (double) (see page 22362)	Tests whether the System::Variant::Variant (see page 22314)'s value is greater than a specified value.
	Variant::> (int) (see page 22362)	Tests whether the System::Variant::Variant (see page 22314)'s value is greater than a specified value.
	Variant::> (TDateTime) (see page 22362)	Tests whether the System::Variant::Variant (see page 22314)'s value is greater than a specified value.
	Variant::> (Variant&) (see page 22362)	Tests whether the System::Variant::Variant (see page 22314)'s value is greater than a specified value.

158.1.30.5.26.1 Variant::> Operator (TDateTime)

Tests whether the System::Variant::Variant (see page 22314)'s value is greater than a specified value.

Pascal

```
operator >(const rhs: Variant&);
operator >(const rhs: char*);
operator >(rhs: Integer);
operator >(rhs: double);
operator >(rhs: TDateTime);
```

C++

```
__fastcall bool operator >(const Variant& rhs) const;
__fastcall bool operator >(const char* rhs) const;
__fastcall bool operator >(int rhs) const;
__fastcall bool operator >(double rhs) const;
__fastcall bool operator >(TDateTime rhs) const;
```

Description

The > System::Variant (see page 22307)::> returns true if the System::Variant::Variant (see page 22314)'s value is greater than the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.27 >= Operator

This is the overview for the >= operator overload.

Overload List

	Name	Description
	Variant::>= (char*) (see page 22363)	Tests whether the System::Variant::Variant (see page 22314)'s value is greater than or equal to a specified value.
	Variant::>= (double) (see page 22363)	Tests whether the System::Variant::Variant (see page 22314)'s value is greater than or equal to a specified value.
	Variant::>= (int) (see page 22363)	Tests whether the System::Variant::Variant (see page 22314)'s value is greater than or equal to a specified value.
	Variant::>= (TDateTime) (see page 22363)	Tests whether the System::Variant::Variant (see page 22314)'s value is greater than or equal to a specified value.
	Variant::>= (Variant&) (see page 22363)	Tests whether the System::Variant::Variant (see page 22314)'s value is greater than or equal to a specified value.

158.1.30.5.27.1 Variant::>= Operator (TDateTime)

Tests whether the System::Variant::Variant (see page 22314)'s value is greater than or equal to a specified value.

Pascal

```
operator >=(const rhs: Variant&);
operator >=(const rhs: char*);
operator >=(rhs: Integer);
operator >=(rhs: double);
operator >=(rhs: TDateTime);
```

C++

```
__fastcall bool operator >=(const Variant& rhs) const;
__fastcall bool operator >=(const char* rhs) const;
__fastcall bool operator >=(int rhs) const;
__fastcall bool operator >=(double rhs) const;
__fastcall bool operator >=(TDateTime rhs) const;
```

Description

The >= System::Variant (see page 22307)::>= returns true if the System::Variant::Variant (see page 22314)'s value is greater than or equal to the value specified by rhs, false otherwise. If the comparison is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.28 >> Operator

This is the overview for the >> operator overload.

Overload List

	Name	Description
	Variant::>> (AnsiString&) (see page 22364)	This is >>, a member of class Variant.
	Variant::>> (double) (see page 22364)	This is >>, a member of class Variant.
	Variant::>> (int) (see page 22364)	This is >>, a member of class Variant.
	Variant::>> (Variant&) (see page 22364)	This is >>, a member of class Variant.

158.1.30.5.28.1 Variant::>> Operator (AnsiString&)

Pascal

```
operator >>(const rhs: AnsiString&);
```

C++

```
__fastcall Variant operator >>(const AnsiString& rhs) const;
```

Description

This is >>, a member of class Variant.

158.1.30.5.28.2 Variant::>> Operator (Variant&)

Pascal

```
operator >>(const rhs: Variant&);
```

C++

```
__fastcall Variant operator >>(const Variant& rhs) const;
```

Description

This is >>, a member of class Variant.

158.1.30.5.28.3 Variant::>> Operator (double)

Pascal

```
operator >>(rhs: double);
```

C++

```
__fastcall Variant operator >>(double rhs) const;
```

Description

This is >>, a member of class Variant.

158.1.30.5.28.4 Variant::>> Operator (int)

Pascal

```
operator >>(rhs: Integer);
```

C++

```
__fastcall Variant operator >>(int rhs) const;
```

Description

This is >>, a member of class Variant.

158.1.30.5.29 Variant::>>= Operator

Performs a bitwise shr (right shift) operation on this System::Variant::Variant (see page 22314).

Pascal

```
operator >>=(const rhs: Variant&);
```

C++

```
__fastcall Variant& operator >>=(const Variant& rhs);
```

Description

If the System::Variant::Variants (see page 23567) can be converted to types that make sense for the given operation, the assignment is performed. If any of these operations is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.30 Variant::AnsiString Operator

Converts the System::Variant::Variant (see page 22314) to an AnsiString object.

Pascal

```
operator AnsiString;
```

C++

```
__fastcall operator AnsiString() const;
```

Description

This conversion System::Variant::AnsiString returns an AnsiString object that is a conversion of this System::Variant::Variant (see page 22314).

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.31 Variant::bool Operator

Converts the System::Variant::Variant (see page 22314) to a boolean value.

Pascal

```
operator bool;
```

C++

```
__fastcall operator bool() const;
```

Description

This conversion System::Variant::bool returns a bool that is a conversion of this System::Variant::Variant (see page 22314).

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.32 Variant::char Operator

Pascal

```
operator char;
```

C++

```
__fastcall operator char() const;
```

Description

This is char, a member of class Variant.

158.1.30.5.33 Variant::Currency Operator

Converts the System::Variant::Variant (see page 22314) to a Currency object.

Pascal

```
operator Currency;
```

C++

```
__fastcall operator Currency() const;
```

Description

The Currency conversion System::Variant::Currency returns a Currency or a reference to a Currency that is a conversion of this System::Variant::Variant (see page 22314). If the Currency* conversion is used, the System::Variant::Currency sets the varByRef (see page 22680) bit, meaning that the System::Variant::Variant (see page 22314) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.34 Variant::CURRENCY Operator

Pascal

```
operator CURRENCY;
```

C++

```
__fastcall operator CURRENCY() const;
```

Description

This is CURRENCY, a member of class Variant.

158.1.30.5.35 Variant::Currency* Operator

Pascal

```
operator Currency*;
```

C++

```
__fastcall operator Currency*();
```

Description

This is Currency*, a member of class Variant.

158.1.30.5.36 Variant::DECIMAL Operator

Pascal

```
operator DECIMAL;
```

C++

```
__fastcall operator DECIMAL() const;
```

Description

This is DECIMAL, a member of class Variant.

158.1.30.5.37 Variant::double Operator

Converts the System::Variant::Variant (see page 22314) to a double value.

Pascal

```
operator double;
```

C++

```
__fastcall operator double() const;
```

Description

The double conversion System::Variant::double returns a double or a reference to a double that is a conversion of this System::Variant::Variant (see page 22314). If the double* conversion is used, the System::Variant::double sets the varByRef (see page 22680) bit, meaning that the System::Variant::Variant (see page 22314) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.38 Variant::double* Operator

Pascal

```
operator double*;
```

C++

```
__fastcall operator double*();
```

Description

This is double*, a member of class Variant.

158.1.30.5.39 Variant::float Operator

Converts the System::Variant::Variant (see page 22314) to a float value.

Pascal

```
operator float;
```

C++

```
__fastcall operator float() const;
```

Description

The float conversion System::Variant::float returns a float or a reference to a float that is a conversion of this System::Variant::Variant (see page 22314). If the float* conversion is used, the System::Variant::float sets the varByRef (see page 22680) bit, meaning that the System::Variant::Variant (see page 22314) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.40 Variant::float* Operator

Pascal

```
operator float*;
```

C++

```
__fastcall operator float*();
```

Description

This is float*, a member of class Variant.

158.1.30.5.41 Variant::IDispatch* Operator

Pascal

```
operator IDispatch*;
```

C++

```
__fastcall operator IDispatch*();
```

Description

This is IDispatch*, a member of class Variant.

158.1.30.5.42 Variant::IInterface* Operator

Pascal

```
operator IInterface*;
```

C++

```
__fastcall operator IInterface*();
```

Description

This is IInterface*, a member of class Variant.

158.1.30.5.43 Variant::int Operator

Converts the System::Variant::Variant (see page 22314) to an integer value.

Pascal

```
operator int;
```

C++

```
__fastcall operator int() const;
```

Description

The int conversion System::Variant::int returns an integer or a reference to an integer that is a conversion of this System::Variant::Variant (see page 22314). If the int* conversion is used, the System::Variant::int sets the varByRef (see page 22680) bit, meaning that the System::Variant::Variant (see page 22314) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.44 Variant::int* Operator

Pascal

```
operator int*;
```

C++

```
__fastcall operator int*();
```

Description

This is int*, a member of class Variant.

158.1.30.5.45 Variant::IUnknown* Operator

Pascal

```
operator IUnknown*;
```

C++

```
__fastcall operator IUnknown*();
```

Description

This is IUnknown*, a member of class Variant.

158.1.30.5.46 Variant::long Operator

Pascal

```
operator long;
```

C++

```
__fastcall operator long() const;
```

Description

This is long, a member of class Variant.

158.1.30.5.47 Variant::long* Operator

Pascal

```
operator long*;
```

C++

```
__fastcall operator long*();
```

Description

This is long*, a member of class Variant.

158.1.30.5.48 Variant::LPSAFEARRAY Operator

Pascal

```
operator LPSAFEARRAY;
```

C++

```
__fastcall operator LPSAFEARRAY();
```

Description

This is LPSAFEARRAY, a member of class Variant.

158.1.30.5.49 Variant::short Operator

Converts the System::Variant::Variant (see page 22314) to a short value.

Pascal

```
operator short;
```

C++

```
__fastcall operator short() const;
```

Description

The short conversion System::Variant::short returns a short or a reference to a short that is a conversion of this System::Variant::Variant (see page 22314). If the short* conversion is used, the System::Variant::short sets the varByRef (see page 22680) bit, meaning that the System::Variant::Variant (see page 22314) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.50 Variant::short* Operator

Pascal

```
operator short*;
```

C++

```
__fastcall operator short*();
```

Description

This is short*, a member of class Variant.

158.1.30.5.51 Variant::signed char Operator

Pascal

```
operator signed char;
```

C++

```
__fastcall operator signed char() const;
```

Description

This is signed char, a member of class Variant.

158.1.30.5.52 Variant::signed char* Operator

Pascal

```
operator signed char*;
```

C++

```
__fastcall operator signed char*();
```

Description

This is signed char*, a member of class Variant.

158.1.30.5.53 Variant::TDateTime Operator

Converts the System::Variant::Variant (see page 22314) to a TDateTime object.

Pascal

```
operator TDateTime;
```

C++

```
__fastcall operator TDateTime() const;
```

Description

The TDateTime conversion System::Variant::TDateTime returns a TDateTime or a reference to a TDateTime that is a conversion of this System::Variant::Variant (see page 22314). If the TDateTime* conversion is used, the System::Variant::TDateTime sets the varByRef (see page 22680) bit, meaning that the System::Variant::Variant (see page 22314) contains a reference as opposed to a value.

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.54 Variant::TDateTime* Operator

Pascal

```
operator TDateTime*;
```

C++

```
__fastcall operator TDateTime*();
```

Description

This is TDateTime*, a member of class Variant.

158.1.30.5.55 Variant::TVariant Operator

Pascal

```
operator TVariant;
```

C++

```
__fastcall operator TVariant();
```

Description

This is TVariant, a member of class Variant.

158.1.30.5.56 Variant::TVariant* Operator

Pascal

```
operator TVariant*;
```

C++

```
__fastcall operator TVariant*();
```

Description

This is TVariant*, a member of class Variant.

158.1.30.5.57 Variant::unsigned char Operator

Pascal

```
operator unsigned char;
```

C++

```
__fastcall operator unsigned char() const;
```

Description

This is unsigned char, a member of class Variant.

158.1.30.5.58 Variant::unsigned char* Operator

Pascal

```
operator unsigned char*;
```

C++

```
__fastcall operator unsigned char*();
```

Description

This is unsigned char*, a member of class Variant.

158.1.30.5.59 Variant::unsigned int Operator

Pascal

```
operator unsigned int;
```

C++

```
__fastcall operator unsigned int() const;
```

Description

This is unsigned int, a member of class Variant.

158.1.30.5.60 Variant::unsigned int* Operator

Pascal

```
operator unsigned int*;
```

C++

```
__fastcall operator unsigned int*();
```

Description

This is unsigned int*, a member of class Variant.

158.1.30.5.61 Variant::unsigned long Operator

Pascal

```
operator unsigned long;
```

C++

```
__fastcall operator unsigned long() const;
```

Description

This is unsigned long, a member of class Variant.

158.1.30.5.62 Variant::unsigned long* Operator

Pascal

```
operator unsigned long*;
```

C++

```
__fastcall operator unsigned long*();
```

Description

This is unsigned long*, a member of class Variant.

158.1.30.5.63 Variant::unsigned short Operator

Pascal

```
operator unsigned short;
```

C++

```
__fastcall operator unsigned short() const;
```

Description

This is unsigned short, a member of class Variant.

158.1.30.5.64 Variant::unsigned short* Operator

Pascal

```
operator unsigned short*;
```

C++

```
__fastcall operator unsigned short*();
```

Description

This is unsigned short*, a member of class Variant.

158.1.30.5.65 Variant::VARIANT Operator

Pascal

```
operator VARIANT;
```

C++

```
__fastcall operator VARIANT();
```

Description

This is VARIANT, a member of class Variant.

158.1.30.5.66 Variant::VARIANT* Operator

Pascal

```
operator VARIANT*;
```

C++

```
__fastcall operator VARIANT*();
```

Description

This is VARIANT*, a member of class Variant.

158.1.30.5.67 Variant::wchar_t* Operator

Converts the System::Variant::Variant (see page 22314) to the specified type and sets the varByRef (see page 22680) bit, meaning that the variant contains a reference as opposed to a value.

Pascal

```
operator wchar_t*;
```

C++

```
__fastcall operator wchar_t*() const;
```

Description

This conversion System::Variant::wchar_t* returns a reference to a wide character array that is a conversion of this System::Variant::Variant (see page 22314).

If the conversion operation is not possible because of an invalid variant type conversion, an ESystem::Variant::VariantError (see page 22375) exception is thrown.

158.1.30.5.68 Variant::wchar_t** Operator

Pascal

```
operator wchar_t**;
```

C++

```
__fastcall operator wchar_t**();
```

Description

This is wchar_t**, a member of class Variant.

158.1.30.5.69 Variant::WideString Operator

Pascal

```
operator WideString;
```

C++

```
__fastcall operator WideString() const;
```

Description

This is WideString, a member of class Variant.

158.1.30.6 Variant Friends

The friends of the Variant class are listed here.

Public Friends

Name	Description
class AutoCmd (see page 22375)	This is friend class AutoCmd.

158.1.30.6.1 friend class AutoCmd Friend

Pascal

```
class AutoCmd
```

C++

```
friend class AutoCmd;
```

Description

This is friend class AutoCmd.

158.1.31 VariantError Class

Class Hierarchy

System::VariantError

Pascal

```
VariantError = class;
```

C++

```
class VariantError;
```

File

sysvari.h

Description

This is class System::VariantError.

158.1.31.1 VariantError Members

The following tables list the members exposed by VariantError.

Protected Data Members

	Name	Description
	m_scode (see page 22376)	This is m_scode, a member of class VariantError.

Public Methods

	Name	Description
	VariantError (see page 22376)	This is VariantError, a member of class VariantError.

Public Operators

	Name	Description
	= (see page 22377)	This is =, a member of class VariantError.
	SCODE (see page 22377)	This is SCODE, a member of class VariantError.

158.1.31.2 VariantError::VariantError Constructor

Pascal

```
constructor Create(err: SCODE = DISP_E_PARAMNOTFOUND);
```

C++

```
VariantError(SCODE err = DISP_E_PARAMNOTFOUND);
```

Description

This is VariantError, a member of class VariantError.

158.1.31.3 VariantError Data Members

The data members of the VariantError class are listed here.

Protected Data Members

	Name	Description
	m_scode (see page 22376)	This is m_scode, a member of class VariantError.

158.1.31.3.1 VariantError::m_scode Data Member

Pascal

```
m_scode: SCODE;
```

C++

```
SCODE m_scode;
```

Description

This is m_scode, a member of class VariantError.

158.1.31.4 VariantError Operators

The operators of the VariantError class are listed here.

Public Operators

	Name	Description
	= (see page 22377)	This is =, a member of class VariantError.
	SCODE (see page 22377)	This is SCODE, a member of class VariantError.

158.1.31.4.1 VariantError::= Operator

Pascal

```
operator =(err: SCODE);
```

C++

```
VariantError& operator =(SCODE err);
```

Description

This is =, a member of class VariantError.

158.1.31.4.2 VariantError::SCODE Operator

Pascal

```
operator SCODE;
```

C++

```
operator SCODE() const;
```

Description

This is SCODE, a member of class VariantError.

158.1.32 WideString Class

System::WideString represents strings of 16-bit characters.

Class Hierarchy

System::WideString

Pascal

```
WideString = class;
```

C++

```
class WideString;
```

File

wstring.h

Description

System::WideString represents strings of 16-bit characters. Each character is stored as a wchar_t value. The C++ class System::WideString is functionally equivalent to a Delphi intrinsic type, also called System::WideString.

Note: Although System::WideString is a platform-independent data (see page 22383) type and often appears in cross-platform code, System::WideString is also useful for working with Microsoft's Component Object Model (COM) System::WideString values are easily converted to or from the BSTR (see page 22393) values used in COM.

158.1.32.1 WideString Members

The following tables list the members exposed by WideString.

Public Methods

	Name	Description
	~WideString (see page 22378)	Frees an instance ofSystem::WideString::WideString (see page 22377).
	Attach (see page 22381)	Uses an existing BSTR (see page 22393) for the underlying implementation.
	c_bstr (see page 22382)	Returns the underlying BSTR (see page 22393) that implements theSystem::WideString::WideString (see page 22377).
	Copy (see page 22382)	This is the overview for the Copy method overload.
	data (see page 22383)	This is data, a member of class WideString.
	Delete (see page 22383)	System::WideString::Deletes a substring from the System::WideString::WideString (see page 22380).
	Detach (see page 22383)	System::WideString::Detaches theSystem::WideString::WideString (see page 22377) from a BSTR (see page 22393) that was previously attached using the Attach (see page 22381) method.
	Empty (see page 22384)	Sets the value of theSystem::WideString::WideString (see page 22377) to an empty string.
	Insert (see page 22384)	System::WideString::Inserts a specified string into theSystem::WideString::WideString (see page 22377).
	IsEmpty (see page 22385)	Returns true if the System::WideString::WideString (see page 22380) is empty.
	Length (see page 22385)	Returns the length of theSystem::WideString::WideString (see page 22377).
	Pos (see page 22385)	Returns the index at which a specified substring begins.
	SetLength (see page 22385)	Changes the length of theSystem::WideString::WideString (see page 22377).
	SubString (see page 22386)	Returns a specified substring of theSystem::WideString::WideString (see page 22377).
	WideString (see page 22379)	This is the overview for the WideString constructor overload.

Public Operators

	Name	Description
	!= (see page 22387)	This is the overview for the != operator overload.
	& (see page 22387)	Returns a pointer to the underlying BSTR (see page 22393).
	[] (see page 22388)	This is the overview for the [] operator overload.
	+ (see page 22388)	Concatenates twoSystem::WideString::WideStrings.
	+= (see page 22389)	Concatenates this System::WideString::WideString (see page 22380) and rhs, and assigns the result to this System::WideString::WideString (see page 22380).
	< (see page 22389)	This is the overview for the < operator overload.
	<= (see page 22390)	This is the overview for the <= operator overload.
	= (see page 22390)	This is the overview for the = operator overload.
	== (see page 22391)	This is the overview for the == operator overload.
	> (see page 22392)	This is the overview for the > operator overload.
	>= (see page 22392)	This is the overview for the >= operator overload.
	BSTR (see page 22393)	Converts the wide string to a System::WideString::BSTR.

158.1.32.2 WideString::~WideString Destructor

Frees an instance ofSystem::WideString::WideString (see page 22377).

Pascal

```
destructor Destroy;
```

C++

```
__fastcall ~WideString();
```

Description

System::WideString (see page 22377)::~WideString (see page 22377) is the destructor forSystem::WideString::WideString (see page 22377).

158.1.32.3 WideString Constructor

This is the overview for the WideString constructor overload.

Overload List

	Name	Description
	WideString::WideString () (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (__int64) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (AnsiString&) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (char) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (char*) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (double) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (float) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (int) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (long) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (long double) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (short) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (unsigned __int64) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (unsigned int) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (unsigned long) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (unsigned short) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (wchar_t) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (wchar_t*) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (wchar_t*, int) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (WideChar) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (WideChar*) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).

	WideString::WideString (WideChar*, int) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).
	WideString::WideString (WideString&) (see page 22380)	Creates an instance of System::WideString::WideString (see page 22377).

158.1.32.3.1 WideString::WideString Constructor ()

Creates an instance of System::WideString::WideString (see page 22377).

Pascal

```
constructor Create;
constructor Create(const src: char*);
constructor Create(const src: WideString&);
constructor Create(const src: AnsiString&);
constructor Create(const src: WideChar*; len: Integer);
constructor Create(const src: WideChar*);
constructor Create(const src: WideChar);
constructor Create(const src: wchar_t*; len: Integer);
constructor Create(const src: wchar_t*);
constructor Create(const src: wchar_t);
constructor Create(src: char);
constructor Create(src: short);
constructor Create(: unsigned short);
constructor Create(src: Integer);
constructor Create(: unsigned int);
constructor Create(: long);
constructor Create(: unsigned long);
constructor Create(: __int64);
constructor Create(: unsigned __int64);
constructor Create(src: float);
constructor Create(src: double);
constructor Create(src: long double);
```

C++

```
__fastcall WideString();
__fastcall WideString(const char* src);
__fastcall WideString(const WideString& src);
__fastcall WideString(const AnsiString& src);
__fastcall WideString(const WideChar* src, int len);
__fastcall WideString(const WideChar* src);
__fastcall explicit WideString(const WideChar src);
__fastcall WideString(const wchar_t* src, int len);
__fastcall WideString(const wchar_t* src);
__fastcall explicit WideString(const wchar_t src);
__fastcall explicit WideString(char src);
__fastcall explicit WideString(short src);
__fastcall explicit WideString(unsigned short);
__fastcall explicit WideString(int src);
__fastcall explicit WideString(unsigned int);
__fastcall explicit WideString(long);
__fastcall explicit WideString(unsigned long);
__fastcall explicit WideString(__int64);
__fastcall explicit WideString(unsigned __int64);
__fastcall explicit WideString(float src);
__fastcall explicit WideString(double src);
__fastcall explicit WideString(long double src);
```

Description

Call System::WideString::WideString (see page 22377) to create and initialize a wide string. If the constructor is given no arguments, the resulting System::WideString::WideString (see page 22377) is an empty string. If the constructor is passed a

single wide character, the resulting System::WideString::WideString (see page 22377) has length one, and contains that character. All other versions of the constructor copy the string passed as an argument, converting characters to wchar_t if necessary. When constructing a System::WideString::WideString (see page 22377) from an array of char or wchar_t, the src string should be null terminated, unless a second argument is given that indicates the number of characters in the array.

158.1.32.4 WideString Methods

The methods of the WideString class are listed here.

Public Methods

	Name	Description
	Attach (see page 22381)	Uses an existing BSTR (see page 22393) for the underlying implementation.
	c_bstr (see page 22382)	Returns the underlying BSTR (see page 22393) that implements theSystem::WideString::WideString (see page 22377).
	Copy (see page 22382)	This is the overview for the Copy method overload.
	data (see page 22383)	This is data, a member of class WideString.
	Delete (see page 22383)	System::WideString::Deletes a substring from the System::WideString::WideString (see page 22380).
	Detach (see page 22383)	System::WideString::Detaches theSystem::WideString::WideString (see page 22377) from a BSTR (see page 22393) that was previously attached using the Attach (see page 22381) method.
	Empty (see page 22384)	Sets the value of theSystem::WideString::WideString (see page 22377) to an empty string.
	Insert (see page 22384)	System::WideString::Inserts a specified string into theSystem::WideString::WideString (see page 22377).
	IsEmpty (see page 22385)	Returns true if the System::WideString::WideString (see page 22380) is empty.
	Length (see page 22385)	Returns the length of theSystem::WideString::WideString (see page 22377).
	Pos (see page 22385)	Returns the index at which a specified substring begins.
	SetLength (see page 22385)	Changes the length of theSystem::WideString::WideString (see page 22377).
	SubString (see page 22386)	Returns a specified substring of theSystem::WideString::WideString (see page 22377).

158.1.32.4.1 WideString::Attach Method

Uses an existing BSTR (see page 22393) for the underlying implementation.

Pascal

```
procedure Attach(src: WideString);
```

C++

```
__fastcall void Attach(BSTR src);
```

Description

System::WideString::Attach uses the BSTR (see page 22393) passed as an argument as the value of theSystem::WideString::WideString (see page 22377). While the source BSTR (see page 22393) is attached, you can access the memory for the BSTR (see page 22393) using either theSystem::WideString::WideString (see page 22377) or the source BSTR (see page 22393).

To subsequently detach from src, use the Detach (see page 22383) method.

Warning: Do not delete the source BSTR (see page 22393) while it is attached to theSystem::WideString::WideString (see page 22377). This will leave theSystem::WideString::WideString (see page 22377) with a dangling reference.

Note: BSTR (see page 22393) values are used with COM objects. Do not use COM objects in platform-independent

applications, since COM is only available under Windows.

See Also

System::WideString::Detach (see page 22383)

System::WideString::c_bstr (see page 22382)

158.1.32.4.2 WideString::c_bstr Method

Returns the underlying BSTR (see page 22393) that implements theSystem::WideString::WideString (see page 22377).

Pascal

```
function c_bstr: WideChar*;
```

C++

```
__fastcall WideChar* c_bstr() const;
```

Description

Use c_System::WideString::c_bstr to access the BSTR (see page 22393) that implements theSystem::WideString::WideString (see page 22377).

Note: BSTR (see page 22393) values are used with COM objects. Do not use COM objects in platform-independent applications, since COM is only available under Window.

See Also

System::WideString::c_bstr

System::WideString::Copy (see page 22382)

System::WideString::& (see page 22387)

158.1.32.4.3 Copy Method

This is the overview for the Copy method overload.

Overload List

	Name	Description
	WideString::Copy () (see page 22382)	Returns a copy of theSystem::WideString::WideString (see page 22377).
	WideString::Copy (wchar_t *, int) (see page 22382)	Returns a copy of theSystem::WideString::WideString (see page 22377).
	WideString::Copy (wchar_t*) (see page 22382)	Returns a copy of theSystem::WideString::WideString (see page 22377).

158.1.32.4.3.1 WideString::Copy Method ()

Returns a copy of theSystem::WideString::WideString (see page 22377).

Pascal

```
function Copy(var src: wchar_t): wchar_t*; static;
function Copy: wchar_t*;
function Copy(var : wchar_t; len: Integer): wchar_t*;
```

C++

```
static __fastcall wchar_t* Copy(wchar_t* src);
__fastcall wchar_t* Copy() const;
__fastcall wchar_t* Copy(wchar_t *, int len) const;
```

Description

Use System::WideString::Copy to copy theSystem::WideString::WideString (see page 22377) into an array of wchar_t. Use the Length (see page 22385) method to ensure that the destination buffer is large enough to hold the contents of theSystem::WideString::WideString (see page 22377).

WideString (see page 22377) also supports a static copy method that copies an arbitrary source string.

See Also

System::WideString::bstr

System::WideString::c_bstr (see page 22382)

System::WideString::& (see page 22387)

System::WideString::Length (see page 22385)

158.1.32.4.4 WideString::data Method

Pascal

```
function data: WideChar*;
```

C++

```
__fastcall WideChar* data();
```

Description

This is data, a member of class WideString.

158.1.32.4.5 WideString::Delete Method

System::WideString::Deletes a substring from the System::WideString::WideString (see page 22380).

Pascal

```
procedure Delete(index: Integer; count: Integer);
```

C++

```
__fastcall void Delete(int index, int count);
```

Description

System::WideString::Delete removes count characters from the System::WideString::WideString (see page 22380), beginning with the character at position index.

See Also

System::WideString::Insert (see page 22384)

System::WideString::[] (see page 22388)

158.1.32.4.6 WideString::Detach Method

System::WideString::Detaches theSystem::WideString::WideString (see page 22377) from a BSTR (see page 22393) that was previously attached using the Attach (see page 22381) method.

Pascal

```
function Detach: WideString;
```

C++

```
__fastcall BSTR Detach();
```

Description

Call System::WideString::Detach to undo the association set up by a call to the Attach (see page 22381) method. System::WideString::Detach returns the BSTR (see page 22393) that is no longer associated with theSystem::WideString::WideString (see page 22377).

Note: BSTR (see page 22393) values are used with COM objects. Do not use COM objects in platform-independent applications, since COM is only available under Windows.

See Also

System::WideString::Attach (see page 22381)

158.1.32.4.7 WideString::Empty Method

Sets the value of theSystem::WideString::WideString (see page 22377) to an empty string.

Pascal

```
procedure Empty;
```

C++

```
__fastcall void Empty();
```

Description

Call System::WideString::Empty to replace the contents of theSystem::WideString::WideString (see page 22377) with an empty string.

See Also

System::WideString::IsEmpty (see page 22385)

158.1.32.4.8 WideString::Insert Method

System::WideString::Inserts a specified string into theSystem::WideString::WideString (see page 22377).

Pascal

```
procedure Insert(const str: WideString&; index: Integer);
```

C++

```
__fastcall void Insert(const WideString& str, int index);
```

Description

Call System::WideString::Insert to inserts the string str into thisSystem::WideString::WideString (see page 22377) beginning at the position index.

See Also

System::WideString::Delete (see page 22383)

System::WideString::[] (see page 22388)

158.1.32.4.9 WideString::IsEmpty Method

Returns true if the System::WideString::WideString (see page 22380) is empty.

Pascal

```
function IsEmpty: bool;
```

C++

```
__fastcall bool IsEmpty() const;
```

Description

Call System::WideString::IsEmpty to determine whether the System::WideString::WideString (see page 22380) represents an empty string.

See Also

System::WideString::Empty (see page 22384)

158.1.32.4.10 WideString::Length Method

Returns the length of theSystem::WideString::WideString (see page 22377).

Pascal

```
function Length: Integer;
```

C++

```
__fastcall int Length() const;
```

Description

System::WideString::Length returns the number of characters in thisSystem::WideString::WideString (see page 22377).

158.1.32.4.11 WideString::Pos Method

Returns the index at which a specified substring begins.

Pascal

```
function Pos(const subStr: WideString&): Integer;
```

C++

```
__fastcall int Pos(const WideString& subStr) const;
```

Description

Use System::WideString::Pos to locate a substring of theSystem::WideString::WideString (see page 22377). System::WideString::Pos returns the index of the first character in subStr. If subStr is not contained in theSystem::WideString::WideString (see page 22377), System::WideString::Pos returns 0.

See Also

System::WideString::Length (see page 22385)

System::WideString::SubString (see page 22386)

158.1.32.4.12 WideString::SetLength Method

Changes the length of theSystem::WideString::WideString (see page 22377).

Pascal

```
procedure SetLength(newLength: Integer);
```

C++

```
__fastcall void SetLength(int newLength);
```

Description

System::WideString::SetLength changes theSystem::WideString::WideString (see page 22377)'s length to newLength, truncating if necessary.

System::WideString::SetLength reallocates the underlying array of characters that stores the value of theSystem::WideString::WideString (see page 22377). Existing characters in the string are preserved, but the content of newly allocated space is undefined. If there is not enough memory available to reallocate theSystem::WideString::WideString (see page 22377), an EOutOfMemory exception is thrown. Following a call to System::WideString::SetLength, theSystem::WideString::WideString (see page 22377) is guaranteed to reference a unique string — that is a string with a reference count of one.

See Also

System::WideString::Length (see page 22385)

158.1.32.4.13 WideString::SubString Method

Returns a specified substring of theSystem::WideString::WideString (see page 22377).

Pascal

```
function SubString(index: Integer; count: Integer): WideString;
```

C++

```
__fastcall WideString SubString(int index, int count) const;
```

Description

System::WideString::SubString returns a newSystem::WideString::WideString (see page 22377) that is a substring of thisSystem::WideString::WideString (see page 22377). The substring contains count characters beginning at index.

See Also

System::WideString::Length (see page 22385)

System::WideString::pos

158.1.32.5 WideString Operators

The operators of the WideString class are listed here.

Public Operators

	Name	Description
	!= (see page 22387)	This is the overview for the != operator overload.
	& (see page 22387)	Returns a pointer to the underlying BSTR (see page 22393).
	[] (see page 22388)	This is the overview for the [] operator overload.
	+ (see page 22388)	Concatenates twoSystem::WideString::WideStrings.
	+= (see page 22389)	Concatenates this System::WideString::WideString (see page 22380) and rhs, and assigns the result to this System::WideString::WideString (see page 22380).
	< (see page 22389)	This is the overview for the < operator overload.

	<= (see page 22390)	This is the overview for the <= operator overload.
	= (see page 22390)	This is the overview for the = operator overload.
	== (see page 22391)	This is the overview for the == operator overload.
	> (see page 22392)	This is the overview for the > operator overload.
	>= (see page 22392)	This is the overview for the >= operator overload.
	BSTR (see page 22393)	Converts the wide string to a System::WideString::BSTR.

158.1.32.5.1 != Operator

This is the overview for the != operator overload.

Overload List

	Name	Description
	WideString::!= (BSTR) (see page 22387)	Tests whether theSystem::WideString::WideString (see page 22377) is different from anotherSystem::WideString::WideString (see page 22377).
	WideString::!= (char*) (see page 22387)	Tests whether theSystem::WideString::WideString (see page 22377) is different from anotherSystem::WideString::WideString (see page 22377).
	WideString::!= (WideString&) (see page 22387)	Tests whether theSystem::WideString::WideString (see page 22377) is different from anotherSystem::WideString::WideString (see page 22377).

158.1.32.5.1.1 WideString::!= Operator (BSTR)

Tests whether theSystem::WideString::WideString (see page 22377) is different from anotherSystem::WideString::WideString (see page 22377).

Pascal

```
operator !=(const rhs: WideString&);
operator !=(const w: WideString);
operator !=(const s: char*);
```

C++

```
__fastcall bool operator !=(const WideString& rhs) const;
__fastcall bool operator !=(const BSTR w) const;
__fastcall bool operator !=(const char* s) const;
```

Description

The != System::WideString (see page 22377)::!= returns true if the strings are not the same, false otherwise.

See Also

System::WideString::== (see page 22391)

158.1.32.5.2 WideString::& Operator

Returns a pointer to the underlying BSTR (see page 22393).

Pascal

```
operator &;
```

C++

```
__fastcall BSTR* operator &();
```

Description

Use the & System::WideString (see page 22377)::& to obtain a pointer to the internal BSTR (see page 22393) that is used to implement theSystem::WideString::WideString (see page 22377).

Note: BSTR (see page 22393) values are used with COM objects. Do not use COM objects in platform-independent applications, since COM is only available under Window.

See Also

System::WideString::bstr

System::WideString::Copy (see page 22382)

System::WideString::c_bstr (see page 22382)

158.1.32.5.3 [] Operator

This is the overview for the [] operator overload.

Overload List

	Name	Description
	WideString::[] (int) (see page 22388)	Returns the character at a specified index in the string.
	WideString::[] (int) (see page 22388)	Returns the character at a specified index in the string.

158.1.32.5.3.1 WideString::[] Operator (int)

Returns the character at a specified index in the string.

Pascal

```
operator [](const idx: Integer);
operator [](const idx: Integer);
```

C++

```
__fastcall WideChar & operator [](const int idx);
__fastcall const WideChar& operator [](const int idx) const;
```

Description

The System::WideString (see page 22377)::[] returns the character in the string at index value idx. The System::WideString (see page 22377)::[] assumes a base index of 1. For example, given the string “Hello” and an index value of 2, the character returned would be ‘e’.

158.1.32.5.4 WideString::+ Operator

Concatenates twoSystem::WideString::WideStrings.

Pascal

```
operator +(const rhs: WideString&);
```

C++

```
__fastcall WideString operator +(const WideString& rhs) const;
```

Description

The + System::WideString (see page 22377)::+ returns aSystem::WideString::WideString (see page 22377) that has the value passed as rhs concatenated to the end. A related friend System::WideString (see page 22377)::+ takes two arguments

and returns the concatenation of lhs with rhs.

158.1.32.5.5 WideString::+= Operator

Concatenates this System::WideString::WideString (see page 22380) and rhs, and assigns the result to this System::WideString::WideString (see page 22380).

Pascal

```
operator +=(const rhs: WideString&);
```

C++

```
__fastcall WideString& operator +=(const WideString& rhs);
```

Description

Use += to concatenate rhs to the end of the System::WideString::WideString (see page 22380). This System::WideString (see page 22377)::+= is not supported when the System::WideString::WideString (see page 22380) is a property value.

158.1.32.5.6 < Operator

This is the overview for the < operator overload.

Overload List

	Name	Description
	WideString::< (BSTR) (see page 22389)	Compares two strings.
	WideString::< (char*) (see page 22389)	Compares two strings.
	WideString::< (WideString&) (see page 22389)	Compares two strings.

158.1.32.5.6.1 WideString::< Operator (BSTR)

Compares two strings.

Pascal

```
operator <(const rhs: WideString&);
operator <(const w: WideString);
operator <(const s: char*);
```

C++

```
__fastcall bool operator <(const WideString& rhs) const;
__fastcall bool operator <(const BSTR w) const;
__fastcall bool operator <(const char* s) const;
```

Description

The < System::WideString (see page 22377)::< returns true if thisSystem::WideString::WideString (see page 22377) is less than rhs, false otherwise. The strings are compared using the numerical value of each character, with case sensitivity.

See Also

System::WideString::<= (see page 22390)

System::WideString::> (see page 22392)

158.1.32.5.7 <= Operator

This is the overview for the <= operator overload.

Overload List

	Name	Description
	WideString::<= (BSTR) (see page 22390)	Compares two strings.
	WideString::<= (char*) (see page 22390)	Compares two strings.
	WideString::<= (WideString&) (see page 22390)	Compares two strings.

158.1.32.5.7.1 WideString::<= Operator (BSTR)

Compares two strings.

Pascal

```
operator <=(const rhs: WideString&);
operator <=(const w: WideString);
operator <=(const s: char*);
```

C++

```
__fastcall bool operator <=(const WideString& rhs) const;
__fastcall bool operator <=(const BSTR w) const;
__fastcall bool operator <=(const char* s) const;
```

Description

The <= System::WideString (see page 22377)::<= returns true if thisSystem::WideString::WideString (see page 22377) is less than or equal to rhs, false otherwise. The strings are compared using their numerical value of each character, with case sensitivity.

See Also

System::WideString::>= (see page 22392)

System::WideString::< (see page 22389)

158.1.32.5.8 = Operator

This is the overview for the = operator overload.

Overload List

	Name	Description
	WideString::= (BSTR) (see page 22390)	Assigns the value of theSystem::WideString::WideString (see page 22377) to equal a source string.
	WideString::= (WideString&) (see page 22390)	Assigns the value of theSystem::WideString::WideString (see page 22377) to equal a source string.

158.1.32.5.8.1 WideString::= Operator (BSTR)

Assigns the value of theSystem::WideString::WideString (see page 22377) to equal a source string.

Pascal

```
operator =(const rhs: WideString&);
operator =(rhs: WideString);
```

C++

```
__fastcall WideString& operator =(const WideString& rhs);
__fastcall WideString& operator =(BSTR rhs);
```

Description

Use the assignment System::WideString (see page 22377)::= to set the value of theSystem::WideString::WideString (see page 22377) to match the string given by rhs.

Note: BSTR (see page 22393) values are used with COM objects. Do not use COM objects in platform-independent applications, since COM is only available under Windows.

158.1.32.5.9 == Operator

This is the overview for the == operator overload.

Overload List

	Name	Description
	WideString::== (BSTR) (see page 22391)	Compares theSystem::WideString::WideString (see page 22377) with a specified string, returning true if they are the same.
	WideString::== (char*) (see page 22391)	Compares theSystem::WideString::WideString (see page 22377) with a specified string, returning true if they are the same.
	WideString::== (WideString&) (see page 22391)	Compares theSystem::WideString::WideString (see page 22377) with a specified string, returning true if they are the same.

158.1.32.5.9.1 WideString::== Operator (BSTR)

Compares theSystem::WideString::WideString (see page 22377) with a specified string, returning true if they are the same.

Pascal

```
operator ==(const rhs: WideString&);
operator ==(const w: WideString);
operator ==(const s: char*);
```

C++

```
__fastcall bool operator ==(const WideString& rhs) const;
__fastcall bool operator ==(const BSTR w) const;
__fastcall bool operator ==(const char* s) const;
```

Description

The equality System::WideString (see page 22377)::== returns true if thisSystem::WideString::WideString (see page 22377) is the same as rhs, false otherwise.

See Also

System::WideString::!= (see page 22387)

158.1.32.5.10 > Operator

This is the overview for the > operator overload.

Overload List

	Name	Description
	WideString::> (BSTR) (see page 22392)	Compares two strings.
	WideString::> (char*) (see page 22392)	Compares two strings.
	WideString::> (WideString&) (see page 22392)	Compares two strings.

158.1.32.5.10.1 WideString::> Operator (BSTR)

Compares two strings.

Pascal

```
operator >(const rhs: WideString&);
operator >(const w: WideString);
operator >(const s: char*);
```

C++

```
__fastcall bool operator >(const WideString& rhs) const;
__fastcall bool operator >(const BSTR w) const;
__fastcall bool operator >(const char* s) const;
```

Description

The System::WideString (see page 22377)::> returns true if thisSystem::WideString::WideString (see page 22377) is greater than rhs, false otherwise. The strings are compared using the numerical value of each character, with case sensitivity.

See Also

System::WideString::>= (see page 22392)

System::WideString::< (see page 22389)

158.1.32.5.11 >= Operator

This is the overview for the >= operator overload.

Overload List

	Name	Description
	WideString::>= (BSTR) (see page 22392)	Compares two strings.
	WideString::>= (char*) (see page 22392)	Compares two strings.
	WideString::>= (WideString&) (see page 22392)	Compares two strings.

158.1.32.5.11.1 WideString::>= Operator (BSTR)

Compares two strings.

Pascal

```
operator >=(const rhs: WideString&);
operator >=(const w: WideString);
```

```
operator >=(const s: char*);
```

C++

```
__fastcall bool operator >=(const WideString& rhs) const;
__fastcall bool operator >=(const BSTR w) const;
__fastcall bool operator >=(const char* s) const;
```

Description

The System::WideString (see page 22377)::>= returns true if thisSystem::WideString::WideString (see page 22377) is greater than or equal to rhs, false otherwise. The strings are compared using the numerical value of each character, with case sensitivity.

See Also

System::WideString::<= (see page 22390)

System::WideString::> (see page 22392)

158.1.32.5.12 WideString::BSTR Operator

Converts the wide string to a System::WideString::BSTR.

Pascal

```
operator BSTR;
```

C++

```
operator BSTR() const;
```

Description

Use the System::WideString::BSTR conversion operator to cast aSystem::WideString::WideString (see page 22377) value to a System::WideString::BSTR.

Note: System::WideString::BSTR values are used with COM objects. Do not use COM objects in platform-independent applications, since COM is only available under Window.

See Also

System::WideString::c_bstr (see page 22382)

System::WideString::Copy (see page 22382)

System::WideString::& (see page 22387)

158.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IDispatch (see page 22394)	This is class System.IDispatch.
	IInterface (see page 22396)	IInterface is the base class for all interfaces defined in Delphi code.
	IInvokable (see page 22398)	IInvokable is the base class for invokable interfaces.

158.2.1 IDispatch Interface

Class Hierarchy

Pascal

```
IDispatch = interface(IUnknown);
```

C++

```
__interface IDispatch : public IUnknown;
```

File

System

Description

This is class System.IDispatch.

158.2.1.1 IDispatch Members

The following tables list the members exposed by IDispatch.

Public Methods

	Name	Description
	GetIDsOfNames (see page 22395)	This is GetIDsOfNames, a member of class IDispatch.
	GetTypeInfo (see page 22395)	This is GetTypeInfo, a member of class IDispatch.
	GetTypeInfoCount (see page 22395)	This is GetTypeInfoCount, a member of class IDispatch.
	Invoke (see page 22395)	This is Invoke, a member of class IDispatch.

158.2.1.2 IDispatch Methods

The methods of the IDispatch class are listed here.

Public Methods

	Name	Description
	GetIDsOfNames (see page 22395)	This is GetIDsOfNames, a member of class IDispatch.

	GetTypeInfo (see page 22395)	This is GetTypeInfo, a member of class IDispatch.
	GetTypeInfoCount (see page 22395)	This is GetTypeInfoCount, a member of class IDispatch.
	Invoke (see page 22395)	This is Invoke, a member of class IDispatch.

158.2.1.2.1 IDispatch.GetIDsOfNames Method

Pascal

```
function GetIDsOfNames(const IID: TGUID; Names: Pointer; NameCount: Integer; LocaleID:
Integer; DispIDs: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetIDsOfNames(const TGUID IID, void * Names, int NameCount, int
LocaleID, void * DispIDs);
```

Description

This is GetIDsOfNames, a member of class IDispatch.

158.2.1.2.2 IDispatch.GetTypeInfo Method

Pascal

```
function GetTypeInfo(Index: Integer; LocaleID: Integer; out TypeInfo): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfo(int Index, int LocaleID,  TypeInfo);
```

Description

This is GetTypeInfo, a member of class IDispatch.

158.2.1.2.3 IDispatch.GetTypeInfoCount Method

Pascal

```
function GetTypeInfoCount(out Count: Integer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT GetTypeInfoCount(int Count);
```

Description

This is GetTypeInfoCount, a member of class IDispatch.

158.2.1.2.4 IDispatch.Invoke Method

Pascal

```
function Invoke(DispID: Integer; const IID: TGUID; LocaleID: Integer; Flags: Word; var Params;
VarResult: Pointer; ExcepInfo: Pointer; ArgErr: Pointer): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT Invoke(int DispID, const TGUID IID, int LocaleID, Word Flags,
Params, void * VarResult, void * ExcepInfo, void * ArgErr);
```

Description

This is Invoke, a member of class IDispatch.

158.2.2 IInterface Interface

IInterface is the base class for all interfaces defined in Delphi code.

Class Hierarchy

System.IInterface

Pascal

```
IInterface = interface;
```

C++

```
__interface IInterface;
```

File

System

Description

IInterface is the base interface for interfaces defined in Delphi code. When used in C++ code, IInterface is considered a child interface of IUnknown (see page 22586) and IUnknown (see page 22586) is considered the base interface for all interfaces.

Note: IInterface introduces the QueryInterface (see page 22398) method, which is useful for discovering and using other interfaces implemented by the same object. IInterface also introduces the reference counting methods, _AddRef (see page 22397) and _Release (see page 22397). The Delphi compiler automatically provides calls to these methods when interfaces are used. The System::TInterfacedObject (see page 22276) class is provided as a base class for objects that implement interfaces. Use of System::TInterfacedObject (see page 22276) is not mandatory, but will often be easier than designing an implementer class from scratch.

Note: C++ method declarations that use IInterface refer to the _di_IInterface type instead. This is a DelphiInterface (see page 22167) wrapper around the IInterface interface:

```
typedef System::DelphiInterfaceDelphiInterface_object< IInterface > _di_IInterface;
```

See Also

System::TInterfacedObject (see page 22276)

IInvokable (see page 22398)

IUnknown (see page 22586)

System::DelphiInterface (see page 22167)

158.2.2.1 IInterface Members

The following tables list the members exposed by IInterface.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.

	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.

158.2.2.2 IInterface Methods

The methods of the IInterface class are listed here.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.

158.2.2.2.1 IInterface._AddRef Method

Increments the reference count for this interface.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

The Delphi compiler automatically generates a call to __AddRef for every reference to this interface. For most implementations, __AddRef increments the reference count for the interface and returns the new reference count. When the caller is through with the interface, the compiler generates a call to the _Release (see page 22397) method, which decrements the reference count. When the reference count drops to zero, the object is automatically freed.

Note: Implementation objects can implement __AddRef and _Release (see page 22397) so that they do not perform any reference counting. For such objects, the reference count never drops to zero and the object is not automatically freed. In these cases, it is the application's responsibility to free the object.

See Also

_Release (see page 22397)

158.2.2.2.2 IInterface._Release Method

Decrements the reference count for this interface.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

The Delphi compiler automatically generates a call to __Release whenever a reference to this interface goes out of scope. For most implementations, __Release decrements the reference count for the interface and returns the new reference count. When the reference count drops to zero, the object is automatically freed.

Note: Implementation objects can implement __Release so that it does not perform any reference counting. For such objects, the reference count never drops to zero and the object is not automatically freed. In these cases, it is the application's responsibility to free the object.

See Also

_AddRef (see page 22397)

158.2.2.2.3 IInterface.QueryInterface Method

Returns a reference to a specified interface if the object supports that interface.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface checks whether the object that implements this interface supports the interface specified by IID. If so, QueryInterface

increments the reference count.

sets the Obj parameter so that it points to an instance of the specified interface.

returns 0 to indicate success.

If the object does not support the interface, QueryInterface returns a nonzero error code such as E_NoInterface.

See Also

_AddRef (see page 22397)

158.2.3 IInvokable Interface

IInvokable is the base class for invokable interfaces.

Class Hierarchy

Pascal

```
IInvokable = interface(IInterface);
```

C++

```
__interface IInvokable : public IInterface;
```

File

System

Description

Use IInvokable as a base interface when defining invokable interfaces. IInvokable does not add any properties or methods to the methods it inherits from IInterface (see page 22396). It exists, rather, to ensure that the interface an all its descendants are compiled with runtime type information (RTTI). This RTTI can be used by Web Service applications or the clients of Web Service applications for translating between the code that implements a method and the symbolic encoding of that method call that is sent between client and server applications.

158.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	!= (see page 22405)	This is function System::!=.
	__currMul (see page 22405)	This is function System::__currMul.
	_CVR_PROBE (see page 22405)	This is function System._CVR_PROBE.
	_CVR_STMTPROBE (see page 22406)	This is function System._CVR_STMTPROBE.
	_roundToInt64 (see page 22406)	This is function System::_roundToInt64.
	+ (see page 22406)	This is function System::+.
	< (see page 22407)	This is function System::<.
	<< (see page 22407)	This is function System::<<.
	<< (see page 22407)	This is function System::<<.
	<< (see page 22408)	This is function System::<<.
	<= (see page 22408)	This is function System::<=.
	== (see page 22408)	This is function System::==.
	> (see page 22409)	This is function System::>.
	>= (see page 22409)	This is function System::>=.
	>> (see page 22409)	This is function System::>>.
	>> (see page 22410)	This is function System::>>.
	Abs (see page 22410)	Returns an absolute value.
	AcquireExceptionObject (see page 22410)	Retains access to exception object.
	AddModuleUnloadProc (see page 22411)	AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.
	AddModuleUnloadProc (see page 22411)	AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.
	Addr (see page 22412)	Returns a pointer to a specified object.
	AllocMem (see page 22413)	AllocMem allocates a memory block and initializes each byte to zero.
	AnsiToUtf8 (see page 22415)	Converts a string encoded in Ansi to UTF-8.
	Append (see page 22415)	Prepares an existing file for adding text to the end.
	ArcTan (see page 22416)	Calculates the arctangent of a given number.
	Assert (see page 22417)	Tests whether a Boolean expression is true.
	Assert (see page 22417)	Tests whether a Boolean expression is true.
	Assigned (see page 22419)	Tests for a nil (unassigned) pointer or procedural variable.
	AssignFile (see page 22420)	Associates the name of an external file with a file variable.
	AttemptToUseSharedMemoryManager (see page 22422)	Attempts to use a shared memory manager.
	BeginThread (see page 22422)	Spawns a separate thread of execution.
	BlockRead (see page 22423)	Reads one or more records from an open file into a variable.
	BlockRead (see page 22423)	Reads one or more records from an open file into a variable.
	BlockWrite (see page 22425)	Writes one or more records from a variable to an open file.
	BlockWrite (see page 22425)	Writes one or more records from a variable to an open file.
	Break (see page 22426)	Causes the flow of control to exit a for, while, or repeat statement.
	ChDir (see page 22429)	Changes the current directory.
	ChDir (see page 22429)	Changes the current directory.
	Chr (see page 22430)	Returns the character for a specified ASCII value.
	Close (see page 22432)	Terminates the association between a file variable and an external file.
	CloseFile (see page 22433)	Terminates the association between file variable and an external disk file.
	CompToCurrency (see page 22435)	Converts a Comp value to a Currency (see page 22145) value.
	CompToDouble (see page 22435)	Converts a Comp value to a double value.

	Concat (see page 22436)	Concatenates two or more strings into one.
	Concat (see page 22436)	Concatenates two or more strings into one.
	Concat (see page 22436)	Concatenates two or more strings into one.
	Continue (see page 22437)	Allows the flow of control to proceed to the next iteration of for, while, or repeat statements.
	Copy (see page 22438)	Returns a substring of a string or a segment of a dynamic array.
	Cos (see page 22440)	Calculates the cosine of an angle.
	CurrencyToComp (see page 22441)	Converts a Currency (see page 22145) value to a Comp value.
	Dec (see page 22441)	Decrements a variable by 1 or N.
	Dec (see page 22441)	Decrements a variable by 1 or N.
	Delete (see page 22443)	Removes a substring from a string.
	Dispose (see page 22444)	Releases memory allocated for a dynamic variable.
	DoubleToComp (see page 22446)	Converts a double value to a Comp.
	DynArrayClear (see page 22446)	This is function System.DynArrayClear.
	DynArrayDim (see page 22446)	This is function System.DynArrayDim.
	DynArraySetLength (see page 22447)	This is function System.DynArraySetLength.
	EndThread (see page 22447)	Terminates the execution of a thread.
	EnumModules (see page 22447)	Executes a callback for all the modules in an application.
	EnumModules (see page 22447)	Executes a callback for all the modules in an application.
	EnumResourceModules (see page 22448)	Executes a callback for all resource modules in an application.
	EnumResourceModules (see page 22448)	Executes a callback for all resource modules in an application.
	Eof (see page 22449)	Tests whether the file position is at the end of a file.
	Eof (see page 22449)	Tests whether the file position is at the end of a file.
	Eof (see page 22449)	Tests whether the file position is at the end of a file.
	Eoln (see page 22450)	Tests whether the file pointer is at the end of a line.
	Eoln (see page 22450)	Tests whether the file pointer is at the end of a line.
	Erase (see page 22451)	Deletes an external file.
	Error (see page 22451)	Error is used to generate a run-time exception.
	ExceptAddr (see page 22452)	Returns the address at which the current exception was raised.
	ExceptObject (see page 22452)	Returns current exception object.
	Exclude (see page 22453)	Removes an element from a Delphi set or removes an event handler in .NET applications.
	Exit (see page 22453)	Exits from the current procedure.
	Exp (see page 22455)	Returns the exponential of X.
	Exp (see page 22455)	Returns the exponential of X.
	FilePos (see page 22456)	Returns the current file position.
	FileSize (see page 22457)	Returns the number of records in a file.
	FillChar (see page 22459)	Fills contiguous bytes with a specified value.
	Finalize (see page 22460)	Uninitializes a dynamically allocated variable.
	Finalize (see page 22460)	Uninitializes a dynamically allocated variable.
	FindClassHInstance (see page 22461)	Returns the instance handle for the module in which a class type is defined.
	FindHInstance (see page 22461)	Returns the instance handle of the module that contains a specified address.
	FindResourceHInstance (see page 22462)	Returns the instance handle of the resource module associated with a specified HInstance.
	Flush (see page 22462)	Empties the buffer of a text file opened for output.
	FPower10 (see page 22463)	This is function System.FPower10.
	Frac (see page 22463)	Returns the fractional part of a real number.
	FreeMem (see page 22464)	FreeMem frees a memory block.
	FreeMem (see page 22464)	FreeMem frees a memory block.
	FreeMemory (see page 22466)	FreeMemory frees a memory block.
	Get8087CW (see page 22466)	Returns the value of the 8087 code word.
	GetDir (see page 22467)	Returns the current directory.
	GetHeapStatus (see page 22468)	Returns the current status of the memory manager.
	GetLastError (see page 22469)	Returns the last error reported by an operating system API call.
	GetMem (see page 22469)	GetMem allocates a memory block.

	GetMemory (see page 22470)	GetMemory allocates a memory block.
	GetMemoryManager (see page 22472)	Returns the entry points of the currently installed memory manager.
	GetMemoryManager (see page 22472)	Returns the entry points of the currently installed memory manager.
	GetMemoryManagerState (see page 22472)	Fetches state information for the Memory Manager.
	GetMemoryMap (see page 22473)	Fetches the memory map.
	GetMinimumBlockAlignment (see page 22473)	Gets the minimum memory block alignment.
	GetModuleFileName (see page 22474)	Returns the fully qualified name for a module, given its handle.
	GetVariantManager (see page 22474)	Returns the entry points of the routines that define variant behavior.
	Halt (see page 22475)	Initiates abnormal termination of a program.
	Halt (see page 22475)	Initiates abnormal termination of a program.
	Hi (see page 22476)	Returns the high-order byte of X as an unsigned value.
	High (see page 22476)	Returns the highest value in the range of an argument.
	Inc (see page 22478)	Increments an ordinal value by one or N.
	Inc (see page 22478)	Increments an ordinal value by one or N.
	Include (see page 22479)	Adds an element to a Delphi set or adds an event handler in .NET applications.
	Initialize (see page 22480)	Initializes a dynamically allocated variable.
	Initialize (see page 22480)	Initializes a dynamically allocated variable.
	Insert (see page 22480)	Inserts a substring into a string beginning at a specified point.
	Int (see page 22481)	Returns the integer part of a real number.
	IOResult (see page 22482)	Returns the status of the last I/O operation performed.
	IsMemoryManagerSet (see page 22483)	Indicates whether the memory manager has been overridden using the SetMemoryManager (see page 22523) procedure.
	IsVariantManagerSet (see page 22483)	Indicates whether variant support is implemented in an application.
	Length (see page 22484)	Returns the number of characters in a string or elements in an array.
	Ln (see page 22485)	Returns the natural log of a real expression.
	Lo (see page 22486)	Returns the low order Byte of argument X.
	LoadResourceModule (see page 22486)	This is function System.LoadResourceModule.
	LoadResString (see page 22487)	This is function System.LoadResString.
	Low (see page 22487)	Returns the lowest value in a range.
	MkDir (see page 22488)	Creates a new subdirectory.
	MkDir (see page 22488)	Creates a new subdirectory.
	Move (see page 22490)	Copies bytes from a source to a destination.
	New (see page 22491)	Creates a new dynamic variable and sets P to point to it.
	Odd (see page 22493)	Returns true if argument is an odd number.
	OleStrToString (see page 22493)	Copies data received from a COM interface to a string.
	OleStrToStrVar (see page 22494)	Copies a string from its COM representation to an existing Delphi string.
	Ord (see page 22494)	Returns the ordinal value of an ordinal-type expression.
	ParamCount (see page 22495)	Returns the number of parameters passed on the command line.
	ParamStr (see page 22496)	Returns a specified parameter from the command-line.
	Pi (see page 22497)	Returns 3.1415926535897932385.
	Pos (see page 22497)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pos (see page 22497)	Returns the index value of the first character in a specified substring that occurs in a given string.
	Pred (see page 22499)	Returns the predecessor of the argument.
	Ptr (see page 22501)	Converts a specified address to a pointer.
	PUCS4Chars (see page 22501)	Converts a UCS4 string to a null-terminated array of UCS4 characters.
	RaiseList (see page 22502)	This is function System.RaiseList.
	Random (see page 22502)	Generates random numbers within a specified range.
	Random (see page 22502)	Generates random numbers within a specified range.
	Randomize (see page 22503)	Initializes the random number generator with a random value.
	Read (see page 22504)	Read reads data from a file.
	Read (see page 22504)	Read reads data from a file.
	Read (see page 22504)	Read reads data from a file.
	Read (see page 22504)	Read reads data from a file.

	ReadLn (see page 22506)	Reads a line of text from a file.
	ReadLn (see page 22506)	Reads a line of text from a file.
	ReadLn (see page 22506)	Reads a line of text from a file.
	ReadLn (see page 22506)	Reads a line of text from a file.
	ReallocMem (see page 22507)	ReallocMem reallocates a memory block.
	ReallocMemory (see page 22508)	ReallocMemory resizes a memory block.
	RegisterExpectedMemoryLeak (see page 22508)	Registers an expected memory leak.
	RegisterModule (see page 22509)	This is function System.RegisterModule.
	ReleaseExceptionObject (see page 22509)	Releases exception object acquired by AcquireExceptionObject (see page 22410).
	RemoveModuleUnloadProc (see page 22510)	RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.
	RemoveModuleUnloadProc (see page 22510)	RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.
	Rename (see page 22510)	Changes the name of an external file.
	Rename (see page 22510)	Changes the name of an external file.
	Reset (see page 22511)	Opens an existing file.
	Reset (see page 22511)	Opens an existing file.
	Reset (see page 22511)	Opens an existing file.
	Reset (see page 22511)	Opens an existing file.
	Rewrite (see page 22513)	Creates a new file and opens it.
	Rewrite (see page 22513)	Creates a new file and opens it.
	RmDir (see page 22515)	Deletes an empty subdirectory.
	RmDir (see page 22515)	Deletes an empty subdirectory.
	Round (see page 22516)	Returns the value of X rounded to the nearest whole number.
	RunError (see page 22517)	Stops execution and generates a runtime error.
	RunError (see page 22517)	Stops execution and generates a runtime error.
	Seek (see page 22518)	Moves the current position of a file to a specified component.
	SeekEof (see page 22519)	Returns the end-of-file status of a file, ignoring whitespace.
	SeekEof (see page 22519)	Returns the end-of-file status of a file, ignoring whitespace.
	SeekEoln (see page 22520)	Returns the end-of-line status of a file, ignoring whitespace.
	SeekEoln (see page 22520)	Returns the end-of-line status of a file, ignoring whitespace.
	Set8087CW (see page 22520)	Sets both the control word in the floating point unit and the variable NoErrMsg (see page 22652) declared in the system unit.
	SetInOutRes (see page 22521)	This is function System.SetInOutRes.
	SetLastError (see page 22521)	SetLastError sets the last API error code.
	SetLength (see page 22522)	Sets the length of a string or dynamic-array variable.
	SetLineBreakStyle (see page 22522)	Determines the end-of-line and end-of-file conventions for text file I/O.
	SetMemoryManager (see page 22523)	Sets entry points of the memory manager.
	SetMemoryManager (see page 22523)	Sets entry points of the memory manager.
	SetMinimumBlockAlignment (see page 22524)	Sets the minimum memory block alignment.
	SetMultiByteConversionCodePage (see page 22524)	SetMultiByteConversionCodePage overrides the default multi byte code conversion page.
	SetRaiseList (see page 22525)	This is function System.SetRaiseList.
	SetString (see page 22525)	Sets the contents and length of the given string.
	SetTextBuf (see page 22526)	Assigns an I/O buffer to a text file.
	SetTextBuf (see page 22526)	Assigns an I/O buffer to a text file.
	SetVariantManager (see page 22527)	Sets the entry points of routines that define variant behavior.
	ShareMemoryManager (see page 22527)	Shares the module's memory manager.
	Sin (see page 22528)	Returns the sine of the angle in radians.
	SizeOf (see page 22528)	Returns the number of bytes occupied by a variable or type.
	Slice (see page 22529)	Returns a sub-section of an array.
	Sqr (see page 22529)	Returns the square of a number.
	Sqr (see page 22529)	Returns the square of a number.
	Sqrt (see page 22530)	Returns the square root of X.
	Str (see page 22530)	Formats a string and returns it to a variable.

	Str (see page 22530)	Formats a string and returns it to a variable.
	StringOfChar (see page 22531)	Returns a string with a specified number of repeating characters.
	StringOfChar (see page 22531)	Returns a string with a specified number of repeating characters.
	StringToOleStr (see page 22531)	Allocates memory and copies an AnsiStringa string to the OLE format.
	StringToWideChar (see page 22532)	Returns a UNICODE string from an AnsiString (see page 22093).
	Succ (see page 22532)	Returns the successor of an argument.
	Swap (see page 22533)	Exchanges high order byte with the low order byte of an integer or word.
	SysAllocMem (see page 22533)	This is function System.SysAllocMem.
	SysFreeMem (see page 22534)	Frees the memory pointed to by a specified pointer.
	SysGetMem (see page 22534)	Allocates a specified number of bytes and returns a pointer to them.
	SysReallocMem (see page 22535)	Returns a pointer to a specified number of bytes, preserving the values pointed to by the Pointer parameter.
	SysRegisterExpectedMemoryLeak (see page 22536)	This is function System.SysRegisterExpectedMemoryLeak.
	SysUnregisterExpectedMemoryLeak (see page 22536)	This is function System.SysUnregisterExpectedMemoryLeak.
	TextStart (see page 22536)	This is function System.TextStart.
	Trunc (see page 22537)	Truncates a real number to an integer.
	Truncate (see page 22537)	Deletes all the records after the current file position.
	UCS4StringToWideString (see page 22538)	Converts a string of 4-byte Unicode characters into a WideString (see page 22377) value.
	UnicodeToUtf8 (see page 22538)	Converts a string of Unicode characters into a UTF-8 string.
	UnicodeToUtf8 (see page 22538)	Converts a string of Unicode characters into a UTF-8 string.
	UniqueString (see page 22539)	Ensures that a given string has a reference count of one.
	UniqueString (see page 22539)	Ensures that a given string has a reference count of one.
	UnregisterExpectedMemoryLeak (see page 22539)	Unregisters an expected memory leak.
	UnregisterModule (see page 22540)	This is function System.UnregisterModule.
	UpCase (see page 22540)	Converts a character to uppercase.
	UTF8Decode (see page 22541)	Converts a UTF8 string to a Unicode string (WideString (see page 22377)).
	UTF8Encode (see page 22541)	Converts a WideString (see page 22377) value to a UTF8 string.
	Utf8ToAnsi (see page 22542)	Converts a UTF8 string to a string of Ansi characters.
	Utf8ToUnicode (see page 22542)	Converts a string of UTF-8 characters to a Unicode string.
	Utf8ToUnicode (see page 22542)	Converts a string of UTF-8 characters to a Unicode string.
	Val (see page 22543)	Converts a string to a numeric representation.
	VarArrayRedim (see page 22544)	Resizes a Variant (see page 22307) array.
	VarArrayRedim (see page 22544)	This is function System::VarArrayRedim.
	VarCast (see page 22545)	This is function System::VarCast.
	VarClear (see page 22545)	Empties a Variant (see page 22307), so that it is unassigned.
	VarClear (see page 22546)	This is function System::VarClear.
	WideCharLenToString (see page 22546)	Converts Unicode characters to single or multi byte character data.
	WideCharLenToStrVar (see page 22546)	WideCharLenToStrVar converts Unicode characters to single or multi byte character data.
	WideCharToString (see page 22547)	Converts null-terminated Unicode string to single or multi byte character data.
	WideCharToStrVar (see page 22547)	Converts Unicode string to a single or multi byte character data.
	WideStringToUCS4String (see page 22548)	Converts a WideString (see page 22377) value to a string of 4-byte Unicode characters.
	Write (see page 22548)	Writes to either a typed file or a text file
	Write (see page 22548)	Writes to either a typed file or a text file
	Write (see page 22548)	Writes to either a typed file or a text file
	Write (see page 22548)	Writes to either a typed file or a text file
	WriteLn (see page 22550)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 22550)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 22550)	Writes to a text file and adds an end-of-line marker.
	WriteLn (see page 22550)	Writes to a text file and adds an end-of-line marker.

158.3.1 System::!= Function

Pascal

```
operator !=(const w: WideString; const rhs: WideString&);
```

C++

```
__fastcall bool operator !=(const BSTR w, const WideString& rhs);
```

File

wstring.h

Description

This is function System::!=.

158.3.2 System::__currMul Function

Pascal

```
procedure __currMul(const c1: System::Currency; var c2: System::Currency);
```

C++

```
__fastcall void __currMul(const System::Currency c1, System::Currency & c2);
```

File

syscurr.h

Description

This is function System::__currMul.

158.3.3 System._CVR_PROBE Function

Pascal

```
procedure _CVR_PROBE(mi: PCVModInfo; probeNum: Cardinal); cdecl;
```

C++

```
__cdecl _CVR_PROBE(PCVModInfo mi, unsigned probeNum);
```

File

System

Description

This is function System._CVR_PROBE.

158.3.4 System._CVR_STMTPROBE Function

Pascal

```
function _CVR_STMTPROBE(mi: PCVModInfo; probeNum: Cardinal; TrueFalse: Cardinal): Boolean;
cdecl;
```

C++

```
__cdecl Boolean _CVR_STMTPROBE(PCVModInfo mi, unsigned probeNum, unsigned TrueFalse);
```

File

System

Description

This is function System._CVR_STMTPROBE.

158.3.5 System::_roundToInt64 Function

Pascal

```
function _roundToInt64(: long double): __int64; cdecl;
```

C++

```
__cdecl __int64 _roundToInt64(long double);
```

File

syscurr.h

Description

This is function System::_roundToInt64.

158.3.6 System::+ Function

Pascal

```
operator +(const : char*; const : AnsiString&);
```

C++

```
__fastcall AnsiString operator +(const char*, const AnsiString&);
```

File

dstring.h

Description

This is function System::+.

158.3.7 System::< Function

Pascal

```
operator <(const w: WideString; const rhs: WideString&);
```

C++

```
__fastcall bool operator <(const BSTR w, const WideString& rhs);
```

File

wstring.h

Description

This is function System::<.

158.3.8 System::<< Function

Pascal

```
operator <<(var os: std::ostream; const arg: Currency&);
```

C++

```
std::ostream& operator <<(std::ostream& os, const Currency& arg);
```

File

syscurr.h

Description

This is function System::<<.

158.3.9 System::<< Function

Pascal

```
operator <<(var os: std::ostream; const arg: TDateTime&);
```

C++

```
std::ostream& operator <<(std::ostream& os, const TDateTime& arg);
```

File

systdate.h

Description

This is function System::<<.

158.3.10 System::<< Function

Pascal

```
operator <<(var os: std::ostream; const arg: Variant&);
```

C++

```
std::ostream& operator <<(std::ostream& os, const Variant& arg);
```

File

sysvari.h

Description

This is function System::<<.

158.3.11 System::<= Function

Pascal

```
operator <=(const w: WideString; const rhs: WideString&);
```

C++

```
__fastcall bool operator <=(const BSTR w, const WideString& rhs);
```

File

wstring.h

Description

This is function System::<=.

158.3.12 System::== Function

Pascal

```
operator ==(const w: WideString; const rhs: WideString&);
```

C++

```
__fastcall bool operator ==(const BSTR w, const WideString& rhs);
```

File

wstring.h

Description

This is function System::==.

158.3.13 System::> Function

Pascal

```
operator >(const w: WideString; const rhs: WideString&);
```

C++

```
__fastcall bool operator >(const BSTR w, const WideString& rhs);
```

File

wstring.h

Description

This is function System::>.

158.3.14 System::>= Function

Pascal

```
operator >=(const w: WideString; const rhs: WideString&);
```

C++

```
__fastcall bool operator >=(const BSTR w, const WideString& rhs);
```

File

wstring.h

Description

This is function System::>=.

158.3.15 System::>> Function

Pascal

```
operator >>(var is: std::istream; var arg: Currency);
```

C++

```
std::istream& operator >>(std::istream& is, Currency& arg);
```

File

syscurr.h

Description

This is function System::>>.

158.3.16 System::>> Function

Pascal

```
operator >>(var is: std::istream; var arg: TDateTime);
```

C++

```
std::istream& operator >>(std::istream& is, TDateTime& arg);
```

File

systdate.h

Description

This is function System::>>.

158.3.17 System.Abs Function

Returns an absolute value.

Pascal

```
procedure Abs(X);
```

C++

```
Abs( X);
```

File

System

Description

Abs returns the absolute value of the argument, X.

X is an integer-type or real-type expression.

Delphi Examples:

```
{
This example converts negative floating point numbers and
integers to postive.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Edit1.Text := '-2.3';
  Edit3.Text := FloatToStr(Abs(StrToFloat(Edit1.Text)));    { 2.3 }
  Edit2.Text := '-157';
  Edit4.Text := IntToStr(Abs(StrToInt(Edit2.Text)));    { 157 }
end;
```

158.3.18 System.AcquireExceptionObject Function

Retains access to exception object.

Pascal

```
function AcquireExceptionObject: Pointer;
```

C++

```
void * AcquireExceptionObject();
```

File

System

Description

AcquireExceptionObject returns a pointer to the current exception object and prevents the exception object from being deallocated when the current exception handler exits.

Note: AcquireExceptionObject increments the exception object's reference count. Make sure that the reference count is decremented when the exception object is no longer needed. This happens automatically if you use the exception object to re-raise the exception. In all other cases, every call to AcquireExceptionObject must have a matching call to ReleaseExceptionObject (see page 22509). AcquireExceptionObject/ReleaseExceptionObject (see page 22509) sequences can be nested.

See Also

ReleaseExceptionObject (see page 22509)

ExceptObject (see page 22452)

on

catch

158.3.19 System.AddModuleUnloadProc Function

AddModuleUnloadProc adds a call to your defined routine when a package is unloaded.

Pascal

```
procedure AddModuleUnloadProc(Proc: TModuleUnloadProc); overload;
procedure AddModuleUnloadProc(Proc: TModuleUnloadProcLW); overload;
```

C++

```
AddModuleUnloadProc(TModuleUnloadProc Proc);
AddModuleUnloadProc(TModuleUnloadProcLW Proc);
```

File

System

Description

Before Delphi unloads a package that was used by your application, it can optionally call your **Proc** routine. In essence, AddModuleUnloadProc adds your callback routine to the head of the list of internal routines that Delphi invokes to perform the unload.

Use RemoveModuleUnloadProc (see page 22510) to reverse the effect of AddModuleUnloadProc.

See Also

RemoveModuleUnloadProc (see page 22510)

TModuleUnloadProc (see page 22617)

158.3.20 System.Addr Function

Returns a pointer to a specified object.

Pascal

```
function Addr(var X): Pointer;
```

C++

```
void * Addr( X);
```

File

System

Description

The Addr function returns the address of a specified object. X is any variable, procedure or function identifier. The result is a pointer to X.

The result of Addr is of the predefined type Pointer, which means that it is assignment-compatible with all pointer types but can't be dereferenced directly without a typecast.

Note: Addr is equivalent to the @ operator except that it is unaffected by the $T compiler directive.

Delphi Examples:

```
{
This example uses the Addr function to get the address of a
numeric value that is stored as custom data in a tree node.
Once the assignment has been made, changes to the entries in
the NodeNumbers array can be read by dereferencing the
pointers that are stored in the Data property of the Tree
nodes.  This example requires a populated TreeView.
}

var
  NodeNumbers: array [0 .. 200] of String;

procedure TForm1.Button1Click(Sender: TObject);
var
  I : Integer;
 begin
  with TreeView1 do
  begin
    for I := 0 to Items.Count - 1 do
    begin
      NodeNumbers[I] := Items[I].Text;
      Items[I].Data := Addr(NodeNumbers[I]);
      StringGrid1.Cells[0, I + 1] := IntToStr(I);
      StringGrid1.Cells[1, I + 1] := IntToStr(Integer(Items[I].Data));
      StringGrid1.Cells[2, I + 1] := NodeNumbers[I];
    end;
  end;
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  I : Integer;
  addr : Pointer;
begin
```

```
    I := StrToInt(Edit2.Text);
    addr := TreeView1.Items[I].Data;
    string(addr^) := Edit1.Text;  // NodeNumbers has been altered
    TreeView1.Items[I].Text := NodeNumbers[I]; // Update TreeView
    StringGrid1.Cells[2, I + 1] := NodeNumbers[I];  // Update StringGrid
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    StringGrid1.Cells[0, 0] := 'Node index';
    StringGrid1.Cells[1, 0] := 'Node addr';
    StringGrid1.Cells[2, 0] := 'Node text';
  end;
```

Ptr (see page 22501)

IDH

158.3.21 System.AllocMem Function

AllocMem allocates a memory block and initializes each byte to zero.

Pascal

```
function AllocMem(Size: Cardinal): Pointer;
```

C++

```
void * AllocMem(unsigned Size);
```

File

System

Description

AllocMem allocates a block of the given **Size** on the heap, and returns the address of this memory. Each byte in the allocated buffer is set to zero. To dispose of the buffer, use FreeMem (see page 22464). If there isn't enough memory available to allocate the block, an EOutOfMemory exception is raised.

Note: If the memory does not need to be zero-initialized, it is more efficient to use GetMem (see page 22469) instead.

C++ Examples:

```
/*
The following example uses a button, a string grid, and an
Open dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the specified file is opened, read into a buffer, and closed.
Then the buffer is displayed in two columns of the string
grid. The first column contains the character values in the
buffer. The second column contains the numeric values of the
characters in the buffer.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int iFileHandle;
  int iFileLength;
  int iBytesRead;
  char *pszBuffer;
```

```
  if (OpenDialog1->Execute())
  {
    try
    {
      iFileHandle = FileOpen(OpenDialog1->FileName, fmOpenRead);
      iFileLength = FileSeek(iFileHandle,0,2);
      FileSeek(iFileHandle,0,0);
      pszBuffer = PChar(AllocMem(iFileLength+1));
//    pszBuffer = new char[iFileLength+1];
      iBytesRead = FileRead(iFileHandle, pszBuffer, iFileLength);
      FileClose(iFileHandle);
      for (int i=0;i<iBytesRead;i++)
      {
        StringGrid1->RowCount += 1;
        StringGrid1->Cells[1][i+1] = pszBuffer[i];
        StringGrid1->Cells[2][i+1] = IntToStr((int)pszBuffer[i]);
      }
      delete [] pszBuffer;
    }
    catch(...)
    {
      Application->MessageBox("Can't perform one of the following file operations: Open, Seek,
Read, Close.", "File Error", IDOK);
    }
  }
}
```

Delphi Examples:

```
{
The following example uses a button, a string grid, and an
Open dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the specified file is opened, read into a buffer, and closed.
Then the buffer is displayed in two columns of the string
grid. The first column contains the character values in the
buffer. The second column contains the numeric values of the
characters in the buffer.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  iFileHandle: Integer;
  iFileLength: Integer;
  iBytesRead: Integer;
  Buffer: PChar;
  i: Integer;
begin
  if OpenDialog1.Execute then
  begin
    try
      iFileHandle := SysUtils.FileOpen(OpenDialog1.FileName, fmOpenRead);
      iFileLength := SysUtils.FileSeek(iFileHandle,0,2);
      FileSeek(iFileHandle,0,0);
      Buffer := PChar(System.AllocMem(iFileLength + 1));
      iBytesRead := SysUtils.FileRead(iFileHandle, Buffer^, iFileLength);
      FileClose(iFileHandle);
      for i := 0 to iBytesRead-1 do
      begin
        StringGrid1.RowCount := StringGrid1.RowCount + 1;
        StringGrid1.Cells[1,i+1] := Buffer[i];
        StringGrid1.Cells[2,i+1] := IntToStr(Integer(Buffer[i]));
      end;
    finally
      FreeMem(Buffer);
    end;
  end;
end;
```

158.3.22 System.AnsiToUtf8 Function

Converts a string encoded in Ansi to UTF-8.

Pascal

```
function AnsiToUtf8(const S: string): UTF8String;
```

C++

```
UTF8String AnsiToUtf8(const AnsiString S);
```

File

System

Description

AnsiToUtf8 converts the string specified by S, which uses the ANSI encoding system, to UTF-8.

See Also

Utf8ToAnsi (see page 22542)

Utf8ToUnicode (see page 22542)

WideStringToUCS4String (see page 22548)

158.3.23 System.Append Function

Prepares an existing file for adding text to the end.

Pascal

```
procedure Append(var F: Text);
```

C++

```
Append(Text F);
```

File

System

Description

Call Append to ensure that a file is opened with write-only access with the file pointer positioned at the end of the file. F is a text file variable and must be associated with an external file using AssignFile (see page 22420). If no external file of the given name exists, an error occurs. If F is already open, it is closed, then reopened. The current file position is set to the end of the file.

Note: If a Ctrl+Z (ASCII 26) is present in the last 128-byte block of the file, the current file position is set so that the next character added to the file overwrites the first Ctrl+Z in the block. In this way, text can be appended to a file that terminates with a Ctrl+Z.

If F was not assigned a name, then, after the call to Append, F refers to the standard output file.

Delphi Examples:

```
{
Append, Flush example
}

procedure TForm1.Button1Click(Sender: TObject);
var
  f: TextFile;
begin
  if OpenDialog1.Execute then
  begin                    { open a text file }
    AssignFile(f, OpenDialog1.FileName);
    Append(f);
    Writeln(f, 'I am appending some stuff to the end of the file.');
    { insert code here that would require a Flush before closing the file }
    Flush(f);  { ensures that the text was actually written to file }
    CloseFile(f);
    MessageDlg(OpenDialog1.FileName + ' has been altered, please validate.', mtInformation,
[mbOK], 0)
  end;
end;
```

Reset (see page 22511)

Rewrite (see page 22513)

IDH

158.3.24 System.ArcTan Function

Calculates the arctangent of a given number.

Pascal

```
function ArcTan(const X: Extended): Extended;
```

C++

```
Extended ArcTan(const Extended X);
```

File

System

Description

In Delphi code, ArcTan returns the arctangent of X.

X is a real-type expression that gives an angle in radians.

Delphi Examples:

```
{
This example shows how to use the ArcTan and FloatToStr
functions.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ex : Extended;
  mystring : String;
begin
  ex := 16 * ArcTan(1/5) - 4 * ArcTan(1/239); // Machin's formula
  mystring := FloatToStr(ex);
  Edit2.Text := mystring;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  ex : Extended;
  myString : String;
begin
  ex := Pi;
  mystring := FloatToStr(ex);
  Edit1.Text := mystring;
end;
```

ArcCos

158.3.25 System.Assert Function

Tests whether a Boolean expression is true.

Pascal

```
procedure Assert(expr: Boolean); overload;
procedure Assert(expr: Boolean; const msg: string); overload;
```

C++

```
Assert(Boolean expr);
Assert(Boolean expr, const AnsiString msg);
```

File

System

Description

In Delphi code, use Assert as a debugging tool to test that conditions assumed to be true are never violated. Assert provides an opportunity to intercept an unexpected condition and halt a program rather than allow execution to continue under unanticipated conditions.

Assert takes a Boolean expression and an optional message string as parameters. If the Boolean test fails, Assert raises an EAssertionFailed exception. If a message string was passed to Assert, the exception object is created with that string. Otherwise it is created with a default string indicating that the assertion failed. The message is displayed along with the complete path, filename, and the line number on which Assert failed.

The SysUtils (see page 22709) unit causes runtime errors to be turned into exceptions. If SysUtils (see page 22709) is not used anywhere in your application, you will get a runtime error 227 rather than an EAssertionFailed exception. This runtime error will halt the program.

Because assertions are not usually used in shipping versions of a product, compiler directives are provided to disable the generation of assertion code:

$ASSERTIONS ON/OFF(long form)

$C +/-(short form)

These are global switches that affect the entire source file where they occur, regardless of their position in the file. It is not possible to enable and disable assertions for something smaller than a source file. Assertions are on by default.

Delphi Examples:

```
{
This example exercises the System Assert function.  The first
call passes and the second call fails.
}

type
  TForm1 = class(TForm)
    Button1: TButton;
    procedure Button1Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

  TStorage = class(TObject)
    FData: string;
    property Data: string read FData write FData;
  private
    { Private declarations }
  public
    { Public declarations }
  end;

  var
  Form1: TForm1;

implementation

{$R *.dfm}

procedure ModifyStorage(AStorage: TStorage; const s: string);
begin
  Assert(AStorage <> nil, '');
  AStorage.Data := s;
end;
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  Storage: TStorage;
begin
  Storage := TStorage.Create;
  try
    ModifyStorage(Storage, 'Hello world');
  finally
    Storage.Free;
  end;

  // The following call is buggy and triggers the Assert
  ModifyStorage(nil, 'Ooops');
end;
```

See Also

EAssertionFailed

158.3.26 System.Assigned Function

Tests for a nil (unassigned) pointer or procedural variable.

Pascal

```
function Assigned(const P): Boolean;
```

C++

```
Boolean Assigned(const  P);
```

File

System

Description

Use Assigned to determine whether the pointer or procedure referenced by P is nil. P must be a variable reference of a pointer or procedural type. Assigned(P) corresponds to the test P<> nil for a pointer variable, and @P <> nil for a procedural variable.

Assigned returns false if P is nil, true otherwise.

Note: Assigned can't detect a dangling pointer--that is, one that isn't nil but no longer points to valid data. For example, in the code example for Assigned, Assigned won't detect the fact that P isn't valid.

Delphi Examples:

```
{
This example demonstrates the System Assigned function succeeds.
}
procedure TForm1.Button1Click(Sender: TObject);
var P: Pointer;
begin
  P := nil;
  if Assigned (P) then
    MessageDlg('You won''t see this', mtInformation, [mbOK], 0);
  GetMem(P, 1024);  {P valid}
  FreeMem(P, 1024); {P no longer valid and still not nil}
  if Assigned (P) then
    MessageDlg('You''ll see this', mtInformation, [mbOK], 0);
end;
```

158.3.27 System.AssignFile Function

Associates the name of an external file with a file variable.

Pascal

```
procedure AssignFile(var F; FileName: string);
```

C++

```
AssignFile( F, AnsiString FileName);
```

File

System

Description

Call AssignFile to initialize a file variable in Delphi code. F is a file variable of any file type. FileName is a string-type expression or an expression of type PChar if extended syntax is enabled.

After calling AssignFile, F is associated with the external file until F is closed. All further operations on the file variable F operate on the external file named by FileName.

When the FileName parameter is empty, AssignFile associates F with the standard input or standard output file. If assigned an empty name, after a call to Reset (see page 22511) (F), F refers to the standard input file, and after a call to Rewrite (see page 22513) (F), F refers to the standard output file.

Do not use AssignFile on a file variable that is already open.

Note: To avoid scope conflicts, AssignFile replaces the Assign procedure that was available in early versions of the Delphi product. However, for backward compatibility Assign is still available.

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File;
  i, filehandle: Integer;
begin
  for i := 0 to (FileListBox1.Items.Count - 1) do begin
  try
    if FileListBox1.Selected[i] then
    begin
      if not FileExists(FileListBox1.Items.Strings[i]) then
      begin

IDH

158.3.28 System.AttemptToUseSharedMemoryManager Function

Attempts to use a shared memory manager.

Pascal

```
function AttemptToUseSharedMemoryManager: Boolean;
```

C++

```
Boolean AttemptToUseSharedMemoryManager();
```

File

System

Description

AttemptToUseSharedMemoryManager searches the current process for a shared memory manager. If no memory has been allocated using this module's memory manager, it will switch to using the shared memory manager. It will return **True** if it found a shared memory manager to which it could switch. It will return **False** otherwise.

Note: The memory manager cannot be changed once memory has been allocated, since the new memory manager cannot free the pointers allocated through a different memory manager. This function is not thread safe.

Sharing Memory

158.3.29 System.BeginThread Function

Spawns a separate thread of execution.

Pascal

```
function BeginThread(SecurityAttributes: Pointer; StackSize: LongWord; ThreadFunc:
TThreadFunc; Parameter: Pointer; CreationFlags: LongWord; var ThreadId: LongWord): Integer;
```

C++

```
int BeginThread(void * SecurityAttributes, LongWord StackSize, TThreadFunc ThreadFunc, void *
Parameter, LongWord CreationFlags, LongWord ThreadId);
```

File

System

Description

Use this routine or a TThread object to spawn separate threads of execution. BeginThread spawns a new thread of execution and sets the global IsMultiThread (see page 22648) variable, thereby making the heap thread-safe.

ThreadFunc is the thread function. This is the code that executes in the new thread of execution. ThreadFunc should handle all of its own exceptions. However, because BeginThread sets up an execution frame, the system's default exception handler will catch any exceptions that escape ThreadFunc.

Parameter points to a single 32-bit parameter that is passed, uninterpreted, to ThreadFunc.

ThreadId returns the unique identifier for the new thread. This ID appears in the Thread Status box of the debugger.

SecurityAttributes is a pointer to a Windows SecurityAttributes record (structure). For details on security attributes, see the Microsoft documentation.

StackSize is the size of the stack reserved for the new thread when CreationFlags includes STACK_SIZE_IS_A_RESERVATION. Otherwise, this parameter is ignored.

CreationFlags is a set of bits or'ed together that are drawn from the following:

Value	Meaning
CREATE_SUSPENDED	The thread is created in a suspended state and does not run until the Windows API ResumeThread function is called. If this flag is not included, the new thread starts running as soon as it is created.
STACK_SIZE_PARAM_IS_A_RESERVATION	The StackSize parameter specifies the stack size for the thread. If this flag is not included, the new thread is assigned a default stack size by the linker.

On Windows, BeginThread returns the Windows thread handle. A return value of 0 indicates failure.

Attribute is a structure containing information about the thread such as its priority, its schedule policy, and its stack size.

On Linux, Begin Thread returns 0 if the thread is successfully spawned, an error code otherwise.

Defining Thread Objects

158.3.30 System.BlockRead Function

Reads one or more records from an open file into a variable.

Pascal

```
procedure BlockRead(var F: File; var Buf; Count: Integer); overload;
procedure BlockRead(var F: File; var Buf; Count: Integer; var AmtTransferred: Integer);
overload;
```

C++

```
BlockRead(File F,  Buf, int Count);
BlockRead(File F,  Buf, int Count, int AmtTransferred);
```

File

System

Description

F is an untyped file variable, Buf is any variable, Count is an expression of type Integer, and AmtTransferred is an optional variable of type Integer.

BlockRead reads Count or fewer records from the file F into memory, starting at the first byte occupied by Buf. The actual number of complete records read (less than or equal to Count) is returned in AmtTransferred.

The entire transferred block occupies at most Count * RecSize bytes. RecSize is the record size specified when the file was opened (or 128 if the record size was not specified).

If the entire block was transferred, AmtTransferred is equal to Count.

If AmtTransferred is less than Count, ReadBlock reached the end of the file before the transfer was complete. If the file's record size is greater than 1, AmtTransferred returns the number of complete records read.

If AmtTransferred isn't specified, an I/O error occurs if the number of records read isn't equal to Count. If the $I+ compiler directive is in effect, errors raise an EInOutError exception.

Delphi Examples:

```
{
This example reads an entire file into a buffer with one
command and then writes it into a saved file.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FromF, ToF: file;
  NumRead, NumWritten: Integer;
  Buf: array[1..2048] of Char;
begin
  if OpenDialog1.Execute then     { Display Open dialog box }
  begin
    AssignFile(FromF, OpenDialog1.FileName);
    Reset(FromF, 1);    { Record size = 1 }
    if SaveDialog1.Execute then      { Display Save dialog box}
    begin
      AssignFile(ToF, SaveDialog1.FileName);    { Open output file }
      Rewrite(ToF, 1);  { Record size = 1 }
      Canvas.TextOut(10, 10, 'Copying ' + IntToStr(FileSize(FromF))
        + ' bytes...');
      repeat
        System.BlockRead(FromF, Buf, SizeOf(Buf), NumRead);
        BlockWrite(ToF, Buf, NumRead, NumWritten);
      until (NumRead = 0) or (NumWritten <> NumRead);
      CloseFile(FromF);
      CloseFile(ToF);
    end;
  end;
end;
{
The following example opens a file of your choice and reads
the entire file into a dynamically allocated buffer. The
buffer and the size of the file are then passed to a routine
that processes the text, and finally the dynamically
allocated buffer is freed and the file is closed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: file;
  Size: Integer;
```

```
    Buffer: PChar;
  begin
    if OpenDialog1.Execute then
    begin
      AssignFile(F, OpenDialog1.FileName);
      Reset(F, 1);
      try
        Size := FileSize(F);
        GetMem(Buffer, Size);
        try
          BlockRead(F, Buffer^, Size);
          Memo1.Lines.Add(Buffer);
        finally
          FreeMem(Buffer);
        end;
      finally
        CloseFile(F);
      end;
    end;
  end;
```

EInOutError

158.3.31 System.BlockWrite Function

Writes one or more records from a variable to an open file.

Pascal

```
procedure BlockWrite(var f: File; var Buf; Count: Integer); overload;
procedure BlockWrite(var f: File; var Buf; Count: Integer; var AmtTransferred: Integer);
overload;
```

C++

```
BlockWrite(File f,  Buf, int Count);
BlockWrite(File f,  Buf, int Count, int AmtTransferred);
```

File

System

Description

F is an untyped file variable, Buf is any variable, Count is an expression of type Integer, and AmtTransferred is an optional variable of type Integer.

BlockWrite writes Count or fewer records to the file F from memory, starting at the first byte occupied by Buf. The actual number of complete records written (less than or equal to Count) is returned in AmtTransferred.

The entire block transferred occupies at most Count * RecSize bytes. RecSize is the record size specified when the file was opened (or 128 if the record size was unspecified).

If the entire block is transferred, AmtTransferred is equal to Count on return.

If AmtTransferred is less than Count, the disk became full before the transfer was complete. In this case, if the file's record size is greater than 1, AmtTransferred returns the number of complete records written.

BlockWrite advances the current file position by AmtTransferred records.

If AmtTransferred isn't specified, an I/O error occurs if the number written isn't equal to Count. If the $I+ compiler directive is in effect, errors raise an EInOutError exception.

Delphi Examples:

```
{
This example reads an entire file into a buffer with one
command and then writes it into a saved file.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FromF, ToF: file;
  NumRead, NumWritten: Integer;
  Buf: array[1..2048] of Char;
begin
  if OpenDialog1.Execute then     { Display Open dialog box }
  begin
    AssignFile(FromF, OpenDialog1.FileName);
    Reset(FromF, 1);    { Record size = 1 }
    if SaveDialog1.Execute then      { Display Save dialog box}
    begin
      AssignFile(ToF, SaveDialog1.FileName);    { Open output file }
      Rewrite(ToF, 1);  { Record size = 1 }
      Canvas.TextOut(10, 10, 'Copying ' + IntToStr(FileSize(FromF))
        + ' bytes...');
      repeat
        System.BlockRead(FromF, Buf, SizeOf(Buf), NumRead);
        BlockWrite(ToF, Buf, NumRead, NumWritten);
      until (NumRead = 0) or (NumWritten <> NumRead);
      CloseFile(FromF);
      CloseFile(ToF);
    end;
  end;
end;
```

EInOutError

158.3.32 System.Break Function

Causes the flow of control to exit a for, while, or repeat statement.

Pascal

```
procedure Break;
```

C++

```
Break();
```

File

System

Description

The Break procedure causes the flow of control in Delphi code to exit a for, while, or repeat statement and continue at the next statement following the loop statement.

A call to Break must be contained in a for, while, or repeat statement, or the compiler reports an error.

Note: Break does not violate the flow of control dictated by a try..finally construct. If a break occurs inside the try clause, the finally clause is entered.

Delphi Examples:

```
{
The following OnFind event handler searches a memo component
for the text specified in the FindText property of a find
dialog component. If found, the first occurrence of the text
in Memo1 is selected. The code uses the Pos function to
compare strings, and stores the number of characters to skip
when determining the selection position in the SkipChars
variable. Because there is no handling of case, whole word,
or search direction in this algorithm, it is assumed that
the Options property of FindDialog1 is set to
[frHideMatchCase, frHideWholeWord, frHideUpDown].
}
procedure TForm1.FindDialog1Find(Sender: TObject);
var
  I, J, PosReturn, SkipChars: Integer;
begin
  for I := 0 to Memo1.Lines.Count do
  begin
    PosReturn := Pos(FindDialog1.FindText,Memo1.Lines[I]);
    if PosReturn <> 0 then {found!}
    begin
      SkipChars := 0;
      for J := 0 to I - 1 do
        SkipChars := SkipChars + Length(Memo1.Lines[J]);
      SkipChars := SkipChars + (I*2);
      SkipChars := SkipChars + PosReturn - 1;
      Memo1.SetFocus;
      Memo1.SelStart := SkipChars;
      Memo1.SelLength := Length(FindDialog1.FindText);
      Break;
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
const Path = 'country.list';
begin
  Memo1.Lines.LoadFromFile(Path);
end;
{
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.
Note:   This OnKeyPress event handler does not deal with the
case when the user types the Delete key. That case must be
caught in the OnKeyDown event handler instead.
Note: Set the TComboBox AutoComplete to false to turn off
default auto completion.
}
procedure TForm1.ComboBox1KeyPress(Sender: TObject; var Key: Char);
var
  Found: boolean;
  i, ct, SelSt: Integer;
  TmpStr: string;
begin
  { first, process the keystroke to obtain the current string }
  { This code requires all items in list to be uppercase}
```

```
    if Key in ['a'..'z'] then Dec(Key,32); {Force Uppercase only!}
    ct := (Sender as TComboBox).Items.Count;
    with (Sender as TComboBox) do
    begin
      SelSt := SelStart;
      if (Key = Chr(vk_Back)) and (SelLength <> 0) then
       TmpStr := Copy(Text, 1, SelStart) + Copy(Text, SelLength + SelStart + 1, 255)
      else if Key = Chr(vk_Back) then {SelLength = 0}
       TmpStr := Copy(Text, 1, SelStart-1) + Copy(Text, SelStart + 1,255)
      else {Key in ['A'..'Z', etc]}
       TmpStr := Copy(Text, 1, SelStart) + Key + Copy(Text, SelLength + SelStart + 1, 255);
      if TmpStr = '' then Exit;
      { update SelSt to the current insertion point }
      if (Key = Chr(vk_Back)) and (SelSt > 0) then Dec(SelSt)
      else if Key <> Chr(vk_Back) then Inc(SelSt);
      Key := #0; { indicate that key was handled }
      if SelSt = 0 then
      begin
        Text:= '';
        Exit;
      end;
     {Now that TmpStr is the currently typed string, see if we can locate a match }
      Found := False;
      for i := 1 to ct do
      begin
        if Copy(Items[i - 1], 1, Length(TmpStr)) = TmpStr then
        begin
          Text := Items[i-1]; { update to the match that was found }
          ItemIndex := i-1;
          Found := True;
          Break;
        end;
      end;
      if Found then { select the untyped end of the string }
      begin
        SelStart := SelSt;
        SelLength := Length(Text) - SelSt;
      end
      else Beep;
    end;
  end;

  var
    CharSetList : TStringList;

  procedure TForm1.AddCharacterSet(const S: string);
  begin
    CharSetList.Add(S);
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    CharSetList := TStringList.Create;
    Graphics.GetCharsetValues(AddCharacterSet);
    ComboBox1.Items := CharSetList;
  end;
```

Halt (see page 22475)

158.3.33 System.ChDir Function

Changes the current directory.

Pascal

```
procedure ChDir(const S: string); overload;
procedure ChDir(P: PChar); overload;
```

C++

```
ChDir(const AnsiString S);
ChDir(const char * P);
```

File

System

Description

Note: ChDir changes the current directory to the path specified by S or P. If this operation fails, EInOutError is raised.

Note: On Windows, the path can include a drive specifier, which causes the current drive to be changed as well.

Note: In Delphi, {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for an I/O error.

Delphi Examples:

```
{
This example shows how to change and display the current
directory through text.  This example requires that a drive
combo box, a file list box, and a directory list box are on
a form. Add this code as the OnChange event handler for the
drive combo box and the OnChange event handler for the
directory list box.  When the user changes the drive using
the combo box, the directory list box and file list box will
update to reflect the new drive and the current directory on
that drive.  When the user double clicks on a directory in
the file list box will update to reflect the new directory.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  System.ChDir(Edit1.Text);
  if IOResult <> 0 then
    MessageDlg('Cannot find directory', mtWarning, [mbOk], 0);
  Edit2.Text := GetCurrentDir;
  FileListBox1.Directory := GetCurrentDir;
  DirectoryListBox1.Directory := GetCurrentDir;
end;

procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
  Edit2.Text := GetCurrentDir;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
```

```
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
  Edit2.Text := GetCurrentDir;
end;
```

158.3.34 System.Chr Function

Returns the character for a specified ASCII value.

Pascal

```
function Chr(X: Byte): Char;
```

C++

```
Char Chr(Byte X);
```

File

System

Description

Chr returns the character with the ordinal value (ASCII value) of the byte-type expression, X.

Delphi Examples:

```
{
This example requires: TRichEdit, TRadioGroup, TCheckBox,
TButton. Clicking the Radio Group control sets the ScrollBar
style of the RichEdit. Toggling the Check Box turns
HideScrollBars on and off.  Clicking the button loads the
Rich Edit with a large amount of contiguous text.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  I: Integer;
begin
  RichEdit1.Lines.Clear;
  for I := 0 to 500 do
  begin
    RichEdit1.Text :=
      RichEdit1.Text + 'test line ' + IntToStr(I) + ' ';
    if (i mod 4 = 0) then
      RichEdit1.Text := RichEdit1.Text + Chr(13);
  end;
  // move text cursor to top of editend;
  RichEdit1.SelStart := 0;
end;

procedure TForm1.CheckBox1Click(Sender: TObject);
```

```
begin
  RichEdit1.HideScrollbars := CheckBox1.Checked;
end;

procedure TForm1.RadioGroup1Click(Sender: TObject);

158.3.35 System.Close Function

Terminates the association between a file variable and an external file.

Pascal

```
procedure Close(var F);
```

C++

```
Close( F);
```

File

System

Description

Close is provided for backward compatibility with existing code. When writing new applications in Delphi, use CloseFile (see page 22433) instead.

F is a file variable of any file type opened using Reset (see page 22511), Rewrite (see page 22513), or Append (see page 22415). The external file associated with F is completely updated and then closed, freeing the file handle for reuse.

158.3.36 System.CloseFile Function

Terminates the association between file variable and an external disk file.

Pascal

```
procedure CloseFile(var F);
```

C++

```
CloseFile( F);
```

File

System

Description

Due to naming conflicts, CloseFile replaces the Close (see page 22432) procedure. Use the CloseFile procedure instead of Close (see page 22432) to terminate the association between a file variable and an external disk file.

F is a file variable of any file type opened using Reset (see page 22511), Rewrite (see page 22513), or Append (see page 22415). The external file associated with F is completely updated and then closed, freeing the file handle for reuse.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for I/O errors.

Delphi Examples:

```
{
This example reads a file one character at a time and writes
it into a file of your chosing.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F1, F2: TextFile;
  Ch: Char;
begin
  if OpenDialog1.Execute then begin
```

```
      AssignFile(F1, OpenDialog1.Filename);
      Reset(F1);
      if SaveDialog1.Execute then begin
        AssignFile(F2, SaveDialog1.Filename);
        Rewrite(F2);
        while not Eof(F1) do
        begin
          Read(F1, Ch);
          Write(F2, Ch);
        end;
        CloseFile(F2);
      end;
      CloseFile(F1);
    end;
  end;
  {
  Use a TOpenDialog to select a file.  Place the first line of
  the file into a TEdit.
  }
  procedure TForm1.Edit1Click(Sender: TObject);
  var
    F: TextFile;
    S: string;
  begin
    if OpenDialog1.Execute then            { Display Open dialog box }
    begin
      AssignFile(F, OpenDialog1.FileName); { File selected in dialog }
      Reset(F);
      Readln(F, S);                        { Read first line of file }
      Edit1.Text := S;                     { Put string in a TEdit control }
      CloseFile(F);
    end;
  end;
  {
  Click the button to open a TOpenDialog, then select a file
  to delete.
  }

  procedure TForm1.Button1Click(Sender: TObject);
  var
    F: Textfile;
  begin
    OpenDialog1.Title := 'Delete File';
    if OpenDialog1.Execute then
    begin
      AssignFile(F, OpenDialog1.FileName);
      try
        Reset(F);
        if MessageDlg('Erase ' + OpenDialog1.FileName + '?',
          mtConfirmation, [mbYes, mbNo], 0) = mrYes then
        begin
          CloseFile(F);
          Erase(F);
        end;
      except
        on EInOutError do
          MessageDlg('File I/O error.', mtError, [mbOk], 0);
      end;
    end;
  end;
```

158.3.37 System.CompToCurrency Function

Converts a Comp value to a Currency (see page 22145) value.

Pascal

```
function CompToCurrency(Value: Comp): Currency; cdecl;
```

C++

```
__cdecl Currency CompToCurrency(Comp Value);
```

File

System

Description

CompToCurrency converts a Comp value into a Currency (see page 22145) value containing the decimal representation of that number.

See Also

CompToDouble (see page 22435)

CurrencyToComp (see page 22441)

DoubleToComp (see page 22446)

158.3.38 System.CompToDouble Function

Converts a Comp value to a double value.

Pascal

```
function CompToDouble(Value: Comp): Double; cdecl;
```

C++

```
__cdecl Double CompToDouble(Comp Value);
```

File

System

Description

CompToDouble converts a Comp value into a double value containing the decimal representation of that number.

See Also

CompToCurrency (see page 22435)

CurrencyToComp (see page 22441)

DoubleToComp (see page 22446)

158.3.39 System.Concat Function

Concatenates two or more strings into one.

Pascal

```
function Concat(s1: string): string; overload;
function Concat(s1: string; s2: string): string; overload;
function Concat(s1: string; s2: string; s3: string): string; overload;
```

C++

```
AnsiString Concat(AnsiString s1);
AnsiString Concat(AnsiString s1, AnsiString s2);
AnsiString Concat(AnsiString s1, AnsiString s2, AnsiString s3);
```

File

System

Description

In Delphi code, use Concat to concatenate an arbitrary number of strings. Each parameter is a string-type expression. The result is the concatenation of all the string parameters.

The syntax shown here for Concat demonstrates that the procedure can take a variable number of arguments.

Using the plus (+) operator has the same effect on two strings as using the Concat function:

S := 'ABC' + 'DEF';

Tip: The plus operator is faster than Concat.

Delphi Examples:

```
{
This example requires a button and three text fields.
Select the button to concatenate the two texts into
the third.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S: string;
begin
  Edit3.Text := Concat(Edit1.Text, Edit2.Text);     { 'ABCDEF' }
end;
```

158.3.40 System.Continue Function

Allows the flow of control to proceed to the next iteration of for, while, or repeat statements.

Pascal

```
procedure Continue;
```

C++

```
Continue();
```

File

System

Description

In Delphi code, the Continue procedure causes the flow of control to proceed to the next iteration of the enclosing for, while, or repeat statement.

The compiler reports an error if a call to Continue isn't enclosed by a for, while, or repeat statement.

Note: Continue does not violate the flow of control dictated by a try..finally construct. If a call to Continue causes control to leave the try clause, the finally clause is entered.

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File;
  i, filehandle: Integer;
begin
  for i := 0 to (FileListBox1.Items.Count - 1) do begin
  try
    if FileListBox1.Selected[i] then
    begin
      if not FileExists(FileListBox1.Items.Strings[i]) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' not found', mtError, [mbOk], 0);
        Continue;
      end;
      filehandle:=  FileOpen(FileListBox1.Items.Strings[i], 1);
      if (filehandle = -1) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' cannot be opened with access mode 1.', mtError, [mbOk], 0);
        Continue;
      end
      else
        FileClose(filehandle);
```

```
        AssignFile(F, FileListBox1.Items.Strings[i]);
        Reset(F, 1);
        ListBox1.Items.Add(
          FileListBox1.Items.Strings[i] + ': ' + IntToStr(FileSize(F)));
        CloseFile(F);
      end;
    finally
    { do something here }
    end;
  end;
end;
```

158.3.41 System.Copy Function

Returns a substring of a string or a segment of a dynamic array.

Pascal

```
function Copy(S; Index: Integer; Count: Integer): array; overload;
```

C++

```
array Copy( S, int Index, int Count);
```

File

System

Description

S is an expression of a string or dynamic-array type. Index and Count are integer-type expressions. Copy returns a substring or subarray containing Count characters or elements starting at S[Index]. The substring or subarray is a unique copy (that is, it does not share memory with S, although if the elements of the array are pointers or objects, these are not copied as well.)

If Index is larger than the length of S, Copy returns an empty string or array.

If Count specifies more characters or array elements than are available, only the characters or elements from S[Index] to the end of S are returned.

Note: When S is a dynamic array, you can omit the Index and Count parameters and Copy copies the entire array.

Delphi Examples:

```
{
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.
Note:   This OnKeyPress event handler does not deal with the
case when the user types the Delete key. That case must be
```

```
  caught in the OnKeyDown event handler instead.
  Note: Set the TComboBox AutoComplete to false to turn off
  default auto completion.
  }
  procedure TForm1.ComboBox1KeyPress(Sender: TObject; var Key: Char);
  var
    Found: boolean;
    i, ct, SelSt: Integer;
    TmpStr: string;
  begin
    { first, process the keystroke to obtain the current string }
    { This code requires all items in list to be uppercase}
    if Key in ['a'..'z'] then Dec(Key,32); {Force Uppercase only!}
    ct := (Sender as TComboBox).Items.Count;
    with (Sender as TComboBox) do
    begin
      SelSt := SelStart;
      if (Key = Chr(vk_Back)) and (SelLength <> 0) then
       TmpStr := Copy(Text, 1, SelStart) + Copy(Text, SelLength + SelStart + 1, 255)
      else if Key = Chr(vk_Back) then {SelLength = 0}
       TmpStr := Copy(Text, 1, SelStart-1) + Copy(Text, SelStart + 1,255)
      else {Key in ['A'..'Z', etc]}
       TmpStr := Copy(Text, 1, SelStart) + Key + Copy(Text, SelLength + SelStart + 1, 255);
      if TmpStr = '' then Exit;
      { update SelSt to the current insertion point }
      if (Key = Chr(vk_Back)) and (SelSt > 0) then Dec(SelSt)
      else if Key <> Chr(vk_Back) then Inc(SelSt);
      Key := #0; { indicate that key was handled }
      if SelSt = 0 then
      begin
        Text:= '';
        Exit;
      end;
     {Now that TmpStr is the currently typed string, see if we can locate a match }
      Found := False;
      for i := 1 to ct do
      begin
        if Copy(Items[i - 1], 1, Length(TmpStr)) = TmpStr then
        begin
          Text := Items[i-1]; { update to the match that was found }
          ItemIndex := i-1;
          Found := True;
          Break;
        end;
      end;
      if Found then { select the untyped end of the string }
      begin
        SelStart := SelSt;
        SelLength := Length(Text) - SelSt;
      end
      else Beep;
    end;
  end;

  var
    CharSetList : TStringList;

  procedure TForm1.AddCharacterSet(const S: string);
  begin
    CharSetList.Add(S);
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    CharSetList := TStringList.Create;
    Graphics.GetCharsetValues(AddCharacterSet);
```

```
  ComboBox1.Items := CharSetList;
end;
```

Parameters

158.3.42 System.Cos Function

Calculates the cosine of an angle.

Pascal

```
function Cos(const X: Extended): Extended;
```

C++

```
Extended Cos(const Extended X);
```

File

System

Description

In Delphi code, Cos returns the cosine of the angle X.

X is a real-type expression that represents an angle in radians.

Delphi Examples:

```
{
This example displays the Cosine of any value between 0 and
12.  Since the scrollbar position is an integer between the
scrollbar  min and max, multiply the range and divide the
position to fine tune it.  With the scrollbar selected use
the left and right buttons to change the position by 1E-6.
Or use the Dec function to decrement (or increment) by a
specific amount.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  new : Integer;
begin
  new := ScrollBar1.Position;
  System.Dec(new, Round(StrToFloat(Edit3.Text)*1000000));
  ScrollBar1.Position := new;
  Edit1.Text := FloatToStr(ScrollBar1.Position/1000000);
  Edit2.Text := FloatToStr(Cos(ScrollBar1.Position/1000000));
end;
```

```
procedure TForm1.FormCreate(Sender: TObject);
begin
  ScrollBar1.Max := Round(Pi * 4000000);   // 4 * Pi
end;

procedure TForm1.ScrollBar1Scroll(Sender: TObject; ScrollCode: TScrollCode;
  var ScrollPos: Integer);
begin
  Edit1.Text := FloatToStr(ScrollPos/1000000);
  Edit2.Text := FloatToStr(Cos(ScrollPos/1000000));
end;
```

158.3.43 System.CurrencyToComp Function

Converts a Currency (see page 22145) value to a Comp value.

Pascal

```
procedure CurrencyToComp(Value: Currency; var Result: Comp); cdecl;
```

C++

```
__cdecl CurrencyToComp(Currency Value, Comp Result);
```

File

System

Description

CurrencyToComp converts a Currency (see page 22145) value into a Comp.

See Also

CompToDouble (see page 22435)

CompToCurrency (see page 22435)

DoubleToComp (see page 22446)

158.3.44 System.Dec Function

Decrements a variable by 1 or N.

Pascal

```
procedure Dec(var X); overload;
procedure Dec(var X; N: Longint); overload;
```

C++

```
Dec( X);
Dec( X, Longint N);
```

File

System

Description

In Delphi code, Dec subtracts one or N from a variable.

X is a variable of an ordinal type (including Int64), or a pointer type if the extended syntax is enabled.

N is an integer-type expression.

X decrements by 1, or by N if N is specified; that is, Dec(X) corresponds to the statement X := X - 1, and Dec(X, N) corresponds to the statement X := X - N. On some platforms, Dec may generate optimized code, especially useful in tight loops.

If X is a pointer type, it decrements X by N times the size of the type pointed to. Thus, given

```
type
  PMyType = ^TMyType;
```

and

```
var
  P: PMyType;
```

the statement `Dec(P)` decrements `P` by `SizeOf (` see page 22528`)(TMyType)`.

Warning: Do not use Dec on ordinal-type properties if the property uses a write procedure.

Delphi Examples:

```
{
This example displays the Cosine of any value between 0 and
12.  Since the scrollbar position is an integer between the
scrollbar  min and max, multiply the range and divide the
position to fine tune it.  With the scrollbar selected use
the left and right buttons to change the position by 1E-6.
Or use the Dec function to decrement (or increment) by a
specific amount.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  new : Integer;
begin
  new := ScrollBar1.Position;
  System.Dec(new, Round(StrToFloat(Edit3.Text)*1000000));
  ScrollBar1.Position := new;
  Edit1.Text := FloatToStr(ScrollBar1.Position/1000000);
  Edit2.Text := FloatToStr(Cos(ScrollBar1.Position/1000000));
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ScrollBar1.Max := Round(Pi * 4000000);   // 4 * Pi
end;

procedure TForm1.ScrollBar1Scroll(Sender: TObject; ScrollCode: TScrollCode;
  var ScrollPos: Integer);
begin
  Edit1.Text := FloatToStr(ScrollPos/1000000);
  Edit2.Text := FloatToStr(Cos(ScrollPos/1000000));
end;
```

See Also

Inc (see page 22478)

158.3.45 System.Delete Function

Removes a substring from a string.

Pascal

```
procedure Delete(var S: string; Index: Integer; Count: Integer);
```

C++

```
Delete(AnsiString S, int Index, int Count);
```

File

System

Description

In Delphi code, Delete removes a substring of Count characters from string S starting with S[Index]. S is a string-type variable. Index and Count are integer-type expressions.

If index is larger than the length of the string or less than 1, no characters are deleted.

If count specifies more characters than remain starting at the index, Delete removes the rest of the string. If count is less than or equal to 0, no characters are deleted.

Delphi Examples:

```
{
This example uses the Delete function to edit a string.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  s: string;
begin
  s := 'Honest Abe Lincoln';
  Canvas.TextOut(10, 10, s);
  Delete(s,8,4);
  Canvas.TextOut(10, 40, s);    { 'Honest Lincoln' }
end;
```

158.3.46 System.Dispose Function

Releases memory allocated for a dynamic variable.

Pascal

```
procedure Dispose(var P: Pointer);
```

C++

```
Dispose(void * P);
```

File

System

Description

Use Dispose in Delphi code to free the memory which a pointer addresses. After a call to Dispose, the value of P is undefined and it is an error to reference P.

Note: If compiling with {$I+}, use exceptions to handle this error. When an invalid pointer is passed to Dispose it raises an EInvalidPointer exception.

Delphi Examples:

```
{
The following code explicitly allocates memory for a pointer
in the OnCreate event of Form1, then releases the memory in
the OnDestroy event. Assume that MyPtr is a Pointer type
field of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  New(MyPtr);
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  Dispose(MyPtr);
end;
{
The following code adds an object to MyList if it isn't
already in the list.
}
type
  PMyList = ^AList;
  AList = record
    I: Integer;
    C: Char;
  end;
var
  Form1: TForm1;
  MyList: TList;
  ARecord1, ARecord2: PMyList;

implementation

{$R *.dfm}

procedure DisplayTList(TheList: TList);
var
```

```
    ARecord: PMyList;
    B: Byte;
    Y: Word;
  begin
      { Now paint the items onto the paintbox}
      Y := 10;             {Variable used in TextOut function}
      for B := 0 to (TheList.Count - 1) do
      begin
        ARecord := TheList.Items[B];
        Form1.PaintBox1.Canvas.TextOut(10, Y, IntToStr(ARecord^.I)); {Display I}
        Y := Y + 30;  {Increment Y Value again}
        Form1.PaintBox1.Canvas.TextOut(10, Y, ARecord^.C);  {Display C}
        Y := Y + 30;  {Increment Y Value}
      end;
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  begin
    if (MyList.IndexOf(ARecord1) = -1) then MyList.Add(ARecord1);
    DisplayTList(MyList);
  end;

  procedure TForm1.Button2Click(Sender: TObject);
  begin
    if (MyList.IndexOf(ARecord2) = -1) then MyList.Add(ARecord2);
    DisplayTList(MyList);
  end;

  procedure TForm1.Button3Click(Sender: TObject);
  var
    ARecord: PMyList;
    B: Integer;
  begin
    if (MyList.Count <> 0) then
    begin
      for B := (MyList.Count - 1) downto 0 do
      begin
        ARecord := MyList.Items[B];
        MyList.Remove(ARecord);
      end;
    end;
    Form1.PaintBox1.Repaint;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    MyList := TList.Create;
    New(ARecord1);
    ARecord1^.I := 100;
    ARecord1^.C := 'Z';
    New(ARecord2);
    ARecord2^.I := 200;
    ARecord2^.C := 'X';
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  begin
    Dispose(ARecord1);
    Dispose(ARecord2);
    MyList.Free;
  end;
```

158.3.48 System.DynArrayClear Function

Pascal

```
procedure DynArrayClear(var a: Pointer; typeInfo: Pointer);
```

C++

```
DynArrayClear(void * a, void * typeInfo);
```

File

System

Description

This is function System.DynArrayClear.

158.3.49 System.DynArrayDim Function

Pascal

```
function DynArrayDim(typeInfo: PDynArrayTypeInfo): Integer;
```

C++

```
int DynArrayDim(PDynArrayTypeInfo typeInfo);
```

File

System

Description

This is function System.DynArrayDim.

158.3.50 System.DynArraySetLength Function

Pascal

```
procedure DynArraySetLength(var a: Pointer; typeInfo: Pointer; dimCnt: Longint; lengthVec:
PLongint);
```

C++

```
DynArraySetLength(void * a, void * typeInfo, Longint dimCnt, PLongint lengthVec);
```

File

System

Description

This is function System.DynArraySetLength.

158.3.51 System.EndThread Function

Terminates the execution of a thread.

Pascal

```
procedure EndThread(ExitCode: Integer);
```

C++

```
EndThread(int ExitCode);
```

File

System

Description

EndThread terminates execution of a thread with the specified ExitCode (see page 22642).

Note: On Windows, EndThread calls the ExitThread WinAPI with the specified ExitCode (see page 22642).

158.3.52 System.EnumModules Function

Executes a callback for all the modules in an application.

Pascal

```
procedure EnumModules(Func: TEnumModuleFunc; Data: Pointer); overload;
procedure EnumModules(Func: TEnumModuleFuncLW; Data: Pointer); overload;
```

C++

```
EnumModules(TEnumModuleFunc Func, void * Data);
EnumModules(TEnumModuleFuncLW Func, void * Data);
```

File

System

Description

EnumModules enumerates the executable and all packages in an application by passing the handle of the executable and then of each package, in turn, to a user-defined callback function. EnumModules continues until the last module in the application is enumerated, or until the callback function returns false. The parameters to EnumModules areas follows:

Parameter	Meaning
Func	The procedure-instance address of the callback function.
Data	A 32-bit user-defined value that is passed to the callback function.

See Also

EnumResourceModules (see page 22448)

Hinstance

158.3.53 System.EnumResourceModules Function

Executes a callback for all resource modules in an application.

Pascal

```
procedure EnumResourceModules(Func: TEnumModuleFunc; Data: Pointer); overload;
procedure EnumResourceModules(Func: TEnumModuleFuncLW; Data: Pointer); overload;
```

C++

```
EnumResourceModules(TEnumModuleFunc Func, void * Data);
EnumResourceModules(TEnumModuleFuncLW Func, void * Data);
```

File

System

Description

EnumResourceModules executes the callback specified by the Func parameter for all of the instance handles associated with resources of the current program. The instance handle (HInstance) of each resource is passed to Func. EnumResourceModules continues until the last resource module in the application is enumerated, or until the callback returns false. The parameters to EnumResourceModules are as follows:

Parameter	Meaning
Func	The procedure-instance address of the callback function.
Data	A 32-bit user-defined value that is passed to the callback function.

Hinstance

158.3.54 System.Eof Function

Tests whether the file position is at the end of a file.

Pascal

```
function Eof: Boolean; overload;
function Eof(var F): Boolean; overload;
function Eof(var F: Text): Boolean; overload;
```

C++

```
Boolean Eof();
Boolean Eof( F);
Boolean Eof(Text F);
```

File

System

Description

In Delphi code, Eof tests whether the current file position is the end-of-file. F is a file variable that has been opened for reading. If F is omitted, the standard file variable Input (see page 22647) is assumed.

Eof(F) returns true if the current file position is beyond the last character of the file or if the file is empty; otherwise, Eof(F) returns false.

Note: Eof fails if the file F has been opened in write-only mode. For example, you can't use Eof with files opened using the Append (see page 22415) or Rewrite (see page 22513), which open a file in write-only mode.

Delphi Examples:

```
{
This example reads a file one character at a time and writes
it into a file of your chosing.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F1, F2: TextFile;
  Ch: Char;
begin
  if OpenDialog1.Execute then begin
    AssignFile(F1, OpenDialog1.Filename);
    Reset(F1);
    if SaveDialog1.Execute then begin
      AssignFile(F2, SaveDialog1.Filename);
      Rewrite(F2);
      while not Eof(F1) do
      begin
        Read(F1, Ch);
        Write(F2, Ch);
      end;
```

```
      CloseFile(F2);
    end;
    CloseFile(F1);
  end;
end;
```

Eoln (see page 22450)

SeekEof (see page 22519)

SetLineBreakStyle (see page 22522)

158.3.55 System.Eoln Function

Tests whether the file pointer is at the end of a line.

Pascal

```
function Eoln: Boolean; overload;
function Eoln(var F: Text): Boolean; overload;
```

C++

```
Boolean Eoln();
Boolean Eoln(Text F);
```

File

System

Description

In Delphi code, Eoln tests whether the current file position is the end-of-line of a text file. F, if specified, is a text file variable. If F is omitted, the standard file variable Input (see page 22647) is assumed.

Eoln(F) returns true if the current file position is at an end-of-line or if Eof (see page 22449)(F) is true; otherwise, Eoln(F) returns false.

Delphi Examples:

```
{
This example waits for keyboard input before continuing.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   WriteLn('Type something on the console and hit return');
   Eoln;
   WriteLn('Write this after you type something');
   Readln;
end;
```

See Also

Eof (see page 22449)

SeekEoln (see page 22520)

SetLineBreakStyle (see page 22522)

158.3.56 System.Erase Function

Deletes an external file.

Pascal

```
procedure Erase(var F);
```

C++

```
Erase( F);
```

File

System

Description

In Delphi code, Erase deletes the external file associated with F. F is a file variable of any file type.

Always close a file before erasing it.

Delphi Examples:

```
{
Click the button to open a TOpenDialog, then select a file
to delete.
}

procedure TForm1.Button1Click(Sender: TObject);
var
  F: Textfile;
begin
  OpenDialog1.Title := 'Delete File';
  if OpenDialog1.Execute then
  begin
    AssignFile(F, OpenDialog1.FileName);
    try
      Reset(F);
      if MessageDlg('Erase ' + OpenDialog1.FileName + '?',
        mtConfirmation, [mbYes, mbNo], 0) = mrYes then
      begin
        CloseFile(F);
        Erase(F);
      end;
    except
      on EInOutError do
        MessageDlg('File I/O error.', mtError, [mbOk], 0);
    end;
  end;
end;
```

See Also

Rename (see page 22510)

158.3.57 System.Error Function

Error is used to generate a run-time exception.

Pascal

```
procedure Error(errorCode: TRuntimeError);
```

C++

```
Error(TRuntimeError errorCode);
```

File

System

Description

Error should be invoked when you want to generate an exception. **errorCode** defines the type of error to be reported.

See Also

TRunTimeError

158.3.58 System.ExceptAddr Function

Returns the address at which the current exception was raised.

Pascal

```
function ExceptAddr: Pointer;
```

C++

```
void * ExceptAddr();
```

File

System

Description

Use ExceptAddr to obtain the address at which an exception was raised. If there is no current exception, ExceptAddr returns nil (Delphi) or NULL (C++).

See Also

ExceptionErrorMessage

ExceptObject (see page 22452)

158.3.59 System.ExceptObject Function

Returns current exception object.

Pascal

```
function ExceptObject: TObject;
```

C++

```
TObject * ExceptObject();
```

File

System

Description

ExceptObject returns the current exception object. This is the Exception object that represents the exception currently being handled. If no exception is currently being handled, ExceptObject returns nil (Delphi) or NULL (C++).

ExceptObject is useful when the exception variable (declared in the Delphi on block or C++ catch statement) is not accessible. This can occur when the exception handler calls a procedure, putting the exception variable is out of scope. This is also true in the Delphi else exception handler, which cannot declare an exception variable.

Note: The object returned by ExceptObject may not exist after the exception handler finishes. Thus you cannot use ExceptObject to retain a reference to the exception object, or to re-raise the exception. If you need to do either of these things, call AcquireExceptionObject (see page 22410).

ExceptionErrorMessage

Exception

on

catch

158.3.60 System.Exclude Function

Removes an element from a Delphi set or removes an event handler in .NET applications.

Pascal

```
procedure Exclude(var S: set of T; I: T);
```

C++

```
Exclude(set of T S, T I);
```

File

System

Description

When the first argument of Include (see page 22479) is a set type variable, the Exclude procedure removes an element from the set. If S is a set type variable, and I is an expression of a type compatible with the base type of S. then `Exclude(S,I)` corresponds to `S := S - [I]` but the Exclude procedure generates more efficient code.

On the .NET platform, Exclude is overloaded. When the first argument of Exclude is a multicast event and the second argument is an event handler, Include (see page 22479) removes the event handler from the event's listeners.

See Also

Include (see page 22479)

158.3.61 System.Exit Function

Exits from the current procedure.

Pascal

```
procedure Exit;
```

C++

```
Exit();
```

File

System

Description

In Delphi, the Exit procedure immediately passes control away from the current procedure. If the current procedure is the main program, Exit causes the program to terminate.

Exit will cause the calling procedure to continue with the statement after the point at which the procedure was called.

Note: Exit passes control away from the current procedure, not merely the current block. But Exit does not violate the flow of control dictated by a try..finally construct; if Exit is called inside the try clause, the finally clause is still executed.

Delphi Examples:

```
{
The following example shows how to complete partial strings
typed into a combo box. The code represents the OnKeyPress
event handler of the combo box, which performs most of the
default keystroke handling before finding a matching list
item and updating the text.
Note:   This OnKeyPress event handler does not deal with the
case when the user types the Delete key. That case must be
caught in the OnKeyDown event handler instead.
Note: Set the TComboBox AutoComplete to false to turn off
default auto completion.
}
procedure TForm1.ComboBox1KeyPress(Sender: TObject; var Key: Char);
var
  Found: boolean;
  i, ct, SelSt: Integer;
  TmpStr: string;
begin
  { first, process the keystroke to obtain the current string }
  { This code requires all items in list to be uppercase}
  if Key in ['a'..'z'] then Dec(Key,32); {Force Uppercase only!}
  ct := (Sender as TComboBox).Items.Count;
  with (Sender as TComboBox) do
  begin
    SelSt := SelStart;
    if (Key = Chr(vk_Back)) and (SelLength <> 0) then
     TmpStr := Copy(Text, 1, SelStart) + Copy(Text, SelLength + SelStart + 1, 255)
    else if Key = Chr(vk_Back) then {SelLength = 0}
     TmpStr := Copy(Text, 1, SelStart-1) + Copy(Text, SelStart + 1,255)
    else {Key in ['A'..'Z', etc]}
     TmpStr := Copy(Text, 1, SelStart) + Key + Copy(Text, SelLength + SelStart + 1, 255);
    if TmpStr = '' then Exit;
    { update SelSt to the current insertion point }
    if (Key = Chr(vk_Back)) and (SelSt > 0) then Dec(SelSt)
    else if Key <> Chr(vk_Back) then Inc(SelSt);
    Key := #0; { indicate that key was handled }
    if SelSt = 0 then
    begin
      Text:= '';
      Exit;
    end;
```

```
    {Now that TmpStr is the currently typed string, see if we can locate a match }
     Found := False;
     for i := 1 to ct do
     begin
       if Copy(Items[i - 1], 1, Length(TmpStr)) = TmpStr then
       begin
         Text := Items[i-1]; { update to the match that was found }
         ItemIndex := i-1;
         Found := True;
         Break;
       end;
     end;
     if Found then { select the untyped end of the string }
     begin
       SelStart := SelSt;
       SelLength := Length(Text) - SelSt;
     end
     else Beep;
   end;
 end;

 var
   CharSetList : TStringList;

 procedure TForm1.AddCharacterSet(const S: string);
 begin
   CharSetList.Add(S);
 end;

 procedure TForm1.FormCreate(Sender: TObject);
 begin
   CharSetList := TStringList.Create;
   Graphics.GetCharsetValues(AddCharacterSet);
   ComboBox1.Items := CharSetList;
 end;
```

Break (see page 22426)

Halt (see page 22475)

Continue (see page 22437)

158.3.62 System.Exp Function

Returns the exponential of X.

Pascal

```
function Exp(X: Real): Real;
function Exp(const X: Extended): Extended;
```

C++

```
Real Exp(Real X);
Extended Exp(const Extended X);
```

File

System

Description

In Delphi code, Exp returns the value of e raised to the power of X, where e is the base of the natural logarithms.

Delphi Examples:

```
{
This example calculated the exponential of 1.0 and then calculates
the natural log of that quantity to show that the natural log
function is the inverse of the exponential function.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   e : real;
   S : string;
begin
   e := Exp(1.0);
   Str(ln(e):3:2, S);
   S := 'e = ' + FloatToStr(e) + '; ln(e) = ' + S;
   Canvas.TextOut(10, 10, S);
end;
```

See Also

Ln (see page 22485)

158.3.63 System.FilePos Function

Returns the current file position.

Pascal

```
function FilePos(var F): Longint;
```

C++

```
Longint FilePos( F);
```

File

System

Description

In Delphi code, use FilePos on the file variable of an open file to determine the current position in the file. If the current position in the file is at the very beginning, FilePos returns 0. Otherwise, FilePos returns the byte offset from the beginning of the current position.

FilePos will not work on a file that is not open.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for I/O errors.

Delphi Examples:

```
{
FileSize, Seek, FilePos example
This example displays a open dialog when the user clicks a button. When the user selects the
file, it reports the size of the file, seeks to halfway through the file, and reports the file
position at that point.
Note:   This example assumes the compiler flag $IOCHECKS ON ($I+). That is, it expects errors
to generate exceptions rather than checking IOResult to be sure that I/O routines succeed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   f: file of Byte;
   size: Longint;
```

```
    S: string;
    y: Integer;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(f, OpenDialog1.FileName);
    Reset(f);
    try
      size := FileSize(f);
      S := 'File size in bytes: ' + IntToStr(size);
      y := 10;
      Canvas.TextOut(5, y, S);
      y := y + Canvas.TextHeight(S) + 5;
      S := 'Seeking halfway into file...';
      Canvas.TextOut(5, y, S);
      y := y + Canvas.TextHeight(S) + 5;
      Seek(f, size div 2);
      S := 'Position is now ' + IntToStr(FilePos(f));
      Canvas.TextOut(5, y, S);
    finally
      CloseFile(f);
    end;
  end;
end;
```

See Also

FileSize (see page 22457)

Seek (see page 22518)

158.3.64 System.FileSize Function

Returns the number of records in a file.

Pascal

```
function FileSize(var F): Integer;
```

C++

```
int FileSize( F);
```

File

System

Description

In Delphi code, call FileSize to determine the size of the file specified by the file variable F. The size is expressed as the number of records in a record file. Thus:

If the file is declared as a file of byte, then the record size defaults to one byte, and FileSize returns the number of bytes in the file.

The Reset (see page 22511) procedure can set the record size (in bytes) when it opens the file. In this case, FileSize returns the number of records in the file.

Note: If the file is declared as an untyped file and you don't specify a record size when you call Reset (see page 22511), then FileSize assumes a record size of 128. That is, FileSize gives the number of bytes divided by 128.

To use FileSize, the file must be open. If the file is empty, FileSize(F) returns 0.

Delphi Examples:

```
{
FileSize, Seek, FilePos example
This example displays a open dialog when the user clicks a button. When the user selects the
file, it reports the size of the file, seeks to halfway through the file, and reports the file
position at that point.
Note:   This example assumes the compiler flag $IOCHECKS ON ($I+). That is, it expects errors
to generate exceptions rather than checking IOResult to be sure that I/O routines succeed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   f: file of Byte;
   size: Longint;
   S: string;
   y: Integer;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(f, OpenDialog1.FileName);
    Reset(f);
    try
      size := FileSize(f);
      S := 'File size in bytes: ' + IntToStr(size);
      y := 10;
      Canvas.TextOut(5, y, S);
      y := y + Canvas.TextHeight(S) + 5;
      S := 'Seeking halfway into file...';
      Canvas.TextOut(5, y, S);
      y := y + Canvas.TextHeight(S) + 5;
      Seek(f, size div 2);
      S := 'Position is now ' + IntToStr(FilePos(f));
      Canvas.TextOut(5, y, S);
    finally
      CloseFile(f);
    end;
  end;
end;
{
The following example opens a file of your choice and reads
the entire file into a dynamically allocated buffer. The
buffer and the size of the file are then passed to a routine
that processes the text, and finally the dynamically
allocated buffer is freed and the file is closed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: file;
  Size: Integer;
  Buffer: PChar;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(F, OpenDialog1.FileName);
    Reset(F, 1);
    try
      Size := FileSize(F);
      GetMem(Buffer, Size);
      try
        BlockRead(F, Buffer^, Size);
        Memo1.Lines.Add(Buffer);
      finally
        FreeMem(Buffer);
      end;
    finally
      CloseFile(F);
    end;
  end;
```

```
end;
```

See Also

FilePos (see page 22456)

Reset (see page 22511)

158.3.65 System.FillChar Function

Fills contiguous bytes with a specified value.

Pascal

```
procedure FillChar(var X; Count: Integer; Value: Byte);
```

C++

```
FillChar( X, int Count, Byte Value);
```

File

System

Description

In Delphi, FillChar fills Count contiguous bytes (referenced by X) with the value specified by Value (Value can be type Byte or Char).

Warning: This function does not perform any range checking.

Delphi Examples:

```
{
This example creates a rotated font and displays it on the
form by assigning the handle of the rotated to the Form's
Canvas Font via the Font's Handle property.  Rotating fonts
is a straightforward process, so long as the Windows Font
Mapper can supply a rotated font based on the font you
request. If you are using a TrueType font there is virtually
no reason for failure.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  lf: LOGFONT; // Windows native font structure
begin
  Canvas.Brush.Style := bsClear; // set the brush style to transparent
  FillChar(lf, SizeOf(lf), Byte(0));
  lf.lfHeight := 20;
  lf.lfEscapement := 10 * 45; // degrees to rotate
  lf.lfOrientation := 10 * 45;
  lf.lfCharSet := DEFAULT_CHARSET;
  StrCopy(lf.lfFaceName, 'Tahoma');

  Canvas.Font.Handle := CreateFontIndirect(lf);
  Canvas.TextOut(10, 100, 'Rotated text'); // output the rotated font
end;
{
This example fills a char array with characters and then
assigns the array to a text edit.
}
procedure TForm1.Button1Click(Sender: TObject);
var
```

```
  S: array[0..79] of char;
begin
  { Set to all Xs }
  FillChar(S, SizeOf(S), Ord('X'));
  Edit1.Text := S;
end;
```

See Also

Move (see page 22490)

StringOfChar (see page 22531)

158.3.66 System.Finalize Function

Uninitializes a dynamically allocated variable.

Pascal

```
procedure Finalize(var V); overload;
procedure Finalize(var V; Count: Integer); overload;
```

C++

```
Finalize( V);
Finalize( V, int Count);
```

File

System

Description

Finalize should be used only in Delphi code where a dynamically allocated variable is deallocated by other means than the Dispose (see page 22444) procedure. Dynamic arrays can never be deallocated using the Dispose (see page 22444) procedure, but can be freed by passing them to Finalize.

For global variables, local variables, objects, and dynamic variables deallocated using Dispose (see page 22444), the compiler generates code that finalizes all long strings, variants, and interfaces contained by the variable when the instance is destroyed.

If a dynamic variable meets the following two conditions, a call to Finalize is required to finalize the variable before it can be deallocated.

The variable is deallocated by other means than the Dispose (see page 22444) standard procedure (for example using FreeMem (see page 22464)).

The variable contains long strings, variants, or interfaces, not all of which are empty or Unassigned.

Finalize simply sets all long strings to empty and all variants and interfaces to Unassigned, thus properly releasing any memory that was referenced by the long strings and variants.

In cases where several variables are deallocated in a contiguous memory block such as a dynamically allocated array of strings, the additional Count parameter can be specified to finalize all variables in one operation.

If the variable specified in a call to Finalize contains no long strings, variants, or interfaces, the compiler eliminates the call and generates no code for it.

Initialize (see page 22480)

158.3.67 System.FindClassHInstance Function

Returns the instance handle for the module in which a class type is defined.

Pascal

```
function FindClassHInstance(ClassType: TClass): LongWord;
```

C++

```
LongWord FindClassHInstance(TClass ClassType);
```

File

System

Description

FindClassHInstance finds the HInstance of the executable or library that "owns", or contains, the runtime type information (RTTI) and the Virtual Method Table (VMT) for the specified class passed in as the Class Type parameter. When reading a component (which is a type), this information is needed in order to be able to load the form file (resources) associated with that component. The component streaming system uses FindClassHInstance for this purpose.

FindClassHInstance returns 0 if the instance is not found. Otherwise it returns the class owner's HInstance.

See Also

FindResourceHInstance (see page 22462)

HInstance

158.3.68 System.FindHInstance Function

Returns the instance handle of the module that contains a specified address.

Pascal

```
function FindHInstance(Address: Pointer): LongWord;
```

C++

```
LongWord FindHInstance(void * Address);
```

File

System

Description

Use FindHInstance to obtain the HInstance of the module that "owns", or contains, the address specified by the Address parameter. If no HInstance is found for that address, FindHInstance returns 0.

See Also

FindClassHInstance (see page 22461)

FindResourceHInstance (see page 22462)

MainInstance (see page 22650)

HInstance

158.3.69 System.FindResourceHInstance Function

Returns the instance handle of the resource module associated with a specified HInstance.

Pascal

```
function FindResourceHInstance(Instance: LongWord): LongWord;
```

C++

```
LongWord FindResourceHInstance(LongWord Instance);
```

File

System

Description

FindResourceHInstance finds and returns the instance handle of the resource module associated with the executable, library, or package identified by the Instance parameter.

FindResourceHInstance returns 0 upon failure.

Note: The Instance parameter must be a valid instance handle.

See Also

FindClassHInstance (see page 22461)

FindHInstance (see page 22461)

158.3.70 System.Flush Function

Empties the buffer of a text file opened for output.

Pascal

```
function Flush(var t: Text): Integer;
```

C++

```
int Flush(Text t);
```

File

System

Description

F is a text file variable.

When a text file is opened for output using Rewrite (see page 22513) or Append (see page 22415), Flush empties the file's buffer. This guarantees that all characters written to the file at that time have actually been written to the external file. Flush has no effect on files opened for input.

Flush returns 0 if the operation succeeded. Otherwise, it returns the error code. When compiled using the {$I-} flag, the IOResult (see page 22482) method returns this value.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for I/O errors.

Delphi Examples:

```
{
Append, Flush example
}

procedure TForm1.Button1Click(Sender: TObject);
var
  f: TextFile;
begin
  if OpenDialog1.Execute then
  begin                    { open a text file }
    AssignFile(f, OpenDialog1.FileName);
    Append(f);
    Writeln(f, 'I am appending some stuff to the end of the file.');
    { insert code here that would require a Flush before closing the file }
    Flush(f);  { ensures that the text was actually written to file }
    CloseFile(f);
    MessageDlg(OpenDialog1.FileName + ' has been altered, please validate.', mtInformation,
[mbOK], 0)
  end;
end;
```

See Also

Append (see page 22415)

Rewrite (see page 22513)

158.3.71 System.FPower10 Function

Pascal

```
procedure FPower10;
```

C++

```
FPower10();
```

File

System

Description

This is function System.FPower10.

158.3.72 System.Frac Function

Returns the fractional part of a real number.

Pascal

```
function Frac(const X: Extended): Extended;
```

C++

```
Extended Frac(const Extended X);
```

File

System

Description

In Delphi code, the Frac function returns the fractional part of the argument X.

X is a real-type expression. The result is the fractional part of X; that is, Frac(X) = X - Int (see page 22481)(X).

Delphi Examples:

```
{
This example illustrates the use of the System Frac function.
The number in the text edit can be a negative or positive
real number.
Notice how the type passed (R) matters.
}
procedure TForm1.Button1Click(Sender: TObject);
var
 R: Extended;
begin
  R := StrToFloat(Edit1.Text);
  ListBox1.Items.Add(FloatToStr(Frac(R)));
end;

procedure TForm1.Button2Click(Sender: TObject);
var
 R: Real;
begin
  R := StrToFloat(Edit1.Text);
  ListBox1.Items.Add(FloatToStr(Frac(R)));
end;
```

158.3.73 System.FreeMem Function

FreeMem frees a memory block.

Pascal

```
procedure FreeMem(var P: Pointer); overload;
procedure FreeMem(var P: Pointer; Size: Integer); overload;
```

C++

```
FreeMem(void * P);
FreeMem(void * P, int Size);
```

File

System

Description

GetMem (see page 22469) allocates a block on the heap. To dispose of the buffer, use FreeMem.

Note: FreeMemory (see page 22466) is the C++ compatible version of FreeMem.

Delphi Examples:

```
{
The following example uses a button, a string grid, and an
Open dialog box on a form. When the button is clicked, the
```

```
user is prompted for a filename. When the user clicks OK,
the specified file is opened, read into a buffer, and closed.
Then the buffer is displayed in two columns of the string
grid. The first column contains the character values in the
buffer. The second column contains the numeric values of the
characters in the buffer.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  iFileHandle: Integer;
  iFileLength: Integer;
  iBytesRead: Integer;
  Buffer: PChar;
  i: Integer;
begin
  if OpenDialog1.Execute then
  begin
    try
      iFileHandle := SysUtils.FileOpen(OpenDialog1.FileName, fmOpenRead);
      iFileLength := SysUtils.FileSeek(iFileHandle,0,2);
      FileSeek(iFileHandle,0,0);
      Buffer := PChar(System.AllocMem(iFileLength + 1));
      iBytesRead := SysUtils.FileRead(iFileHandle, Buffer^, iFileLength);
      FileClose(iFileHandle);
      for i := 0 to iBytesRead-1 do
      begin
        StringGrid1.RowCount := StringGrid1.RowCount + 1;
        StringGrid1.Cells[1,i+1] := Buffer[i];
        StringGrid1.Cells[2,i+1] := IntToStr(Integer(Buffer[i]));
      end;
    finally
      FreeMem(Buffer);
    end;
  end;
end;
{
The following example opens a file of your choice and reads
the entire file into a dynamically allocated buffer. The
buffer and the size of the file are then passed to a routine
that processes the text, and finally the dynamically
allocated buffer is freed and the file is closed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: file;
  Size: Integer;
  Buffer: PChar;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(F, OpenDialog1.FileName);
    Reset(F, 1);
    try
      Size := FileSize(F);
      GetMem(Buffer, Size);
      try
        BlockRead(F, Buffer^, Size);
        Memo1.Lines.Add(Buffer);
      finally
        FreeMem(Buffer);
      end;
    finally
      CloseFile(F);
    end;
  end;
end;
```

158.3.74 System.FreeMemory Function

FreeMemory frees a memory block.

Pascal

```
function FreeMemory(P: Pointer): Integer; cdecl;
```

C++

```
__cdecl int FreeMemory(void * P);
```

File

System

Description

GetMemory (see page 22470) allocates a block on the heap. To dispose of the buffer, use FreeMemory.

Note: FreeMemory is the C++ compatible version of FreeMem (see page 22464).

158.3.75 System.Get8087CW Function

Returns the value of the 8087 code word.

Pascal

```
function Get8087CW: Word;
```

C++

```
Word Get8087CW();
```

File

System

Description

Use Get8087CW to determine the current value of the floating-point unit control word. This control word controls the precision of floating point calculations, the rounding mode, and whether certain floating-point operations trigger exceptions. See Intel's processor documentation for details.

158.3.76 System.GetDir Function

Returns the current directory.

Pascal

```
procedure GetDir(D: Byte; var S: string);
```

C++

```
GetDir(Byte D, AnsiString S);
```

File

System

Description

Note: On Windows, GetDir sets the S parameter to the current directory on the drive specified by the D parameter. D can be set to any of the following values:

Value	Drive
0	Default
1	A
2	B
3	C

Note: GetDir performs no error checking. For example, if the invalid value 5 (J) were specified, S would return J:\ as if it were the root directory of the invalid drive.

Note: On Linux, GetDir returns the current working directory using the S parameter. The first parameter is ignored.

Delphi Examples:

```
{
This example reports the current directory and drive.  Set
Help on GetDir for reporting information on other drives.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  s : string;
begin
  GetDir(0,s); { 0 = Current drive }
  MessageDlg('Current drive and directory: ' + s, mtInformation, [mbOk] , 0);
end;
```

GetCurrentDir

158.3.77 System.GetHeapStatus Function

Returns the current status of the memory manager.

Pascal

```
function GetHeapStatus: THeapStatus; deprecated; platform;
```

C++

```
THeapStatus GetHeapStatus();
```

File

System

Description

GetHeapStatus returns the current status of the memory manager in a THeapStatus (see page 22558) type. If the ShareMem unit is not included in the current project, GetHeapStatus returns information about the global heap. If the ShareMem unit is included, GetHeapStatus returns information about memory that can be shared between between the current project and other binary modules (such as DLLs) that also make use of the ShareMem unit. GetHeapStatus can only return useful information if the built-in memory manager is used. For example, when using CodeGuard, the memory manager is replaced and GetHeapStatus always returns nil (Delphi) or NULL (C++).

If you want information about the memory manager that is shared between modules, make sure to call the function GetHeapStatus provided in the ShareMem unit. The function GetHeapStatus in the System (see page 22079) unit returns no values for a project that uses shared memory.

Warning: ShareMem must be the first unit included in the project file to prevent mixing of memory management models.

158.3.78 System.GetLastError Function

Returns the last error reported by an operating system API call.

Pascal

```
function GetLastError: Integer; stdcall;
```

C++

```
__stdcall int GetLastError();
```

File

System

Description

GetLastError returns the last error reported by an API call into the operating system. Calling this function usually resets the operating system error state.

Win32Check

158.3.79 System.GetMem Function

GetMem allocates a memory block.

Pascal

```
procedure GetMem(var P: Pointer; Size: Integer);
```

C++

```
GetMem(void * P, int Size);
```

File

System

Description

GetMem allocates a block of the given **Size** on the heap, and returns the address of this memory in parameter **P**. The bytes of the allocated buffer are not set to zero. To dispose of the buffer, use FreeMem (see page 22464). If there isn't enough memory available to allocate the block, an EOutOfMemory exception is raised.

Note: If the memory needs to be zero-initialized, use AllocMem (see page 22413) instead.

Delphi Examples:

```
{
The following example opens a file of your choice and reads
the entire file into a dynamically allocated buffer. The
buffer and the size of the file are then passed to a routine
that processes the text, and finally the dynamically
allocated buffer is freed and the file is closed.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  F: file;
  Size: Integer;
  Buffer: PChar;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(F, OpenDialog1.FileName);
    Reset(F, 1);
    try
      Size := FileSize(F);
      GetMem(Buffer, Size);
      try
        BlockRead(F, Buffer^, Size);
        Memo1.Lines.Add(Buffer);
      finally
        FreeMem(Buffer);
      end;
    finally
      CloseFile(F);
    end;
  end;
end;
```

158.3.80 System.GetMemory Function

GetMemory allocates a memory block.

Pascal

```
function GetMemory(Size: Integer): Pointer; cdecl;
```

C++

```
__cdecl void * GetMemory(int Size);
```

File

System

Description

GetMemory allocates a block of the given **Size** on the heap, and returns the address of this memory. The bytes of the allocated buffer are not set to zero. To dispose of the buffer, use FreeMem (see page 22464). If there isn't enough memory available to allocate the block, an EOutOfMemory exception is raised.

Note: If the memory needs to be zero-initialized, use AllocMem (see page 22413) instead.

Note: GetMemory is the C++ compatible version of GetMem (see page 22469).

Delphi Examples:

```
{
This example requires a button, a test edit, and a populated
ClientDataSet.  Pipe the ClientDataSet through a DataSource
to a DGGrid or DBNavigator to control the current field.
Cast the data correctly according to the field type when
assigning to the test edit.
}

{$IFNDEF UNICODE}
uses SwSystem;
{$ENDIF}

procedure TForm1.Button1Click(Sender: TObject);
var MyBuffer: Pointer;
begin
{ Retrieve the "raw" data from Field1 }
with CDS.Fields[0] do
  begin
    if not IsBlob then { this does not work for BLOB fields }
    begin
      { Allocate space }
      MyBuffer:= GetMemory(DataSize);
      try
        if not GetData(MyBuffer) then
          MessageDlg(DisplayName + ' is NULL', mtInformation, [mbOK], 0)
        else
          { Do something with the data };
          Edit1.Text:= string(MyBuffer); // for a stringfield
      finally
        { Free the space }
        FreeMem(MyBuffer, DataSize);
      end;
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
{$IFDEF UNICODE}
  CDS.LoadFromFile(GetCurrentDir + '\CDS.XML');
{$ELSE}
  CDS.LoadFromFile(gsAppPath + 'CDS.XML');
{$ENDIF}
end;
```

158.3.81 System.GetMemoryManager Function

Returns the entry points of the currently installed memory manager.

Pascal

```
procedure GetMemoryManager(var MemMgr: TMemoryManager); overload; deprecated;
procedure GetMemoryManager(var MemMgrEx: TMemoryManagerEx); overload;
```

C++

```
GetMemoryManager(TMemoryManager MemMgr);
GetMemoryManager(TMemoryManagerEx MemMgrEx);
```

File

System

Description

GetMemoryManager returns the entry points of the currently installed memory manager in a TMemoryManager (see page 22562) record.

See Also

SetMemoryManager (see page 22523)

IsMemoryManagerSet (see page 22483)

158.3.82 System.GetMemoryManagerState Function

Fetches state information for the Memory Manager.

Pascal

```
procedure GetMemoryManagerState(var AMemoryManagerState: TMemoryManagerState);
```

C++

```
GetMemoryManagerState(TMemoryManagerState AMemoryManagerState);
```

File

System

Description

GetMemoryManagerState returns a structure containing memory usage statistics for each block type - small, medium and large blocks. In the current implementation, small blocks are blocks that are smaller than roughly 2.5K, large blocks are blocks that are larger than roughly 256K, and medium blocks are the sizes in between. It provides additional detail for the small block type (which is usually the most frequently used block type) down to each individual block size.

The structure returned by this procedure makes a distinction between the reserved address space and the allocated address space for each block type. The allocated address space is that part of the address space that is currently in use by the application, i.e. memory that was allocated through GetMem (see page 22469) and not yet freed. The reserved address space is the amount of address space that was obtained from the operating system for current and future use by the application, i.e. the allocated address space plus all overhead.

158.3.83 System.GetMemoryMap Function

Fetches the memory map.

Pascal

```
procedure GetMemoryMap(var AMemoryMap: TMemoryMap);
```

C++

```
GetMemoryMap(TMemoryMap AMemoryMap);
```

File

System

Description

GetMemoryMap returns a map of the address space of the process. For the purposes of the map, the entire 4GB address space is broken down into 64K chunks. There are 65536 such chunks. GetMemoryMap obtains a status value for each of them in the TMemoryMap (see page 22617) array. The sum of the number of blocks with the status of **csUnallocated** multiplied by the chunk size (64K) gives an indication of how much more memory the application can allocate before it will run out of address space.

Status Value	Description
csUnallocated	Free
csAllocated	In use by the process
csReserved	Reserved for future use by the process
csSysAllocated	In use by the operating system
csSysReserved	Reserved for future use by the operating system

158.3.84 System.GetMinimumBlockAlignment Function

Gets the minimum memory block alignment.

Pascal

```
function GetMinimumBlockAlignment: TMinimumBlockAlignment;
```

C++

```
TMinimumBlockAlignment GetMinimumBlockAlignment();
```

File

System

Description

GetMinimumBlockAlignment fetches the Memory Manager's minimum block alignment.

See Also

Memory Management

Configuring the Memory Manager

158.3.85 System.GetModuleFileName Function

Returns the fully qualified name for a module, given its handle.

Pascal

```
function GetModuleFileName(Module: HMODULE; Buffer: PChar; BufLen: Integer): Integer;
```

C++

```
int GetModuleFileName(HMODULE Module, const char * Buffer, int BufLen);
```

File

System

Description

Call GetModuleFileName to obtain the fully qualified name of a module, given its handle. The version of GetModuleFileName defined in the System (see page 22079) unit is available only on Linux. On Windows, use the Windows API with the same name instead.

Module is the handle of the module whose file name is required.

Buffer is a buffer that receives the file name.

BufLen is the number of bytes in Buffer.

GetModuleFileName returns the number of bytes written to Buffer.

Warning: GetModuleFileName is not always successful. Depending on the way the application is called, the presence of the /proc file system, and other factors, there are times when GetModuleFileName may return a name that is not fully qualified or in some cases, no file name at all. Be sure to check the results of this function before using the returned value.

GetModuleName

158.3.86 System.GetVariantManager Function

Returns the entry points of the routines that define variant behavior.

Pascal

```
procedure GetVariantManager(var VarMgr: TVariantManager); deprecated;
```

C++

```
GetVariantManager(TVariantManager VarMgr);
```

File

System

Description

GetVariantManager returns the entry points of the routines that perform variant type conversion and define other variant behavior.

Note: Although GetVariantManager is defined in System.hpp, do not use this procedure in C++ code. Working directly with the Variant (see page 22307) manger is not guaranteed to work in C++.

See Also

SetVariantManager (see page 22527)

IsVariantManagerSet (see page 22483)

158.3.87 System.Halt Function

Initiates abnormal termination of a program.

Pascal

```
procedure Halt; overload;
procedure Halt(Exitcode: Integer); overload;
```

C++

```
Halt();
Halt(int Exitcode);
```

File

System

Description

Halt performs an abnormal termination of a program and returns to the operating system.

To perform a normal termination of a Delphi application, call the Terminate method on the global Application object. If the application does not use a unit that provides an Application object, call the Exit (see page 22453) procedure from the main Program block.

Exitcode is an optional expression that specifies an exit code for the program.

Delphi Examples:

```
{
This example halts before the TextOut and terminates the
application.  Do not expect to one step this procedure.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   if 1 = 1 then
     begin
       if 2 = 2 then
```

```
          begin
            if 3 = 3 then
              begin
                Halt(1); { Halt right here! }
              end;
          end;
      end;
    Canvas.TextOut(10, 10, 'This will not be executed');
  end;
```

158.3.88 System.Hi Function

Returns the high-order byte of X as an unsigned value.

Pascal

```
function Hi(X): Byte;
```

C++

```
Byte Hi( X);
```

File

System

Description

In Delphi code, use Hi to obtain the high-order byte of an expression of type Word or Integer.

Note: Hi treats Integer as a 16-bit value, even if it is 32-bit.

Delphi Examples:

```
{
This example demonstrate use of the System Hi function to
store the high byte of a word or integer into a byte.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  B : Byte;
begin
  B := Hi($1234);
  ShowMessage(Format('High byte of $1234 = $%x', [B]));
end;
```

See Also

Lo (see page 22486)

158.3.89 System.High Function

Returns the highest value in the range of an argument.

Pascal

```
procedure High(X);
```

C++

```
High( X);
```

File

System

Description

In Delphi code, call High to obtain the upper limit of an Ordinal, Array, or ShortString value. The result type is X, or the index type of X.

X is either a type identifier or a variable reference. The type denoted by X, or the type of the variable denoted by X, must be one of the following:

For this type	High returns
Ordinal type (includes Int64)	The highest value in the range of the type
Array type	The highest value within the range of the index type of the array. For empty arrays, High returns –1.
short string type	The declared size of the string
Open array	The value, of type Integer, giving the number of elements in the actual parameter minus one
short string parameter	The value, of type Integer, giving the number of elements in the actual parameter minus one

Delphi Examples:

```
{
This example requires a button and two list boxes.  Two lists
of floating point numbers are generated initially and
displayed in the list boxes. Clicking the button sums the lists.
Notice that the range of the list arrays can be any integers,
as long as Low is less than High.
}
var
  List1: array[0..3] of Double;
  List2: array[5..17] of Double;

function Sum( var X: array of Double): Double;
var
  I: Word;
  S: Real;
begin
  S := 0; { Note that open array index range is always zero-based. }
  for I := 0 to High(X) do S := S + X[I];
  Sum := S;
end;

procedure TForm1.Button1Click(Sender: TObject);
var
  S, TempStr: string;
begin
  Str(Sum(List1):4:2, S);
  S := 'Sum of List1: ' + S + #13#10;
  S := S + 'Sum of List2: ';
  Str(Sum(List2):4:2, TempStr);
  S := S + TempStr;
  MessageDlg(S, mtInformation, [mbOk], 0);

end;

procedure TForm1.FormCreate(Sender: TObject);
var
  X: Word;
begin
  for X := Low(List1) to High(List1) do
```

```
    begin
        List1[X] := X * 3.4;
        ListBox1.Items.Add(FloatToStr(List1[X]));
    end;
    for X := Low(List2) to High(List2) do
    begin
        List2[X] := X * 0.0123;
        ListBox2.Items.Add(FloatToStr(List2[X]));
    end;
  end;
```

See Also

Low (see page 22487)

VarArrayHighBound

158.3.90 System.Inc Function

Increments an ordinal value by one or N.

Pascal

```
procedure Inc(var X); overload;
procedure Inc(var X; N: Longint); overload;
```

C++

```
Inc( X);
Inc( X, Longint N);
```

File

System

Description

In Delphi code, Inc adds one or N to the variable X.

X is a variable of an ordinal type (including Int64), or a pointer type if the extended syntax is enabled.

N is an integer-type expression.

X increments by 1, or by N if N is specified; that is, Inc(X) corresponds to the statement X := X + 1, and Inc(X, N) corresponds to the statement X := X + N. On some platforms, Inc may generate optimized code, especially useful in tight loops.

If X is a pointer type, it increments X by N times the size of the type pointed to. Thus, given

```
type
  PMyType = ^TMyType;
```

and

```
var
  P: PMyType;
```

the statement `Inc(P)` increments `P` by `SizeOf (``see page 22528``)(TMyType)`.

Warning: You can't use Inc on properties because it modifies the parameter.

Note: Inc(S, I) where S is a ShortInt and I is a number greater than 127 will cause an EIntOverFlow exception to be raised if range and overflow checking are on. In Delphi 1.0, this did not raise an exception.

Delphi Examples:

```
{
```

```
This example requires two buttons and two text fields.  The
text fields can be set to any integer and long integer value.
Click the buttons to execute Inc.
Inc example
}
procedure TForm1.Button1Click(Sender: TObject);
var
  IntVar: Integer;
begin
  IntVar := StrToInt(Edit1.Text);
  Inc(IntVar);
  Edit1.Text := IntToStr(IntVar);       { IntVar := IntVar + 1 }
end;

procedure TForm1.Button2Click(Sender: TObject);
var
  LongintVar: Longint;
begin
  LongintVar := StrToInt(Edit2.Text);
  Inc(LongintVar, 5);
  Edit2.Text := IntToStr(LongintVar);   { LongintVar := LongintVar + 5 }
end;
```

158.3.91 System.Include Function

Adds an element to a Delphi set or adds an event handler in .NET applications.

Pascal

```
procedure Include(var S: set of T; I: T);
```

C++

```
Include(set of T S, T I);
```

File

System

Description

When the first argument of Include is a set type variable, Include adds an element to the set. The expression `Include(S,I)` corresponds to `S := S + [I]`, where S is a set type variable, and I is an expression of a type compatible with the base type of S. The Include procedure generates more efficient code than using the + operator.

On the .NET platform, Include is overloaded. When the first argument of Include is a multicast event, and the second argument is an event handler, Include adds the event handler as a listener to the event.

See Also

Exclude (see page 22453)

158.3.92 System.Initialize Function

Initializes a dynamically allocated variable.

Pascal

```
procedure Initialize(var V); overload;
procedure Initialize(var V; Count: Integer); overload;
```

C++

```
Initialize( V);
Initialize( V, int Count);
```

File

System

Description

Initialize should be used only in Delphi code where a variable is dynamically allocated by other means than the New (see page 22491) standard procedure.

For global variables, local variables, objects, and dynamic variables allocated using New (see page 22491), the compiler generates code that initializes all long strings and variants contained by a variable upon creation of the variable. A call to Initialize is required to initialize a variable before it can be used if:

- the dynamic variable is created by other means than the New (see page 22491) standard function (for example using GetMem (see page 22469) or ReallocMem (see page 22507)).
- the variable contains long strings, variants, or interfaces.
- the dynamic variable is created by other means than the New (see page 22491) standard function (for example using GetMem (see page 22469) or ReallocMem (see page 22507)).
- the variable contains long strings, variants, or interfaces.
- the memory allocated for the variable is not initialized to zeros.

Initialize simply zeros out the memory occupied by long strings, variants, and interfaces, causing long strings to be empty and variants and interfaces to be Unassigned.

In cases where several variables are allocated in a contiguous memory block, the additional Count parameter can be specified to initialize all variables in one operation.

If the variable specified in a call to Initialize contains no long strings, variants, or interfaces, the compiler eliminates the call and generates no code for it.

Finalize (see page 22460)

New (see page 22491)

158.3.93 System.Insert Function

Inserts a substring into a string beginning at a specified point.

Pascal

```
procedure Insert(Source: string; var S: string; Index: Integer);
```

C++

```
Insert(AnsiString Source, AnsiString S, int Index);
```

File

System

Description

In Delphi code, Insert merges Source into S at the position S[index].

Source is a string-type expression. S is a string-type variable of any length. Index is an integer-type expression. It is a character index and not a byte index.

If Index is less than 1, it is mapped to a 1. If it is past the end of the string, it is set to the length of the string, turning the operation into an append.

If the Source parameter is an empty string, Insert does nothing.

Insert throws an EOutOfMemory exception if it is unable to allocate enough memory to accomodate the new returned string.

Delphi Examples:

```
{
This example uses the Insert function to edit a string.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S: string;
begin
  S := 'Honest Lincoln';
  Canvas.TextOut(10, 10, S);
  Insert('Abe ', S, 8);                    { 'Honest Abe Lincoln' }
  Canvas.TextOut(10, 40, S);
end;
```

158.3.94 System.Int Function

Returns the integer part of a real number.

Pascal

```
function Int(const X: Extended): Extended;
```

C++

```
Extended Int(const Extended X);
```

File

System

Description

In Delphi code, Int returns the integer part of X; that is, X rounded toward zero. X is a real-type expression.

Delphi Examples:

```
{
Click the button to display the integer part of any positive or
negative real number.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  R: Real;
begin
  R := StrToFloat(Edit1.Text);     { 123.456 }
  R := Int(R);                     { 123.0 }
  Edit2.Text := FloatToStr(R);
end;
```

See Also

Frac (see page 22463)

Round (see page 22516)

Trunc (see page 22537)

158.3.95 System.IOResult Function

Returns the status of the last I/O operation performed.

Pascal

```
function IOResult: Integer;
```

C++

```
int IOResult();
```

File

System

Description

IOResult returns the result of the last Delphi I/O routine when I/O-checking is off (that is, when using the {$I-} compiler option). If IOResult returns 0, the last I/O operation succeeded. Otherwise, IOResult returns an error code.

If an I/O error occurs and I/O-checking is off, all subsequent I/O operations are ignored until the internal error flag is cleared. Calling IOResult clears the internal error flag.

An alternative way to handle I/O errors is to use exception handling with the {$I+} compiler option.

Delphi Examples:

```
{
IOResult example
This example illustrates how to use IOResult to check the success of the Reset
method. If the call to Reset is successful, a message dialog displays the size
of the file that the user selects in an Open dialog. If the call to Reset fails,
a message warns the user that there was a file access error. To test the failure
```

```
  part of this example, just misspell a file name in the open dialog.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    F: File of Byte;
  begin
    if OpenDialog1.Execute then
    begin
      AssignFile(F, OpenDialog1.FileName);
      {$I-}
      Reset(F);
      {$I+}
      if IOResult = 0 then
      begin
        MessageDlg('File size in bytes: ' + IntToStr(FileSize(F)),
          mtInformation, [mbOk], 0);
        CloseFile(F);
      end
      else
        MessageDlg('File access error', mtWarning, [mbOk], 0);
    end;
  end;
```

158.3.96 System.IsMemoryManagerSet Function

Indicates whether the memory manager has been overridden using the SetMemoryManager (see page 22523) procedure.

Pascal

```
function IsMemoryManagerSet: Boolean;
```

C++

```
Boolean IsMemoryManagerSet();
```

File

System

Description

Call IsMemoryManagerSet to determine whether the default system memory management has been changed by a call to SetMemoryManager (see page 22523). IsMemoryManagerSet returns false if the default system memory management is in place, true otherwise.

See Also

GetMemoryManager (see page 22472)

SetMemoryManager (see page 22523)

158.3.97 System.IsVariantManagerSet Function

Indicates whether variant support is implemented in an application.

Pascal

```
function IsVariantManagerSet: Boolean; deprecated;
```

C++

```
Boolean IsVariantManagerSet();
```

File

System

Description

Use IsVariantManagerSet in Delphi code to determine whether the compiler knows the locations of functions that define variant behavior. In any program or unit that uses the Variants (see page 23567) unit (directly or indirectly), IsVariantManagerSet should return true.

Note: Although IsVariantManagerSet is defined in System.hpp, do not use this function in C++ code. Working directly with the Variant (see page 22307) manger is not guaranteed to work in C++.

See Also

GetVariantManager (see page 22474)

SetVariantManager (see page 22527)

158.3.98 System.Length Function

Returns the number of characters in a string or elements in an array.

Pascal

```
function Length(S): Integer;
```

C++

```
int Length( S);
```

File

System

Description

In Delphi code, Length returns the number of characters actually used in the string or the number of elements in the array. In C++ code, use the method of the same name on the AnsiString (see page 22093) or DynamicArray (see page 22172) class.

For single-byte and multibyte strings, Length returns the number of bytes used by the string. For Unicode (WideString (see page 22377)) strings, Length returns the number of bytes divided by two.

S is a string- or array-valued expression.

Delphi Examples:

```
{
The following example uses an edit control, a button, and a
label on a form. When the button is clicked, the hexadecimal
value of each character in the edit control is displayed in
the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
begin
  Label1.Caption := '';
  for i := 1 to Length(Edit1.Text) do
  begin
```

```
      try
        Label1.Caption :=
          Label1.Caption +
          SysUtils.IntToHex(Byte(Edit1.Text[i]),2) + ' ';
      except
        Beep;
      end;
    end;
  end;
```

See Also

Concat (see page 22436)

Copy (see page 22438)

Delete (see page 22443)

Insert (see page 22480)

Pos (see page 22497)

158.3.99 System.Ln Function

Returns the natural log of a real expression.

Pascal

```
function Ln(const X: Extended): Extended;
```

C++

```
Extended Ln(const Extended X);
```

File

System

Description

In Delphi code, Ln returns the natural logarithm (Ln(e) = 1) of the real-type expression X.

Delphi Examples:

```
{
This example calculated the exponential of 1.0 and then calculates
the natural log of that quantity to show that the natural log
function is the inverse of the exponential function.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   e : real;
   S : string;
begin
   e := Exp(1.0);
   Str(ln(e):3:2, S);
   S := 'e = ' + FloatToStr(e) + '; ln(e) = ' + S;
   Canvas.TextOut(10, 10, S);
end;
```

See Also

Exp (see page 22455)

LnXP1

158.3.100 System.Lo Function

Returns the low order Byte of argument X.

Pascal

```
function Lo(X): Byte;
```

C++

```
Byte Lo( X);
```

File

System

Description

In Delphi code, Lo returns the low-order Byte of the argument X as an unsigned value. X is an expression of type Integer.

Delphi Examples:

```
{
This example demonstrate use of the System Lo function to
store the low byte of a word or integer into a byte.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  B : Byte;
begin
  B := Lo($1234);
  ShowMessage(Format('Low byte of $1234 = $%x', [B]));
end;
```

Hi (see page 22476)

158.3.101 System.LoadResourceModule Function

Pascal

```
function LoadResourceModule(ModuleName: PChar; CheckOwner: Boolean = True): LongWord;
```

C++

```
LongWord LoadResourceModule(const char * ModuleName, Boolean CheckOwner = True);
```

File

System

Description

This is function System.LoadResourceModule.

158.3.102 System.LoadResString Function

Pascal

```
function LoadResString(ResStringRec: PResStringRec): string;
```

C++

```
AnsiString LoadResString(PResStringRec ResStringRec);
```

File

System

Description

This is function System.LoadResString.

158.3.103 System.Low Function

Returns the lowest value in a range.

Pascal

```
procedure Low(X);
```

C++

```
Low( X);
```

File

System

Description

In Delphi code, call Low to obtain the lowest value or first element of an Ordinal, Array or ShortString. Result type is X, or the index type of X where X is either a type identifier or a variable reference.

Type	Low returns
Ordinal type (includes Int64)	The lowest value in the range of the type
Array type	The lowest value within the range of the index type of the array
short string type	Returns 0
Open array	Returns 0
short string parameter	Returns 0

Delphi Examples:

```
{
This example requires a button and two list boxes.  Two lists
of floating point numbers are generated initially and
displayed in the list boxes. Clicking the button sums the lists.
Notice that the range of the list arrays can be any integers,
as long as Low is less than High.
}
var
  List1: array[0..3] of Double;
```

```
    List2: array[5..17] of Double;

  function Sum( var X: array of Double): Double;
  var
    I: Word;
    S: Real;
  begin
    S := 0; { Note that open array index range is always zero-based. }
    for I := 0 to High(X) do S := S + X[I];
    Sum := S;
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    S, TempStr: string;
  begin
    Str(Sum(List1):4:2, S);
    S := 'Sum of List1: ' + S + #13#10;
    S := S + 'Sum of List2: ';
    Str(Sum(List2):4:2, TempStr);
    S := S + TempStr;
    MessageDlg(S, mtInformation, [mbOk], 0);

  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    X: Word;
  begin
    for X := Low(List1) to High(List1) do
    begin
        List1[X] := X * 3.4;
        ListBox1.Items.Add(FloatToStr(List1[X]));
    end;
    for X := Low(List2) to High(List2) do
    begin
        List2[X] := X * 0.0123;
        ListBox2.Items.Add(FloatToStr(List2[X]));
    end;
  end;
```

High (see page 22476)

VarArrayLowBound

158.3.104 System.MkDir Function

Creates a new subdirectory.

Pascal

```
procedure MkDir(const S: string); overload;
procedure MkDir(P: PChar); overload;
```

C++

```
MkDir(const AnsiString S);
MkDir(const char * P);
```

File

System

Description

MkDir creates a new subdirectory with the path specified by string S or P. The last item in the path cannot be an existing file name.

Note: In Delphi, {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for an I/O error.

Delphi Examples:

```
{
The following sample code sets the directory of
DirectoryListBox1 to C:\WINDOWS when the form is created.
When Button1 is pressed, a subdirectory called
mytemp is added to C:\WINDOWS, but note that it is not
updated in DirectoryListBox1 until Button2 is pressed
and Update is called.
Note: A EInOutError will occur if you add a directory that
already exists.  Also, you must add the new directory to
your current path to see the magic happen.
}

procedure TForm1.Button1Click(Sender: TObject);
begin
  MkDir(Edit1.Text);
end;

procedure TForm1.Button2Click(Sender: TObject);
begin
  DirectoryListBox1.Update;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  DirectoryListBox1.Directory := 'c:\WINDOWS';
end;
{
This example creates a directory using the path and directory name
entered in the text edit.  The path is relative to the project
directory.  Type in the name of an existing directory to induce the
error.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  {$I-}
  { Get directory name from TEdit control }
  MkDir(Edit1.Text);
  if IOResult <> 0 then
    MessageDlg('Cannot create directory', mtWarning, [mbOk], 0, mbOk)
  else
    MessageDlg('New directory created', mtInformation, [mbOk], 0, mbOk);
end;
```

RmDir (see page 22515)

ForceDirectories

158.3.105 System.Move Function

Copies bytes from a source to a destination.

Pascal

```
procedure Move(const Source; var Dest; Count: Integer);
```

C++

```
Move(const  Source,  Dest, int Count);
```

File

System

Description

Move copies Count bytes from Source to Dest. No range checking is performed. Move compensates for overlaps between the source and destination blocks.

Whenever possible, use the global SizeOf (see page 22528) function (Delphi) or the sizeof operator (C++) to determine the count.

Delphi Examples:

```
{
This example moves characters from a Char array into an integer.
Displaying the integer as a hex, you can see that 'W' (0x57) is
stored in the least significant byte of the integer.
}
var
  A: array[1..4] of Char;
  B: Integer;

procedure DisplayAB;
begin
  Form1.ListBox1.Items[0] := A[1];
  Form1.ListBox1.Items[1] := A[2];
  Form1.ListBox1.Items[2] := A[3];
  Form1.ListBox1.Items[3] := A[4];
  Form1.Edit1.Text := IntToHex(B, 1);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Move(A, B, SizeOf(B));  { SizeOf = safety! }
  DisplayAB;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  I : Integer;
begin
  A[1] := 'W';
  A[2] := 'H';
  A[3] := 'A';
  A[4] := 'T';
  B := 5;
  DisplayAB;
end;
```

158.3.106 System.New Function

Creates a new dynamic variable and sets P to point to it.

Pascal

```
procedure New(var P: Pointer);
```

C++

```
New(void * P);
```

File

System

Description

In Delphi code, the New procedure creates a new dynamic variable and sets a pointer variable to point to it. P is a variable of any pointer type. The size of the allocated memory block corresponds to the size of the type that P points to. The newly created variable can be referenced as P^. If there isn't enough memory available to allocate the dynamic variable, an EOutOfMemory exception is raised.

When an application is finished using a dynamic variable created with New, it should dispose of the memory allocated for the variable using the Dispose (see page 22444) standard procedure.

Delphi Examples:

```
{
The following code explicitly allocates memory for a pointer
in the OnCreate event of Form1, then releases the memory in
the OnDestroy event. Assume that MyPtr is a Pointer type
field of TForm1.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  New(MyPtr);
end;

procedure TForm1.FormDestroy(Sender: TObject);
begin
  Dispose(MyPtr);
end;
{
This example requires three buttons, four TEdits, two labels
and a populated TreeView.  The following code defines a
record type of TMyRec and a record pointer type of PMyRec.
}
type
  TForm1 = class(TForm)
    Button1: TButton;
    Button2: TButton;
    Edit1: TEdit;
    TreeView1: TTreeView;
    Label2: TLabel;
    Label3: TLabel;
    Button3: TButton;
    Edit4: TEdit;
    Edit2: TEdit;
    Edit3: TEdit;
    procedure Button1Click(Sender: TObject);
    procedure Button2Click(Sender: TObject);
    procedure Button3Click(Sender: TObject);
```

```
    private
      { Private declarations }
    public
      { Public declarations }
    end;
    type
    PMyRec = ^TMyRec;
    TMyRec = record
      FName: string;
      LName: string;
    end;

  var
    Form1: TForm1;

  implementation

  {$R *.dfm}

  {
  Assuming these types are used, the following code adds a
  node to TreeView1 as the last sibling of the selected node.
  A TMyRec record is associated with the added item. The FName
  and LName fields are obtained from edit boxes Edit1 and
  Edit2.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    MyRecPtr: PMyRec;
    TreeViewIndex: LongInt;
  begin
    New(MyRecPtr);
    MyRecPtr^.FName := Edit1.Text;
    MyRecPtr^.LName := Edit2.Text;
    with TreeView1 do
    begin
      TreeViewIndex := Selected.AbsoluteIndex;
      if Items.Count = 0 then
        Items.AddObject(nil, 'Item' + IntToStr(TreeViewIndex), MyRecPtr)
      else if (TreeViewIndex < Items.Count) and (TreeViewIndex >= 0) then
        Items.AddObject(Items[TreeViewIndex], 'Item' + IntToStr(TreeViewIndex), MyRecPtr);
    end;
  end;
  {
  After an item containing a TMyRec record has been added, the
  following code retrieves the FName and LName values
  associated with the item and displays the values in a label.
  }
  procedure TForm1.Button2Click(Sender: TObject);
  begin
    if (TreeView1.Selected.Data <> nil) then { query only works on new nodes }
      Edit3.Text := PMyRec(TreeView1.Selected.Data)^.FName + ' ' +
                    PMyRec(TreeView1.Selected.Data)^.LName;
  end;
  procedure TForm1.Button3Click(Sender: TObject);
  begin
    Edit4.Text := IntToStr(TreeView1.Selected.AbsoluteIndex);
  end;
```

GetMem (see page 22469)

158.3.107 System.Odd Function

Returns true if argument is an odd number.

Pascal

```
function Odd(X: Integer): Boolean;
```

C++

```
Boolean Odd(int X);
```

File

System

Description

In Delphi code, Odd tests if the argument is an odd number. It returns true if X is an odd number, false if X is even.

Delphi Examples:

```
{
This example requires a text edit and a button with some clear
canvas in the top left ocrner of the form.  Enter the number to be
tested in the text edit and click to button to test if the entry
is odd.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   Canvas.TextOut(10, 10, '                                        ');
   if Odd(StrToInt(Edit1.Text)) then
     Canvas.TextOut(10, 10, Edit1.Text + ' is odd.')
   else
     Canvas.TextOut(10, 10, Edit1.Text + ' is even.');
end;
```

158.3.108 System.OleStrToString Function

Copies data received from a COM interface to a string.

Pascal

```
function OleStrToString(Source: PWideChar): string;
```

C++

```
AnsiString OleStrToString(PWideChar Source);
```

File

System

Description

OleStrToString copies data from the format used by COM into a Delphi string.

See Also

OleStrToStrVar (see page 22494)

StringToOleStr (see page 22531)

158.3.109 System.OleStrToStrVar Function

Copies a string from its COM representation to an existing Delphi string.

Pascal

```
procedure OleStrToStrVar(Source: PWideChar; var Dest: string);
```

C++

```
OleStrToStrVar(PWideChar Source, AnsiString Dest);
```

File

System

Description

OleStrToStrVar converts a wide string (the format used by COM interfaces) into an existing string variable.

See Also

OleStrToString (see page 22493)

StringToOleStr (see page 22531)

158.3.110 System.Ord Function

Returns the ordinal value of an ordinal-type expression.

Pascal

```
procedure Ord(X);
```

C++

```
Ord( X);
```

File

System

Description

X is a Delphi ordinal-type expression. The result is the ordinal position of X; its type is the smallest standard integer type that can hold all values of X's type.

Ord cannot operate on Int64 values.

Delphi Examples:

```
{
This example displays the ordinal value for different enumerations.
}
procedure TForm1.Button1Click(Sender: TObject);
type
   Colors = (RED,BLUE,GREEN);
var
  S: string;
begin
  S := 'BLUE has an ordinal value of ' + IntToStr(Ord(BLUE)) + #13#10;
  S := S + 'The ASCII code for "c" is ' + IntToStr(Ord('c')) +  ' decimal';
```

```
  MessageDlg(S, mtInformation, [mbOk], 0, mbOK);
end;
```

See Also

Chr (see page 22430)

158.3.111 System.ParamCount Function

Returns the number of parameters passed on the command line.

Pascal

```
function ParamCount: Integer;
```

C++

```
int ParamCount();
```

File

System

Description

ParamCount returns the number of parameters passed to the program on the command line. Separate parameters with spaces or tabs. Use double quotes to wrap multiple words as one parameter (such as long file names containing spaces).

Delphi Examples:

```
{
The following example beeps once for each "beep" passed in
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//     'System ParamCount = ' + IntToStr(System.ParamCount),
//     mtConfirmation, [mbOK], 0);
  for i := 1 to System.ParamCount do
  begin
    if LowerCase(ParamStr(i)) = 'beep' then
      Beep
    else if LowerCase(ParamStr(i)) = 'exit' then
      Application.Terminate;
    Sleep(250);
  end;
end;
```

See Also

ParamStr (see page 22496)

CmdLine (see page 22635)

158.3.112 System.ParamStr Function

Returns a specified parameter from the command-line.

Pascal

```
function ParamStr(Index: Integer): string;
```

C++

```
AnsiString ParamStr(int Index);
```

File

System

Description

ParamStr returns the parameter from the command line that corresponds to Index, or an empty string if Index is greater than ParamCount (see page 22495). For example, an Index value of 2 returns the second command-line parameter.

Note: On Windows, ParamStr(0) returns the path and file name of the executing program (for example, C:\TEST\MYPROG.EXE).

Note: On Linux, ParamStr(0) returns the command used to execute the program, without parameters (for example, ./myprogram). This behavior is dependent on information returned by the shell program and may not be consistent among all shells.

Note: Use double quotes to wrap multiple words as one parameter (such as long file names containing spaces).

Delphi Examples:

```
{
The following example beeps once for each "beep" passed in
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//     'System ParamCount = ' + IntToStr(System.ParamCount),
//    mtConfirmation, [mbOK], 0);
  for i := 1 to System.ParamCount do
  begin
    if LowerCase(ParamStr(i)) = 'beep' then
      Beep
    else if LowerCase(ParamStr(i)) = 'exit' then
      Application.Terminate;
    Sleep(250);
  end;
end;
```

See Also

ParamCount (see page 22495)

CmdLine (see page 22635)

158.3.113 System.Pi Function

Returns 3.1415926535897932385.

Pascal

```
function Pi: Extended;
```

C++

```
Extended Pi();
```

File

System

Description

Use Pi in Delphi code to represent the mathematical value pi, the ratio of a circle's circumference to its diameter. Pi is approximated as 3.1415926535897932385.

Delphi Examples:

```
{
This example shows how to use the ArcTan and FloatToStr
functions.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ex : Extended;
  mystring : String;
begin
  ex := 16 * ArcTan(1/5) - 4 * ArcTan(1/239); // Machin's formula
  mystring := FloatToStr(ex);
  Edit2.Text := mystring;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  ex : Extended;
  myString : String;
begin
  ex := Pi;
  mystring := FloatToStr(ex);
  Edit1.Text := mystring;
end;
```

158.3.114 System.Pos Function

Returns the index value of the first character in a specified substring that occurs in a given string.

Pascal

```
function Pos(const substr: AnsiString; const str: AnsiString): Integer; overload;
function Pos(const substr: WideString; const str: WideString): Integer; overload;
```

C++

```
int Pos(const AnsiString substr, const AnsiString str);
int Pos(const BSTR substr, const BSTR str);
```

File

System

Description

In Delphi, Pos searches for a substring, Substr, in a string, S. Substr and S are string-type expressions.

Pos searches for Substr within S and returns an integer value that is the index of the first character of Substr within S. Pos is case-sensitive. If Substr is not found, Pos returns zero.

The PosEx function is similar to Pos, but provides additional features and can be used in C++ code.

Delphi Examples:

```
{
The following example updates the strings in a list box
given the strings contained in another list box. If a string
in the source list box has the form Name=Value and the
destination list box contains a string with the same Name
part, the Value part in the destination list box will be
replaced by the source's value.  TListBox objects that are
not name-value pairs are not assigned a Name and IndexOfName
will return -1.
}
procedure MergeStrings(Dest, Source: TStrings);
var
  I, DI: Integer;
  begin
  for I := 0 to Source.Count - 1 do
  begin
    if Pos ('=', Source[I]) > 1 then
    begin
      DI := Dest.IndexOfName(Source.Names[I]);
      if DI > -1 then Dest[DI] := Source[I];
    end;
  end;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  MergeStrings(ListBox1.Items, ListBox2.Items);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Plants = 10');
  ListBox1.Items.Add('Animals = 20');
  ListBox1.Items.Add('Minerals = 15');
  ListBox2.Items.Add('Animals = 4');
  ListBox2.Items.Add('Plants = 3');
  ListBox2.Items.Add('Minerals = 78');
end;
{
This example demonstrates how to edit particular elements of a string.
}
procedure TForm1.Button1Click(Sender: TObject);
var S: string;
begin
  S := Edit1.Text;
  { Convert spaces to zeros }
  while Pos(' ', S) > 0 do
```

```
    S[Pos(' ', S)] := '0';
  Edit1.Text := S;
end;
```

Length (see page 22484)

158.3.115 System.Pred Function

Returns the predecessor of the argument.

Pascal

```
procedure Pred(X);
```

C++

```
Pred( X);
```

File

System

Description

X is an expression of a Delphi ordinal type (including Int64). The result, of the same type as X, is the predecessor of X.

Delphi Examples:

```
{
AssertErrorProc example
The following code is a self-contained unit that you can add to a project
that logs failed assertions to the event log rather than raising an
exception. If /Debug is passed to the application as a command-line
parameter, all failed Assert calls cause a call to OutputDebugString,
which sends a messages to the Event Log window if run from Delphi, or
does nothing if run outside the IDE (OutputDebugString is a no-op if not
run from within a debugger). A nice side benefit is that all the line
numbers and unit names can be stripped from the EXE by turning off
assertions and rebuilding the project.
Note: AssertErrorHandler should do as little as possible.  This routine
does no cleanup, so no variables, no compiler generated variables.
Procedure calls are OK.
Note:   This example was originally provided by Brian Long.
}
type
  TForm1 = class(TForm)
    procedure Button1Click(Sender: TObject);

begin
  S := 'The predecessor of 5 is ' + IntToStr(Pred(5)) + #13#10;
  S := S + 'The successor of 10 is ' + IntToStr(Succ(10)) + #13#10;
  if Succ(RED) = BLUE then
    S := S + 'In the type Colors, RED is the predecessor of BLUE.';
  MessageDlg(S, mtInformation, [mbOk], 0, mbOk);
end;
```

See Also

Succ (see page 22532)

158.3.116 System.Ptr Function

Converts a specified address to a pointer.

Pascal

```
function Ptr(Address: Integer): Pointer;
```

C++

```
void * Ptr(int Address);
```

File

System

Description

In Delphi code, Ptr converts the given address to a pointer. A call to this function generates no code, but simply treats the 32-bit value given by Address as a pointer. Like nil, the result of Ptr is assignment compatible with all pointer types.

See Also

Addr (see page 22412)

158.3.117 System.PUCS4Chars Function

Converts a UCS4 string to a null-terminated array of UCS4 characters.

Pascal

```
function PUCS4Chars(const S: UCS4String): PUCS4Char;
```

C++

```
PUCS4Char PUCS4Chars(const UCS4String S);
```

File

System

Description

PUCS4Chars converts the UCS-4 string specified by S to a null-terminated sequence of UCS4Char (see page 22626) values.

See Also

UCS4StringToWideString (see page 22538)

Utf8ToUnicode (see page 22542)

WideStringToUCS4String (see page 22548)

158.3.118 System.RaiseList Function

Pascal

```
function RaiseList: Pointer; deprecated;
```

C++

```
void * RaiseList();
```

File

System

Description

This is function System.RaiseList.

158.3.119 System.Random Function

Generates random numbers within a specified range.

Pascal

```
function Random(const ARange: Integer): Integer; overload;
function Random: Extended; overload;
```

C++

```
int Random(const int ARange);
Extended Random();
```

File

System

Description

In Delphi code, Random returns a random number within the range 0 <= X < Range. If Range is not specified, the result is a real-type random number within the range

`0 <= X < 1.`

To initialize the random number generator, add a single call Randomize (see page 22503) or assign a value to the RandSeed (see page 22654) variable before making any calls to Random.

Note: Because the implementation of the Random function may change between compiler versions, we do not recommend using Random for encryption or other purposes that require reproducible sequences of pseudo-random numbers.

Delphi Examples:

```
{
This example draws many rectangles of various sizes and
colors on a form maximized to fill the entire screen. To run
the code, drop a TTimer component on the form and use the
object inspector to create the OnTimer and OnActivate event
handlers.
}
var
  X, Y: Integer;
procedure TForm1.FormActivate(Sender: TObject);
begin
  WindowState := wsMaximized;
  Timer1.Interval := 50;
  Randomize;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  X := Random(Screen.Width - 10);
  Y := Random(Screen.Height - 10);
  Canvas.Pen.Color := Random(65535);
  case Random(5) of
    0: Canvas.Pen.Style := psSolid;
    1: Canvas.Pen.Style := psDash;
    2: Canvas.Pen.Style := psDot;
    3: Canvas.Pen.Style := psDashDot;
    4: Canvas.Pen.Style := psDashDotDot;
  end;
  Canvas.Rectangle(X, Y, X + Random(400), Y + Random(400));
end;
```

See Also

RandSeed (see page 22654)

158.3.120 System.Randomize Function

Initializes the random number generator with a random value.

Pascal

```
procedure Randomize;
```

C++

```
Randomize();
```

File

System

Description

Randomize initializes the built-in random number generator with a random value (obtained from the system clock). The random number generator should be initialized by making a call to Randomize, or by assigning a value to RandSeed (see page 22654).

Do not combine the call to Randomize in a loop with calls to the Random (see page 22502) function. Typically, Randomize is

called only once, before all calls to Random (see page 22502).

Delphi Examples:

```
{
This example draws many rectangles of various sizes and
colors on a form maximized to fill the entire screen. To run
the code, drop a TTimer component on the form and use the
object inspector to create the OnTimer and OnActivate event
handlers.
}
var
  X, Y: Integer;
procedure TForm1.FormActivate(Sender: TObject);
begin
  WindowState := wsMaximized;
  Timer1.Interval := 50;
  Randomize;
end;

procedure TForm1.Timer1Timer(Sender: TObject);
begin
  X := Random(Screen.Width - 10);
  Y := Random(Screen.Height - 10);
  Canvas.Pen.Color := Random(65535);
  case Random(5) of
    0: Canvas.Pen.Style := psSolid;
    1: Canvas.Pen.Style := psDash;
    2: Canvas.Pen.Style := psDot;
    3: Canvas.Pen.Style := psDashDot;
    4: Canvas.Pen.Style := psDashDotDot;
  end;
  Canvas.Rectangle(X, Y, X + Random(400), Y + Random(400));
end;
```

RandSeed (see page 22654)

Random (see page 22502)

158.3.121 System.Read Function

Read reads data from a file.

Pascal

```
procedure Read(F; V1); overload;
procedure Read(F; V1; Vn); overload;
procedure Read(F: Text; V1); overload;
procedure Read(F: Text; V1; Vn); overload;
```

C++

```
Read( F,  V1);
Read( F,  V1,  Vn);
Read(Text F,  V1);
Read(Text F,  V1,  Vn);
```

File

System

Description

The Read procedure can be used in Delphi code in the following ways.

For typed files, it reads a file component into a variable.

For text files, it reads one or more values into one or more variables.

The syntax shown here for Read demonstrates that the procedure can take a variable number of arguments.

Read reads all characters up to, but not including, the next end-of-line marker or until Eof (see page 22449)(F) becomes true; it does not skip to the next line after reading. If the resulting string is longer than the maximum length of the string variable, it is truncated.

After the first Read, each subsequent Read sees the end-of-line marker and returns a zero-length string.

Use multiple Readln calls to read successive string values.

When the extended syntax is enabled, Read can read null-terminated strings into zero-based character arrays.

Read reads one character from the file and assigns it to the variable. If CRLF mode is enabled and Eof (see page 22449)(F) was true before Read was executed, the value Chr (see page 22430)(26) (a Ctrl-Z character) is assigned to the variable. (To enable CRLF mode, use SetLineBreakStyle (see page 22522).)

Read skips any blanks, tabs, or end-of-line markers preceding the numeric string.

If the numeric string does not conform to the expected format, an I/O error occurs; otherwise, the value is assigned to the variable.

The next Read starts with the blank, tab, or end-of-line marker that terminated the numeric string.

Delphi Examples:

```
{
This example reads a file one character at a time and writes
it into a file of your chosing.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F1, F2: TextFile;
  Ch: Char;
begin
  if OpenDialog1.Execute then begin
    AssignFile(F1, OpenDialog1.Filename);
    Reset(F1);
    if SaveDialog1.Execute then begin
      AssignFile(F2, SaveDialog1.Filename);
      Rewrite(F2);
      while not Eof(F1) do
      begin
        Read(F1, Ch);
        Write(F2, Ch);
      end;
      CloseFile(F2);
    end;
    CloseFile(F1);
  end;
end;
```

See Also

Eof (see page 22449)

Readln

Write (see page 22548)

Writeln

SetLineBreakStyle (see page 22522)

158.3.122 System.ReadLn Function

Reads a line of text from a file.

Pascal

```
procedure ReadLn(V1); overload;
procedure ReadLn(V1; Vn); overload;
procedure ReadLn(var F: Text; V1); overload;
procedure ReadLn(var F: Text; V1; Vn); overload;
```

C++

```
ReadLn( V1);
ReadLn( V1,  Vn);
ReadLn(Text F,  V1);
ReadLn(Text F,  V1,  Vn);
```

File

System

Description

In Delphi code, the ReadLn procedure reads a line of text and then skips to the next line of the file.

The syntax shown here for ReadLn demonstrates that the procedure can take a variable number of arguments.

ReadLn(F) with no parameters causes the current file position to advance to the beginning of the next line if there is one; otherwise, it goes to the end of the file.

If F is omitted, the global variable Input (see page 22647) is used, which accesses the processes standard input file. Use of Input (see page 22647) in GUI applications raises special issues.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for I/O errors.

Delphi Examples:

```
{
This example assumes you are compiling as a console
application.  Notice how the form deactivates when the button
click procedure exits.
}

{$APPTYPE CONSOLE}

procedure TForm1.Button1Click(Sender: TObject);
var
  s : string;
begin
  Write('Enter a line of text: ');
  Readln(s);
  Writeln('You typed: ',s);
  Writeln('Hit <Enter> to exit');
  Readln;
end;
{
Use a TOpenDialog to select a file.  Place the first line of
the file into a TEdit.
}
```

```
procedure TForm1.Edit1Click(Sender: TObject);
var
  F: TextFile;
  S: string;
begin
  if OpenDialog1.Execute then            { Display Open dialog box }
  begin
    AssignFile(F, OpenDialog1.FileName); { File selected in dialog }
    Reset(F);
    Readln(F, S);                        { Read first line of file }
    Edit1.Text := S;                     { Put string in a TEdit control }
    CloseFile(F);
  end;
end;
```

Read (see page 22504)

Writeln

SetLineBreakStyle (see page 22522)

158.3.123 System.ReallocMem Function

ReallocMem reallocates a memory block.

Pascal

```
procedure ReallocMem(var P: Pointer; Size: Integer);
```

C++

```
ReallocMem(void * P, int Size);
```

File

System

Description

GetMem (see page 22469) allocates a block of the given **Size** on the heap. If you need to change the size of this memory block, call ReallocMem, passing the existing memory block pointer in **P**, and the revised block size in **Size**. If ReallocMem can't expand the memory block pointed to by **P**, it frees the referenced memory and copies the values to the newly allocated memory that is returned.

If there isn't enough memory available to extend the memory block to the desired size, an EOutOfMemory exception is raised.

Note: ReallocMemory (see page 22508) is the C++ compatible version of ReallocMem.

See Also

AllocMem (see page 22413)

FreeMem (see page 22464)

FreeMemory (see page 22466)

GetMemory (see page 22470)

EOutOfMemory (see page 22742)

ReallocMemory (see page 22508)

158.3.124 System.ReallocMemory Function

ReallocMemory resizes a memory block.

Pascal

```
function ReallocMemory(P: Pointer; Size: Integer): Pointer; cdecl;
```

C++

```
__cdecl void * ReallocMemory(void * P, int Size);
```

File

System

Description

GetMem (see page 22469) allocates a block of the given **Size** on the heap. If you need to change the size of this memory block, call ReallocMemory, passing the existing memory block pointer in **P**, and the revised block size in **Size**. A pointer to the resized memory block is returned. If ReallocMemory can't expand the memory block pointed to by **P**, it frees the referenced memory and copies the values to the newly allocated memory that is returned.

If there isn't enough memory available to extend the memory block to the desired size, an EOutOfMemory exception is raised.

Note: ReallocMemory is the C++ compatible version of ReallocMem (see page 22507).

See Also

AllocMem (see page 22413)

FreeMem (see page 22464)

FreeMemory (see page 22466)

GetMemory (see page 22470)

EOutOfMemory (see page 22742)

ReallocMem (see page 22507)

158.3.125 System.RegisterExpectedMemoryLeak Function

Registers an expected memory leak.

Pascal

```
function RegisterExpectedMemoryLeak(P: Pointer): boolean;
```

C++

```
boolean RegisterExpectedMemoryLeak(void * P);
```

File

System

Description

RegisterExpectedMemoryLeak registers a memory location that an application has allocated and does not expect to free.

See Also

Memory Management

Configuring the Memory Manager

Registering Memory Leaks

UnregisterExpectedMemoryLeak (see page 22539)

ReportMemoryLeakOnShutdown

158.3.126 System.RegisterModule Function

Pascal

```
procedure RegisterModule(LibModule: PLibModule);
```

C++

```
RegisterModule(PLibModule LibModule);
```

File

System

Description

This is function System.RegisterModule.

158.3.127 System.ReleaseExceptionObject Function

Releases exception object acquired by AcquireExceptionObject (see page 22410).

Pascal

```
procedure ReleaseExceptionObject;
```

C++

```
ReleaseExceptionObject();
```

File

System

Description

ReleaseExceptionObject releases an exception object previously acquired by AcquireExceptionObject (see page 22410).

See Also

AcquireExceptionObject (see page 22410)

ExceptObject (see page 22452)

158.3.128 System.RemoveModuleUnloadProc Function

RemoveModuleUnloadProc removes a call to your defined routine when a package is unloaded.

Pascal

```
procedure RemoveModuleUnloadProc(Proc: TModuleUnloadProc); overload;
procedure RemoveModuleUnloadProc(Proc: TModuleUnloadProcLW); overload;
```

C++

```
RemoveModuleUnloadProc(TModuleUnloadProc Proc);
RemoveModuleUnloadProc(TModuleUnloadProcLW Proc);
```

File

System

Description

Before Delphi unloads a package that was used by your application, it can optionally call your **Proc** routine. In essence, AddModuleUnloadProc (see page 22411) adds your routine to the head of the list of internal routines that Delphi invokes to perform the unload. RemoveModuleUnloadProc reverses the effect of AddModuleUnloadProc (see page 22411).

See Also

AddModuleUnloadProc (see page 22411)

TModuleUnloadProc (see page 22617)

158.3.129 System.Rename Function

Changes the name of an external file.

Pascal

```
procedure Rename(var F; Newname: string); overload;
procedure Rename(var F; Newname: PChar); overload;
```

C++

```
Rename( F, AnsiString Newname);
Rename( F, const char * Newname);
```

File

System

Description

The external file associated with F is renamed Newname. Further operations on F operate on the external file with the new name.

F is a variable of any file type. Newname is a string-type expression or an expression of type PChar if the extended syntax is enabled.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for I/O errors.

Delphi Examples:

```
{
This example requires a button, an open dialog and a save
```

```
dialog.  Click the button to rename a file.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  f : file;
begin
  OpenDialog1.Title := 'Choose a file... ';
  if OpenDialog1.Execute then
  begin
    SaveDialog1.Title := 'Rename to...';
    if SaveDialog1.Execute then
    begin
      AssignFile(f, OpenDialog1.FileName);
      Canvas.TextOut(5, 10, 'Renaming ' + OpenDialog1.FileName +
                     ' to ' + SaveDialog1.FileName);
      Rename(f, SaveDialog1.FileName);
    end;
  end;
end;
```

See Also

Rename File

158.3.130 System.Reset Function

Opens an existing file.

Pascal

```
procedure Reset(var F); overload;
procedure Reset(var F; RecSize: Word); overload;
procedure Reset(var F: File); overload;
procedure Reset(var F: File; RecSize: Word); overload;
```

C++

```
Reset( F);
Reset( F, Word RecSize);
Reset(File F);
Reset(File F, Word RecSize);
```

File

System

Description

In Delphi code, Reset opens the existing external file with the name assigned to F using the mode specified by the global FileMode (see page 22644) variable. An error results if no existing external file of the given name exists or if the file can't be opened with the current file mode. If F is already open, it is first closed and then reopened. The current file position is set to the beginning of the file.

Warning: The default value of FileMode (see page 22644) is 2 (Read (see page 22504)/Write (see page 22548) access). If this is not changed to a read-only file mode before calling Reset, attempts to open read-only files will fail.

F is a variable of any file type associated with an external file using AssignFile (see page 22420). RecSize is an optional expression, which can be specified only if F is an untyped file. If F is an untyped file, RecSize specifies the record size to be used in data transfers. If RecSize is omitted, a default record size of 128 bytes is assumed.

If F is assigned an empty name, such as AssignFile (see page 22420)(F, ''), then after the call to Reset, F refers to the standard input file.

If F is a text file, F becomes read-only.

After a call to Reset, Eof (see page 22449)(F) is true if the file is empty; otherwise, Eof (see page 22449)(F) is false.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for I/O errors.

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File;
  i, filehandle: Integer;
begin
  for i := 0 to (FileListBox1.Items.Count - 1) do begin
  try
    if FileListBox1.Selected[i] then
    begin
      if not FileExists(FileListBox1.Items.Strings[i]) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' not found', mtError, [mbOk], 0);
        Continue;
      end;
      filehandle:=  FileOpen(FileListBox1.Items.Strings[i], 1);
      if (filehandle = -1) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' cannot be opened with access mode 1.', mtError, [mbOk], 0);
        Continue;
      end
      else
        FileClose(filehandle);

      AssignFile(F, FileListBox1.Items.Strings[i]);
      Reset(F, 1);
      ListBox1.Items.Add(
        FileListBox1.Items.Strings[i] + ': ' + IntToStr(FileSize(F)));
      CloseFile(F);
    end;
   finally
   { do something here }
   end;
  end;
end;
{
This example should be executed from a command line
formatted like this: "SystemReset_proj foo.txt".  The file
path is relative to the project directory.
}
function FileIsThere(FileName: string): Boolean;
{ Boolean function that returns True if the file exists; otherwise,
  it returns False. Closes the file if it exists. }
 var
  F: file;
begin
```

```
    {$I-}
    AssignFile(F, FileName);
    FileMode := 0;  {Set file access to read only }
    Reset(F);

158.3.131 System.Rewrite Function

Creates a new file and opens it.

Pascal

```
procedure Rewrite(var F: File); overload;
procedure Rewrite(var F: File; Recsize: Word); overload;
```

C++

```
Rewrite(File F);
Rewrite(File F, Word Recsize);
```

File

System

Description

In Delphi code, Rewrite creates a new external file with the name assigned to F.

F is a variable of any file type associated with an external file using AssignFile (see page 22420). RecSize is an optional expression, which can be specified only if F is an untyped file. If F is an untyped file, RecSize specifies the record size to be used in data transfers. If RecSize is omitted, a default record size of 128 bytes is assumed.

If an external file with the same name already exists, it is deleted and a new empty file is created in its place.

If F is already open, it is first closed and then re-created. The current file position is set to the beginning of the empty file.

If F was assigned an empty name, such as AssignFile (see page 22420)(F,''), then after the call to Rewrite, F refers to the standard output file.

If F is a text file, F becomes write-only.

After calling Rewrite, Eof (see page 22449)(F) is always true.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for I/O errors.

Delphi Examples:

```
{
This example reads an entire file into a buffer with one
command and then writes it into a saved file.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FromF, ToF: file;
  NumRead, NumWritten: Integer;
  Buf: array[1..2048] of Char;
begin
  if OpenDialog1.Execute then     { Display Open dialog box }
  begin
    AssignFile(FromF, OpenDialog1.FileName);
    Reset(FromF, 1);    { Record size = 1 }
    if SaveDialog1.Execute then      { Display Save dialog box}
    begin
      AssignFile(ToF, SaveDialog1.FileName);    { Open output file }
      Rewrite(ToF, 1);  { Record size = 1 }
      Canvas.TextOut(10, 10, 'Copying ' + IntToStr(FileSize(FromF))
        + ' bytes...');
      repeat
        System.BlockRead(FromF, Buf, SizeOf(Buf), NumRead);
        BlockWrite(ToF, Buf, NumRead, NumWritten);
      until (NumRead = 0) or (NumWritten <> NumRead);
      CloseFile(FromF);
      CloseFile(ToF);
    end;
  end;
end;
```

```
{
Rewrite example
}

procedure TForm1.Button1Click(Sender: TObject);
var F: TextFile;
begin
  AssignFile(F, 'NEWFILE.$$$');
  Rewrite(F);  // default record size is 128 bytes
  Writeln(F, 'Just created file with this text in it...');
  CloseFile(F);
  MessageDlg('NEWFILE.$$$ has been created in the ' + GetCurrentDir + ' directory.',
    mtInformation, [mbOk], 0, mbOK);
end;
```

158.3.132 System.RmDir Function

Deletes an empty subdirectory.

Pascal

```
procedure RmDir(const S: string); overload;
procedure RmDir(P: PChar); overload;
```

C++

```
RmDir(const AnsiString S);
RmDir(const char * P);
```

File

System

Description

RmDir removes the subdirectory with the path specified by S or P. If the path does not exist, is non-empty, or is the currently logged directory, an I/O error occurs.

Note: In Delphi, {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for I/O errors.

Delphi Examples:

```
{
This example requires a text edit and a button.  Enter the
folder to remove in the text edit and click the button.  The
path is relative to the project folder.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   {$I-}
   { Get directory name from TEdit control }
   RmDir(Edit1.Text);
```

```
    if IOResult <> 0 then
      MessageDlg('Cannot remove directory', mtWarning, [mbOk], 0, mbOk)
    else
      MessageDlg('Directory removed', mtInformation, [mbOk], 0, mbOk);
end;
```

RemoveDir

158.3.133 System.Round Function

Returns the value of X rounded to the nearest whole number.

Pascal

```
function Round(X: Extended): Int64;
```

C++

```
Int64 Round(Extended X);
```

File

System

Description

In Delphi, the Round function rounds a real-type value to an integer-type value.

X is a real-type expression. Round returns an Int64 value that is the value of X rounded to the nearest whole number. If X is exactly halfway between two whole numbers, the result is always the even number. This method of rounding is often called "Banker's Rounding".

If the rounded value of X is not within the Int64 range, a runtime error is generated, which can be handled using the EInvalidOp exception.

Note: The behavior of Round can be affected by the Set8087CW (see page 22520) procedure or SetRoundMode function.

Delphi Examples:

```
{
This example displays the Cosine of any value between 0 and
12.  Since the scrollbar position is an integer between the
scrollbar  min and max, multiply the range and divide the
position to fine tune it.  With the scrollbar selected use
the left and right buttons to change the position by 1E-6.
Or use the Dec function to decrement (or increment) by a
specific amount.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  new : Integer;
begin
  new := ScrollBar1.Position;
  System.Dec(new, Round(StrToFloat(Edit3.Text)*1000000));
```

```
    ScrollBar1.Position := new;
    Edit1.Text := FloatToStr(ScrollBar1.Position/1000000);
    Edit2.Text := FloatToStr(Cos(ScrollBar1.Position/1000000));
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ScrollBar1.Max := Round(Pi * 4000000);   // 4 * Pi
  end;

  procedure TForm1.ScrollBar1Scroll(Sender: TObject; ScrollCode: TScrollCode;
    var ScrollPos: Integer);
  begin
    Edit1.Text := FloatToStr(ScrollPos/1000000);
    Edit2.Text := FloatToStr(Cos(ScrollPos/1000000));
  end;
  {
  This example illustrates the rules for rounding positive and
  negative real numbers to integers.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
     S, T: string;
  begin
     Str(1.4:2:1, T);
     S := T + ' rounds to ' + IntToStr(Round(1.4)) + #13#10;
     Str(1.5:2:1, T);
     S := S + T + ' rounds to ' + IntToStr(Round(1.5)) + #13#10;
     Str(-1.4:2:1, T);
     S := S + T + ' rounds to ' + IntToStr(Round(-1.4)) + #13#10;
     Str(-1.5:2:1, T);
     S := S + T + ' rounds to ' + IntToStr(Round(-1.5));
     MessageDlg(S, mtInformation, [mbOk], 0, mbOk);
  end;
```

158.3.134 System.RunError Function

Stops execution and generates a runtime error.

Pascal

```
procedure RunError; overload;
procedure RunError(Errorcode: Byte); overload;
```

C++

```
RunError();
RunError(Byte Errorcode);
```

File

System

Description

In Delphi, the RunError procedure stops program execution by generating a runtime error with the given number at the current statement. Errorcode is the runtime error number (0 if omitted).

Delphi Examples:

```
{
This example demonstrates how to set a run error and the behavior of
execution and the message that follows.
}
var P: Pointer;

procedure TForm1.Button1Click(Sender: TObject);
begin
{$IFDEF Debug}
  if P = nil then
    RunError(204);
{$ENDIF}
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  P:= nil;
end;
```

See Also

Halt (see page 22475)

158.3.135 System.Seek Function

Moves the current position of a file to a specified component.

Pascal

```
procedure Seek(var F; N: Longint);
```

C++

```
Seek( F, Longint N);
```

File

System

Description

Use Seek in Delphi code to move to a specified position in open typed or untyped files. The current file position of F moves to component number N, where the number of the first component of a file is 0.

In the above syntax, F is a typed or untyped file variable. The file specified by F must be open. N is an expression of type Longint

To expand a file, seek one component beyond the last component; that is, the statement Seek(F, FileSize (see page 22457)(F)) moves the current file position to the end of the file.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for I/O errors.

Delphi Examples:

```
{
FileSize, Seek, FilePos example
This example displays a open dialog when the user clicks a button. When the user selects the
file, it reports the size of the file, seeks to halfway through the file, and reports the file
position at that point.
Note:   This example assumes the compiler flag $IOCHECKS ON ($I+). That is, it expects errors
to generate exceptions rather than checking IOResult to be sure that I/O routines succeed.
}
procedure TForm1.Button1Click(Sender: TObject);
var
   f: file of Byte;
   size: Longint;
   S: string;
   y: Integer;
begin
  if OpenDialog1.Execute then
  begin
    AssignFile(f, OpenDialog1.FileName);
    Reset(f);
    try
      size := FileSize(f);
      S := 'File size in bytes: ' + IntToStr(size);
      y := 10;
      Canvas.TextOut(5, y, S);
      y := y + Canvas.TextHeight(S) + 5;
      S := 'Seeking halfway into file...';
      Canvas.TextOut(5, y, S);
      y := y + Canvas.TextHeight(S) + 5;
      Seek(f, size div 2);
      S := 'Position is now ' + IntToStr(FilePos(f));
      Canvas.TextOut(5, y, S);
    finally
      CloseFile(f);
    end;
  end;
end;
```

See Also

FilePos (see page 22456)

158.3.136 System.SeekEof Function

Returns the end-of-file status of a file, ignoring whitespace.

Pascal

```
function SeekEof: Boolean; overload;
function SeekEof(var F: Text): Boolean; overload;
```

C++

```
Boolean SeekEof();
Boolean SeekEof(Text F);
```

File

System

Description

In Delphi code, call SeekEof to determine whether there is only whitespace between the file pointer and the end of a file.

SeekEof moves the file pointer past any whitespace, leaving it positioned at the end of a file or on the next non-whitespace character, whichever comes first. If it leaves the file pointer at the end of the file, SeekEof returns true. Otherwise, it returns false.

SeekEof can only be used on open text files.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for I/O errors.

158.3.137 System.SeekEoln Function

Returns the end-of-line status of a file, ignoring whitespace.

Pascal

```
function SeekEoln: Boolean; overload;
function SeekEoln(var F: Text): Boolean; overload;
```

C++

```
Boolean SeekEoln();
Boolean SeekEoln(Text F);
```

File

System

Description

In Delphi code, call SeekEoln to determine whether there is only whitespace between the file pointer and the end of the current line. SeekEoln moves the file pointer past any whitespace, leaving it positioned at the end of the current line, the end of the file, or on the next non-whitespace character (whichever comes first). If SeekEoln leaves the file pointer at the end of the current line or at the end of the file, it returns true. Otherwise, it returns false.

SeekEoln can be used only on open text files.

Note: {$I+} handles runtime errors using exceptions. When using {$I-}, use IOResult (see page 22482) to check for I/O errors.

158.3.138 System.Set8087CW Function

Sets both the control word in the floating point unit and the variable NoErrMsg (see page 22652) declared in the system unit.

Pascal

```
procedure Set8087CW(NewCW: Word);
```

C++

```
Set8087CW(Word NewCW);
```

File

System

Description

The floating-point unit control word controls the precision of floating point calculations, the rounding mode, and whether certain floating-point operations trigger exceptions. See Intel's processor documentation for details.

This routine allows the programmer to have direct access to the CW. Be aware that using this routine to change the value of the 8087CW will change the behavior of the program's FP calculations. It is the programmer's responsibility to reset it.

It is recommended that you disable all floating-point exceptions when using OpenGL to render 3D graphics. To do this, call Set8087CW(0x133f) in your main form's OnCreate event before calling any OpenGL functions.

SetRoundMode

158.3.139 System.SetInOutRes Function

Pascal

```
procedure SetInOutRes(NewValue: Integer);
```

C++

```
SetInOutRes(int NewValue);
```

File

System

Description

This is function System.SetInOutRes.

158.3.140 System.SetLastError Function

SetLastError sets the last API error code.

Pascal

```
procedure SetLastError(ErrorCode: Integer); stdcall;
```

C++

```
__stdcall SetLastError(int ErrorCode);
```

File

System

Description

GetLastError (see page 22469) returns the last API error code encountered. It then resets it to 0. SetLastError forces the API error code to the specified **ErrorCode** value. A call to GetLastError (see page 22469) will then return this value before again resetting the error code to 0.

See Also

GetLastError (see page 22469)

158.3.141 System.SetLength Function

Sets the length of a string or dynamic-array variable.

Pascal

```
procedure SetLength(var S; NewLength: Integer);
```

C++

```
SetLength( S, int NewLength);
```

File

System

Description

S is a Delphi string or dynamic-array variable.

NewLength is the new number of characters or elements in S.

For a short-string variable, SetLength simply sets the length-indicator character (the character at S[0]) to the given value. In this case, NewLength must be a value between 0 and 255.

For a long-string or dynamic-array variable, SetLength reallocates the string or array referenced by S to the given length. Existing characters in the string or elements in the array are preserved, but the content of newly allocated space is undefined. The one exception is when increasing the length of a dynamic array in which the elements are types that must be initialized (strings, Variants (see page 23567), Variant (see page 22307) arrays, or records that contain such types). When S is a dynamic array of types that must be initialized, newly allocated space is set to 0 or nil.

For dynamic arrays, SetLength may take more than one length parameter (up to the number of array dimensions). Each parameter specifies the number of elements along a particular dimension.

Following a call to SetLength, S is guaranteed to reference a unique string or array—that is, a string or array with a reference count of one. If there is not enough memory available to reallocate the variable, SetLength raises an EOutOfMemory exception.

EOutOfMemory

string

IDH

158.3.142 System.SetLineBreakStyle Function

Determines the end-of-line and end-of-file conventions for text file I/O.

Pascal

```
procedure SetLineBreakStyle(var T: Text; Style: TTextLineBreakStyle);
```

C++

```
SetLineBreakStyle(Text T, TTextLineBreakStyle Style);
```

File

System

Description

In Delphi, call SetLineBreakStyle to determine how text file routines find or mark the end of a line and the end of a file. Affected routines include Read (see page 22504), Write (see page 22548), Readln, Writeln, Eof (see page 22449), Eoln (see page 22450), SeekEof (see page 22519), and SeekEoln (see page 22520).

T is the text file whose line break style is altered. It must be closed, or SetLineBreakStyle generates a runtime error.

Style indicates the style to use. When Style is tlbsLF, end-of-line is marked using only a linefeed character. When Style is tlbsCRLF, end-of-line is marked using a carriage return and linefeed.

158.3.143 System.SetMemoryManager Function

Sets entry points of the memory manager.

Pascal

```
procedure SetMemoryManager(const MemMgr: TMemoryManager); overload; deprecated;
procedure SetMemoryManager(const MemMgrEx: TMemoryManagerEx); overload;
```

C++

```
SetMemoryManager(const TMemoryManager MemMgr);
SetMemoryManager(const TMemoryManagerEx MemMgrEx);
```

File

System

Description

SetMemoryManager sets the entry points of the memory manager to the three functions encapsulated by the MemMgr

parameter. Use SetMemoryManager to change the memory allocation routines that are used for:

Allocation and deallocation of dynamic strings and dynamic arrays.

The GetMem (see page 22469), ReallocMem (see page 22507), and FreeMem (see page 22464) standard procedures (Delphi only)

The New (see page 22491) and Dispose (see page 22444) standard procedures (Delphi only).

IsMemorymanagerSet

158.3.144 System.SetMinimumBlockAlignment Function

Sets the minimum memory block alignment.

Pascal

```
procedure SetMinimumBlockAlignment(AMinimumBlockAlignment: TMinimumBlockAlignment);
```

C++

```
SetMinimumBlockAlignment(TMinimumBlockAlignment AMinimumBlockAlignment);
```

File

System

Description

SetMinimumBlockAlignment sets the Memory Manager's minimum block alignment. Existing allocations are not affected if this setting is changed. The memory manager will enforce the new setting for all allocations made after the change.

Memory Management

Configuring the Memory Manager

158.3.145 System.SetMultiByteConversionCodePage Function

SetMultiByteConversionCodePage overrides the default multi byte code conversion page.

Pascal

```
procedure SetMultiByteConversionCodePage(CodePage: Integer);
```

C++

```
SetMultiByteConversionCodePage(int CodePage);
```

File

System

Description

RAD Studion textual elements such as captions are stored as WideStrings. When running under 9x, they are automatically converted to AnsiStrings. This conversion uses, by default, the System (see page 22079) Code Page. SetMultiByteConversionCodePage allows you to specify the **CodePage** that is used in such conversions.

GetLastError (see page 22469)

158.3.146 System.SetRaiseList Function

Pascal

```
function SetRaiseList(NewPtr: Pointer): Pointer; deprecated;
```

C++

```
void * SetRaiseList(void * NewPtr);
```

File

System

Description

This is function System.SetRaiseList.

158.3.147 System.SetString Function

Sets the contents and length of the given string.

Pascal

```
procedure SetString(var s: string; buffer: PChar; len: Integer);
```

C++

```
SetString(AnsiString s, const char * buffer, int len);
```

File

System

Description

In Delphi code, SetString sets the contents and length of the given string variable to the block of characters given by the Buffer and Len parameters.

For a short string variable, SetString sets the length indicator character (the character at S[0]) to the value given by Len and then, if the Buffer parameter is not nil, copies Len characters from Buffer into the string starting at S[1]. For a short string variable, the Len parameter must be a value between 0 and 255.

For a long string variable, SetString sets S to reference a newly allocated string of the given length. If the Buffer parameter is not nil, SetString then copies Len characters from Buffer into the string; otherwise, the contents of the new string is left uninitialized. If there is not enough memory available to create the string, an EOutOfMemory exception is raised. Following a call to SetString, S is guaranteed to reference a unique string, that is a string with a reference count of one.

See Also

EOutOfMemory

string

158.3.148 System.SetTextBuf Function

Assigns an I/O buffer to a text file.

Pascal

```
procedure SetTextBuf(var F: Text; var Buf); overload;
procedure SetTextBuf(var F: Text; var Buf; Size: Integer); overload;
```

C++

```
SetTextBuf(Text F,  Buf);
SetTextBuf(Text F,  Buf, int Size);
```

File

System

Description

In Delphi code, SetTextBuf changes the text file F to use the buffer specified by Buf instead of F's internal buffer. F is a text file variable, Buf is any variable, and Size is an optional expression.

Each Text file variable has an internal 128-byte buffer that buffers Read (see page 22504) and Write (see page 22548) operations. This buffer is adequate for most operations. However, heavily I/O-bound programs benefit from a larger buffer to reduce disk head movement and file system overhead.

Size specifies the size of the buffer in bytes. If Size is omitted, SizeOf (see page 22528)(Buf) is assumed. The new buffer remains in effect until F is next passed to AssignFile (see page 22420).

SetTextBuf can be called immediately after Reset (see page 22511), Rewrite (see page 22513), and Append (see page 22415), but never apply it to an open file.

When SetTextBuf is called on an open file once I/O operations have taken place, data could be lost because of the change of buffer.

The Delphi runtime library does not ensure that the buffer exists for the entire duration of I/O operations on the file. A common error is to install a local variable as a buffer, then use the file outside the procedure that declared the buffer.

Write (see page 22548)

158.3.149 System.SetVariantManager Function

Sets the entry points of routines that define variant behavior.

Pascal

```
procedure SetVariantManager(const VarMgr: TVariantManager); deprecated;
```

C++

```
SetVariantManager(const TVariantManager VarMgr);
```

File

System

Description

SetVariantManager sets the entry points of the routines that perform variant type conversion and define other variant behavior.

Note: Although System.hpp defines the SetVariantManager procedure, do not use this routine in C++ code. Customized Variant (see page 22307) support is not fully supported in C++.

See Also

GetVariantManager (see page 22474)

IsVariantManagerSet (see page 22483)

158.3.150 System.ShareMemoryManager Function

Shares the module's memory manager.

Pascal

```
function ShareMemoryManager: Boolean;
```

C++

```
Boolean ShareMemoryManager();
```

File

System

Description

ShareMemoryManager makes the module's memory manager available for sharing to other modules in the same process. Only one memory manager may be shared per process. It returns **False** if another module in the process is already sharing its memory manager.

Note: This function is not thread safe.

See Also

Memory Management

Configuring the Memory Manager

Sharing Memory

158.3.151 System.Sin Function

Returns the sine of the angle in radians.

Pascal

```
function Sin(const X: Extended): Extended;
```

C++

```
Extended Sin(const Extended X);
```

File

System

Description

In Delphi code, the Sin function returns the sine of the argument.

X is a real-type expression. Sin returns the sine of the angle X in radians.

See Also

ArcTan (see page 22416)

Cos (see page 22440)

158.3.152 System.SizeOf Function

Returns the number of bytes occupied by a variable or type.

Pascal

```
function SizeOf(X): Integer;
```

C++

```
int SizeOf( X);
```

File

System

Description

Pass a Delphi variable reference to SizeOf to determine the number of bytes used to represent the variable. Pass a type identifier to SizeOf to determine the number of bytes used to represent instances of that type. SizeOf is useful for determining the amount of memory to specify for the FillChar (see page 22459), Move (see page 22490), or GetMem (see page 22469) procedures.

SizeOf returns 0 when the argument is an untyped variable.

Delphi Examples:

```
{
This example fills a char array with characters and then
assigns the array to a text edit.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
var
  S: array[0..79] of char;
begin
  { Set to all Xs }
  FillChar(S, SizeOf(S), Ord('X'));
  Edit1.Text := S;
end;
```

See Also

FillChar (see page 22459)

GetMem (see page 22469)

Move (see page 22490)

158.3.153 System.Slice Function

Returns a sub-section of an array.

Pascal

```
function Slice(var A: array; Count: Integer): array;
```

C++

```
array Slice(array A, int Count);
```

File

System

Description

In Delphi code, use Slice to select a sub-section (slice) of an array to be passed as an open array parameter. Slice is only allowed as a parameter in a call to a procedure or function that expects an open array parameter. Slice selects the first Count elements of the array given by A to be passed as an open array parameter. A can be an open array parameter itself, allowing dynamically allocated arrays to be passed to open array parameters.

See Also

SetLength (see page 22522)

IDH

158.3.154 System.Sqr Function

Returns the square of a number.

Pascal

```
function Sqr(X: Extended): Extended; overload;
function Sqr(X: Integer): Integer; overload;
```

C++

```
Extended Sqr(Extended X);
int Sqr(int X);
```

File

System

Description

In Delphi code, the Sqr function returns the square of the argument.

X is a floating-point expression. The result, of the same type as X, is the square of X, or X*X.

See Also

Sqrt (see page 22530)

Power

158.3.155 System.Sqrt Function

Returns the square root of X.

Pascal

```
function Sqrt(const X: Extended): Extended;
```

C++

```
Extended Sqrt(const Extended X);
```

File

System

Description

X is a Delphi floating-point expression. The result is the square root of X.

See Also

Sqr (see page 22529)

158.3.156 System.Str Function

Formats a string and returns it to a variable.

Pascal

```
procedure Str(X: Width; var S); overload;
procedure Str(X: Decimals; var S); overload;
```

C++

```
Str(Width X,  S);
Str(Decimals X,  S);
```

File

System

Description

In Delphi code, Str converts X to a string representation according to the Width and Decimals formatting parameters. The effect is like a call to Write (see page 22548) except the resulting string is stored in S instead of being written to a text file.

X is an integer-type or real-type expression. Width and Decimals are integer-type expressions. S is a string-type variable or a zero-based character array variable if extended syntax is enabled.

See Also

Write (see page 22548)

158.3.157 System.StringOfChar Function

Returns a string with a specified number of repeating characters.

Pascal

```
function StringOfChar(ch: AnsiChar; Count: Integer): AnsiString; overload;
function StringOfChar(ch: WideChar; Count: Integer): WideString; overload;
```

C++

```
AnsiString StringOfChar(AnsiChar ch, int Count);
BSTR StringOfChar(WideChar ch, int Count);
```

File

System

Description

In Delphi code, StringOfChar returns a string containing Count characters with the character value given by Ch. For example,

S := StringOfChar('A', 10);

sets S to the string 'AAAAAAAAAA'.

See Also

FillChar (see page 22459)

DupeString

158.3.158 System.StringToOleStr Function

Allocates memory and copies an AnsiStringa string to the OLE format.

Pascal

```
function StringToOleStr(const Source: string): PWideChar;
```

C++

```
PWideChar StringToOleStr(const AnsiString Source);
```

File

System

Description

StringToOleStr allocates memory and copies string data from a native AnsiString (see page 22093) into a format that can be passed to OLE functions.

See Also

OleStrToString (see page 22493)

OleStrToStrVar (see page 22494)

StringToWideChar (see page 22532)

158.3.159 System.StringToWideChar Function

Returns a UNICODE string from an AnsiString (see page 22093).

Pascal

```
function StringToWideChar(const Source: string; Dest: PWideChar; DestSize: Integer): PWideChar;
```

C++

```
PWideChar StringToWideChar(const AnsiString Source, PWideChar Dest, int DestSize);
```

File

System

Description

StringToWideChar converts a string from ANSI to UNICODE and stores the result in a specified buffer.

Source is the string to convert. It must include at most DestSize – 1 characters.

Dest is the buffer into which StringToWideChar writes the corresponding UNICODE string. The caller allocates this memory to include at least DestSize wide characters. Following the call, Dest contains at most DestSize - 1 characters, terminated by a NULL wide character.

DestSize is the size of the buffer Dest.

StringToWideChar returns a pointer to Dest.

See Also

WideCharToString (see page 22547)

WideCharLenToString (see page 22546)

WideCharToStrVar (see page 22547)

WideCharlenToStrVar

158.3.160 System.Succ Function

Returns the successor of an argument.

Pascal

```
procedure Succ(X);
```

C++

```
Succ( X);
```

File

System

Description

In Delphi code, Succ returns the successor of the argument, X.

X is an expression of an ordinal type (including Int64). The result, of the same type as X, is the successor of X.

Delphi Examples:

```
{
This example demonstrates how Pred and Succ can be used to
manage enumerations.
}
procedure TForm1.Button1Click(Sender: TObject);
type
  Colors = (RED,BLUE,GREEN);
var
  S: string;
begin
  S := 'The predecessor of 5 is ' + IntToStr(Pred(5)) + #13#10;
  S := S + 'The successor of 10 is ' + IntToStr(Succ(10)) + #13#10;
  if Succ(RED) = BLUE then
    S := S + 'In the type Colors, RED is the predecessor of BLUE.';
  MessageDlg(S, mtInformation, [mbOk], 0, mbOk);
end;
```

See Also

Pred (see page 22499)

158.3.161 System.Swap Function

Exchanges high order byte with the low order byte of an integer or word.

Pascal

```
procedure Swap(X);
```

C++

```
Swap( X);
```

File

System

Description

In Delphi code, Swap exchanges the high-order bytes with the low-order bytes of the argument. X is an expression of type SmallInt, as a 16-bit value, or Word. This is provided for backward compatibility only.

See Also

Hi (see page 22476)

Lo (see page 22486)

158.3.162 System.SysAllocMem Function

Pascal

```
function SysAllocMem(Size: Cardinal): Pointer;
```

C++

```
void * SysAllocMem(unsigned Size);
```

File

System

Description

This is function System.SysAllocMem.

158.3.163 System.SysFreeMem Function

Frees the memory pointed to by a specified pointer.

Pascal

```
function SysFreeMem(P: Pointer): Integer;
```

C++

```
int SysFreeMem(void * P);
```

File

System

Description

When implementing a custom memory manager, use SysFreeMem to free the memory pointed to by the P parameter.

Note: On Windows, the System (see page 22079) unit provides a limited implementation of SysFreeMem. If the custom memory manager needs to support reference counting and objects that can be shared between processes, use the implementation of SysFreeMem provided by the ShareMem unit. When used, ShareMem must be the first unit in the project file, to enforce a consistent memory management model.

Note: On Linux, the System (see page 22079) unit provides an implementation of SysFreeMem that supports reference counting and shared objects. The ShareMem unit is not provided for Linux.

See Also

GetHeapStatus (see page 22468)

SysGetMem (see page 22534)

SetMemoryManager (see page 22523)

158.3.164 System.SysGetMem Function

Allocates a specified number of bytes and returns a pointer to them.

Pascal

```
function SysGetMem(Size: Integer): Pointer;
```

C++

```
void * SysGetMem(int Size);
```

File

System

Description

When implementing a custom memory manager, use SysGetMem to dynamically allocate Size bytes of memory.

Note: On Windows, the System (see page 22079) unit provides a limited implementation of SysGetMem. If the custom memory manager needs to support reference counting and objects that can be shared between processes, use the implementation of SysGetMem provided by the ShareMem unit. When used, ShareMem must be the first unit in the project file, to enforce a consistent memory management model.

Note: On Linux, the System (see page 22079) unit provides an implementation of SysGetMem that supports reference counting and shared objects. The ShareMem unit is not provided for Linux.

See Also

SysFreeMem (see page 22534)

SysReallocMem (see page 22535)

SetMemoryManager (see page 22523)

158.3.165 System.SysReallocMem Function

Returns a pointer to a specified number of bytes, preserving the values pointed to by the Pointer parameter.

Pascal

```
function SysReallocMem(P: Pointer; Size: Integer): Pointer;
```

C++

```
void * SysReallocMem(void * P, int Size);
```

File

System

Description

When implementing a custom memory manager, use SysReallocMem to change the size of a dynamically allocated chunk of memory. If SysReallocMem can't expand the memory block point to by P, it frees the referenced memory and copies the values to the newly allocated memory that is returned. If Size is less than the number of bytes pointed to by P, only the first Size bytes are preserved. Otherwise, the entire value of the memory pointed to by P is preserved in the newly allocated memory.

Note: On Windows, the System (see page 22079) unit provides a limited implementation of SysReallocMem. If the custom memory manager needs to support reference counting and objects that can be shared between processes, use the implementation of SysReallocMem provided by the ShareMem unit. When used, ShareMem must be the first unit in the project file, to enforce a consistent memory management model.

Note: On Linux, the System (see page 22079) unit provides an implementation of SysReallocMem that supports reference counting and shared objects. The ShareMem unit is not provided for Linux.

SysFreeMem (see page 22534)

SysGetMem (see page 22534)

SetMemoryManager (see page 22523)

158.3.166 System.SysRegisterExpectedMemoryLeak Function

Pascal

```
function SysRegisterExpectedMemoryLeak(P: Pointer): Boolean;
```

C++

```
Boolean SysRegisterExpectedMemoryLeak(void * P);
```

File

System

Description

This is function System.SysRegisterExpectedMemoryLeak.

158.3.167 System.SysUnregisterExpectedMemoryLeak Function

Pascal

```
function SysUnregisterExpectedMemoryLeak(P: Pointer): Boolean;
```

C++

```
Boolean SysUnregisterExpectedMemoryLeak(void * P);
```

File

System

Description

This is function System.SysUnregisterExpectedMemoryLeak.

158.3.168 System.TextStart Function

Pascal

```
procedure TextStart; deprecated;
```

C++

```
TextStart();
```

File

System

Description

This is function System.TextStart.

158.3.169 System.Trunc Function

Truncates a real number to an integer.

Pascal

```
function Trunc(X: Extended): Int64;
```

C++

```
Int64 Trunc(Extended X);
```

File

System

Description

In Delphi code, the Trunc function truncates a real-type value to an integer-type value. X is a real-type expression. Trunc returns an Int64 value that is the value of X rounded toward zero.

If the truncated value of X is not within the Int64 range, an EInvalidOp exception is raised.

See Also

Int (see page 22481)

Round (see page 22516)

Floor (see page 15945)

Ceil (see page 15937)

158.3.170 System.Truncate Function

Deletes all the records after the current file position.

Pascal

```
procedure Truncate(var F);
```

C++

```
Truncate( F);
```

File

System

Description

In Delphi code, Call Truncate to cause the current file position to become end-of-file (Eof (see page 22449)(F) is true).

F is a file variable of any type except a text file. Truncate does not work on text files. F must be open.

See Also

Reset (see page 22511)

Rewrite (see page 22513)

Seek (see page 22518)

158.3.171 System.UCS4StringToWideString Function

Converts a string of 4-byte Unicode characters into a WideString (see page 22377) value.

Pascal

```
function UCS4StringToWideString(const S: UCS4String): WideString;
```

C++

```
BSTR UCS4StringToWideString(const UCS4String S);
```

File

System

Description

Call UCS4StringToWideString to convert a string of UCS4 (4-byte Unicode) characters into a WideString (see page 22377) value. UCS4 strings are returned by some Linux operating system calls.

See Also

WideStringToUCS4String (see page 22548)

PUCS4Chars (see page 22501)

UnicodeToUtf8 (see page 22538)

Utf8ToUnicode (see page 22542)

158.3.172 System.UnicodeToUtf8 Function

Converts a string of Unicode characters into a UTF-8 string.

Pascal

```
function UnicodeToUtf8(Dest: PChar; Source: PWideChar; MaxBytes: Integer): Integer; overload;
deprecated;
function UnicodeToUtf8(Dest: PChar; MaxDestBytes: Cardinal; Source: PWideChar; SourceChars:
Cardinal): Cardinal; overload;
```

C++

```
int UnicodeToUtf8(const char * Dest, PWideChar Source, int MaxBytes);
unsigned UnicodeToUtf8(const char * Dest, unsigned MaxDestBytes, PWideChar Source, unsigned
SourceChars);
```

File

System

Description

Call UnicodeToUtf8 to convert a Unicode string to a null-terminated sequence of UTF-8 characters. Use the second syntax. The deprecated syntax is included only for backward compatibility.

Dest receives the resulting null-terminated array of UTF-8 characters.

MaxDestBytes or MaxBytes indicates the number of bytes available in the buffer specified by Dest, including the byte for the null terminator.

Source is an array of Unicode characters.

SourceChars is the number of characters in Source. If SourceChars is not specified, Source must be null-terminated.

UnicodeToUtf8 returns the number of bytes written to Dest.

See Also

UCS4StringToWideString (see page 22538)

Utf8ToUnicode (see page 22542)

Utf8Encode

Utf8Decode

UTF8String (see page 22627)

158.3.173 System.UniqueString Function

Ensures that a given string has a reference count of one.

Pascal

```
procedure UniqueString(var str: AnsiString); overload;
procedure UniqueString(var str: WideString); overload;
```

C++

```
UniqueString(AnsiString str);
UniqueString(BSTR str);
```

File

System

Description

UniqueString forces the reference count on an AnsiString (see page 22093) to one, copying the string in memory if necessary. For normal string handling, there is no need to call UniqueString. UniqueString is used only in cases where an application modifies the contents of a string after

Note: casting the string to a PChar or PWideChar in Delphi.

Note: using the c_str() method of AnsiString (see page 22093) or the c_bstr() method of WideString (see page 22377) in C++.

See Also

SetString (see page 22525)

SetLength (see page 22522)

158.3.174 System.UnregisterExpectedMemoryLeak Function

Unregisters an expected memory leak.

Pascal

```
function UnregisterExpectedMemoryLeak(P: Pointer): boolean;
```

C++

```
boolean UnregisterExpectedMemoryLeak(void * P);
```

File

System

Description

UnregisterExpectedMemoryLeak removes a memory location from the Memory Manager's list of expected memory leaks.

See Also

Memory Management

Configuring the Memory Manager

Registering Memory Leaks

RegisterExpectedMemoryLeak (see page 22508)

ReportMemoryLeakOnShutdown

158.3.175 System.UnregisterModule Function

Pascal

```
procedure UnregisterModule(LibModule: PLibModule);
```

C++

```
UnregisterModule(PLibModule LibModule);
```

File

System

Description

This is function System.UnregisterModule.

158.3.176 System.UpCase Function

Converts a character to uppercase.

Pascal

```
function UpCase(Ch: Char): Char;
```

C++

```
Char UpCase(Char Ch);
```

File

System

Description

UpCase converts a character to uppercase. Ch is an expression of type Char. Character values not in the range a..z are unaffected.

See Also

AnsiUpperCase

StrUpper

UpperCase

158.3.177 System.UTF8Decode Function

Converts a UTF8 string to a Unicode string (WideString (see page 22377)).

Pascal

```
function UTF8Decode(const S: UTF8String): WideString;
```

C++

```
BSTR UTF8Decode(const UTF8String S);
```

File

System

Description

Call UTF8Decode to convert a UTF-8 string to Unicode. S is a string encoded in UTF-8. UTF8Decode returns the corresponding WideString (see page 22377) value that represents the string in Unicode.

See Also

UnicodeToUtf8 (see page 22538)

UTF8Encode (see page 22541)

Utf8ToUnicode (see page 22542)

Utf8ToAnsi (see page 22542)

AnsiToUtf8 (see page 22415)

158.3.178 System.UTF8Encode Function

Converts a WideString (see page 22377) value to a UTF8 string.

Pascal

```
function UTF8Encode(const WS: WideString): UTF8String;
```

C++

```
UTF8String UTF8Encode(const BSTR WS);
```

File

System

Description

Call Utf8Encode to convert a Unicode string to UTF-8. WS is the Unicode string to convert. Utf8Encode returns the corresponding UTF-8 string.

See Also

UnicodeToUtf8 (see page 22538)

UTF8Decode (see page 22541)

Utf8ToUnicode (see page 22542)

158.3.179 System.Utf8ToAnsi Function

Converts a UTF8 string to a string of Ansi characters.

Pascal

```
function Utf8ToAnsi(const S: UTF8String): string;
```

C++

```
AnsiString Utf8ToAnsi(const UTF8String S);
```

File

System

Description

Call Utf8ToAnsi to convert a UTF-8 string to Ansi. S is a string encoded in UTF-8. Utf8ToAnsi returns the corresponding string that uses the Ansi character set.

See Also

UnicodeToUtf8 (see page 22538)

Utf8Encode

Utf8ToUnicode (see page 22542)

Utf8Decode

AnsiToUtf8 (see page 22415)

158.3.180 System.Utf8ToUnicode Function

Converts a string of UTF-8 characters to a Unicode string.

Pascal

```
function Utf8ToUnicode(Dest: PWideChar; Source: PChar; MaxChars: Integer): Integer; overload;
deprecated;
function Utf8ToUnicode(Dest: PWideChar; MaxDestChars: Cardinal; Source: PChar; SourceBytes:
Cardinal): Cardinal; overload;
```

C++

```
int Utf8ToUnicode(PWideChar Dest, const char * Source, int MaxChars);
unsigned Utf8ToUnicode(PWideChar Dest, unsigned MaxDestChars, const char * Source, unsigned
```

```
SourceBytes);
```

File

System

Description

Call Utf8ToUnicode to convert a UTF-8 string to Unicode. Use the second syntax. The deprecated syntax is provided for backward compatibility only.

Dest receives the resulting null-terminated array of Unicode characters.

MaxDestChars or MaxChars indicates the maximum number of Unicode characters that the buffer specified by Dest can hold, not counting the null terminator.

Source is an array of UTF-8 characters.

SourceBytes is the number of bytes in Source. If SourceBytes is not specified, Source must be null-terminated.

Utf8ToUnicode returns the number of characters written to Dest.

In case of errors, the Utf8ToUnicode ... : Cardinal variant returns `Cardinal(-1) == $FFFFFFFF` and the Utf8ToUnicode ... : Integer returns `-1`.

See Also

UCS4StringToWideString (see page 22538)

UnicodeToUtf8 (see page 22538)

Utf8Encode

Utf8Decode

UTF8String (see page 22627)

158.3.181 System.Val Function

Converts a string to a numeric representation.

Pascal

```
procedure Val(S; var V; var Code: Integer);
```

C++

```
Val( S,  V, int Code);
```

File

System

Description

In Delphi code, Val converts the string value S to its numeric representation, as if it were read from a text file with Read (see page 22504).

S is a string-type expression; it must be a sequence of characters that form a signed real number.

V is an integer-type or real-type variable. If V is an integer-type variable, S must form a whole number.

Code is a variable of type Integer.

If the string is invalid, the index of the offending character is stored in Code; otherwise, Code is set to zero. For a null-terminated

string, the error position returned in Code is one larger than the actual zero-based index of the character in error.

See Also

Str (see page 22530)

158.3.182 System.VarArrayRedim Function

Resizes a Variant (see page 22307) array.

Pascal

```
procedure VarArrayRedim(A: Variant; HighBound: Integer);
```

C++

```
VarArrayRedim(Variant A, int HighBound);
```

File

System

Description

VarArrayRedim resizes the given Variant (see page 22307) array by changing the high bound of the rightmost dimension to the given value. The A parameter can be a Variant (see page 22307) or an OleVariant (see page 22193), and it must be possible to assign a value to A (A must be an lvalue).

Existing elements of the array are preserved, and new elements are set to zero or empty. An EVariantArrayCreateError exception is thrown if the Variant (see page 22307) given by A is not an array, or if there is not enough memory to resize the array.

Note: A Variant (see page 22307) array can't be resized while it is locked.

See Also

VarArrayCreate

VarArrayLock

EVariantArrayCreateError

158.3.183 System::VarArrayRedim Function

Pascal

```
procedure VarArrayRedim(var a: Variant; high: Integer);
```

C++

```
__fastcall void VarArrayRedim(Variant& a, int high);
```

File

sysvari.h

Description

This is function System::VarArrayRedim.

158.3.184 System::VarCast Function

Pascal

```
procedure VarCast(var dest: Variant; const source: Variant&; type: Integer);
```

C++

```
__fastcall void VarCast(Variant & dest, const Variant& source, int type);
```

File

sysvari.h

Description

This is function System::VarCast.

158.3.185 System.VarClear Function

Empties a Variant (see page 22307), so that it is unassigned.

Pascal

```
procedure VarClear(V: Variant);
```

C++

```
VarClear(Variant V);
```

File

System

Description

Calling VarClear is equivalent to assigning the Unassigned constant to the Variant (see page 22307). V can be either a Variant (see page 22307) or an OleVariant (see page 22193), but it must be possible to assign a value to it (it must be an lvalue).

After calling VarClear, the VarIsEmpty function returns true, and the VarType function returns varEmpty (see page 22683). Using an unassigned variant in an expression causes an exception to be thrown. Likewise, if you attempt to convert an unassigned Variant (see page 22307) to another type (using VarAsType), an exception is thrown.

Note: Do not confuse clearing a Variant (see page 22307), which leaves it unassigned, with assigning a Null value. A Null Variant (see page 22307) is still assigned, but has the value Null. Unlike unassigned Variants (see page 23567), Null Variants (see page 23567) can be used in expressions and can be converted to other types of Variants (see page 23567).

See Also

Unassigned

VarIsEmpty

VarAsType

VarType

158.3.186 System::VarClear Function

Pascal

```
procedure VarClear(var v: Variant);
```

C++

```
__fastcall void VarClear(Variant& v);
```

File

sysvari.h

Description

This is function System::VarClear.

158.3.187 System.WideCharLenToString Function

Converts Unicode characters to single or multi byte character data.

Pascal

```
function WideCharLenToString(Source: PWideChar; SourceLen: Integer): string;
```

C++

```
AnsiString WideCharLenToString(PWideChar Source, int SourceLen);
```

File

System

Description

WideCharLenToString converts SourceLen Unicode characters from the buffer given by Source to a string made up of single or multi byte characters.

See Also

StringToWideChar (see page 22532)

WideCharToString (see page 22547)

158.3.188 System.WideCharLenToStrVar Function

WideCharLenToStrVar converts Unicode characters to single or multi byte character data.

Pascal

```
procedure WideCharLenToStrVar(Source: PWideChar; SourceLen: Integer; var Dest: string);
```

C++

```
WideCharLenToStrVar(PWideChar Source, int SourceLen, AnsiString Dest);
```

File

System

Description

The WideCharToStrVar (see page 22547) procedure converts SourceLen WideChar (Unicode) characters from Source into single or multi byte character data, and copies the result into Dest.

See Also

WideCharToString (see page 22547)

158.3.189 System.WideCharToString Function

Converts null-terminated Unicode string to single or multi byte character data.

Pascal

```
function WideCharToString(Source: PWideChar): string;
```

C++

```
AnsiString WideCharToString(PWideChar Source);
```

File

System

Description

WideCharToString converts the given null-terminated Unicode string to a string made up of single- or multi-byte characters.

See Also

StringToWideChar (see page 22532)

WideCharLenToString (see page 22546)

158.3.190 System.WideCharToStrVar Function

Converts Unicode string to a single or multi byte character data.

Pascal

```
procedure WideCharToStrVar(Source: PWideChar; var Dest: string);
```

C++

```
WideCharToStrVar(PWideChar Source, AnsiString Dest);
```

File

System

Description

WideCharToStrVar converts UNICODE string Source into single or multi byte character data, and copies the result into Dest. The source must be null-terminated.

See Also

WideCharToString (see page 22547)

158.3.191 System.WideStringToUCS4String Function

Converts a WideString (see page 22377) value to a string of 4-byte Unicode characters.

Pascal

```
function WideStringToUCS4String(const S: WideString): UCS4String;
```

C++

```
UCS4String WideStringToUCS4String(const BSTR S);
```

File

System

Description

Call WideStringToUCS4String to convert a WideString (see page 22377) value to a string of UCS4 (4-byte Unicode) characters. UCS4 strings are used by some Linux operating system calls.

158.3.192 System.Write Function

Writes to either a typed file or a text file

Pascal

```
procedure Write(P1); overload;
procedure Write(P1; Pn); overload;
procedure Write(var F: Text; P1); overload;
procedure Write(var F: Text; P1; Pn); overload;
```

C++

```
Write( P1);
Write( P1,  Pn);
Write(Text F,  P1);
Write(Text F,  P1,  Pn);
```

File

System

Description

The syntax shown here for the Write procedure is an example that illustrates that Write can take a variable number of arguments.

Write procedure for typed files:

In Delphi code, Write writes a file to a file component. F is a file variable, and each V is a variable of the same type as the component type of F. For each variable written, the current file position is advanced to the next component. If the current file position is at the end of the file (that is, if Eof (see page 22449)(F) is true), the file is expanded.

Write procedure for text files:

In Delphi code, Write writes one or more values to a text file. F, if specified, is a text file variable. If F is omitted, the standard file

variable Output (see page 22653) is assumed. Each P is a write parameter. Each write parameter includes an output expression whose value is to be written to the file. A write parameter can also contain the specifications of a field width and a number of decimal places. Each output expression must be of a type Char, one of the Integer types (Byte, Shortint, Word, Longint, Cardinal), one of the floating-point types (Single, Real, Double, Extended, Currency (see page 22145)), one of the string types (PChar, AnsiString (see page 22093), ShortString), a packed string, or one of the Boolean types (Boolean, Bool).

A write parameter has the form:

```
OutExpr [: MinWidth [: DecPlaces ] ]
```

where OutExpr is an output expression. MinWidth and DecPlaces are type integer expressions.

MinWidth specifies the minimum field width, which must be greater than 0. Exactly MinWidth characters are written (using leading blanks if necessary) except when OutExpr has a value that must be represented in more than MinWidth characters. In that case, enough characters are written to represent the value of OutExpr. Likewise, if MinWidth is omitted, then the necessary number of characters is written to represent the value of OutExpr.

DecPlaces specifies the number of decimal places in a fixed-point representation of one of the Real types. It can be specified only if OutExpr is one of the Real types, and if MinWidth is also specified. When MinWidth is specified, it must be greater than or equal to 0.

Write with a character-type value: If MinWidth is omitted, the character value of OutExpr is written to the file. Otherwise, MinWidth - 1 blanks followed by the character value of OutExpr is written.

Write with one of the integer type values: If MinWidth is omitted, the decimal representation of OutExpr is written to the file with no preceding blanks. If MinWidth is specified and its value is larger than the length of the decimal string, enough blanks are written before the decimal string to make the field width MinWidth.

Write with one of the real type values: If OutExpr has one of the real type values, its decimal representation is written to the file. The format of the representation depends on the presence or absence of DecPlaces. If DecPlaces is omitted (or if it's present but has a negative value), a floating-point decimal string is written. If MinWidth is also omitted, a default MinWidth of 17 is assumed; otherwise, if MinWidth is less than 8, it's assumed to be 8. The format of the floating-point string is:

```
[   | - ] <digit> . <decimals> E [ + | - ] <exponent>
```

The following table lists the components of the output string.

Component	Meaning
[| —]	" “ or “-”l, according to the sign of OutExpr
<digit>	Single digit, “0” only if OutExpr is 0
<decimals>	Digit string of MinWidth-7 (but at most 10) digits
E	Uppercase [E] character
[+ | —]	According to the sign of the exponent
<exponent>	Two-digit decimal exponent

If DecPlaces is present, a fixed-point decimal string is written. If DecPlaces is larger than 11, it's assumed to be 11. The format of the fixed-point string follows:

```
 [<blanks>] [ - ] <digits> [.<decimals>]
```

The following table lists the components of the fixed-point string:

Component	Meaning
[<blanks>	Blanks to satisfy MinWidth
[-]	If OutExpr is negative
<digits>	At least one digit, but no leading zeros

[.<decimals>]	Decimals if DecPlaces > 0

Write with one of the string-type values: If MinWidth is omitted, the string value of OutExpr is written to the file with no leading blanks. If MinWidth is specified, and its value is larger than the length of OutExpr, enough blanks are written before the decimal string to make the field width MinWidth.

Write with a packed string-type value: If OutExpr is of packed string type, the effect is the same as writing a string whose length is the number of elements in the packed string type.

Write with one of the Boolean type values: If OutExpr is of type Boolean, the effect is the same as writing the strings true or false, depending on the value of OutExpr.

Note: When using Write the file must be open for output.

Delphi Examples:

```
{
This example reads a file one character at a time and writes
it into a file of your chosing.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F1, F2: TextFile;
  Ch: Char;
begin
  if OpenDialog1.Execute then begin
    AssignFile(F1, OpenDialog1.Filename);
    Reset(F1);
    if SaveDialog1.Execute then begin
      AssignFile(F2, SaveDialog1.Filename);
      Rewrite(F2);
      while not Eof(F1) do
      begin
        Read(F1, Ch);
        Write(F2, Ch);
      end;
      CloseFile(F2);
    end;
    CloseFile(F1);
  end;
end;
```

See Also

WriteLn (see page 22550)

158.3.193 System.WriteLn Function

Writes to a text file and adds an end-of-line marker.

Pascal

```
procedure WriteLn(P1); overload;
procedure WriteLn(P1; Pn); overload;
procedure WriteLn(var F: Text; P1); overload;
procedure WriteLn(var F: Text; P1; Pn); overload;
```

C++

```
WriteLn( P1);
WriteLn( P1,  Pn);
```

```
WriteLn(Text F,  P1);
WriteLn(Text F,  P1,  Pn);
```

File

System

Description

WriteLn is an extension to the Write (see page 22548) procedure, as it is defined for text files.

The syntax shown here for the WriteLn procedure is an example that illustrates that WriteLn can take a variable number of arguments.

After executing Write (see page 22548), WriteLn writes an end-of-line marker (line feed or carriage return/line feed) to the file.

If F is omitted, the global variable Output (see page 22653) is used, which accesses the processes standard input file. Use of Output (see page 22653) in GUI applications raises special issues.

Delphi Examples:

```
{
This example assumes you are compiling as a console
application.  Notice how the form deactivates when the button
click procedure exits.
}

{$APPTYPE CONSOLE}

procedure TForm1.Button1Click(Sender: TObject);
var
  s : string;
begin
  Write('Enter a line of text: ');
  Readln(s);
  Writeln('You typed: ',s);
  Writeln('Hit <Enter> to exit');
  Readln;
end;
```

Output (see page 22653)

158.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TChunkStatus (see page 22554)	TChunkStatus enumerates the possible states of a chunk of memory.
	TMinimumBlockAlignment (see page 22566)	TMinimumBlockAlignment defines the mimimum byte alignment for memory block allocation.
	TRuntimeError (see page 22567)	This is record System.TRuntimeError.
	TTextLineBreakStyle (see page 22569)	TTextLineBreakStyle indicates the default set of characters used to divide lines in text.

Records

	Name	Description
	PackageInfoTable (see page 22553)	This is record System.PackageInfoTable.
	PackageUnitEntry (see page 22553)	This is record System.PackageUnitEntry.
	TCallDesc (see page 22553)	TCallDesc is the dispatch call descriptor for variants, and PCallDesc (see page 22588) is a pointer to this descriptior.
	TCVModInfo (see page 22555)	This is record System.TCVModInfo.
	TDispatchMessage (see page 22555)	This is record System.TDispatchMessage.
	TDispDesc (see page 22556)	This is record System.TDispDesc.
	TDynArrayTypeInfo (see page 22556)	This is record System.TDynArrayTypeInfo.
	TFileRec (see page 22557)	TFileRec is the internal format for typed and untyped files in the Delphi language.
	TGUID (see page 22558)	TGUID is a structured form of the value that uniquely identifies an interface.
	THeapStatus (see page 22558)	THeapStatus represents information about the global heap.
	TInitContext (see page 22560)	This is record System.TInitContext.
	TInterfaceEntry (see page 22560)	This is record System::TInterfaceEntry.
	TInterfaceTable (see page 22561)	This is record System::TInterfaceTable.
	TLibModule (see page 22561)	TLibModule describes a module that is compiled with the application.
	TMemoryManager (see page 22562)	TMemoryManager defines the memory block entry points.
	TMemoryManagerEx (see page 22563)	TMemoryManagerEx defines extended memory block entry points.
	TMemoryManagerState (see page 22564)	TMemoryManagerState holds statistics about memory allocations.
	TMethod (see page 22565)	TMethod stores Code and Data fields to represent a method.
	TModuleUnloadRec (see page 22566)	This is record System.TModuleUnloadRec.
	TResStringRec (see page 22567)	This is record System.TResStringRec.
	TSmallBlockTypeState (see page 22568)	TSmallBlockTypeState holds statistics about a small memory block.
	TTextRec (see page 22569)	TTextRec is the internal format for text files.
	TVarArray (see page 22570)	This is record System.TVarArray.
	TVarArrayBound (see page 22571)	This is record System.TVarArrayBound.
	TVarData (see page 22571)	TVarData represents Variant (see page 22307) information.
	TVariantManager (see page 22575)	TVariantManager defines entry points for variant conversion routines and other procedures that define variant behavior.
	TVarRec (see page 22577)	This is class System::TVarRec.

Structures

Name	Description
TCallDesc (see page 22578)	This is type System::TCallDesc.
TDispDesc (see page 22578)	This is type System::TDispDesc.

158.4.1 System.PackageInfoTable Record

Pascal

```
PackageInfoTable = packed record
  UnitCount: Integer;
  UnitInfo: PUnitEntryTable;
end;
```

C++

```
struct PackageInfoTable {
  int UnitCount;
  PUnitEntryTable UnitInfo;
};
```

File

System

Description

This is record System.PackageInfoTable.

158.4.2 System.PackageUnitEntry Record

Pascal

```
PackageUnitEntry = packed record
  FInit: Pointer;
  Init: Pointer;
end;
```

C++

```
struct PackageUnitEntry {
  void * FInit;
  void * Init;
};
```

File

System

Description

This is record System.PackageUnitEntry.

158.4.3 System.TCallDesc Record

TCallDesc is the dispatch call descriptor for variants, and PCallDesc (see page 22588) is a pointer to this descriptior.

Pascal

```
TCallDesc = packed record
  CallType: Byte;
  ArgCount: Byte;
```

```
    NamedArgCount: Byte;
    ArgTypes: array[0..255] of Byte;
  end;
```

C++

```
  struct TCallDesc {
    Byte CallType;
    Byte ArgCount;
    Byte NamedArgCount;
    array[0..255] of Byte ArgTypes;
  };
```

File

System

Description

TCallDesc identifies a method call that was made using a Variant (see page 22307).

CallType identifies the method that was called.

ArgCount indicates the total number of arguments passed to the method.

NamedArgCount

ArgTypes is an array giving the type codes for each argument.

See Also

PCallDesc (see page 22588)

158.4.4 System.TChunkStatus Enumeration

TChunkStatus enumerates the possible states of a chunk of memory.

Pascal

```
  TChunkStatus = (
    csUnallocated,
    csAllocated,
    csReserved,
    csSysAllocated,
    csSysReserved
  );
```

C++

```
  enum TChunkStatus {
    csUnallocated,
    csAllocated,
    csReserved,
    csSysAllocated,
    csSysReserved
  };
```

File

System

Description

GetMemoryMap (see page 22473) returns a map of the address space of the current process. For the purposes of the map, the entire 4GB address space is broken down into 64K chunks. There are 65536 such chunks. TMemoryMap (see page 22617) obtains a TChunkStatus status value for each of them in the TMemoryMap (see page 22617) array. TChunkStatus

defines the following values :

Status value	Meaning
csUnallocated	Free
csAllocated	In use by the process
csReserved	Reserved for future use by the process
csSysAllocated	In use by the operating system
csSysReserved	Reserved for future use by the operating system

See Also

GetMemoryMap (see page 22473)

TMemoryMap (see page 22617)

158.4.5 System.TCVModInfo Record

Pascal

```
TCVModInfo = packed record
  ModName: PChar;
  LibName: PChar;
  UserData: Pointer;
end;
```

C++

```
struct TCVModInfo {
  const char * ModName;
  const char * LibName;
  void * UserData;
};
```

File

System

Description

This is record System.TCVModInfo.

158.4.6 System.TDispatchMessage Record

Pascal

```
TDispatchMessage = record
  MsgID: Word;
end;
```

C++

```
struct TDispatchMessage {
  Word MsgID;
};
```

File

System

Description

This is record System.TDispatchMessage.

158.4.7 System.TDispDesc Record

Pascal

```
TDispDesc = packed record
  DispID: Integer;
  ResType: Byte;
  CallDesc: TCallDesc;
end;
```

C++

```
struct TDispDesc {
  int DispID;
  Byte ResType;
  TCallDesc CallDesc;
};
```

File

System

Description

This is record System.TDispDesc.

158.4.8 System.TDynArrayTypeInfo Record

Pascal

```
TDynArrayTypeInfo = packed record
  kind: Byte;
  name: string[0];
  elSize: Longint;
  elType: ^PDynArrayTypeInfo;
  varType: Integer;
end;
```

C++

```
struct TDynArrayTypeInfo {
  Byte kind;
  string[0] name;
  Longint elSize;
  ^PDynArrayTypeInfo elType;
  int varType;
};
```

File

System

Description

This is record System.TDynArrayTypeInfo.

158.4.9 System.TFileRec Record

TFileRec is the internal format for typed and untyped files in the Delphi language.

Pascal

```
TFileRec = packed record
  Handle: Integer;
  Mode: Word;
  Flags: Word;
  case Byte of
    0: (RecSize: Cardinal;);
    1: (BufSize: Cardinal;
        BufPos: Cardinal;
        BufEnd: Cardinal;
        BufPtr: PChar;
        OpenFunc: Pointer;
        InOutFunc: Pointer;
        FlushFunc: Pointer;
        CloseFunc: Pointer;
        UserData: array[1..32] of Byte;
        Name: array[0..259] of Char;);
end;
```

C++

```
struct TFileRec {
  int Handle;
  Word Mode;
  Word Flags;
  unsigned RecSize;
  unsigned BufSize;
  unsigned BufPos;
  unsigned BufEnd;
  const char * BufPtr;
  void * OpenFunc;
  void * InOutFunc;
  void * FlushFunc;
  void * CloseFunc;
  array[1..32] of Byte UserData;
  array[0..259] of Char Name;
};
```

File

System

Description

TFileRec is the internal format for typed and untyped files. TFileRec enables you to typecast a Delphi file variable to access its internal fields.

Note: You would normally never declare a variable of this type.

158.4.10 System.TGUID Record

TGUID is a structured form of the value that uniquely identifies an interface.

Pascal

```
TGUID = packed record
  D1: LongWord;
  D2: Word;
  D3: Word;
  D4: array[0..7] of Byte;
end;
```

C++

```
struct TGUID {
  LongWord D1;
  Word D2;
  Word D3;
  array[0..7] of Byte D4;
};
```

File

System

Description

An interface declaration can specify a globally unique identifier (GUID), represented by a string literal enclosed in brackets immediately preceding the member list. The GUID part of the declaration must have the form :

['{xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx}']

where each x is a hexadecimal digit (0 through 9 or A through F). On Windows, the Type Library editor automatically generates GUIDs for new interfaces. You can also generate GUIDs by pressing Ctrl+Shift+G in the Code editor.

TGUID provides a structured access to this GUID :

D1 maps to the first 8 hexadecimal digits.

D2 maps to the next 4 hexadecimal digits.

D3 maps to the next 4 hexadecimal digits.

D4 maps to the final 8 hexadecimal digits.

158.4.11 System.THeapStatus Record

THeapStatus represents information about the global heap.

Pascal

```
THeapStatus = record
  TotalAddrSpace: Cardinal;
  TotalUncommitted: Cardinal;
  TotalCommitted: Cardinal;
  TotalAllocated: Cardinal;
  TotalFree: Cardinal;
  FreeSmall: Cardinal;
  FreeBig: Cardinal;
```

```
    Unused: Cardinal;
    Overhead: Cardinal;
    HeapErrorCode: Cardinal;
  end;
```

C++

```
  struct THeapStatus {
    unsigned TotalAddrSpace;
    unsigned TotalUncommitted;
    unsigned TotalCommitted;
    unsigned TotalAllocated;
    unsigned TotalFree;
    unsigned FreeSmall;
    unsigned FreeBig;
    unsigned Unused;
    unsigned Overhead;
    unsigned HeapErrorCode;
  };
```

File

System

Description

THeapStatus represents information about the current memory manager. These are the meanings of the values in each field:

Field	Meaning
TotalAddrSpace	The (current) total address space available to your program, in bytes. This will grow as your program's dynamic memory usage grows.
TotalUncommitted	The total number of bytes (of TotalAddrSpace) for which space has not been allocated in the swap file.
TotalCommitted	The total number of bytes (of TotalAddrSpace) for which space has been allocated in the swap file. Note : TotalUncommitted + TotalCommitted = TotalAddrSpace
TotalAllocated	The total number of bytes dynamically allocated by your program.
TotalFree	The total number of free bytes available in the (current) address space for allocation by your program. If this number is exceeded, and enough virtual memory is available, more address space will be allocated from the OS; TotalAddrSpace will be incremented accordingly.
FreeSmall	Total bytes of small memory blocks which are not currently allocated by your program.
FreeBig	Total bytes of big memory blocks which are not currently allocated by your program. Large free blocks can be created by coalescing smaller, contiguous, free blocks or by freeing a large dynamic allocation. (The exact size of the blocks is immaterial).
Unused	Total bytes which have never been allocated by your program. Note : Unused + FreeBig + FreeSmall = TotalFree These three fields (Unused, FreeBig, and FreeSmall) refer to dynamic allocation by the user program.
Overhead	The total number of bytes required by the heap manager to manage all the blocks dynamically allocated by your program.
HeapErrorCode	Indicates the current status of the heap, as internally determined.

Note: TotalAddrSpace, TotalUncommitted and TotalCommitted refer to OS memory used by the program, whereas TotalAllocated and TotalFree refer to the heap memory used within the program by dynamic allocations. Therefore, to monitor dynamic memory used in your program use TotalAllocated and TotalFree.

158.4.12 System.TInitContext Record

Pascal

```
TInitContext = record
  OuterContext: PInitContext;
  ExcFrame: Pointer;
  InitTable: PackageInfo;
  InitCount: Integer;
  Module: PLibModule;
  DLLSaveEBP: Pointer;
  DLLSaveEBX: Pointer;
  DLLSaveESI: Pointer;
  DLLSaveEDI: Pointer;
  ExitProcessTLS: procedure;
  DLLInitState: Byte;
end;
```

C++

```
struct TInitContext {
  PInitContext OuterContext;
  void * ExcFrame;
  PackageInfo InitTable;
  int InitCount;
  PLibModule Module;
  void * DLLSaveEBP;
  void * DLLSaveEBX;
  void * DLLSaveESI;
  void * DLLSaveEDI;
  procedure ExitProcessTLS;
  Byte DLLInitState;
};
```

File

System

Description

This is record System.TInitContext.

158.4.13 System::TInterfaceEntry Record

Pascal

```
TInterfaceEntry = packed record
  IID: TGUID;
  VTable: Pointer;
  IOffset: Integer;
  ImplGetter: Integer;
end;
```

C++

```
struct TInterfaceEntry {
  TGUID IID;
  Pointer VTable;
  Integer IOffset;
  Integer ImplGetter;
```

```
};
```

File

System.pas

Description

This is record System::TInterfaceEntry.

158.4.14 System::TInterfaceTable Record

Pascal

```
TInterfaceTable = packed record
  EntryCount: Integer;
  Entries: array[0..9999] of TInterfaceEntry;
end;
```

C++

```
struct TInterfaceTable {
  Integer EntryCount;
  array[0..9999] of TInterfaceEntry Entries;
};
```

File

System.pas

Description

This is record System::TInterfaceTable.

158.4.15 System.TLibModule Record

TLibModule describes a module that is compiled with the application.

Pascal

```
TLibModule = record
  Next: PLibModule;
  Instance: LongWord;
  CodeInstance: LongWord;
  DataInstance: LongWord;
  ResInstance: LongWord;
  Reserved: Integer;
end;
```

C++

```
struct TLibModule {
  PLibModule Next;
  LongWord Instance;
  LongWord CodeInstance;
  LongWord DataInstance;
  LongWord ResInstance;
  int Reserved;
};
```

File

System

Description

TLibModule is an entry in a linked list of data structures that describe the modules in an application.

Next is a pointer to the next entry in the list.

The **Instance** field represents the instance handle of the executable or package and the instance handles of the text, data, and resource associated with that executable instance.

The additional fields on Linux are used internally to access information in the module header.

See Also

PLibModule (see page 22596)

158.4.16 System.TMemoryManager Record

TMemoryManager defines the memory block entry points.

Pascal

```
TMemoryManager = record
  GetMem: function(Size: Integer): Pointer;
  FreeMem: function(P: Pointer): Integer;
  ReallocMem: function(P: Pointer; Size: Integer): Pointer;
end;
```

C++

```
struct TMemoryManager {
  function(Size: Integer): Pointer GetMem;
  function(P: Pointer): Integer FreeMem;
  function(P: Pointer; Size: Integer): Pointer ReallocMem;
};
```

File

System

Description

The TMemoryManager type is used by the GetMemoryManager (see page 22472) and SetMemoryManager (see page 22523) procedures. It defines the routines that allocate and free memory.

The GetMem field (Delphi) or method (C++) must specify a function that allocates the given number of bytes and returns a pointer to the newly allocated block, as invoked by the GetMemory (see page 22470) routine.

The Size parameter passed to the GetMem function will never be zero. If the GetMem function cannot allocate a block of the given size, it should return nil (Delphi) or NULL (C++).

The FreeMem field (Delphi) or method (C++) must specify a function that deallocates the given block. The pointer parameter passed to the FreeMem function will never be nil (Delphi) or NULL (C++). If the FreeMem function successfully deallocates the given block, it should return zero. Otherwise, it should return a non-zero value. As invoked by the FreeMemory (see page 22466) routine.

The ReallocMem field (Delphi) or method (C++) must specify a function that reallocates the given block to the given new size. The pointer parameter passed to the ReallocMem function will never be nil (Delphi) or NULL (C++), and the Size parameter will never be zero. The ReallocMem function must reallocate the given block to the given new size, possibly moving the block if it

cannot be resized in place. Any existing contents of the block must be preserved, but newly allocated space can be uninitialized. The ReallocMem function must return a pointer to the reallocated block, or nil (Delphi) or NULL (C++) if the block cannot be reallocated. As invoked by the ReallocMem routine.

GetMemoryManager (see page 22472)

ReallocMem (see page 22507)

SetMemoryManager (see page 22523)

158.4.17 System.TMemoryManagerEx Record

TMemoryManagerEx defines extended memory block entry points.

Pascal

```
TMemoryManagerEx = record
  GetMem: function(Size: Integer): Pointer;
  FreeMem: function(P: Pointer): Integer;
  ReallocMem: function(P: Pointer; Size: Integer): Pointer;
  AllocMem: function(Size: Cardinal): Pointer;
  RegisterExpectedMemoryLeak: function(P: Pointer): Boolean;
  UnregisterExpectedMemoryLeak: function(P: Pointer): Boolean;
end;
```

C++

```
struct TMemoryManagerEx {
  function(Size: Integer): Pointer GetMem;
  function(P: Pointer): Integer FreeMem;
  function(P: Pointer; Size: Integer): Pointer ReallocMem;
  function(Size: Cardinal): Pointer AllocMem;
  function(P: Pointer): Boolean RegisterExpectedMemoryLeak;
  function(P: Pointer): Boolean UnregisterExpectedMemoryLeak;
};
```

File

System

Description

The RegisterExpectedMemoryLeak type is used by the GetMemoryManager (see page 22472) and SetMemoryManager (see page 22523) procedures. It defines the routines that allocate and free memory.

The GetMem field (Delphi) or method (C++) must specify a function that allocates the given number of bytes and returns a pointer to the newly allocated block, as invoked by the GetMemory (see page 22470) routine.

The Size parameter passed to the GetMem function will never be zero. If the GetMem function cannot allocate a block of the given size, it should return nil (Delphi) or NULL (C++).

The FreeMem field (Delphi) or method (C++) must specify a function that deallocates the given block. The pointer parameter passed to the FreeMem function will never be nil (Delphi) or NULL (C++). If the FreeMem function successfully deallocates the given block, it should return zero. Otherwise, it should return a non-zero value. As invoked by the FreeMemory (see page 22466) routine.

The ReallocMem field (Delphi) or method (C++) must specify a function that reallocates the given block to the given new size. The pointer parameter passed to the ReallocMem function will never be nil (Delphi) or NULL (C++), and the Size parameter will never be zero. The ReallocMem function must reallocate the given block to the given new size, possibly moving the block if it cannot be resized in place. Any existing contents of the block must be preserved, but newly allocated space can be uninitialized. The ReallocMem function must return a pointer to the reallocated block, or nil (Delphi) or NULL (C++) if the block cannot be reallocated. As invoked by the ReallocMem routine.

The AllocMem field (Delphi) or method (C++) must specify a function that allocates the given number of bytes and returns a pointer to the newly allocated block, as invoked by the AllocMem routine.

The RegisterExpectedMemoryLeak field (Delphi) or method (C++) must specify a function that registers a memory location that an application has allocated and does not expect to free, as invoked by the RegisterExpectedMemoryLeak routine.

The UnregisterExpectedMemoryLeak field (Delphi) or method (C++) must specify a function that removes a memory location from the Memory Manager's list of expected memory leaks, as invoked by the UnregisterExpectedMemoryLeak routine.

158.4.18 System.TMemoryManagerState Record

TMemoryManagerState holds statistics about memory allocations.

Pascal

```
TMemoryManagerState = packed record
  SmallBlockTypeStates: TSmallBlockTypeStates;
  AllocatedMediumBlockCount: Cardinal;
  TotalAllocatedMediumBlockSize: Cardinal;
  ReservedMediumBlockAddressSpace: Cardinal;
  AllocatedLargeBlockCount: Cardinal;
  TotalAllocatedLargeBlockSize: Cardinal;
  ReservedLargeBlockAddressSpace: Cardinal;
end;
```

C++

```
struct TMemoryManagerState {
  TSmallBlockTypeStates SmallBlockTypeStates;
  unsigned AllocatedMediumBlockCount;
  unsigned TotalAllocatedMediumBlockSize;
  unsigned ReservedMediumBlockAddressSpace;
  unsigned AllocatedLargeBlockCount;
  unsigned TotalAllocatedLargeBlockSize;
  unsigned ReservedLargeBlockAddressSpace;
};
```

File

System

Description

GetMemoryManagerState (see page 22472) returns a structure containing memory usage statistics for each block type - small, medium and large blocks. It returns this data in a TMemoryManagerState record. AllocMem (see page 22413) and GetMemory (see page 22470) can be used to allocate memory blocks. The record holds the following information :

Field	Meaning
SmallBlockTypeStates	An array of small memory block information records.
AllocatedMediumBlockCount	The number of medium sized memory blocks (blocks less than 264,749 bytes in size).
TotalAllocatedMediumBlockSize	The total number of bytes oiccupied by the medium memory blocks.
ReservedMediumBlockAddressSpace	The amount of memory reserved for medium memory blocks.
AllocatedLargeBlockCount	The number of large sized memory blocks (blocks greater than 264,748 bytes in size).
TotalAllocatedLargeBlockSize	The total number of bytes oiccupied by the large memory blocks.
ReservedLargeBlockAddressSpace	The amount of memory reserved for large memory blocks.

158.4.19 System.TMethod Record

TMethod stores Code and Data fields to represent a method.

Pascal

```
TMethod = record
  Code: Pointer;
  Data: Pointer;
end;
```

C++

```
struct TMethod {
  void * Code;
  void * Data;
};
```

File

System

Description

The TMethod stores the Code and Data pointers for a method. This type can be used in a type cast of a method pointer to access the code and data parts of the method pointer.

You can also furnish a TMethod variable by assigning Data a pointer to an object, and assigning Code using MethodAddress, specifying the method name as a string parameter to that method.

See Also

MethodAddress (see page 22306)

158.4.20 System.TMinimumBlockAlignment Enumeration

TMinimumBlockAlignment defines the mimimum byte alignment for memory block allocation.

Pascal

```
TMinimumBlockAlignment = (
  mba8Byte,
  mba16Byte
);
```

C++

```
enum TMinimumBlockAlignment {
  mba8Byte,
  mba16Byte
};
```

File

System

Description

The TMinimumBlockAlignment type defines either 8 byte (**mba8Byte**) or 16 byte (**mba16Byte**) block alignments. Namely, that the memory address is divisible exactly by 8 or 16 respectively.

AllocMem (see page 22413)

GetMemory (see page 22470)

158.4.21 System.TModuleUnloadRec Record

Pascal

```
TModuleUnloadRec = record
  Next: PModuleUnloadRec;
  Proc: TModuleUnloadProcLW;
end;
```

C++

```
struct TModuleUnloadRec {
  PModuleUnloadRec Next;
  TModuleUnloadProcLW Proc;
};
```

File

System

Description

This is record System.TModuleUnloadRec.

158.4.22 System.TResStringRec Record

Pascal

```
TResStringRec = packed record
  Module: ^Cardinal;
  Identifier: Integer;
end;
```

C++

```
struct TResStringRec {
  ^Cardinal Module;
  int Identifier;
};
```

File

System

Description

This is record System.TResStringRec.

158.4.23 System.TRuntimeError Enumeration

Pascal

```
TRuntimeError = (
  reNone,
  reOutOfMemory,
  reInvalidPtr,
  reDivByZero,
  reRangeError,
  reIntOverflow,
  reInvalidOp,
  reZeroDivide,
  reOverflow,
  reUnderflow,
  reInvalidCast,
  reAccessViolation,
  rePrivInstruction,
  reControlBreak,
  reStackOverflow,
  reVarTypeCast,
  reVarInvalidOp,
  reVarDispatch,
  reVarArrayCreate,
  reVarNotArray,
  reVarArrayBounds,
  reAssertionFailed,
  reExternalException,
  reIntfCastError,
  reSafeCallError
);
```

C++

```
enum TRuntimeError {
  reNone,
```

```
    reOutOfMemory,
    reInvalidPtr,
    reDivByZero,
    reRangeError,
    reIntOverflow,
    reInvalidOp,
    reZeroDivide,
    reOverflow,
    reUnderflow,
    reInvalidCast,
    reAccessViolation,
    rePrivInstruction,
    reControlBreak,
    reStackOverflow,
    reVarTypeCast,
    reVarInvalidOp,
    reVarDispatch,
    reVarArrayCreate,
    reVarNotArray,
    reVarArrayBounds,
    reAssertionFailed,
    reExternalException,
    reIntfCastError,
    reSafeCallError
  };
```

File

System

Description

This is record System.TRuntimeError.

158.4.24 System.TSmallBlockTypeState Record

TSmallBlockTypeState holds statistics about a small memory block.

Pascal

```
  TSmallBlockTypeState = packed record
    InternalBlockSize: Cardinal;
    UseableBlockSize: Cardinal;
    AllocatedBlockCount: Cardinal;
    ReservedAddressSpace: Cardinal;
  end;
```

C++

```
  struct TSmallBlockTypeState {
    unsigned InternalBlockSize;
    unsigned UseableBlockSize;
    unsigned AllocatedBlockCount;
    unsigned ReservedAddressSpace;
  };
```

File

System

Description

GetMemoryManagerState (see page 22472) returns a structure containing memory usage statistics for each block type - small, medium and large blocks. It returns this data in a TMemoryManagerState (see page 22564) record. Within that record is

held a TSmallBlockTypeStates (see page 22620) field - an array of TSmallBlockTypeState records. Each TSmallBlockTypeState record holds the following information :

Field	Meaning
InternalBlockSize	Actual memory allocated to each small memory block - at least 4 bytes of which are not available in the UseableBlockSize.
UseableBlockSize	The useable size of each allocated small memory block.
AllocatedBlockCount	The number of small memory blocks allocated of the given InternalBlockSize.
ReservedAddressSpace	The amount memory reserved for this group of small memory blocks.

See Also

TSmallBlockTypeStates (see page 22620)

GetMemoryManagerState (see page 22472)

158.4.25 System.TTextLineBreakStyle Enumeration

TTextLineBreakStyle indicates the default set of characters used to divide lines in text.

Pascal

```
TTextLineBreakStyle = (
  tlbsLF,
  tlbsCRLF
);
```

C++

```
enum TTextLineBreakStyle {
  tlbsLF,
  tlbsCRLF
};
```

File

System

Description

TTextLineBreakStyle can have one of the following values:

Value	Meaning
tlbsLF	Linefeed only
tlbsCRLF	Carriage return followed by Linefeed

158.4.26 System.TTextRec Record

TTextRec is the internal format for text files.

Pascal

```
TTextRec = packed record
  Handle: Integer;
```

```
    Mode: Word;
    Flags: Word;
    BufSize: Cardinal;
    BufPos: Cardinal;
    BufEnd: Cardinal;
    BufPtr: PChar;
    OpenFunc: Pointer;
    InOutFunc: Pointer;
    FlushFunc: Pointer;
    CloseFunc: Pointer;
    UserData: array[1..32] of Byte;
    Name: array[0..259] of Char;
    Buffer: TTextBuf;
  end;
```

C++

```
  struct TTextRec {
    int Handle;
    Word Mode;
    Word Flags;
    unsigned BufSize;
    unsigned BufPos;
    unsigned BufEnd;
    const char * BufPtr;
    void * OpenFunc;
    void * InOutFunc;
    void * FlushFunc;
    void * CloseFunc;
    array[1..32] of Byte UserData;
    array[0..259] of Char Name;
    TTextBuf Buffer;
  };
```

File

System

Description

TTextRec is the internal format of a Delphi variable of type text. You would never declare a variable of this type. However, you can use TTextRec to typecast a text file variable to access the internal data fields, such as the file name.

TextBuf is the type of the Buffer entry in the TTextRec record, and indicates the size of the buffer used.

Note: Do not use this unless you are familiar with writing text file device drivers for the Delphi language.

158.4.27 System.TVarArray Record

Pascal

```
  TVarArray = packed record
    DimCount: Word;
    Flags: Word;
    ElementSize: Integer;
    LockCount: Integer;
    Data: Pointer;
    Bounds: TVarArrayBoundArray;
  end;
```

C++

```
  struct TVarArray {
    Word DimCount;
```

```
    Word Flags;
    int ElementSize;
    int LockCount;
    void * Data;
    TVarArrayBoundArray Bounds;
  };
```

File

System

Description

This is record System.TVarArray.

158.4.28 System.TVarArrayBound Record

Pascal

```
  TVarArrayBound = packed record
    ElementCount: Integer;
    LowBound: Integer;
  end;
```

C++

```
  struct TVarArrayBound {
    int ElementCount;
    int LowBound;
  };
```

File

System

Description

This is record System.TVarArrayBound.

158.4.29 System.TVarData Record

TVarData represents Variant (see page 22307) information.

Pascal

```
  TVarData = packed record
    case Integer of
      0: (VType: TVarType;
          Reserved1: Word;
          Reserved2: Word;
          Reserved3: Word;);
      1: (VLongs: array[0..2] of LongInt);
          RawData: array [0..3] of LongInt););
      2: (VWords: array [0..6] of Word);
          VBytes: array [0..13] of Byte););
      varAny: (VAny: Pointer;);
      varArray: (VArray: PVarArray;);
      varBoolean: (VBoolean: WordBool;);
      varByRef: (VPointer: Pointer;);
      varByte: (VByte: Byte;);
      varCurrency: (VCurrency: Currency;);
```

```
    varDate: (VDate: TDateTime;);
    varDispatch: (VDispatch: Pointer;);
    varDouble: (VDouble: Double;);
    varError: (VError: HRESULT;);
    varInt64: (VInt64: Int64;);
    varInteger: (VInteger: Integer;);
    varLongWord: (VLongWord: LongWord;);
    varOleStr: (VOleStr: PWideChar;);
    varShortInt: (VShortInt: ShortInt;);
    varSingle: (VSingle: Single;);
    varSmallInt: (VSmallInt: SmallInt;);
    varString: (VString: Pointer;);
    varUnknown: (VUnknown: Pointer;);
    varWord: (VWord: Word;);
end;
```

C++

```
struct TVarData {
  TVarType VType;
  Word Reserved1;
  Word Reserved2;
  Word Reserved3;
  SmallInt VSmallInt;
  int VInteger;
  Single VSingle;
  Double VDouble;
  Currency VCurrency;
  TDateTime VDate;
  PWideChar VOleStr;
  void * VDispatch;
  HRESULT VError;
  WordBool VBoolean;
  void * VUnknown;
  ShortInt VShortInt;
  Byte VByte;
  Word VWord;
  LongWord VLongWord;
  Int64 VInt64;
  void * VString;
  void * VAny;
  PVarArray VArray;
  void * VPointer;
  array[0..2] of LongInt) VLongs;
  array [0..6] of Word) VWords;
  array [0..13] of Byte) VBytes;
  array [0..3] of LongInt) RawData;
};
```

File

System

Description

TVarData is the base class for Variant (see page 22307).

Note: The internal structure of a Variant (see page 22307) as designated by TVarData is identical to the Variant (see page 22307) type used by OLE and the Win32 APIs.

struct TVarData

```
  {
union
    {
      Word     VType;    // Delphi-compatible - Variant Type member
      VARTYPE  vt;       // tagVARIANT compatible member
    };
```

```
    Word Reserved1;
    Word Reserved2;
    Word Reserved3;
union
    {
      // Delphi-compatible Variant members
      Smallint      VSmallint;    //  iVal
      Integer       VInteger;     //  lVal
      Single        VSingle;      //  fltVal
      Double        VDouble;      //  dblVal
      CurrencyBase  VCurrency;    //  cyVal
      TDateTimeBase VDate;        //  date
      PWideChar     VOleStr;      //  bstrVal
      IDispatch*    VDispatch;    //  pdispVal
      HResult       VError;       //  scode
      WordBool      VBoolean;     //  boolVal
      IUnknown*     VUnknown;     //  punkVal
      Byte          VByte;        //  bVal
      Pointer       VString;      //  ??????
      PVarArray     VArray;       //  parray
      Pointer       VPointer;     //  byref
      // tagVARIANT compatible members (from OAIDL.H)
      // Allowing all types marked as [V] (may appear in a VARIANT to be initialized
      LONG          lVal;
      BYTE          bVal;
      SHORT         iVal;
      FLOAT         fltVal;
      DOUBLE        dblVal;
      VARIANT_BOOL  boolVal;
      SCODE         scode;
      CY            cyVal;
      DATE          date;
      BSTR          bstrVal;
      IUnknown     *punkVal;
      IDispatch    *pdispVal;
      SAFEARRAY    *parray;
      BYTE         *pbVal;SHORT        *piVal;
      LONG         *plVal;
      FLOAT        *pfltVal;
      DOUBLE       *pdblVal;
      VARIANT_BOOL *pboolVal;
      SCODE        *pscode;
      CY           *pcyVal;
      DATE         *pdate;
      BSTR         *pbstrVal;
      IUnknown    **ppunkVal;
      IDispatch   **ppdispVal;
      SAFEARRAY   **pparray;
      VARIANT      *pvarVal;
      PVOID         byref;
      CHAR          cVal;
      USHORT        uiVal;
      ULONG         ulVal;
      INT           intVal;
      UINT          uintVal;
      DECIMAL      *pdecVal;
      CHAR         *pcVal;
      USHORT       *puiVal;
      ULONG        *pulVal;
      INT          *pintVal;
      UINT         *puintVal;
    };
  };
```

The VType of TVarData contains the type code of the variant in the lower twelve bits (the bits defined by varTypeMask (see page 22689)).

The following values are used for VType:

#define varEmpty (see page 22683) (Byte)(0)

```
#define varNull (ByteByte_Type)(1)
#define varSmallint (ByteByte_Type)(2)
#define varInteger (ByteByte_Type)(3)
#define varSingle (ByteByte_Type)(4)
#define varDouble (ByteByte_Type)(5)
#define varCurrency (ByteByte_Type)(6)
#define varDate (ByteByte_Type)(7)
#define varOleStr (ByteByte_Type)(8)
#define varDispatch (ByteByte_Type)(9)
#define varError (ByteByte_Type)(10)
#define varBoolean (ByteByte_Type)(11)
#define varVariant (ByteByte_Type)(12)
#define varUnknown (ByteByte_Type)(13)
#define varByte (ByteByte_Type)(17)
#define varString (WordWord_Type)(256)
#define varTypeMask (WordWord_Type)(4095)
#define varArray (WordWord_Type)(8192)
#define varByRef (WordWord_Type)(16384)
#define varStrArg (ByteByte_Type)(72)
#define vtInteger (ByteByte_Type)(0)
#define vtBoolean (ByteByte_Type)(1)
#define vtChar (ByteByte_Type)(2)
#define vtExtended (ByteByte_Type)(3)
#define vtString (ByteByte_Type)(4)
#define vtPointer (ByteByte_Type)(5)
#define vtPChar (ByteByte_Type)(6)
#define vtObject (ByteByte_Type)(7)
#define vtClass (ByteByte_Type)(8)
#define vtWideChar (ByteByte_Type)(9)
#define vtPWideChar (ByteByte_Type)(10)
#define vtAnsiString (ByteByte_Type)(11)
#define vtCurrency (ByteByte_Type)(12)
#define vtVariant (ByteByte_Type)(13)
```

In addition, the varArray (see page 22679) bit may be set to indicate that the variant is an array, and the varByRef (see page 22680) bit may be set to indicate that the variant contains a reference as opposed to a value.

Word Reserved1;

```
    Word Reserved2;
    Word Reserved3;
```

The Reserved1, Reserved2, and Reserved3 members of TVarData are unused.

union { Smallint VSmallint;

```
      Integer VInteger;
      Single VSingle;
      Double VDouble;
      CurrencyBase VCurrency;
      TDateTimeBase VDate;
      PWideChar VOleStr;
      Ole2::IDispatch* VDispatch;
      Integer VError;
      WordBool VBoolean;
      Ole2::IUnknown* VUnknown;
      Byte VByte;
      Pointer VString;
      PVarArray VArray;
      Pointer VPointer;
    };
};
```

The contents of the remaining eight bytes of TVarData depend on the VType field. If neither the varArray (see page 22679) nor

the varByRef (see page 22680) bits are set, the variant contains a value of the given type.

If the varArray (see page 22679) bit is set, the variant contains a pointer to a TVarArray (see page 22570) structure that defines the specifics of the array. The type of each array element is given by the varTypeMask (see page 22689) bits in VType.

If the varByRef (see page 22680) bit is set, the variant contains a reference to a value of the type given by the varTypeMask (see page 22689) and varArray (see page 22679) bits in VType.

158.4.30 System.TVariantManager Record

TVariantManager defines entry points for variant conversion routines and other procedures that define variant behavior.

Pascal

```
TVariantManager = record
  VarClear: procedure(var V : Variant);
  VarCopy: procedure(var Dest: Variant; const Source: Variant);
  VarCopyNoInd: procedure;
  VarCast: procedure(var Dest: Variant; const Source: Variant; VarType: Integer);
  VarCastOle: procedure(var Dest: Variant; const Source: Variant; VarType: Integer);
  VarToInt: function(const V: Variant): Integer;
  VarToInt64: function(const V: Variant): Int64;
  VarToBool: function(const V: Variant): Boolean;
  VarToReal: function(const V: Variant): Extended;
  VarToCurr: function(const V: Variant): Currency;
  VarToPStr: procedure(var S; const V: Variant);
  VarToLStr: procedure(var S: string; const V: Variant);
  VarToWStr: procedure(var S: WideString; const V: Variant);

System

Description

The TVariantManager type is used by the GetVariantManager (see page 22474) and SetVariantManager (see page 22527) procedures. It defines routines that perform Variant (see page 22307) type conversions and other tasks that implement Variant (see page 22307) behavior.

Note: Although a version of TVariantManager is declared in sysclass.h, it should not be used in C++ code. The use of a Variant (see page 22307) manager to customize the behavior of Variants (see page 23567) is not fully supported in C++.

See Also

GetVariantManager (see page 22474)

SetVariantManager (see page 22527)

158.4.31 System::TVarRec Record

Pascal

```
TVarRec = record
  case Byte of
    vtAnsiString: (VAnsiString: Pointer;);
    vtBoolean: (VBoolean: Boolean;);
    vtChar: (VChar: Char;);
    vtClass: (VClass: TClass;);
    vtCurrency: (VCurrency: PCurrency;);
    vtExtended: (VExtended: PExtended;);
    vtInt64: (VInt64: PInt64;);
    vtInteger: (VInteger: Integer;
                VType: Byte;);
    vtInterface: (VInterface: Pointer;);
    vtObject: (VObject: TObject;);
    vtPChar: (VPChar: PChar;);
    vtPointer: (VPointer: Pointer;);
    vtPWideChar: (VPWideChar: PWideChar;);
    vtString: (VString: PShortString;);
    vtVariant: (VVariant: PVariant;);
    vtWideChar: (VWideChar: WideChar;);
    vtWideString: (VWideString: Pointer;);
end;
```

C++

```
struct TVarRec {
  Integer VInteger;
  Byte VType;
  Boolean VBoolean;
  Char VChar;
  PExtended VExtended;
  PShortString VString;
  Pointer VPointer;
  PChar VPChar;
  TObject VObject;
  TClass VClass;
  WideChar VWideChar;
  PWideChar VPWideChar;

  Pointer VWideString;
  PInt64 VInt64;
};
```

File

System.pas

Description

This is class System::TVarRec.

158.4.32 System::TCallDesc Structure

Pascal

```
TCallDesc = struct TCallDesc@1;
```

C++

```
typedef struct {
  unsigned char CallType;
  unsigned char ArgCount;
  unsigned char NamedArgCount;
  unsigned char ArgTypes[256];
} TCallDesc, * PCallDesc;
```

File

systvar.h

Description

This is type System::TCallDesc.

158.4.33 System::TDispDesc Structure

Pascal

```
TDispDesc = struct TDispDesc@1;
```

C++

```
typedef struct {
  int DispID;
  unsigned char ResType;
  TCallDesc CallDesc;
} TDispDesc, * PDispDesc;
```

File

systvar.h

Description

This is type System::TDispDesc.

158.5 Types

The following table lists types in this documentation.

Types

Name	Description
ArrayOfboolean (see page 22581)	This is type System::ArrayOfboolean.
ArrayOfbyte (see page 22582)	This is type System::ArrayOfbyte.
ArrayOfdouble (see page 22582)	This is type System::ArrayOfdouble.
ArrayOfint (see page 22582)	This is type System::ArrayOfint.
ArrayOflong (see page 22583)	This is type System::ArrayOflong.
ArrayOfshort (see page 22583)	This is type System::ArrayOfshort.
ArrayOfstring (see page 22583)	This is type System::ArrayOfstring.
ArrayOfwidestring (see page 22584)	This is type System::ArrayOfwidestring.
GetPackageInfoTable (see page 22584)	This is type System.GetPackageInfoTable.
HGLOBAL (see page 22584)	This is type System.HGLOBAL.
HINST (see page 22585)	This is type System.HINST.
HMODULE (see page 22585)	This is type System.HMODULE.
HRESULT (see page 22585)	This is type System.HRESULT.
HRSRC (see page 22586)	This is type System.HRSRC.
IntegerArray (see page 22586)	This is type System.IntegerArray.
IUnknown (see page 22586)	IUnknown is a special base interface.
PackageInfo (see page 22587)	This is type System.PackageInfo.
PAnsiString (see page 22587)	PAnsiString is a pointer to an AnsiString (see page 22093) variable.
PBoolean (see page 22587)	PBoolean is a pointer to a Boolean variable.
PByte (see page 22588)	PByte is a pointer to a Byte variable.
PCallDesc (see page 22588)	This is type System::PCallDesc.
PCardinal (see page 22589)	PCardinal is a pointer to a Cardinal variable.
PComp (see page 22589)	PComp is a pointer to a Comp variable.
PCurrency (see page 22589)	PCurrency is a pointer to a Currency (see page 22145) variable.
PCVModInfo (see page 22590)	This is type System.PCVModInfo.
PDate (see page 22590)	PDate is a pointer to a Date variable.
PDateTime (see page 22591)	PDateTime is a pointer to a TDateTime (see page 22256) variable.
PDispatch (see page 22591)	This is type System.PDispatch.
PDispDesc (see page 22591)	This is type System::PDispDesc.
PDouble (see page 22592)	PDouble is a pointer to a Double variable.
PDynArrayTypeInfo (see page 22592)	This is type System.PDynArrayTypeInfo.
PError (see page 22592)	This is type System.PError.
PExtended (see page 22593)	PExtended is a pointer to an Extended variable.
PGUID (see page 22593)	PGUID is a pointer to a TGUID (see page 22558) variable.
PInitContext (see page 22593)	This is type System.PInitContext.
PInt64 (see page 22594)	PInt64 is a pointer to an Int64 variable.
PInteger (see page 22594)	PInteger is a pointer to an Integer variable.
PIntegerArray (see page 22595)	PIntegerArray is a pointer to an IntegerArray (see page 22586) variable.
PInterfaceEntry (see page 22595)	This is type System::PInterfaceEntry.
PInterfaceTable (see page 22595)	This is type System::PInterfaceTable.
PLibModule (see page 22596)	PLibModule is a pointer to a TLibModule (see page 22561) variable.
PLongint (see page 22596)	This is type System.PLongint.
PLongWord (see page 22596)	PLongWord is a pointer to a LongWord variable.
PMemoryManager (see page 22597)	PMemoryManager is a pointer to a TMemoryManager (see page 22562) variable.

PMemoryManagerEx (see page 22597)	PMemoryManagerEx is a pointer to a TMemoryManagerEx (see page 22563) variable.
PModuleUnloadRec (see page 22598)	This is type System.PModuleUnloadRec.
PointerArray (see page 22598)	This is type System.PointerArray.
POleVariant (see page 22598)	This is type System.POleVariant.
PPAnsiChar (see page 22599)	This is type System.PPAnsiChar.
PPChar (see page 22599)	This is type System.PPChar.
PPCharArray (see page 22599)	This is type System.PPCharArray.
PPDispatch (see page 22600)	This is type System.PPDispatch.
PPointer (see page 22600)	PPointer is a pointer to a Pointer variable.
PPointerArray (see page 22600)	PPointerArray is a pointer to a PointerArray (see page 22598) variable.
PPUnknown (see page 22601)	This is type System.PPUnknown.
PPWideChar (see page 22601)	This is type System.PPWideChar.
PResStringRec (see page 22601)	This is type System.PResStringRec.
PShortInt (see page 22602)	PShortInt is a pointer to a ShortInt variable.
PShortString (see page 22602)	PShortString is a pointer to a ShortString variable.
PSingle (see page 22602)	PSingle is a pointer to a Single variable.
PSmallInt (see page 22603)	PSmallInt is a pointer to a SmallInt variable.
PString (see page 22603)	PString is a pointer to a String variable.
PTextBuf (see page 22604)	This is type System.PTextBuf.
PUCS2Char (see page 22604)	This is type System.PUCS2Char.
PUCS4Char (see page 22604)	This is type System.PUCS4Char.
PUCS4CharArray (see page 22605)	This is type System.PUCS4CharArray.
PUnitEntryTable (see page 22605)	This is type System.PUnitEntryTable.
PUnknown (see page 22605)	PUnknown is a pointer to an IUnknown (see page 22586) variable.
PUTF8String (see page 22606)	This is type System.PUTF8String.
PVarArray (see page 22606)	This is type System.PVarArray.
PVarArrayBoundArray (see page 22606)	This is type System.PVarArrayBoundArray.
PVarArrayCoorArray (see page 22607)	This is type System.PVarArrayCoorArray.
PVarData (see page 22607)	This is type System.PVarData.
PVariant (see page 22607)	PVariant is a pointer to a Variant (see page 22307) variable.
PVariantManager (see page 22608)	This is type System.PVariantManager.
PVarRec (see page 22608)	This is type System::PVarRec.
PWideString (see page 22608)	PWideString is a pointer to a WideString (see page 22377) variable.
PWord (see page 22609)	PWord is a pointer to a Word variable.
PWordBool (see page 22609)	PWordBool is a pointer to a WordBool variable.
SCODE (see page 22609)	This is type System::SCODE.
TAssertErrorProc (see page 22610)	This is type System.TAssertErrorProc.
TBooleanDynArray (see page 22610)	This is type System::TBooleanDynArray.
TBoundArray (see page 22610)	This is type System.TBoundArray.
TByteDynArray (see page 22611)	This is type System::TByteDynArray.
TCardinalDynArray (see page 22611)	This is type System::TCardinalDynArray.
TClass (see page 22611)	TClass defines the metaclass for TObject (see page 22285).
TDateTime (see page 22612)	TDateTime represents a date-and-time value in the Delphi language.
TDLLProc (see page 22613)	This is type System.TDLLProc.
TDLLProcEx (see page 22613)	This is type System.TDLLProcEx.
TDoubleDynArray (see page 22614)	This is type System::TDoubleDynArray.
TEnumModuleFunc (see page 22614)	This is type System.TEnumModuleFunc.
TEnumModuleFuncLW (see page 22614)	This is type System.TEnumModuleFuncLW.
TFileIOFunc (see page 22615)	This is type System.TFileIOFunc.
THandle (see page 22615)	THandle is a general purpose data reference (handle).
TInt64DynArray (see page 22615)	This is type System::TInt64DynArray.
TIntegerDynArray (see page 22616)	This is type System::TIntegerDynArray.
TInterfacedClass (see page 22616)	TInterfacedClass defines the metaclass for TInterfacedObject (see page 22276).

TLongWordDynArray (see page 22616)	This is type System::TLongWordDynArray.
TMemoryMap (see page 22617)	TMemoryMap is a map of an application's address space as an array of TChunkStatus (see page 22554) values.
TModuleUnloadProc (see page 22617)	TModuleUnloadProc dehines a procedure that can be called during package unload.
TModuleUnloadProcLW (see page 22618)	This is type System.TModuleUnloadProcLW.
TPCharArray (see page 22618)	This is type System.TPCharArray.
TResourceHandle (see page 22619)	This is type System.TResourceHandle.
TSafeCallErrorProc (see page 22619)	This is type System.TSafeCallErrorProc.
TShortIntDynArray (see page 22619)	This is type System::TShortIntDynArray.
TSingleDynArray (see page 22620)	This is type System::TSingleDynArray.
TSmallBlockTypeStates (see page 22620)	TSmallBlockTypeStates is an array of small memory block information records.
TSmallIntDynArray (see page 22620)	This is type System::TSmallIntDynArray.
TStringDynArray (see page 22621)	This is type System::TStringDynArray.
TSystemThreadEndProc (see page 22621)	This is type System.TSystemThreadEndProc.
TSystemThreadFuncProc (see page 22621)	This is type System.TSystemThreadFuncProc.
TTextBuf (see page 22622)	This is type System.TTextBuf.
TTextIOFunc (see page 22622)	This is type System.TTextIOFunc.
TThreadFunc (see page 22622)	TThreadFunc defines a new thread of execution.
TUCS4CharArray (see page 22623)	This is type System.TUCS4CharArray.
TVarArrayBoundArray (see page 22623)	This is type System.TVarArrayBoundArray.
TVarArrayCoorArray (see page 22623)	This is type System.TVarArrayCoorArray.
TVarOp (see page 22624)	TVarOp defines a Variant (see page 22307) operation.
TVarType (see page 22625)	This is type System.TVarType.
TWideStringDynArray (see page 22625)	This is type System::TWideStringDynArray.
TWordDynArray (see page 22626)	This is type System::TWordDynArray.
UCS2Char (see page 22626)	This is type System.UCS2Char.
UCS4Char (see page 22626)	UCS4Char is used for working with 4–byte Unicode characters.
UCS4String (see page 22627)	UCS4String is used for working with 4–byte Unicode characters.
UnitEntryTable (see page 22627)	This is type System.UnitEntryTable.
UTF8String (see page 22627)	This is type System.UTF8String.

158.5.1 System::ArrayOfboolean Type

Pascal

```
ArrayOfboolean = DynamicArray<bool>;
```

C++

```
typedef DynamicArray<bool> ArrayOfboolean;
```

File

sysdyn.h

Description

This is type System::ArrayOfboolean.

158.5.2 System::ArrayOfbyte Type

Pascal

```
ArrayOfbyte = DynamicArray<Byte>;
```

C++

```
typedef DynamicArray<Byte> ArrayOfbyte;
```

File

sysdyn.h

Description

This is type System::ArrayOfbyte.

158.5.3 System::ArrayOfdouble Type

Pascal

```
ArrayOfdouble = DynamicArray<double>;
```

C++

```
typedef DynamicArray<double> ArrayOfdouble;
```

File

sysdyn.h

Description

This is type System::ArrayOfdouble.

158.5.4 System::ArrayOfint Type

Pascal

```
ArrayOfint = DynamicArray<int>;
```

C++

```
typedef DynamicArray<int> ArrayOfint;
```

File

sysdyn.h

Description

This is type System::ArrayOfint.

158.5.5 System::ArrayOflong Type

Pascal

```
ArrayOflong = DynamicArray<long>;
```

C++

```
typedef DynamicArray<long> ArrayOflong;
```

File

sysdyn.h

Description

This is type System::ArrayOflong.

158.5.6 System::ArrayOfshort Type

Pascal

```
ArrayOfshort = DynamicArray<short>;
```

C++

```
typedef DynamicArray<short> ArrayOfshort;
```

File

sysdyn.h

Description

This is type System::ArrayOfshort.

158.5.7 System::ArrayOfstring Type

Pascal

```
ArrayOfstring = DynamicArray<AnsiString>;
```

C++

```
typedef DynamicArray<AnsiString> ArrayOfstring;
```

File

sysdyn.h

Description

This is type System::ArrayOfstring.

158.5.8 System::ArrayOfwidestring Type

Pascal

```
ArrayOfwidestring = DynamicArray<WideString>;
```

C++

```
typedef DynamicArray<WideString> ArrayOfwidestring;
```

File

sysdyn.h

Description

This is type System::ArrayOfwidestring.

158.5.9 System.GetPackageInfoTable Type

Pascal

```
GetPackageInfoTable = function : PackageInfo;
```

C++

```
: PackageInfo ( GetPackageInfoTable)();
```

File

System

Description

This is type System.GetPackageInfoTable.

158.5.10 System.HGLOBAL Type

Pascal

```
HGLOBAL = THandle;
```

C++

```
THandle HGLOBAL;
```

File

System

Description

This is type System.HGLOBAL.

158.5.11 System.HINST Type

Pascal

```
HINST = THandle;
```

C++

```
THandle HINST;
```

File

System

Description

This is type System.HINST.

158.5.12 System.HMODULE Type

Pascal

```
HMODULE = HINST;
```

C++

```
HINST HMODULE;
```

File

System

Description

This is type System.HMODULE.

158.5.13 System.HRESULT Type

Pascal

```
HRESULT = type Longint;
```

C++

```
type Longint HRESULT;
```

File

System

Description

This is type System.HRESULT.

158.5.14 System.HRSRC Type

Pascal

```
HRSRC = THandle;
```

C++

```
THandle HRSRC;
```

File

System

Description

This is type System.HRSRC.

158.5.15 System.IntegerArray Type

Pascal

```
IntegerArray = array[0..$efffff] of Integer;
```

C++

```
array[0..$efffff] of Integer IntegerArray;
```

File

System

Description

This is type System.IntegerArray.

158.5.16 System.IUnknown Type

IUnknown is a special base interface.

Pascal

```
IUnknown = IInterface;
```

C++

```
IInterface IUnknown;
```

File

System

Description

IUnknown is a base interface with features that are important to C++ programmers and also programmers who utilize COM objects.

Note: In Delphi code, IUnknown is simply another name for IInterface (see page 22396). Descending from IUnknown instead of IInterface (see page 22396) informs the Delphi compiler that the interface must be compatible with COM objects.

Cross-platform applications can use interfaces descended from IUnknown, but must not use them to access COM objects, which are only available under Windows.

See Also

IInterface (see page 22396)

System::DelphiInterface (see page 22167)

158.5.17 System.PackageInfo Type

Pascal

```
PackageInfo = ^PackageInfoTable;
```

C++

```
^PackageInfoTable PackageInfo;
```

File

System

Description

This is type System.PackageInfo.

158.5.18 System.PAnsiString Type

PAnsiString is a pointer to an AnsiString (see page 22093) variable.

Pascal

```
PAnsiString = ^AnsiString;
```

C++

```
^AnsiString PAnsiString;
```

File

System

Description

PAnsiString is a pointer to an AnsiString (see page 22093) variable.

See Also

AnsiString (see page 22093)

158.5.19 System.PBoolean Type

PBoolean is a pointer to a Boolean variable.

Pascal

```
PBoolean = ^Boolean;
```

C++

```
^Boolean PBoolean;
```

File

System

Description

PBoolean is a pointer to a Boolean variable.

See Also

Boolean

158.5.20 System.PByte Type

PByte is a pointer to a Byte variable.

Pascal

```
PByte = ^Byte;
```

C++

```
^Byte PByte;
```

File

System

Description

PByte is a pointer to a Byte variable.

See Also

Byte

158.5.21 System::PCallDesc Type

Pascal

```
PCallDesc = ^TCallDesc;
```

C++

```
^TCallDesc PCallDesc;
```

File

System.pas

Description

This is type System::PCallDesc.

158.5.22 System.PCardinal Type

PCardinal is a pointer to a Cardinal variable.

Pascal

```
PCardinal = ^Cardinal;
```

C++

```
^Cardinal PCardinal;
```

File

System

Description

PCardinal is a pointer to a Cardinal variable.

See Also

Cardinal

158.5.23 System.PComp Type

PComp is a pointer to a Comp variable.

Pascal

```
PComp = ^Comp;
```

C++

```
^Comp PComp;
```

File

System

Description

PComp is a pointer to a Comp variable.

Note: The Comp data type is deprecated.

See Also

Comp

158.5.24 System.PCurrency Type

PCurrency is a pointer to a Currency (see page 22145) variable.

Pascal

```
PCurrency = ^Currency;
```

C++

```
^Currency PCurrency;
```

File

System

Description

PCurrency is a pointer to a Currency (see page 22145) variable.

See Also

Currency (see page 22145)

158.5.25 System.PCVModInfo Type

Pascal

```
PCVModInfo = ^TCVModInfo;
```

C++

```
^TCVModInfo PCVModInfo;
```

File

System

Description

This is type System.PCVModInfo.

158.5.26 System.PDate Type

PDate is a pointer to a Date variable.

Pascal

```
PDate = ^Double;
```

C++

```
^Double PDate;
```

File

System

Description

PDate is a pointer to a Date variable.

See Also

Date

158.5.27 System.PDateTime Type

PDateTime is a pointer to a TDateTime (see page 22256) variable.

Pascal

```
PDateTime = ^TDateTime;
```

C++

```
^TDateTime PDateTime;
```

File

System

Description

PDateTime is a pointer to a TDateTime (see page 22256) variable.

See Also

TDateTime (see page 22612)

158.5.28 System.PDispatch Type

Pascal

```
PDispatch = ^IDispatch;
```

C++

```
^IDispatch PDispatch;
```

File

System

Description

This is type System.PDispatch.

158.5.29 System::PDispDesc Type

Pascal

```
PDispDesc = ^TDispDesc;
```

C++

```
^TDispDesc PDispDesc;
```

File

System.pas

Description

This is type System::PDispDesc.

158.5.30 System.PDouble Type

PDouble is a pointer to a Double variable.

Pascal

```
PDouble = ^Double;
```

C++

```
^Double PDouble;
```

File

System

Description

PDouble is a pointer to a Double variable.

See Also

Double

158.5.31 System.PDynArrayTypeInfo Type

Pascal

```
PDynArrayTypeInfo = ^TDynArrayTypeInfo;
```

C++

```
^TDynArrayTypeInfo PDynArrayTypeInfo;
```

File

System

Description

This is type System.PDynArrayTypeInfo.

158.5.32 System.PError Type

Pascal

```
PError = ^LongWord;
```

C++

```
^LongWord PError;
```

File

System

Description

This is type System.PError.

158.5.33 System.PExtended Type

PExtended is a pointer to an Extended variable.

Pascal

```
PExtended = ^Extended;
```

C++

```
^Extended PExtended;
```

File

System

Description

PExtended is a pointer to an Extended variable.

See Also

Extended

158.5.34 System.PGUID Type

PGUID is a pointer to a TGUID (see page 22558) variable.

Pascal

```
PGUID = ^TGUID;
```

C++

```
^TGUID PGUID;
```

File

System

Description

PGUID is a pointer to a TGUID (see page 22558) variable.

See Also

TGUID (see page 22558)

158.5.35 System.PInitContext Type

Pascal

```
PInitContext = ^TInitContext;
```

C++

```
^TInitContext PInitContext;
```

File

System

Description

This is type System.PInitContext.

158.5.36 System.PInt64 Type

PInt64 is a pointer to an Int64 variable.

Pascal

```
PInt64 = ^Int64;
```

C++

```
^Int64 PInt64;
```

File

System

Description

PInt64 is a pointer to an Int64 variable.

See Also

Int64

158.5.37 System.PInteger Type

PInteger is a pointer to an Integer variable.

Pascal

```
PInteger = ^Integer;
```

C++

```
^Integer PInteger;
```

File

System

Description

PInteger is a pointer to an Integer variable.

See Also

Integer

158.5.38 System.PIntegerArray Type

PIntegerArray is a pointer to an IntegerArray (see page 22586) variable.

Pascal

```
PIntegerArray = ^IntegerArray;
```

C++

```
^IntegerArray PIntegerArray;
```

File

System

Description

PIntegerArray is a pointer to an IntegerArray (see page 22586) variable.

See Also

IntegerArray (see page 22586)

158.5.39 System::PInterfaceEntry Type

Pascal

```
PInterfaceEntry = ^TInterfaceEntry;
```

C++

```
^TInterfaceEntry PInterfaceEntry;
```

File

System.pas

Description

This is type System::PInterfaceEntry.

158.5.40 System::PInterfaceTable Type

Pascal

```
PInterfaceTable = ^TInterfaceTable;
```

C++

```
^TInterfaceTable PInterfaceTable;
```

File

System.pas

Description

This is type System::PInterfaceTable.

158.5.41 System.PLibModule Type

PLibModule is a pointer to a TLibModule (see page 22561) variable.

Pascal

```
PLibModule = ^TLibModule;
```

C++

```
^TLibModule PLibModule;
```

File

System

Description

PLibModule is a pointer to a TLibModule (see page 22561) variable.

See Also

TLibModule (see page 22561)

158.5.42 System.PLongint Type

Pascal

```
PLongint = ^Longint;
```

C++

```
^Longint PLongint;
```

File

System

Description

This is type System.PLongint.

158.5.43 System.PLongWord Type

PLongWord is a pointer to a LongWord variable.

Pascal

```
PLongWord = ^LongWord;
```

C++

```
^LongWord PLongWord;
```

File

System

Description

PLongWord is a pointer to a LongWord variable.

See Also

LongWord

158.5.44 System.PMemoryManager Type

PMemoryManager is a pointer to a TMemoryManager (see page 22562) variable.

Pascal

```
PMemoryManager = ^TMemoryManager;
```

C++

```
^TMemoryManager PMemoryManager;
```

File

System

Description

PMemoryManager is a pointer to a TMemoryManager (see page 22562) variable.

See Also

TMemoryManager (see page 22562)

158.5.45 System.PMemoryManagerEx Type

PMemoryManagerEx is a pointer to a TMemoryManagerEx (see page 22563) variable.

Pascal

```
PMemoryManagerEx = ^TMemoryManagerEx;
```

C++

```
^TMemoryManagerEx PMemoryManagerEx;
```

File

System

Description

PMemoryManagerEx is a pointer to a TMemoryManagerEx (see page 22563) variable.

See Also

TMemoryManagerEx (see page 22563)

158.5.46 System.PModuleUnloadRec Type

Pascal

```
PModuleUnloadRec = ^TModuleUnloadRec;
```

C++

```
^TModuleUnloadRec PModuleUnloadRec;
```

File

System

Description

This is type System.PModuleUnloadRec.

158.5.47 System.PointerArray Type

Pascal

```
PointerArray = array [0..512*1024*1024 - 2] of Pointer;
```

C++

```
array [0..512*1024*1024 - 2] of Pointer PointerArray;
```

File

System

Description

This is type System.PointerArray.

158.5.48 System.POleVariant Type

Pascal

```
POleVariant = ^OleVariant;
```

C++

```
^OleVariant POleVariant;
```

File

System

Description

This is type System.POleVariant.

158.5.49 System.PPAnsiChar Type

Pascal

```
PPAnsiChar = PPChar;
```

C++

```
PPChar PPAnsiChar;
```

File

System

Description

This is type System.PPAnsiChar.

158.5.50 System.PPChar Type

Pascal

```
PPChar = ^PChar;
```

C++

```
^PChar PPChar;
```

File

System

Description

This is type System.PPChar.

158.5.51 System.PPCharArray Type

Pascal

```
PPCharArray = ^TPCharArray;
```

C++

```
^TPCharArray PPCharArray;
```

File

System

Description

This is type System.PPCharArray.

158.5.52 System.PPDispatch Type

Pascal

```
PPDispatch = ^PDispatch;
```

C++

```
^PDispatch PPDispatch;
```

File

System

Description

This is type System.PPDispatch.

158.5.53 System.PPointer Type

PPointer is a pointer to a Pointer variable.

Pascal

```
PPointer = ^Pointer;
```

C++

```
^Pointer PPointer;
```

File

System

Description

PPointer is a pointer to a Pointer variable.

See Also

Pointer

158.5.54 System.PPointerArray Type

PPointerArray is a pointer to a PointerArray (see page 22598) variable.

Pascal

```
PPointerArray = ^PointerArray;
```

C++

```
^PointerArray PPointerArray;
```

File

System

Description

PPointerArray is a pointer to a PointerArray (see page 22598) variable.

See Also

PointerArray (see page 22598)

158.5.55 System.PPUnknown Type

Pascal

```
PPUnknown = ^PUnknown;
```

C++

```
^PUnknown PPUnknown;
```

File

System

Description

This is type System.PPUnknown.

158.5.56 System.PPWideChar Type

Pascal

```
PPWideChar = ^PWideChar;
```

C++

```
^PWideChar PPWideChar;
```

File

System

Description

This is type System.PPWideChar.

158.5.57 System.PResStringRec Type

Pascal

```
PResStringRec = ^TResStringRec;
```

C++

```
^TResStringRec PResStringRec;
```

File

System

Description

This is type System.PResStringRec.

158.5.58 System.PShortInt Type

PShortInt is a pointer to a ShortInt variable.

Pascal

```
PShortInt = ^ShortInt;
```

C++

```
^ShortInt PShortInt;
```

File

System

Description

PShortInt is a pointer to a ShortInt variable.

See Also

ShortInt

158.5.59 System.PShortString Type

PShortString is a pointer to a ShortString variable.

Pascal

```
PShortString = ^ShortString;
```

C++

```
^ShortString PShortString;
```

File

System

Description

PShortString is a pointer to a ShortString variable.

See Also

ShortString

158.5.60 System.PSingle Type

PSingle is a pointer to a Single variable.

Pascal

```
PSingle = ^Single;
```

C++

```
^Single PSingle;
```

File

System

Description

PSingle is a pointer to a Single variable.

See Also

Single

158.5.61 System.PSmallInt Type

PSmallInt is a pointer to a SmallInt variable.

Pascal

```
PSmallInt = ^SmallInt;
```

C++

```
^SmallInt PSmallInt;
```

File

System

Description

PSmallInt is a pointer to a SmallInt variable.

See Also

SmallInt

158.5.62 System.PString Type

PString is a pointer to a String variable.

Pascal

```
PString = PAnsiString;
```

C++

```
PAnsiString PString;
```

File

System

Description

PString is a pointer to a String variable.

See Also

String

158.5.63 System.PTextBuf Type

Pascal

```
PTextBuf = ^TTextBuf;
```

C++

```
^TTextBuf PTextBuf;
```

File

System

Description

This is type System.PTextBuf.

158.5.64 System.PUCS2Char Type

Pascal

```
PUCS2Char = PWideChar;
```

C++

```
PWideChar PUCS2Char;
```

File

System

Description

This is type System.PUCS2Char.

158.5.65 System.PUCS4Char Type

Pascal

```
PUCS4Char = ^UCS4Char;
```

C++

```
^UCS4Char PUCS4Char;
```

File

System

Description

This is type System.PUCS4Char.

158.5.66 System.PUCS4CharArray Type

Pascal

```
PUCS4CharArray = ^TUCS4CharArray;
```

C++

```
^TUCS4CharArray PUCS4CharArray;
```

File

System

Description

This is type System.PUCS4CharArray.

158.5.67 System.PUnitEntryTable Type

Pascal

```
PUnitEntryTable = ^UnitEntryTable;
```

C++

```
^UnitEntryTable PUnitEntryTable;
```

File

System

Description

This is type System.PUnitEntryTable.

158.5.68 System.PUnknown Type

PUnknown is a pointer to an IUnknown (see page 22586) variable.

Pascal

```
PUnknown = ^IUnknown;
```

C++

```
^IUnknown PUnknown;
```

File

System

Description

PUnknown is a pointer to an IUnknown (see page 22586) variable.

See Also

IUnknown (see page 22586)

158.5.69 System.PUTF8String Type

Pascal

```
PUTF8String = ^UTF8String;
```

C++

```
^UTF8String PUTF8String;
```

File

System

Description

This is type System.PUTF8String.

158.5.70 System.PVarArray Type

Pascal

```
PVarArray = ^TVarArray;
```

C++

```
^TVarArray PVarArray;
```

File

System

Description

This is type System.PVarArray.

158.5.71 System.PVarArrayBoundArray Type

Pascal

```
PVarArrayBoundArray = ^TVarArrayBoundArray;
```

C++

```
^TVarArrayBoundArray PVarArrayBoundArray;
```

File

System

Description

This is type System.PVarArrayBoundArray.

158.5.72 System.PVarArrayCoorArray Type

Pascal

```
PVarArrayCoorArray = ^TVarArrayCoorArray;
```

C++

```
^TVarArrayCoorArray PVarArrayCoorArray;
```

File

System

Description

This is type System.PVarArrayCoorArray.

158.5.73 System.PVarData Type

Pascal

```
PVarData = ^TVarData;
```

C++

```
^TVarData PVarData;
```

File

System

Description

This is type System.PVarData.

158.5.74 System.PVariant Type

PVariant is a pointer to a Variant (see page 22307) variable.

Pascal

```
PVariant = ^Variant;
```

C++

```
^Variant PVariant;
```

File

System

Description

PVariant is a pointer to a Variant (see page 22307) variable.

See Also

Variant (see page 22307)

158.5.75 System.PVariantManager Type

Pascal

```
PVariantManager = ^TVariantManager;
```

C++

```
^TVariantManager PVariantManager;
```

File

System

Description

This is type System.PVariantManager.

158.5.76 System::PVarRec Type

Pascal

```
PVarRec = ^TVarRec;
```

C++

```
^TVarRec PVarRec;
```

File

System.pas

Description

This is type System::PVarRec.

158.5.77 System.PWideString Type

PWideString is a pointer to a WideString (see page 22377) variable.

Pascal

```
PWideString = ^WideString;
```

C++

```
^WideString PWideString;
```

File

System

Description

PWideString is a pointer to a WideString (see page 22377) variable.

See Also

WideString (see page 22377)

158.5.78 System.PWord Type

PWord is a pointer to a Word variable.

Pascal

```
PWord = ^Word;
```

C++

```
^Word PWord;
```

File

System

Description

PWord is a pointer to a Word variable.

See Also

Word

158.5.79 System.PWordBool Type

PWordBool is a pointer to a WordBool variable.

Pascal

```
PWordBool = ^WordBool;
```

C++

```
^WordBool PWordBool;
```

File

System

Description

PWordBool is a pointer to a WordBool variable.

See Also

WordBool

158.5.80 System::SCODE Type

Pascal

```
SCODE = uint32_t;
```

C++

```
typedef uint32_t SCODE;
```

File

sysvari.h

Description

This is type System::SCODE.

158.5.81 System.TAssertErrorProc Type

Pascal

```
TAssertErrorProc = procedure (const Message, Filename: string; LineNumber: Integer; ErrorAddr:
Pointer);
```

C++

```
(const Message, Filename: string; LineNumber: Integer; ErrorAddr: Pointer) (
TAssertErrorProc)();
```

File

System

Description

This is type System.TAssertErrorProc.

158.5.82 System::TBooleanDynArray Type

Pascal

```
TBooleanDynArray = DynamicArray<Boolean>;
```

C++

```
typedef DynamicArray<Boolean> TBooleanDynArray;
```

File

sysdyn.h

Description

This is type System::TBooleanDynArray.

158.5.83 System.TBoundArray Type

Pascal

```
TBoundArray = array of Integer;
```

C++

```
array of Integer TBoundArray;
```

File

System

Description

This is type System.TBoundArray.

158.5.84 System::TByteDynArray Type

Pascal

```
TByteDynArray = DynamicArray<Byte>;
```

C++

```
typedef DynamicArray<Byte> TByteDynArray;
```

File

sysdyn.h

Description

This is type System::TByteDynArray.

158.5.85 System::TCardinalDynArray Type

Pascal

```
TCardinalDynArray = DynamicArray<Cardinal>;
```

C++

```
typedef DynamicArray<Cardinal> TCardinalDynArray;
```

File

sysdyn.h

Description

This is type System::TCardinalDynArray.

158.5.86 System.TClass Type

TClass defines the metaclass for TObject (see page 22285).

Pascal

```
TClass = class of TObject;
```

C++

```
TObject * TClass;
```

File

System

Description

TClass is the metaclass for TObject (see page 22285). Its value is the class reference for TObject (see page 22285) or for

one of its descendants.

Delphi Examples:

```
{
This example shows how to obtain the ancestry of a component
using the ClassType and ClassParent properties. It uses a
button and a list box on a form. When the user clicks the
button, the name of the button's class and the names of its
parent classes are added to the list box.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ClassRef: TClass;
begin
  ListBox1.Clear;
  ClassRef := Sender.ClassType;
  while ClassRef <> nil do
  begin
    ListBox1.Items.Add(ClassRef.ClassName);
    ClassRef := ClassRef.ClassParent;
  end;
end;
{
The list box contains the following strings after the user clicks the button:
    TButton
    TButtonControl
    TWinControl or TWinControl
    TControl
    TComponent
    TPersistent
    TObject
}
```

See Also

TObject (see page 22285)

158.5.87 System.TDateTime Type

TDateTime represents a date-and-time value in the Delphi language.

Pascal

```
TDateTime = type Double;
```

C++

```
type Double TDateTime;
```

File

System

Description

In Delphi, TDateTime is a type that maps to a Double. In C++, the TDateTime class corresponds to the Delphi TDateTime type.

The integral part of a Delphi TDateTime value is the number of days that have passed since 12/30/1899. The fractional part of the TDateTime value is fraction of a 24 hour day that has elapsed.

Following are some examples of TDateTime values and their corresponding dates and times:

0	12/30/1899 12:00 am
2.75	1/1/1900 6:00 pm
-1.25	12/29/1899 6:00 am
35065	1/1/1996 12:00 am

To find the fractional number of days between two dates, simply subtract the two values, unless one of the TDateTime values is negative. Similarly, to increment a date and time value by a certain fractional number of days, add the fractional number to the date and time value if the TDateTime value is positive.

When working with negative TDateTime values, computations must handle time portion separately. The fractional part reflects the fraction of a 24-hour day without regard to the sign of the TDateTime value. For example, 6:00 am on 12/29/1899 is –1.25, not –1 + 0.25, which would be –0.75. There are no TDateTime values between –1 and 0.

Note: Delphi 1.0 calculated the date from year 1 instead of from 1899. To convert a Delphi 1.0 date to a TDateTime value in later versions of the Delphi language, subtract 693594.0 from the Delphi 1.0 date.

TTimeStamp

TDate

TSQLTimeStamp

158.5.88 System.TDLLProc Type

Pascal

```
TDLLProc = procedure (Reason: Integer);
```

C++

```
(Reason: Integer) ( TDLLProc)();
```

File

System

Description

This is type System.TDLLProc.

158.5.89 System.TDLLProcEx Type

Pascal

```
TDLLProcEx = procedure (Reason: Integer; Reserved: Integer);
```

C++

```
(Reason: Integer; Reserved: Integer) ( TDLLProcEx)();
```

File

System

Description

This is type System.TDLLProcEx.

158.5.90 System::TDoubleDynArray Type

Pascal

```
TDoubleDynArray = DynamicArray<Double>;
```

C++

```
typedef DynamicArray<Double> TDoubleDynArray;
```

File

sysdyn.h

Description

This is type System::TDoubleDynArray.

158.5.91 System.TEnumModuleFunc Type

Pascal

```
TEnumModuleFunc = function (HInstance: Integer; Data: Pointer): Boolean;
```

C++

```
(HInstance: Integer; Data: Pointer): Boolean ( TEnumModuleFunc)();
```

File

System

Description

This is type System.TEnumModuleFunc.

158.5.92 System.TEnumModuleFuncLW Type

Pascal

```
TEnumModuleFuncLW = function (HInstance: LongWord; Data: Pointer): Boolean;
```

C++

```
(HInstance: LongWord; Data: Pointer): Boolean ( TEnumModuleFuncLW)();
```

File

System

Description

This is type System.TEnumModuleFuncLW.

158.5.93 System.TFileIOFunc Type

Pascal

```
TFileIOFunc = function (var F: TFileRec): Integer;
```

C++

```
(var F: TFileRec): Integer ( TFileIOFunc)();
```

File

System

Description

This is type System.TFileIOFunc.

158.5.94 System.THandle Type

THandle is a general purpose data reference (handle).

Pascal

```
THandle = LongWord;
```

C++

```
LongWord THandle;
```

File

System

Description

For example, the SaveToClipboardFormat uses a THandle variable to hold a handle to the data of a bit map. SetAsHandle can then be used to store the bit map data, via its handle, to the clipboard.

Handles are used extensively in communication with Windows APIs.

See Also

SaveToClipboardFormat (see page 14415)

SetAsHandle (see page 3343)

158.5.95 System::TInt64DynArray Type

Pascal

```
TInt64DynArray = DynamicArray<__int64>;
```

C++

```
typedef DynamicArray<__int64> TInt64DynArray;
```

File

sysdyn.h

Description

This is type System::TInt64DynArray.

158.5.96 System::TIntegerDynArray Type

Pascal

```
TIntegerDynArray = DynamicArray<Integer>;
```

C++

```
typedef DynamicArray<Integer> TIntegerDynArray;
```

File

sysdyn.h

Description

This is type System::TIntegerDynArray.

158.5.97 System.TInterfacedClass Type

TInterfacedClass defines the metaclass for TInterfacedObject (see page 22276).

Pascal

```
TInterfacedClass = class of TInterfacedObject;
```

C++

```
TInterfacedObject TInterfacedClass;
```

File

System

Description

TInterfacedClass is the metaclass for TInterfacedObject (see page 22276). Its value is the class reference for TInterfacedObject (see page 22276) or for one of its descendants.

See Also

TInterfacedObject (see page 22276)

158.5.98 System::TLongWordDynArray Type

Pascal

```
TLongWordDynArray = DynamicArray<unsigned>;
```

C++

```
typedef DynamicArray<unsigned> TLongWordDynArray;
```

File

sysdyn.h

Description

This is type System::TLongWordDynArray.

158.5.99 System.TMemoryMap Type

TMemoryMap is a map of an application's address space as an array of TChunkStatus (see page 22554) values.

Pascal

```
TMemoryMap = array[0..65535] of TChunkStatus;
```

C++

```
array[0..65535] of TChunkStatus TMemoryMap;
```

File

System

Description

GetMemoryMap (see page 22473) returns a map of the address space of the current process. For the purposes of the map, the entire 4GB address space is broken down into 64K chunks. There are 65536 such chunks. TMemoryMap obtains a status value for each of them in the TMemoryMap array. Each TMemoryMap array element may have the following value :

Status value	Meaning
csUnallocated	Free
csAllocated	In use by the process
csReserved	Reserved for future use by the process
csSysAllocated	In use by the operating system
csSysReserved	Reserved for future use by the operating system

See Also

GetMemoryMap (see page 22473)

158.5.100 System.TModuleUnloadProc Type

TModuleUnloadProc dehines a procedure that can be called during package unload.

Pascal

```
TModuleUnloadProc = procedure (HInstance: Integer);
```

C++

```
(HInstance: Integer) ( TModuleUnloadProc)();
```

File

System

Description

Before Delphi unloads a package that was used by your application, it can optionally call your TModuleUnloadProcLW (see page 22618) routine. In essence, AddModuleUnloadProc (see page 22411) adds your callback routine to the head of the list of internal routines that Delphi invokes to perform the unload.

Proc is the Handle to the DLL Package instance being unloaded.

The LW part of the name refers to the Long Word type of package handle. This is in line with Windows handles, and the THandle (see page 22615) type.

See Also

AddModuleUnloadProcLW

TModuleUnloadProcLW (see page 22618)

158.5.101 System.TModuleUnloadProcLW Type

Pascal

```
TModuleUnloadProcLW = procedure (HInstance: LongWord);
```

C++

```
(HInstance: LongWord) ( TModuleUnloadProcLW)();
```

File

System

Description

This is type System.TModuleUnloadProcLW.

158.5.102 System.TPCharArray Type

Pascal

```
TPCharArray = array[0..(MaxLongint div SizeOf(PChar))-1] of PChar;
```

C++

```
array[0..(MaxLongint div SizeOf(PChar))-1] of PChar TPCharArray;
```

File

System

Description

This is type System.TPCharArray.

158.5.103 System.TResourceHandle Type

Pascal

```
TResourceHandle = HRSRC;
```

C++

```
HRSRC TResourceHandle;
```

File

System

Description

This is type System.TResourceHandle.

158.5.104 System.TSafeCallErrorProc Type

Pascal

```
TSafeCallErrorProc = procedure (ErrorCode: HResult; ErrorAddr: Pointer);
```

C++

```
(ErrorCode: HResult; ErrorAddr: Pointer) ( TSafeCallErrorProc)();
```

File

System

Description

This is type System.TSafeCallErrorProc.

158.5.105 System::TShortIntDynArray Type

Pascal

```
TShortIntDynArray = DynamicArray<Shortint>;
```

C++

```
typedef DynamicArray<Shortint> TShortIntDynArray;
```

File

sysdyn.h

Description

This is type System::TShortIntDynArray.

158.5.106 System::TSingleDynArray Type

Pascal

```
TSingleDynArray = DynamicArray<Single>;
```

C++

```
typedef DynamicArray<Single> TSingleDynArray;
```

File

sysdyn.h

Description

This is type System::TSingleDynArray.

158.5.107 System.TSmallBlockTypeStates Type

TSmallBlockTypeStates is an array of small memory block information records.

Pascal

```
TSmallBlockTypeStates = array[0..NumSmallBlockTypes - 1] of TSmallBlockTypeState;
```

C++

```
array[0..NumSmallBlockTypes - 1] of TSmallBlockTypeState TSmallBlockTypeStates;
```

File

System

Description

GetMemoryManagerState (see page 22472) returns a structure containing memory usage statistics for each block type - small, medium and large blocks. It returns this data in a TMemoryManagerState (see page 22564) record. Within that record is held a TSmallBlockTypeStates field - an array of TSmallBlockTypeState (see page 22568) records. There are NumSmallBlockTypes (see page 22666) (55) different small memory block sizes, and therefore 55 TSmallBlockTypeState (see page 22568) records in this array.

See Also

GetMemoryManagerState (see page 22472)

NumSmallBlockTypes (see page 22666)

TSmallBlockTypeState (see page 22568)

158.5.108 System::TSmallIntDynArray Type

Pascal

```
TSmallIntDynArray = DynamicArray<Smallint>;
```

C++

```
typedef DynamicArray<Smallint> TSmallIntDynArray;
```

File

sysdyn.h

Description

This is type System::TSmallIntDynArray.

158.5.109 System::TStringDynArray Type

Pascal

```
TStringDynArray = DynamicArray<String>;
```

C++

```
typedef DynamicArray<String> TStringDynArray;
```

File

sysdyn.h

Description

This is type System::TStringDynArray.

158.5.110 System.TSystemThreadEndProc Type

Pascal

```
TSystemThreadEndProc = procedure (ExitCode: Integer);
```

C++

```
(ExitCode: Integer) ( TSystemThreadEndProc)();
```

File

System

Description

This is type System.TSystemThreadEndProc.

158.5.111 System.TSystemThreadFuncProc Type

Pascal

```
TSystemThreadFuncProc = function (ThreadFunc: TThreadFunc; Parameter: Pointer): Pointer;
```

C++

```
(ThreadFunc: TThreadFunc; Parameter: Pointer): Pointer ( TSystemThreadFuncProc)();
```

File

System

Description

This is type System.TSystemThreadFuncProc.

158.5.112 System.TTextBuf Type

Pascal

```
TTextBuf = array[0..127] of Char;
```

C++

```
array[0..127] of Char TTextBuf;
```

File

System

Description

This is type System.TTextBuf.

158.5.113 System.TTextIOFunc Type

Pascal

```
TTextIOFunc = function (var F: TTextRec): Integer;
```

C++

```
(var F: TTextRec): Integer ( TTextIOFunc)();
```

File

System

Description

This is type System.TTextIOFunc.

158.5.114 System.TThreadFunc Type

TThreadFunc defines a new thread of execution.

Pascal

```
TThreadFunc = function (Parameter: Pointer): Integer;
```

C++

```
(Parameter: Pointer): Integer ( TThreadFunc)();
```

File

System

Description

Use BeginThread (see page 22422) or a TThread object to spawn separate threads of execution. BeginThread (see page 22422) spawns a new thread of execution via the TThreadFunc defined function.

Parameter is a pointer to any data you want to pass to the new thread.

When the thread completes, it returns a status code.

See Also

BeginThread (see page 22422)

TThread

158.5.115 System.TUCS4CharArray Type

Pascal

```
TUCS4CharArray = array [0..$effffff] of UCS4Char;
```

C++

```
array [0..$effffff] of UCS4Char TUCS4CharArray;
```

File

System

Description

This is type System.TUCS4CharArray.

158.5.116 System.TVarArrayBoundArray Type

Pascal

```
TVarArrayBoundArray = array [0..0] of TVarArrayBound;
```

C++

```
array [0..0] of TVarArrayBound TVarArrayBoundArray;
```

File

System

Description

This is type System.TVarArrayBoundArray.

158.5.117 System.TVarArrayCoorArray Type

Pascal

```
TVarArrayCoorArray = array [0..0] of Integer;
```

C++

```
array [0..0] of Integer TVarArrayCoorArray;
```

File

System

Description

This is type System.TVarArrayCoorArray.

158.5.118 System.TVarOp Type

TVarOp defines a Variant (see page 22307) operation.

Pascal

```
TVarOp = Integer;
```

C++

```
int TVarOp;
```

File

System

Description

TVarOp is used to define an Variant (see page 22307) operation. There are three operation categories :

Type	Meaning
Two operand processing	A logical operation of left and right operands. Such as BinaryOp.
Two operand comparison	A comparison of left and right operands. Such as CompareOp.
One operand processing	Processing of a single operand. Such as UnaryOp.

TVarOp may hold one of the following values :

Value	Meaning
opAdd (see page 22667)	Addition.
opAnd (see page 22667)	Bitwise and.
opCmpEQ (see page 22668)	Compare for equality.
opCmpGE (see page 22668)	Compare left greater than or equal to right.
opCmpGT (see page 22669)	Compare left greater than right.
opCmpLE (see page 22669)	Compare left less than or equal to right.
opCmpLT (see page 22670)	Compare left less than right.
opCmpNE (see page 22670)	Compare for inequality.
opCompare (see page 22671)	Generalised comparison.
opDivide (see page 22671)	Division of left by right.
opIntDivide (see page 22672)	Integer division of left by right.
opModulus (see page 22672)	Remainder of left divide by right.

opMultiply (see page 22673)	Left multiplied by right.
opNegate (see page 22673)	Negation of a single operand value.
opNot (see page 22674)	Bitwise negation of a single operand.
opOr (see page 22674)	Bitwise or.
opShiftLeft (see page 22675)	Bitwise shift left.
opShiftRight (see page 22675)	Bitwise shift right.
opSubtract (see page 22676)	Right subtracted from left.
opXor (see page 22676)	Bitwise exclusive or.

See Also

BinaryOp

CompareOp (see page 23590)

UnaryOp

158.5.119 System.TVarType Type

Pascal

```
TVarType = Word;
```

C++

```
Word TVarType;
```

File

System

Description

This is type System.TVarType.

158.5.120 System::TWideStringDynArray Type

Pascal

```
TWideStringDynArray = DynamicArray<WideString>;
```

C++

```
typedef DynamicArray<WideString> TWideStringDynArray;
```

File

sysdyn.h

Description

This is type System::TWideStringDynArray.

158.5.121 System::TWordDynArray Type

Pascal

```
TWordDynArray = DynamicArray<Word>;
```

C++

```
typedef DynamicArray<Word> TWordDynArray;
```

File

sysdyn.h

Description

This is type System::TWordDynArray.

158.5.122 System.UCS2Char Type

Pascal

```
UCS2Char = WideChar;
```

C++

```
WideChar UCS2Char;
```

File

System

Description

This is type System.UCS2Char.

158.5.123 System.UCS4Char Type

UCS4Char is used for working with 4–byte Unicode characters.

Pascal

```
UCS4Char = type LongWord;
```

C++

```
type LongWord UCS4Char;
```

File

System

Description

UCS4Char represents a 4–byte Unicode character. UCS4String (see page 22627) is a dynamic array of UCS4Char.

See Also

UCS4String (see page 22627)

UCS4StringToWideString

158.5.124 System.UCS4String Type

UCS4String is used for working with 4–byte Unicode characters.

Pascal

```
UCS4String = array of UCS4Char;
```

C++

```
array of UCS4Char UCS4String;
```

File

System

Description

UCS4Char (see page 22626) represents a 4–byte Unicode character. UCS4String, which is a dynamic array of UCS4Char (see page 22626), represents a string encoded using UCS4 (4–byte Unicode).

See Also

UCS4Char (see page 22626)

UCS4StringToWideString

158.5.125 System.UnitEntryTable Type

Pascal

```
UnitEntryTable = array [0..9999999] of PackageUnitEntry;
```

C++

```
array [0..9999999] of PackageUnitEntry UnitEntryTable;
```

File

System

Description

This is type System.UnitEntryTable.

158.5.126 System.UTF8String Type

Pascal

```
UTF8String = type string;
```

C++

```
type string UTF8String;
```

File

System

Description

This is type System.UTF8String.

158.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
AbstractErrorProc (see page 22630)	AbstractErrorProc defines a callback routine for abstract method call errors.
AllocMemCount (see page 22630)	Represents the total number of allocated memory blocks in a Delphi application.
AllocMemSize (see page 22631)	Represents the total size of allocated memory blocks.
AssertErrorProc (see page 22633)	Points to the assertion error-handler.
CmdLine (see page 22635)	Points to the command-line arguments specified when the application is invoked.
CmdShow (see page 22635)	Specifies the flags for displaying the application's main window.
DebugHook (see page 22636)	DebugHook is set if an application is running under the IDE debugger.
Default8087CW (see page 22636)	Specifies the Default 8087 control word.
DefaultTextLineBreakStyle (see page 22636)	Specifies the characters that are used by default to separate lines in text.
DispCallByIDProc (see page 22637)	This is variable System.DispCallByIDProc.
DLLProc (see page 22637)	Points to a procedure invoked by a DLL entry point.
envp (see page 22638)	This is variable System.envp.
ErrorAddr (see page 22638)	Contains the address of a statement causing a runtime error.
ErrorProc (see page 22639)	Points to the RTL runtime error handler.
ErrOutput (see page 22640)	ErrOutput specifies a write-only Text file associated with the process's error output file.
ExceptClsProc (see page 22640)	ExceptClsProc defines a pointer to a function called during exception handling.
ExceptionClass (see page 22641)	This is variable System.ExceptionClass.
ExceptObjProc (see page 22641)	ExceptObjProc defines a pointer to a function called during exception handling.
ExceptProc (see page 22641)	Points to the lowest-level exception handler.
ExitCode (see page 22642)	Contains the application's exit code.
ExitProc (see page 22643)	Points to a program's exit procedure (provided for backward compatibility).
ExitProcessProc (see page 22644)	Specifies the last procedure to execute before the application shuts down.
FileMode (see page 22644)	Indicates the access mode on typed and untyped files opened by the Reset (see page 22511) procedure.
HeapAllocFlags (see page 22645)	Indicates how the memory manager obtains memory from the operating system.
HPrevInst (see page 22645)	This is variable System.HPrevInst.
InitProc (see page 22646)	InitProc is the last installed initialization procedure.
Input (see page 22647)	Specifies a read-only Text file associated with the processes standard Input file.
IsConsole (see page 22647)	Indicates whether the module was compiled as a console application.
IsLibrary (see page 22648)	Indicates whether the module is a shared library.
IsMultiThread (see page 22648)	Indicates whether the application spawned additional threads using BeginThread (see page 22422) or TThread objects.
JITEnable (see page 22649)	Controls (see page 5711) when the just-in-time debugger is called.
LibModuleList (see page 22650)	Lists module records for enumeration procedures.
MainInstance (see page 22650)	Indicates the instance handle for the main executable.
MainThreadID (see page 22651)	Indicates the instance handle for the current module's main thread of execution.
MaxDispArgs (see page 22651)	This is variable System::MaxDispArgs.
ModuleUnloadList (see page 22651)	This is variable System.ModuleUnloadList.
NeverSleepOnMMThreadContention (see page 22652)	Dictates memory manager behavior during a thread contention.
NoErrMsg (see page 22652)	Controls (see page 5711) whether the application displays an error message when a runtime error occurs.
