Output (see page 22653)	Specifies a write-only Text file associated with the process's standard output file.
RaiseExceptionProc (see page 22653)	Points to RaiseException Windows function.
RandSeed (see page 22654)	RandSeed stores the built-in random number generator's seed.
ReportMemoryLeaksOnShutdown (see page 22654)	Report memory leaks on shutdown.

RTLUnwindProc (see page 22655)	This is variable System.RTLUnwindProc.
SafeCallErrorProc (see page 22655)	SafeCallErrorProc defines a procedure that is called when a safecall routine incurs an error.
SystemThreadEndProc (see page 22656)	This is variable System.SystemThreadEndProc.
SystemThreadFuncProc (see page 22656)	This is variable System.SystemThreadFuncProc.
Test8086 (see page 22656)	This is variable System.Test8086.
Test8087 (see page 22657)	This is variable System.Test8087.
TestFDIV (see page 22657)	This is variable System.TestFDIV.
VarAddRefProc (see page 22657)	This is variable System.VarAddRefProc.
VarClearProc (see page 22658)	This is variable System.VarClearProc.
VarCopyProc (see page 22658)	This is variable System.VarCopyProc.
VarToLStrProc (see page 22658)	This is variable System.VarToLStrProc.
VarToWStrProc (see page 22659)	This is variable System.VarToWStrProc.

158.6.1 System.AbstractErrorProc Variable

AbstractErrorProc defines a callback routine for abstract method call errors.

Pascal

```
AbstractErrorProc: procedure;
```

C++

```
procedure AbstractErrorProc;
```

File

System

Description

An abstract method is a virtual or dynamic method that has no implementation in the class where it is declared. Its implementation is deferred to a descendant class. An EAbstractError exception will be thrown if a call is attempted to an abstact method.

You can define an AbstractErrorProc routine that will be called prior to the exception throw.

See Also

EAbstractError (see page 22722)

158.6.2 System.AllocMemCount Variable

Represents the total number of allocated memory blocks in a Delphi application.

Pascal

```
AllocMemCount: Integer deprecated;
```

C++

```
Integer deprecated AllocMemCount;
```

File

System

Description

Note: On Windows, AllocMemCount is the number of currently allocated blocks of memory that were requested by the user. AllocMemCount is incremented each time a block of memory is allocated and is decremented each time a block of memory is freed. Use AllocMemCount to find out how many unfreed blocks of memory remain.

Note: On Linux, the AllocMemCount variable is not maintained by default. Unless it is updated by a third-party memory manager, this variable always has a value of zero.

Warning: Caution:Because AllocMemCount is a global variable declared in the System (see page 22079) unit, it is not always safe to access it directly. In situations where modules are statically linked to the RTL, each module will have a different instance of AllocMemCount. The following table is a summary. Note that applications that use runtime packages are dynamically linked to the RTL, whereas applications that do not are statically linked.

Application type	Accessibility of AllocMemCount
EXE	Applications that do not use packages or Delphi DLLs can safely access this global variable directly because there is only one instance of it.
EXE with packages and no Delphi DLLs	Applications that use runtime packages and do not use any statically linked libraries can safely access AllocMemCount directly. In this situation all modules are dynamically linked to the RTL and there is only one instance of the variable. Unlike standard DLLs, packages allow access to global variables.
EXE with statically linked DLLs	If an application is statically linked to the RTL and also uses libraries that are statically linked to the RTL, then the AllocMemCount variable should never be accessed directly, since the EXE and each library will have its own instance of it. Instead, use the GetAllocMemCount function, implemented in BorlandMM, which returns the instance of the AllocMemCount global variable in the BorlandMM DLL. This DLL manages the memory allocation for all modules that include the ShareMem unit as the first unit in the application or library's uses clause. It is, therefore, this instance of the variable that contains the correct value. A function is used to access AllocMemCount in this situation because global variables in a DLL are private to the DLL.
EXE with packages and statically linked DLLs	It is not advisable to create applications that mix runtime packages with statically linked libraries. In this circumstance, use caution when allocating, freeing, and accessing memory. Be aware that each version of the RTL contains an instance of AllocMemCount that references memory that is allocated and freed only by that particular module.

See Also

AllocMemSize (see page 22631)

AllocMem (see page 22413)

158.6.3 System.AllocMemSize Variable

Represents the total size of allocated memory blocks.

Pascal

```
AllocMemSize: Integer deprecated;
```

C++

```
Integer deprecated AllocMemSize;
```

File

System

Description

Note: On Windows, AllocMemSize is the total size, in bytes, of all currently allocated blocks of memory in use by an application. Use AllocMemSize to find out how many bytes of memory an application is currently using.

Note: On Linux, the AllocMemSize variable is not maintained by default. Unless it is updated by a third-party memory manager, this variable always has a value of zero.

Warning: Caution:Because AllocMemSize is a global variable declared in the System (see page 22079) unit, it is not always safe to access it directly. In situations where modules are statically linked to the RTL, each module will have a different instance of AllocMemSize. The following table is a summary. Note that applications that use runtime packages are dynamically linked to the RTL, whereas applications that do not are statically linked.

Application type	Accessibility of AllocMemSize
EXE	Applications that do not use packages or Delphi DLLs can safely access this global variable directly because there is only one instance of it.
EXE with packages and no Delphi DLLs	Applications that use runtime packages and do not use any statically linked DLLs can safely access AllocMemSize directly. In this situation all modules are dynamically linked to the RTL and there is only one instance of the variable. Unlike standard DLLs, packages allow access to global variables.
EXE with statically linked DLLs	If an application is statically linked to the RTL and if that application is also using DLLs that are statically linked to the RTL then the AllocMemSize variable should never be accessed directly, since the EXE and each DLL will have its own instance of it. Instead use the GetAllocMemSize function, implemented in BorlandMM, which returns the instance of the AllocMemSize global variable in the BorlandMM DLL. This DLL manages the memory allocation for all modules that include the ShareMem unit as the first unit in the application or library's uses clause. It is, therefore, this instance of the variable that contains the correct value. A function is used to access AllocMemSize in this situation because global variables in a DLL are private to the DLL.
EXE with packages and statically linked DLLS	It is not advisable to create applications that mix runtime packages with statically linked DLLs. In this circumstance use caution when allocating, freeing, and accessing memory. Be aware that each version of the RTL contains an instance of AllocMemSize that references memory that is allocated and freed only by that particular module.

158.6.4 System.AssertErrorProc Variable

Points to the assertion error-handler.

Pascal

```
AssertErrorProc: TAssertErrorProc;
```

C++

```
TAssertErrorProc AssertErrorProc;
```

File

System

Description

AssertErrorProc points to a routine that produces runtime error 227 in Delphi code. The SysUtils (see page 22709) unit replaces it to cause an EAssertionFailed exception. If you do not use assertions, you can replace this with a method that that does something else, such as call OutputDebugString to add messages to the event log (see the example).

The value of AssertErrorProc must be a procedure with the following signature

procedure AssertErrorHandler(const Message, Filename: string; LineNumber: Integer; ErrorAddr (see page 22638): Pointer);

Delphi Examples:

```
{
AssertErrorProc example
The following code is a self-contained unit that you can add to a project
that logs failed assertions to the event log rather than raising an
exception. If /Debug is passed to the application as a command-line
parameter, all failed Assert calls cause a call to OutputDebugString,
which sends a messages to the Event Log window if run from Delphi, or
does nothing if run outside the IDE (OutputDebugString is a no-op if not
run from within a debugger). A nice side benefit is that all the line
numbers and unit names can be stripped from the EXE by turning off
assertions and rebuilding the project.
Note: AssertErrorHandler should do as little as possible.  This routine
does no cleanup, so no variables, no compiler generated variables.
Procedure calls are OK.
Note:   This example was originally provided by Brian Long.
}
type
  TForm1 = class(TForm)
    procedure Button1Click(Sender: TObject);
  private
    { Private declarations }
  public
    { Public declarations }
  end;

  TStorage = class(TObject)
    FData: string;
    property Data: string read FData write FData;
  private
    { Private declarations }
  public
    { Public declarations }
  end;

  var
  Form1: TForm1;
```

```
procedure AssertErrorHandler(const Message, Filename: string;  LineNumber: Integer; ErrorAddr:
Pointer);

implementation

{$R *.dfm}

{$ASSERTIONS ON}

type
  EMyAssert = class(Exception);

procedure DoMessage(Message, Filename: String; LineNumber: Integer; ErrorAddr: Pointer);
var
  S: String;
begin
  S := Format('%s (%s, line %d, address $%x)',
    [Message, Filename, LineNumber, Pred(Integer(ErrorAddr))]);
  OutputDebugString(PChar(S));
end;

procedure AssertErrorHandler(const Message, Filename: string;  LineNumber: Integer; ErrorAddr:
Pointer);
{ No local variables.  Not compiler generated temporary variables. }
{ Using the call stack here will cause Access Violation errors. }
begin
  DoMessage(Message, Filename, LineNumber, ErrorAddr);
  raise EMyAssert.Create('Boom!');
end;

procedure AssertErrorNoHandler(const Message, Filename: string; LineNumber: Integer;
ErrorAddr: Pointer);
begin
end;

procedure ModifyStorage(AStorage: TStorage; const s: string);
begin
  Assert(AStorage <> nil, 'Value');
  AStorage.Data := s;
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  ModifyStorage(nil, 'Oops');
end;

EAssertionFailed

Assert (see page 22417)

ErrorProc (see page 22639)

158.6.5 System.CmdLine Variable

Points to the command-line arguments specified when the application is invoked.

Pascal

```
CmdLine: PChar platform;
```

C++

```
PChar platform CmdLine;
```

File

System

Description

Note: On Windows, the CmdLine variable points to a null-terminated string that contains the command-line arguments specified when the application was started. Use ParamStr (see page 22496) to access individual arguments. In a library (DLL), CmdLine is nil (Delphi) or NULL (C++).

Note: On Linux, CmdLine is always nil (Delphi) or NULL (C++).

See Also

ParamStr (see page 22496)

158.6.6 System.CmdShow Variable

Specifies the flags for displaying the application's main window.

Pascal

```
CmdShow: Integer platform;
```

C++

```
Integer platform CmdShow;
```

File

System

Description

Note: On Windows, CmdShow specifies the parameter that should be passed to the Windows API ShowWindow when displaying the main window of the application. In a library (DLL), CmdShow is always 0.

Note: On Linux, CmdShow is always 0. It exists only for compatibility with Windows code in cross-platform applications.

158.6.7 System.DebugHook Variable

DebugHook is set if an application is running under the IDE debugger.

Pascal

```
DebugHook: Byte platform = 0;
```

C++

```
Byte platform DebugHook = 0;
```

File

System

Description

DebugHook is 0 when an application operates outside the IDE debugger. DebugHook is 1 when an application operates inside the IDE debugger.

158.6.8 System.Default8087CW Variable

Specifies the Default 8087 control word.

Pascal

```
Default8087CW: Word = $1332;
```

C++

```
Word Default8087CW = 0x1332;
```

File

System

Description

Default8087CW is the value to which the Floating Point Unit (FPU) control register is set. The FPU control word includes bits that control the FPU's precision, rounding mode, and whether exceptions generate signals if they occur. See Intel's processor documentation for details.

The Set8087CW (see page 22520) procedure allows the programmer to have direct access to the Default8087CW. Setting the floating-point precision and rounding mechanism can be useful if you are reusing old code that is sensitive to the floating-point precision standard used. However, be aware that using this procedure to change the value of the 8087CW will change the behavior of the program's FP calculations. It is the programmer's responsibility to reset it.

See Also

Set8087CW (see page 22520)

158.6.9 System.DefaultTextLineBreakStyle Variable

Specifies the characters that are used by default to separate lines in text.

Pascal

```
DefaultTextLineBreakStyle: TTextLineBreakStyle = tlbsCRLF;
```

C++

```
TTextLineBreakStyle DefaultTextLineBreakStyle = tlbsCRLF;
```

File

System

Description

DefaultTextLineBreakStyle controls how the code editor represents the separation between lines of text in new files. For existing files, it maintains the line break style that the file currently uses.

See Also

SetLineBreakStyle (see page 22522)

158.6.10 System.DispCallByIDProc Variable

Pascal

```
DispCallByIDProc: Pointer;
```

C++

```
void * DispCallByIDProc;
```

File

System

Description

This is variable System.DispCallByIDProc.

158.6.11 System.DLLProc Variable

Points to a procedure invoked by a DLL entry point.

Pascal

```
DLLProc: Pointer;
```

C++

```
void * DLLProc;
```

File

System

Description

DLLProc is used to specify a procedure that is invoked every time a DLL's entry point is called. A procedure assigned to DLLProc must take one parameter of type Integer or int. For example,

- procedure LibraryProc(Reason: Integer); { Delphi }
- void LibraryProc(int Reason); // C++

- When the procedure is invoked, this single parameter contains a value between 0 and 3 as defined by the following group of constants (from the Windows unit):
- const
- DLL_PROCESS_DETACH = 0;
- DLL_PROCESS_ATTACH = 1;
- DLL_THREAD_ATTACH = 2;
- DLL_THREAD_DETACH = 3;
- For further details on the meaning of these constants, refer to the description of the DllEntryPoint function in the Win32 API online help.

Note: DLL_PROCESS_ATTACH is passed to the procedure only if the DLL's initialization code calls the procedure and specifies DLL_PROCESS_ATTACH as a parameter.

Note: When the Reason parameter is DLL_PROCESS_ATTACH, setting ExitCode (see page 22642) to a nonzero value causes the entry point to return false.

158.6.12 System.envp Variable

Pascal

```
envp: PPChar platform;
```

C++

```
PPChar platform envp;
```

File

System

Description

This is variable System.envp.

158.6.13 System.ErrorAddr Variable

Contains the address of a statement causing a runtime error.

Pascal

```
ErrorAddr: Pointer = nil;
```

C++

```
void * ErrorAddr = nil;
```

File

System

Description

If a program terminates normally or stops due to a call to Halt (see page 22475), ErrorAddr is nil (Delphi) or NULL (C++). If a program ends because of a runtime error, ErrorAddr contains the address of the statement in error.

See Also

ErrorProc (see page 22639)

ExceptProc (see page 22641)

AcquireExceptionObject (see page 22410)

ExceptAddr (see page 22452)

ExceptionErrorMessage

ExceptObject (see page 22452)

GetLastError (see page 22469)

158.6.14 System.ErrorProc Variable

Points to the RTL runtime error handler.

Pascal

```
ErrorProc: procedure (ErrorCode: Byte; ErrorAddr: Pointer);
```

C++

```
procedure (ErrorCode: Byte; ErrorAddr: Pointer) ErrorProc;
```

File

System

Description

In Delphi, ErrorProc is a procedure variable pointing to the runtime error handler. The standard ErrorProc procedure reports the runtime error and terminates the program.

The ErrorProc variable is retained primarily for compatibility with older code. Newer applications should not specify an alternate runtime error procedure using ErrorProc as SysUtils (see page 22709) uses this variable to convert runtime errors into exceptions.

If you use SysUtils (see page 22709) in your program, it will force ErrorProc to its own routine and convert the runtime error into an exception. When a runtime library error occurs, the ErrorProc is called. The ErrorCode parameter contains the runtime error number and the ErrorAddr (see page 22638) parameter contains the machine code address that caused the runtime error.

See Also

ErrorAddr (see page 22638)

ExceptAddr (see page 22452)

ExceptionErrorMessage

ExceptObject (see page 22452)

GetLastError (see page 22469)

ExceptProc (see page 22641)

GetLastError (see page 22469)

AcquireExceptionObject (see page 22410)

158.6.15 System.ErrOutput Variable

ErrOutput specifies a write-only Text file associated with the process's error output file.

Pascal

```
ErrOutput: Text;
```

C++

```
Text ErrOutput;
```

File

System

Description

In Delphi, the ErrOutput variable is a write-only Text file associated with the process's error output file.

Note: On Windows, most processes don't have an error output file, and writing to ErrOutput raises an error. Delphi programs have a standard output file if they are linked as console applications.

Note: On Linux, all processes have an error output file. There are various ways to view the error output. One simple method is to run the program from a shell window.

Input (see page 22647)

Output (see page 22653)

TextFile

158.6.16 System.ExceptClsProc Variable

ExceptClsProc defines a pointer to a function called during exception handling.

Pascal

```
ExceptClsProc: Pointer;
```

C++

```
void * ExceptClsProc;
```

File

System

Description

By default, ExceptClsProc is defined internally to point to a function that handles exceptions on your behalf. It returns the exception class. If you override ExceptClsProc to point to your function, that function will be called when an exception occurs in a try-except block. It will be passed an updateable TExceptionRecord value that describes the exception.

Internally, the class returned is used to determine which exception handler to use before ExceptObjProc (see page 22641) is called to create the exception instance.

See Also

ExceptObjProc (see page 22641)

TExceptionRecord

158.6.17 System.ExceptionClass Variable

Pascal

```
ExceptionClass: TClass;
```

C++

```
TClass ExceptionClass;
```

File

System

Description

This is variable System.ExceptionClass.

158.6.18 System.ExceptObjProc Variable

ExceptObjProc defines a pointer to a function called during exception handling.

Pascal

```
ExceptObjProc: Pointer;
```

C++

```
void * ExceptObjProc;
```

File

System

Description

ExceptClsProc (see page 22640) defines the function that returns a class that is used to determine which exception handler to use before an exception object is created.

You can override the default exception object creation by defining your own function that returns a TObject (see page 22285). You point ExceptObjProc to that function. It is passed the an updateable version of the TExceptionRecord.

See Also

ExceptClsProc (see page 22640)

TExceptionRecord

158.6.19 System.ExceptProc Variable

Points to the lowest-level exception handler.

Pascal

```
ExceptProc: Pointer;
```

C++

```
void * ExceptProc;
```

File

System

Description

In Delphi code, ExceptProc handles unhandled exceptions (exceptions that have not been caught in the except portion of a try..except statement.) If your application has a TApplication object, it automatically catches exceptions and generates an OnException event (to which you can respond using either the application's or a TApplicationEvents object's OnException event handler). Thus, because the TApplication object catches the exceptions, they never reach the ExceptProc handler. However, even if you have a TApplication object, it does not catch exceptions generated during initialization and finalization. These are handled by ExceptProc.

You can hook into ExceptProc to change how unhandled exceptions are reported. To do so, save the contexts of ExceptProc before changing it to the address of your own exception handler. The first statement of your new exception handler must then reinstall the saved value of ExceptProc. In this way, the ExceptProc procedure becomes part of a chain of exception procedures, each of which is executed in reverse order of installation.

The procedure assigned to ExceptProc must have a signature such as the following:

procedure ExceptHandler(ExceptObject (see page 22452): TObject (see page 22285); ExceptAddr (see page 22452): Pointer);

Note: :On Linux, ExceptProc may be called when most of the runtime has already shut down. This happens if an application terminates with an unhandled exception.

See Also

ErrorAddr (see page 22638)

ErrorProc (see page 22639)

OnException

TApplication

ExceptObject (see page 22452)

158.6.20 System.ExitCode Variable

Contains the application's exit code.

Pascal

```
ExitCode: Integer = 0;
```

C++

```
int ExitCode = 0;
```

File

System

Description

In Delphi code, the ExitCode variable contains the application's exit code. An exit procedure can learn the cause of termination by examining ExitCode. If the program terminates normally, ExitCode is zero. If the program terminates due to a call to Halt (see page 22475), ExitCode contains the value passed to Halt (see page 22475). If the program terminates due to a runtime error, ExitCode contains the error code.

Note: On Windows, setting the ExitCode variable to a value other than 0 in the initialization section of a unit will make loading of a DLL fail (DllMain will return false). You can also set ExitCode in code called from DllProc or DllProcEx to signal failure of loading.

Note: On Linux, although the ExitCode variable is accessible from shared object code, its value does not affect the loader of the shared object. Thus, using ExitCode in a shared object has no effect.

See Also

AddExitProc

AddTerminateProc

CallTerminateProcs

ExitProc (see page 22643)

158.6.21 System.ExitProc Variable

Points to a program's exit procedure (provided for backward compatibility).

Pascal

```
ExitProc: Pointer;
```

C++

```
void * ExitProc;
```

File

System

Description

In Delphi code, ExitProc points to an exit procedure in an application. The exit procedure always gets called as part of a program's termination. ExitProc is only used when generating executable files.

An exit procedure takes no parameters and must be compiled with a far procedure directive to force it to use the far call model.

Do not use ExitProc in a dynamically loaded package. This procedure is called when the process halts, not when a package or DLL is unloaded. If you set ExitProc from a package or DLL, it may interfere with the ExitProc of the host executable. Because ExitProc is not compatible with packages, it is recommended that you add code to the finalization section of a unit instead. Inside a DLL, you can use the DLLProc (see page 22637) variable instead.

See Also

AddExitProc

ExitCode (see page 22642)

AddTerminateProc

CallTerminateProcs

DLLProc (see page 22637)

158.6.22 System.ExitProcessProc Variable

Specifies the last procedure to execute before the application shuts down.

Pascal

```
ExitProcessProc: procedure;
```

C++

```
procedure ExitProcessProc;
```

File

System

Description

Assign a value to ExitProcessProc to specify a procedure that you want to execute when the application shuts down. The value of ExitProcessProc is a procedure with no parameters.

See Also

InitProc (see page 22646)

158.6.23 System.FileMode Variable

Indicates the access mode on typed and untyped files opened by the Reset (see page 22511) procedure.

Pascal

```
FileMode: Byte = 2;
```

C++

```
Byte FileMode = 2;
```

File

System

Description

In Delphi code, FileMode determines the access mode to use when typed and untyped files (not text files) are opened using the Reset (see page 22511) procedure.

The default FileMode is 2 (Read (see page 22504)/Write (see page 22548) access). Assigning another value to FileMode causes all subsequent Resets to use that mode. The SysUtils (see page 22709) unit declares a number of file open mode constants that can be assigned to the FileMode variable.

Note: Be sure to reset FileMode before calling Reset (see page 22511) with a read-only file. Even if you are only reading from the file, the default FileMode value (Read (see page 22504)/Write (see page 22548) access) will cause an attempt to open a read-only file to fail.

Warning: FileMode is declared as a variable, not as a threadvar. Therefore this variable is not thread-safe.

See Also

Reset (see page 22511)

Rewrite (see page 22513)

TFileStream

158.6.24 System.HeapAllocFlags Variable

Indicates how the memory manager obtains memory from the operating system.

Pascal

```
HeapAllocFlags: Word platform = 2;
```

C++

```
Word platform HeapAllocFlags = 2;
```

File

System

Description

On Windows, use HeapAllocFlags to customize the flags that the system memory manager uses when requesting blocks of memory from the operating system. By default, the value is GMEM_MOVEABLE.

HeapAllocFlags can be a combination of the following values:

GMEM_FIXED	Allocates fixed memory. The operating system can't move blocks, so there is no need to lock memory when obtaining a pointer. (can't be combined with GMEM_MOVEABLE).
GMEM_MOVEABLE	Allocates movable memory. In Win32, memory blocks are never moved in physical memory, but they can be moved within the default heap.
GMEM_ZEROINIT	Initializes memory contents to zero.
GMEM_MODIFY	Used to modify the attributes of an already-allocated block of memory.
GMEM_DDESHARE GMEM_SHARE	This flag is primarily for compatibility with 16-bit Window, but. can be used to enhance the performance of DDE operations. It should only be specified if the memory is to be used for DDE.
GPTR	Combines the GMEM_FIXED and GMEM_ZEROINIT flags.
GHND	Combines the GMEM_MOVEABLE and GMEM_ZEROINIT flags.

SetMemoryManager (see page 22523)

158.6.25 System.HPrevInst Variable

Pascal

```
HPrevInst: LongWord deprecated;
```

C++

```
LongWord deprecated HPrevInst;
```

File

System

Description

This is variable System.HPrevInst.

158.6.26 System.InitProc Variable

InitProc is the last installed initialization procedure.

Pascal

```
InitProc: Pointer;
```

C++

```
void * InitProc;
```

File

System

Description

Assign a value to InitProc to specify a procedure that you want to execute when the application starts up. The value of InitProc is a procedure with no parameters. For example:

In Delphi, the assignment can be made in the initialization section of a unit:

```
procedure MyInitProcedure;
...
initialization
  InitProc = @MyInitProcedure;
begin
end;
```

In C++, the assignment is most easily made in the project source file. This example is for Windows. On Linux applications, the code is similar.

```
WINAPI WinMain(HINSTANCE, HINSTANCE, LPSTR, int)
{
  try
  {
    // Note that call must precede call to Application->Initialize();
    System.InitProc = MyInitProcedure;
    Application->Initialize();
    Application->CreateForm(__classid(TForm1), &Form1);
    Application->Run();
  }
  catch (Exception &exception)
  {
    Application->ShowException(&exception);
  }
  catch (...)
  {
    try
    {
      throw Exception("");
    }
```

```
    catch (Exception &exception)
    {
      Application->ShowException(&exception);
    }
  }
  return 0;
}
```

Only one initialization procedure can be assigned to the InitProc variable. If your application defines more than one initialization procedure, only the last assignment to InitProc executes. To allow other initialization procedures to execute, you must "chain" the procedures together, calling the previously assigned value of InitProc from the new value.

TApplication

ExitProcessProc (see page 22644)

158.6.27 System.Input Variable

Specifies a read-only Text file associated with the processes standard Input file.

Pascal

```
Input: Text;
```

C++

```
Text Input;
```

File

System

Description

In Delphi, the Input variable is a read-only Text file associated with the process's standard Input file.

Note: On Windows, most processes don't have a standard Input file, and reading from Input raises an error. Delphi programs have a standard Input file if they are linked as console applications.

Note: On Linux, all processes have a standard Input file. There are various ways to use the standard Input. One simple method is to run the program from a shell window.

See Also

Output (see page 22653)

TextFile

158.6.28 System.IsConsole Variable

Indicates whether the module was compiled as a console application.

Pascal

```
IsConsole: Boolean;
```

C++

```
Boolean IsConsole;
```

File

System

Description

The IsConsole variable is true if the module was linked as a console application. This applies both to an executable and a shared library.

Note: On Linux, IsConsole is always true.

See Also

IsLibrary (see page 22648)

IsMultiThread (see page 22648)

Input (see page 22647)

Output (see page 22653)

ErrOutput (see page 22640)

158.6.29 System.IsLibrary Variable

Indicates whether the module is a shared library.

Pascal

```
IsLibrary: Boolean;
```

C++

```
Boolean IsLibrary;
```

File

System

Description

The IsLibrary variable is true if the module is a dynamic link library (Windows) or shared object (Linux).

See Also

IsConsole (see page 22647)

IsMultiThread (see page 22648)

158.6.30 System.IsMultiThread Variable

Indicates whether the application spawned additional threads using BeginThread (see page 22422) or TThread objects.

Pascal

```
IsMultiThread: Boolean;
```

C++

```
Boolean IsMultiThread;
```

File

System

Description

IsMultiThread is set to true to indicate that the memory manager should support multiple threads. IsMultiThread is set to true by BeginThread (see page 22422) and class factories.

See Also

BeginThread (see page 22422)

IsConsole (see page 22647)

IsLibrary (see page 22648)

CoInitFlags

TComObjectFactory

158.6.31 System.JITEnable Variable

Controls (see page 5711) when the just-in-time debugger is called.

Pascal

```
JITEnable: Byte platform = 0;
```

C++

```
Byte platform JITEnable = 0;
```

File

System

Description

Use JITEnable to indicate what types of exceptions trigger the just-in-time debugger. JITEnable only has an effect on applications that run under Windows.

When JITEnable is 0 (the default), all exceptions are handled using the application's exception handling mechanism. The just-in-time debugger is only called if the application provides no mechanism to catch exceptions. Note that any application that includes the Forms (see page 13657) unit provides exception handling (via the Application object) for all but the initialization and finalization sections in Delphi units and does not trigger the just-in-time debugger.

When JITEnable is 1, any non-native exceptions (Exceptions raised by code that was compiled using other products) trigger the just-in-time debugger. Native exceptions are handled by the application's exception handling mechanism.

When JITEnable is greater than 1, all exceptions trigger the just-in-time debugger.

Note: When you install the IDE, it is registered as the just-in-time debugger. If you install other tools with debuggers, they may register themselves, overriding the registration of the IDE.

158.6.32 System.LibModuleList Variable

Lists module records for enumeration procedures.

Pascal

```
LibModuleList: PLibModule = nil;
```

C++

```
PLibModule LibModuleList = nil;
```

File

System

Description

LibModuleList implements a linked list of records for executables and packages in an application. LibModuleList is used by the EnumModules (see page 22447) and the EnumResourceModules (see page 22448) procedures.

See Also

EnumModules (see page 22447)

EnumResourceModules (see page 22448)

158.6.33 System.MainInstance Variable

Indicates the instance handle for the main executable.

Pascal

```
MainInstance: LongWord;
```

C++

```
LongWord MainInstance;
```

File

System

Description

Use MainInstance to obtain the instance handle for the main executable of an application. This is useful in applications that use runtime libraries or packages, when you need the handle for the executable rather than for the library.

Note:

See Also

HInstance

FindHInstance (see page 22461)

158.6.34 System.MainThreadID Variable

Indicates the instance handle for the current module's main thread of execution.

Pascal

```
MainThreadID: LongWord;
```

C++

```
LongWord MainThreadID;
```

File

System

Description

Use MainThreadID to obtain the thread ID for the main execution thread (the current thread when the module was initialized).

During debugging, this ID appears in the thread status box for the main thread.

Note: On Windows, the value of MainThreadID is compatible with the thread ID required by some Win32 API calls.

See Also

TThread

158.6.35 System::MaxDispArgs Variable

Pascal

```
MaxDispArgs: const short int = $20;
```

C++

```
const short int MaxDispArgs = 0x20;
```

File

sysvari.h

Description

This is variable System::MaxDispArgs.

158.6.36 System.ModuleUnloadList Variable

Pascal

```
ModuleUnloadList: PModuleUnloadRec = nil;
```

C++

```
PModuleUnloadRec ModuleUnloadList = nil;
```

File

System

Description

This is variable System.ModuleUnloadList.

158.6.37 System.NeverSleepOnMMThreadContention Variable

Dictates memory manager behavior during a thread contention.

Pascal

```
NeverSleepOnMMThreadContention: Boolean;
```

C++

```
Boolean NeverSleepOnMMThreadContention;
```

File

System

Description

The Memory Manager is a shared resource, and when many threads in the application attempt to perform a memory operation at the same time, one or more threads may have to wait for a pending operation in another thread to complete before it can continue. This situation is called a thread contention. When a thread contention occurs inside the Memory Manager the default behavior is to first relinquish the remaining time in the thread's time slice. If the resource is still not available when the thread enters its next time slice, the Memory Manager calls the OS procedure Sleep before trying again.

This behavior works well on machines with single or dual core CPUs, and also when the ratio of the number of running threads to number of CPU cores is relatively high (greater than 2:1). In other situations, better performance can be obtained by entering a busy waiting loop until the resource becomes available. If NeverSleepOnMMThreadContention is **True**, the Memory Manager will use this alternate strategy when a thread contention occurs. The default value for NeverSleepOnMMThreadContention is **False**.

See Also

Memory Management

Configuring the Memory Manager

158.6.38 System.NoErrMsg Variable

Controls (see page 5711) whether the application displays an error message when a runtime error occurs.

Pascal

```
NoErrMsg: Boolean platform = False;
```

C++

```
Boolean platform NoErrMsg = False;
```

File

System

Description

Note: On Windows, set NoErrMsg to control whether a message appears to indicate that a runtime error has occurred. When NoErrMsg is false (the default), runtime errors cause the application to display a message box indicating the type of error that occurred. When NoErrMsg is true, these messages are suppressed.

On Linux, NoErrMsg only no effect.

Note: The SysUtils (see page 22709) unit turns most runtime errors into exceptions. If your application includes SysUtils (see page 22709), the runtime error message box is unlikely to appear, even if NoErrMsg is false.

158.6.39 System.Output Variable

Specifies a write-only Text file associated with the process's standard output file.

Pascal

```
Output: Text;
```

C++

```
Text Output;
```

File

System

Description

In Delphi, the Output variable is a write-only Text file associated with the process's standard output file.

Note: On Windows, most processes don't have a standard output file, and writing to Output raises an error. Delphi programs have a standard output file if they are linked as console applications.

Note: On Linux, all processes have a standard output file. There are various ways to view the standard error output. One simple method is to run the program from a shell window.

See Also

Input (see page 22647)

TextFile

158.6.40 System.RaiseExceptionProc Variable

Points to RaiseException Windows function.

Pascal

```
RaiseExceptionProc: Pointer;
```

C++

```
void * RaiseExceptionProc;
```

File

System

Description

RaiseExceptionProc points to the RaiseException Windows API function. This can be used to invoke the function from assembly language.

See Also

RaiseException Function (MSDN)

158.6.41 System.RandSeed Variable

RandSeed stores the built-in random number generator's seed.

Pascal

```
RandSeed: Longint = 0;
```

C++

```
Longint RandSeed = 0;
```

File

System

Description

By assigning a specific value to RandSeed, you can use the Random (see page 22502) function to repetitively generate a specific sequence of random numbers. This is useful for applications that deal with data statistics and simulations. For applications that deal with encryption see the note under the Random (see page 22502) function.

See Also

Random (see page 22502)

Randomize (see page 22503)

158.6.42 System.ReportMemoryLeaksOnShutdown Variable

Report memory leaks on shutdown.

Pascal

```
ReportMemoryLeaksOnShutdown: Boolean;
```

C++

```
Boolean ReportMemoryLeaksOnShutdown;
```

File

System

Description

Set ReportMemoryLeaksOnShutdown to report memory leaks on shutdown.

The memory manager can report memory that was allocated but not freed by the time the memory manager shuts down. Such memory blocks are called memory leaks and are often the result of programming errors. When this global variable is set to **True**, the Memory Manager will scan the memory pool when it shuts down and report all unregistered memory leaks in a message

dialog. The default value for ReportMemoryLeaksOnShutdown is **False**.

Expected memory leaks can be registered so the Memory Manager will ignore them during its checks for memory leaks. Use the procedures RegisterExpectedMemoryLeak (see page 22508) and UnregisterExpectedMemoryLeak (see page 22539) to control the memory areas that the Memory Manager checks for leaks.

See Also

Memory Management

Configuring the Memory Manager

Registering Memory Leaks

RegisterExpectedMemoryLeak

UnregisterExpectedMemoryLeak

158.6.43 System.RTLUnwindProc Variable

Pascal

```
RTLUnwindProc: Pointer;
```

C++

```
void * RTLUnwindProc;
```

File

System

Description

This is variable System.RTLUnwindProc.

158.6.44 System.SafeCallErrorProc Variable

SafeCallErrorProc defines a procedure that is called when a safecall routine incurs an error.

Pascal

```
SafeCallErrorProc: TSafeCallErrorProc;
```

C++

```
TSafeCallErrorProc SafeCallErrorProc;
```

File

System

Description

A function or procedure defined with the safecall directive is invoked using a safe calling convention. When such a routine incurs an error, the SafeCallException is invoked. However, you can override this call by defining your own handling routine, and setting SafeCallErrorProc to point to it.

SafeCallErrorProc should point to a procedure that takes two parameters :

ErrorCode is an integer holding the error code.

ErrorAddr (see page 22638) is the code address at the time of error.

If SafeCallErrorProc returns normally, or is set to nil, then the ESafeCallException is raised.

See Also

ESafeCallException

SafeCallException

158.6.45 System.SystemThreadEndProc Variable

Pascal

```
SystemThreadEndProc: TSystemThreadEndProc = nil;
```

C++

```
TSystemThreadEndProc SystemThreadEndProc = nil;
```

File

System

Description

This is variable System.SystemThreadEndProc.

158.6.46 System.SystemThreadFuncProc Variable

Pascal

```
SystemThreadFuncProc: TSystemThreadFuncProc = nil;
```

C++

```
TSystemThreadFuncProc SystemThreadFuncProc = nil;
```

File

System

Description

This is variable System.SystemThreadFuncProc.

158.6.47 System.Test8086 Variable

Pascal

```
Test8086: Byte;
```

C++

```
Byte Test8086;
```

File

System

Description

This is variable System.Test8086.

158.6.48 System.Test8087 Variable

Pascal

```
Test8087: Byte = 3;
```

C++

```
Byte Test8087 = 3;
```

File

System

Description

This is variable System.Test8087.

158.6.49 System.TestFDIV Variable

Pascal

```
TestFDIV: Shortint;
```

C++

```
Shortint TestFDIV;
```

File

System

Description

This is variable System.TestFDIV.

158.6.50 System.VarAddRefProc Variable

Pascal

```
VarAddRefProc: procedure (var v: TVarData) = nil;
```

C++

```
procedure (var v: TVarData) VarAddRefProc = nil;
```

File

System

Description

This is variable System.VarAddRefProc.

158.6.51 System.VarClearProc Variable

Pascal

```
VarClearProc: procedure (var v: TVarData) = nil;
```

C++

```
procedure (var v: TVarData) VarClearProc = nil;
```

File

System

Description

This is variable System.VarClearProc.

158.6.52 System.VarCopyProc Variable

Pascal

```
VarCopyProc: procedure (var Dest: TVarData; const Source: TVarData) = nil;
```

C++

```
procedure (var Dest: TVarData; const Source: TVarData) VarCopyProc = nil;
```

File

System

Description

This is variable System.VarCopyProc.

158.6.53 System.VarToLStrProc Variable

Pascal

```
VarToLStrProc: procedure (var Dest: AnsiString; const Source: TVarData) = nil;
```

C++

```
procedure (var Dest: AnsiString; const Source: TVarData) VarToLStrProc = nil;
```

File

System

Description

This is variable System.VarToLStrProc.

158.6.54 System.VarToWStrProc Variable

Pascal

```
VarToWStrProc: procedure (var Dest: WideString; const Source: TVarData) = nil;
```

C++

```
procedure (var Dest: WideString; const Source: TVarData) VarToWStrProc = nil;
```

File

System

Description

This is variable System.VarToWStrProc.

158.7 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CompilerVersion (see page 22662)	Designates the version number of the Delphi compiler.
CPUi386 (see page 22662)	This is constant System.CPUi386.
CPUi486 (see page 22663)	This is constant System.CPUi486.
CPUPentium (see page 22663)	This is constant System.CPUPentium.
E_NOINTERFACE (see page 22663)	This is constant System.E_NOINTERFACE.
E_NOTIMPL (see page 22664)	This is constant System.E_NOTIMPL.
E_UNEXPECTED (see page 22664)	This is constant System.E_UNEXPECTED.
fmClosed (see page 22664)	This is constant System.fmClosed.
fmInOut (see page 22665)	This is constant System.fmInOut.
fmInput (see page 22665)	This is constant System.fmInput.
fmOutput (see page 22665)	This is constant System.fmOutput.
MaxInt (see page 22666)	The maximum value of the Integer data type.
MaxLongint (see page 22666)	The maximum value of the Longint data type.
NumSmallBlockTypes (see page 22666)	NumSmallBlockTypes is the number of small memory block types employed by the default memory manager.
opAdd (see page 22667)	opAdd defines an addition operation.
opAnd (see page 22667)	opAnd defines a logical and operation.
opCmpEQ (see page 22668)	opCmpEQ defines an equality comparison operator.
opCmpGE (see page 22668)	opCmpGE defines a greater than or equal comparison operator.
opCmpGT (see page 22669)	opCmpGT defines a greater than comparison operator.
opCmpLE (see page 22669)	opCmpLE defines a less than or equal comparison operator.
opCmpLT (see page 22670)	opCmpLT defines a less than comparison operator.
opCmpNE (see page 22670)	opCmpNE defines an inequality comparison operator.
opCompare (see page 22671)	opCompare defines a comparison operation.
opDivide (see page 22671)	opDivide defines a divide operation.
opIntDivide (see page 22672)	opIntDivide defines an integer divide operation.
opModulus (see page 22672)	opModulus defines a modulus operation.
opMultiply (see page 22673)	opMultiply defines a multiply operation.
opNegate (see page 22673)	opNegate defines a negate operation.
opNot (see page 22674)	opNot defines a binary negation operation.
opOr (see page 22674)	opOr defines a logical or operation.
opShiftLeft (see page 22675)	opShiftLeft defines a bitwise shift left operation.
opShiftRight (see page 22675)	opShiftRight defines a bitwise shift right operation.
opSubtract (see page 22676)	opSubtract defines a subtraction operation.
opXor (see page 22676)	opXor defines a logical exclusive or operation.
RTLVersion (see page 22677)	Designates the version number of the Delphi runtime library.
S_FALSE (see page 22677)	This is constant System.S_FALSE.
S_OK (see page 22677)	This is constant System.S_OK.
sLineBreak (see page 22678)	Represents the character(s) used to generate a line feed.
tfCRLF (see page 22678)	This is constant System.tfCRLF.
varAny (see page 22678)	Represents a Variant (see page 22307) that can hold any value.
varArray (see page 22679)	Represents a Variant (see page 22307) that holds dynamic array data.
varBoolean (see page 22680)	Represents a Variant (see page 22307) that holds WordBool data.
varByRef (see page 22680)	Represents a Variant (see page 22307) that points to another variable.
varByte (see page 22681)	Represents a Variant (see page 22307) that holds byte data.

varCurrency (see page 22681)	Represents a Variant (see page 22307) that holds a monetary floating point value.
varDate (see page 22682)	Represents a Variant (see page 22307) that holds a TDateTime (see page 22256) value.
varDispatch (see page 22682)	Represents a Variant (see page 22307) that has been assigned an IDispatch (see page 22394) value.
varDouble (see page 22683)	Represents a Variant (see page 22307) that holds a floating point value.
varEmpty (see page 22683)	Represents a Variant (see page 22307) that has not yet been assigned a value.
varError (see page 22684)	Represents a Variant (see page 22307) that holds a 32 bit error code.
varInt64 (see page 22684)	Represents a Variant (see page 22307) that holds Int64 data.
varInteger (see page 22685)	Represents a Variant (see page 22307) that holds Integer data.
varLongWord (see page 22685)	Represents a Variant (see page 22307) that holds LongWord data.
varNull (see page 22686)	Represents a Variant (see page 22307) that holds a null value.
varOleStr (see page 22686)	Represents a Variant (see page 22307) that has been assigned a COM interface type string value.
varShortInt (see page 22687)	Represents a Variant (see page 22307) that holds ShortInt data.
varSingle (see page 22687)	Represents a Variant (see page 22307) that holds byte data.
varSmallint (see page 22688)	This is constant System.varSmallint.
varStrArg (see page 22688)	Represents a Variant (see page 22307) that has holds a COM compatible string value.
varString (see page 22688)	Represents a Variant (see page 22307) that holds string data.
varTypeMask (see page 22689)	Defines a mask for filtering out the meta data part of a Variant (see page 22307) data type.
varUnknown (see page 22690)	Represents a Variant (see page 22307) that holds an unknown value.
varVariant (see page 22690)	Represents a Variant (see page 22307) data type.
varWord (see page 22691)	Represents a Variant (see page 22307) that holds Word data.
vmtAddRef (see page 22691)	This is constant System.vmtAddRef.
vmtAfterConstruction (see page 22691)	This is constant System.vmtAfterConstruction.
vmtAutoTable (see page 22692)	This is constant System.vmtAutoTable.
vmtBeforeDestruction (see page 22692)	This is constant System.vmtBeforeDestruction.
vmtClassName (see page 22692)	This is constant System.vmtClassName.
vmtCreateObject (see page 22693)	This is constant System.vmtCreateObject.
vmtDefaultHandler (see page 22693)	This is constant System.vmtDefaultHandler.
vmtDestroy (see page 22693)	This is constant System.vmtDestroy.
vmtDispatch (see page 22694)	This is constant System.vmtDispatch.
vmtDynamicTable (see page 22694)	This is constant System.vmtDynamicTable.
vmtFieldTable (see page 22694)	This is constant System.vmtFieldTable.
vmtFreeInstance (see page 22695)	This is constant System.vmtFreeInstance.
vmtInitTable (see page 22695)	This is constant System.vmtInitTable.
vmtInstanceSize (see page 22695)	This is constant System.vmtInstanceSize.
vmtIntfTable (see page 22696)	This is constant System.vmtIntfTable.
vmtMethodTable (see page 22696)	This is constant System.vmtMethodTable.
vmtNewInstance (see page 22696)	This is constant System.vmtNewInstance.
vmtParent (see page 22697)	This is constant System.vmtParent.
vmtQueryInterface (see page 22697)	This is constant System.vmtQueryInterface.
vmtRelease (see page 22697)	This is constant System.vmtRelease.
vmtSafeCallException (see page 22698)	This is constant System.vmtSafeCallException.
vmtSelfPtr (see page 22698)	This is constant System.vmtSelfPtr.
vmtTypeInfo (see page 22698)	This is constant System.vmtTypeInfo.
vtAnsiString (see page 22699)	vtAnsiString defines an AnsiString (see page 22093) TVarData (see page 22571) VType value.
vtBoolean (see page 22699)	vtBoolean defines a Boolean TVarData (see page 22571) VType value.
vtChar (see page 22700)	vtChar defines a Char TVarData (see page 22571) VType value.
vtClass (see page 22700)	vtClass defines a TClass (see page 22611) TVarData (see page 22571) VType value.

vtCurrency (see page 22701)	vtCurrency defines a Currency (see page 22145) TVarData (see page 22571) VType value.
vtExtended (see page 22701)	vtExtended defines an Extended TVarData (see page 22571) VType value.
vtInt64 (see page 22702)	vtInt64 defines an Int64 TVarData (see page 22571) VType value.
vtInteger (see page 22702)	vtInteger defines an Integer TVarData (see page 22571) VType value.
vtInterface (see page 22703)	vtInterface defines an Interface pointer TVarData (see page 22571) VType value.
vtObject (see page 22703)	vtObject defines a TObject (see page 22285) TVarData (see page 22571) VType value.
vtPChar (see page 22704)	vtPChar defines a PChar TVarData (see page 22571) VType value.
vtPointer (see page 22704)	vtPointer defines a Pointer TVarData (see page 22571) VType value.
vtPWideChar (see page 22705)	vtPWideChar defines a PWideChar TVarData (see page 22571) VType value.
vtString (see page 22705)	vtString defines a Variant (see page 22307) TVarData (see page 22571) VType value.
vtVariant (see page 22706)	This is constant System.vtVariant.
vtWideChar (see page 22706)	vtWideChar defines a WideChar TVarData (see page 22571) VType value.
vtWideString (see page 22706)	vtWideString defines a WideString (see page 22377) TVarData (see page 22571) VType value.

158.7.1 System.CompilerVersion Constant

Designates the version number of the Delphi compiler.

Pascal

```
CompilerVersion = 18.0;
```

C++

```
CompilerVersion = 18.0;
```

File

System

Description

Use CompilerVersion to test the version level of the Delphi compiler. This is useful if you want to conditionalize code that takes advantage of newer features in the Delphi language.

See Also

RTLVersion (see page 22677)

158.7.2 System.CPUi386 Constant

Pascal

```
CPUi386 = 2;
```

C++

```
CPUi386 = 2;
```

File

System

Description

This is constant System.CPUi386.

158.7.3 System.CPUi486 Constant

Pascal

```
CPUi486 = 3;
```

C++

```
CPUi486 = 3;
```

File

System

Description

This is constant System.CPUi486.

158.7.4 System.CPUPentium Constant

Pascal

```
CPUPentium = 4;
```

C++

```
CPUPentium = 4;
```

File

System

Description

This is constant System.CPUPentium.

158.7.5 System.E_NOINTERFACE Constant

Pascal

```
E_NOINTERFACE = HRESULT($80004002);
```

C++

```
E_NOINTERFACE = HRESULT($80004002);
```

File

System

Description

This is constant System.E_NOINTERFACE.

158.7.6 System.E_NOTIMPL Constant

Pascal

```
E_NOTIMPL = HRESULT($80004001);
```

C++

```
E_NOTIMPL = HRESULT($80004001);
```

File

System

Description

This is constant System.E_NOTIMPL.

158.7.7 System.E_UNEXPECTED Constant

Pascal

```
E_UNEXPECTED = HRESULT($8000FFFF);
```

C++

```
E_UNEXPECTED = HRESULT($8000FFFF);
```

File

System

Description

This is constant System.E_UNEXPECTED.

158.7.8 System.fmClosed Constant

Pascal

```
fmClosed = $D7B0;
```

C++

```
fmClosed = 0xD7B0;
```

File

System

Description

This is constant System.fmClosed.

158.7.9 System.fmInOut Constant

Pascal

```
fmInOut = $D7B3;
```

C++

```
fmInOut = 0xD7B3;
```

File

System

Description

This is constant System.fmInOut.

158.7.10 System.fmInput Constant

Pascal

```
fmInput = $D7B1;
```

C++

```
fmInput = 0xD7B1;
```

File

System

Description

This is constant System.fmInput.

158.7.11 System.fmOutput Constant

Pascal

```
fmOutput = $D7B2;
```

C++

```
fmOutput = 0xD7B2;
```

File

System

Description

This is constant System.fmOutput.

158.7.12 System.MaxInt Constant

The maximum value of the Integer data type.

Pascal

```
MaxInt = 2147483647;
```

C++

```
MaxInt = 2147483647;
```

File

System

Description

MaxInt represents the highest value in the range of the integer data type (2147483647).

See Also

High (see page 22476)

Integer

158.7.13 System.MaxLongint Constant

The maximum value of the Longint data type.

Pascal

```
MaxLongint = 2147483647;
```

C++

```
MaxLongint = 2147483647;
```

File

System

Description

MaxLongint represents the highest value in the range of the Longint (Delphi) or int (C++) data type (2147483647).

See Also

High (see page 22476)

Longint

158.7.14 System.NumSmallBlockTypes Constant

NumSmallBlockTypes is the number of small memory block types employed by the default memory manager.

Pascal

```
NumSmallBlockTypes = 55;
```

C++

```
NumSmallBlockTypes = 55;
```

File

System

Description

GetMemoryManagerState (see page 22472) returns a structure containing memory usage statistics for each block type - small, medium and large blocks. It returns this data in a TMemoryManagerState (see page 22564) record. Within that record is held a TSmallBlockTypeStates (see page 22620) field - an array of TSmallBlockTypeState (see page 22568) records. There are NumSmallBlockTypes (55) different small memory block sizes, and therefore 55 TSmallBlockTypeState (see page 22568) records in this array.

See Also

GetMemoryManagerState (see page 22472)

TMemoryManagerState (see page 22564)

TSmallBlockTypeState (see page 22568)

TSmallBlockTypeStates (see page 22620)

158.7.15 System.opAdd Constant

opAdd defines an addition operation.

Pascal

```
opAdd = 0;
```

C++

```
opAdd = 0;
```

File

System

Description

opAdd is one of the operation types that TVarOp (see page 22624) may be set to when performing binary operations such as BinaryOp.

opAdd represents an addition of two operands.

See Also

BinaryOp

BinaryOp

TVarOp (see page 22624)

158.7.16 System.opAnd Constant

opAnd defines a logical and operation.

Pascal

```
opAnd = 8;
```

C++

```
opAnd = 8;
```

File

System

Description

opAnd is one of the operation types that TVarOp (see page 22624) may be set to when performing binary operations such as BinaryOp.

opAnd represents a logical and of two operands.

See Also

BinaryOp

BinaryOp

TVarOp (see page 22624)

158.7.17 System.opCmpEQ Constant

opCmpEQ defines an equality comparison operator.

Pascal

```
opCmpEQ = 14;
```

C++

```
opCmpEQ = 14;
```

File

System

Description

opCmpEQ is one of the opCmp* comparison values that TVarOp (see page 22624) may be set to when performing left/right operand comparisons, such as CompareOp.

opCmpEQ represents a comparison that two operands are equal in value.

See Also

CompareOp (see page 23590)

CompareOp

TVarOp (see page 22624)

158.7.18 System.opCmpGE Constant

opCmpGE defines a greater than or equal comparison operator.

Pascal

```
opCmpGE = 19;
```

C++

```
opCmpGE = 19;
```

File

System

Description

opCmpGE is one of the opCmp* comparison values that TVarOp (see page 22624) may be set to when performing left/right operand comparisons, such as CompareOp.

opCmpGE represents the comparison : left operand greater than or equal to the right operand.

See Also

CompareOp (see page 23590)

CompareOp

TVarOp (see page 22624)

158.7.19 System.opCmpGT Constant

opCmpGT defines a greater than comparison operator.

Pascal

```
opCmpGT = 18;
```

C++

```
opCmpGT = 18;
```

File

System

Description

opCmpGT is one of the opCmp* comparison values that TVarOp (see page 22624) may be set to when performing left/right operand comparisons, such as CompareOp.

opCmpGT represents the comparison : left operand greater than the right operand.

See Also

CompareOp (see page 23590)

CompareOp

TVarOp (see page 22624)

158.7.20 System.opCmpLE Constant

opCmpLE defines a less than or equal comparison operator.

Pascal

```
opCmpLE = 17;
```

C++

```
opCmpLE = 17;
```

File

System

Description

opCmpLE is one of the opCmp* comparison values that TVarOp (see page 22624) may be set to when performing left/right operand comparisons, such as CompareOp.

opCmpLE represents the comparison : left operand less than or equal to the right operand.

See Also

CompareOp (see page 23590)

CompareOp

TVarOp (see page 22624)

158.7.21 System.opCmpLT Constant

opCmpLT defines a less than comparison operator.

Pascal

```
opCmpLT = 16;
```

C++

```
opCmpLT = 16;
```

File

System

Description

opCmpLT is one of the opCmp* comparison values that TVarOp (see page 22624) may be set to when performing left/right operand comparisons, such as CompareOp.

opCmpLT represents the comparison : left operand less than the right operand.

See Also

CompareOp (see page 23590)

CompareOp

TVarOp (see page 22624)

158.7.22 System.opCmpNE Constant

opCmpNE defines an inequality comparison operator.

Pascal

```
opCmpNE = 15;
```

C++

```
opCmpNE = 15;
```

File

System

Description

opCmpNE is one of the opCmp* comparison values that TVarOp (see page 22624) may be set to when performing left/right operand comparisons, such as CompareOp.

opCmpNE represents a comparison that two operands are not equal in value.

See Also

CompareOp (see page 23590)

CompareOp

TVarOp (see page 22624)

158.7.23 System.opCompare Constant

opCompare defines a comparison operation.

Pascal

```
opCompare = 11;
```

C++

```
opCompare = 11;
```

File

System

Description

opCompare defines a comparison operation.

See Also

TVarOp (see page 22624)

158.7.24 System.opDivide Constant

opDivide defines a divide operation.

Pascal

```
opDivide = 3;
```

C++

```
opDivide = 3;
```

File

System

Description

opDivide is one of the operation types that TVarOp (see page 22624) may be set to when performing binary operations such as BinaryOp.

opDivide represents the division of the left operand by the right operation.

See Also

BinaryOp

BinaryOp

TVarOp (see page 22624)

158.7.25 System.opIntDivide Constant

opIntDivide defines an integer divide operation.

Pascal

```
opIntDivide = 4;
```

C++

```
opIntDivide = 4;
```

File

System

Description

opIntDivide is one of the operation types that TVarOp (see page 22624) may be set to when performing binary operations such as BinaryOp.

opIntDivide represents the integer division of the left operand by the right operation.

See Also

BinaryOp

BinaryOp

TVarOp (see page 22624)

158.7.26 System.opModulus Constant

opModulus defines a modulus operation.

Pascal

```
opModulus = 5;
```

C++

```
opModulus = 5;
```

File

System

Description

opModulus is one of the operation types that TVarOp (see page 22624) may be set to when performing binary operations such as BinaryOp.

opModulus represents the remainder of the division of the left operand by the right operand.

See Also

BinaryOp

BinaryOp

TVarOp (see page 22624)

158.7.27 System.opMultiply Constant

opMultiply defines a multiply operation.

Pascal

```
opMultiply = 2;
```

C++

```
opMultiply = 2;
```

File

System

Description

opMultiply is one of the operation types that TVarOp (see page 22624) may be set to when performing binary operations such as BinaryOp.

opMultiply represents the multiplication of the left operand by the right operation.

See Also

BinaryOp

BinaryOp

TVarOp (see page 22624)

158.7.28 System.opNegate Constant

opNegate defines a negate operation.

Pascal

```
opNegate = 12;
```

C++

```
opNegate = 12;
```

File

System

Description

opNegate is one of the operation types that TVarOp (see page 22624) may be set to when performing unary operations such as UnaryOp.

opNegate represents the inversion of an operand value.

See Also

UnaryOp

TVarOp (see page 22624)

158.7.29 System.opNot Constant

opNot defines a binary negation operation.

Pascal

```
opNot = 13;
```

C++

```
opNot = 13;
```

File

System

Description

opNegate (see page 22673) represents the binary (bitwise) inversion of an operand value.

See Also

TVarOp (see page 22624)

158.7.30 System.opOr Constant

opOr defines a logical or operation.

Pascal

```
opOr = 9;
```

C++

```
opOr = 9;
```

File

System

Description

opOr is one of the operation types that TVarOp (see page 22624) may be set to when performing binary operations such as BinaryOp.

opOr represents a logical or of two operands.

See Also

BinaryOp

BinaryOp

TVarOp (see page 22624)

158.7.31 System.opShiftLeft Constant

opShiftLeft defines a bitwise shift left operation.

Pascal

```
opShiftLeft = 6;
```

C++

```
opShiftLeft = 6;
```

File

System

Description

opShiftLeft is one of the operation types that TVarOp (see page 22624) may be set to when performing binary operations such as BinaryOp.

opShiftLeft represents the left operand shifted left N times, where N is the numeric value of the right operand.

See Also

BinaryOp

BinaryOp

TVarOp (see page 22624)

158.7.32 System.opShiftRight Constant

opShiftRight defines a bitwise shift right operation.

Pascal

```
opShiftRight = 7;
```

C++

```
opShiftRight = 7;
```

File

System

Description

opShiftRight is one of the operation types that TVarOp (see page 22624) may be set to when performing binary operations such as BinaryOp.

opShiftRight represents the left operand shifted right N times, where N is the numeric value of the right operand.

See Also

BinaryOp

BinaryOp

TVarOp (see page 22624)

158.7.33 System.opSubtract Constant

opSubtract defines a subtraction operation.

Pascal

```
opSubtract = 1;
```

C++

```
opSubtract = 1;
```

File

System

Description

opSubtract is one of the operation types that TVarOp (see page 22624) may be set to when performing binary operations such as BinaryOp.

opSubtract represents the right operand subtracted from the left operand.

See Also

BinaryOp

BinaryOp

TVarOp (see page 22624)

158.7.34 System.opXor Constant

opXor defines a logical exclusive or operation.

Pascal

```
opXor = 10;
```

C++

```
opXor = 10;
```

File

System

Description

opXor is one of the operation types that TVarOp (see page 22624) may be set to when performing binary operations such as BinaryOp.

opXor represents a logical exclusive or of two operands.

See Also

BinaryOp

BinaryOp

TVarOp (see page 22624)

158.7.35 System.RTLVersion Constant

Designates the version number of the Delphi runtime library.

Pascal

```
RTLVersion = 18.00;
```

C++

```
RTLVersion = 18.00;
```

File

System

Description

Use RTLVersion to test the Delphi runtime library version level independently of the compiler version level.

See Also

CompilerVersion (see page 22662)

158.7.36 System.S_FALSE Constant

Pascal

```
S_FALSE = $00000001;
```

C++

```
S_FALSE = 0x00000001;
```

File

System

Description

This is constant System.S_FALSE.

158.7.37 System.S_OK Constant

Pascal

```
S_OK = 0;
```

C++

```
S_OK = 0;
```

File

System

Description

This is constant System.S_OK.

158.7.38 System.sLineBreak Constant

Represents the character(s) used to generate a line feed.

Pascal

```
sLineBreak = #13#10;
```

C++

```
sLineBreak = #13#10;
```

File

System

Description

Windows systems define sLineBreak as a combination of carriage return (#13) and line feed (#10).

Linux systems define sLineBreak as simply a line feed (#10).

It is preferable to use this constabnt rather than hard code #13#10 or #10 (as appropriate) to move to a new line in a text output.

158.7.39 System.tfCRLF Constant

Pascal

```
tfCRLF = $1;
```

C++

```
tfCRLF = 0x1;
```

File

System

Description

This is constant System.tfCRLF.

158.7.40 System.varAny Constant

Represents a Variant (see page 22307) that can hold any value.

Pascal

```
varAny = $0101;
```

C++

```
varAny = 0x0101;
```

File

System

Description

A variant with a varAny type is used as a placeholder for any variant value, such as when passed as a paremeter to a routine. A varAny variant cannot be directly processed - use ChangeAnyProc to convert it to a variant type that can be processed.

See Also

TVarType

ChangeAnyProc (see page 23677)

VarType (see page 23667)

158.7.41 System.varArray Constant

Represents a Variant (see page 22307) that holds dynamic array data.

Pascal

```
varArray = $2000;
```

C++

```
varArray = 0x2000;
```

File

System

Description

The VarType routine returns a TVarType (see page 22625) value that describes the current data type used to hold the contents of a Variant (see page 22307) data type. The data type is a 16 bit value, split into a high order 4 bits and a low order 12 bits. The low order bits determine the basic data type, such as varDouble (see page 22683), varSmallInt.

The high order bits represent meta data types varArray and varByRef (see page 22680).

Logically And varArray with a Variant (see page 22307) to determine if a Variant (see page 22307) holds array data.

Use VarArrayCreate to generate an array Variant (see page 22307);

See Also

TVarType

VarArrayCreate (see page 23644)

VarType (see page 23667)

158.7.42 System.varBoolean Constant

Represents a Variant (see page 22307) that holds WordBool data.

Pascal

```
varBoolean = $000B;
```

C++

```
varBoolean = 0x000B;
```

File

System

Description

varBoolean represents a Variant (see page 22307) variable that currently holds a 16-bit boolean (type WordBool) value.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.43 System.varByRef Constant

Represents a Variant (see page 22307) that points to another variable.

Pascal

```
varByRef = $4000;
```

C++

```
varByRef = 0x4000;
```

File

System

Description

The VarType routine returns a TVarType (see page 22625) value that describes the current data type used to hold the contents of a Variant (see page 22307) data type. The data type is a 16 bit value, split into a high order 4 bits and a low order 12 bits. The low order bits determine the basic data type, such as varDouble (see page 22683), varSmallInt.

The high order bits represent meta data types varArray (see page 22679) and varByRef.

In essence, a varByRef variant is a pointer. The data type of the variable it points to is determined in the low order bits.

Logically And varByRef with a Variant (see page 22307) to determine if a Variant (see page 22307) is a pointer.

See Also

TVarType

VarType (see page 23667)

158.7.44 System.varByte Constant

Represents a Variant (see page 22307) that holds byte data.

Pascal

```
varByte = $0011;
```

C++

```
varByte = 0x0011;
```

File

System

Description

When a Variant (see page 22307) is assigned an integer value less than 256, it will be set to a varByte Variant (see page 22307) type. varByte represents a Variant (see page 22307) variable that currently holds a byte data value.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.45 System.varCurrency Constant

Represents a Variant (see page 22307) that holds a monetary floating point value.

Pascal

```
varCurrency = $0006;
```

C++

```
varCurrency = 0x0006;
```

File

System

Description

When a Variant (see page 22307) is assigned a floating point value with less than 5 decimal places, it is set to the varCurrency type.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.46 System.varDate Constant

Represents a Variant (see page 22307) that holds a TDateTime (see page 22256) value.

Pascal

```
varDate = $0007;
```

C++

```
varDate = 0x0007;
```

File

System

Description

When a Variant (see page 22307) is assignned a TDateTime (see page 22256) value, it is set to the varDate type.

Use VarType to determine the variant type.

See Also

TDateTime (see page 22612)

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.47 System.varDispatch Constant

Represents a Variant (see page 22307) that has been assigned an IDispatch (see page 22394) value.

Pascal

```
varDispatch = $0009;
```

C++

```
varDispatch = 0x0009;
```

File

System

Description

When a Variant (see page 22307) is assigned an IDispatch (see page 22394) value, it is set to the varDispatch type.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.48 System.varDouble Constant

Represents a Variant (see page 22307) that holds a floating point value.

Pascal

```
varDouble = $0005;
```

C++

```
varDouble = 0x0005;
```

File

System

Description

When a Variant (see page 22307) is assigned a floating point value with more than 4 decimal places, it is set to the varDouble type.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.49 System.varEmpty Constant

Represents a Variant (see page 22307) that has not yet been assigned a value.

Pascal

```
varEmpty = $0000;
```

C++

```
varEmpty = 0x0000;
```

File

System

Description

When a Variant (see page 22307) is first created, it is set to the varEmpty type.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarIsEmpty (see page 23657)

VarType (see page 23667)

158.7.50 System.varError Constant

Represents a Variant (see page 22307) that holds a 32 bit error code.

Pascal

```
varError = $000A;
```

C++

```
varError = 0x000A;
```

File

System

Description

When a Variant (see page 22307) is assigned a 32 bit error code, it is set to the varError type.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarIsEmpty (see page 23657)

VarType (see page 23667)

158.7.51 System.varInt64 Constant

Represents a Variant (see page 22307) that holds Int64 data.

Pascal

```
varInt64 = $0014;
```

C++

```
varInt64 = 0x0014;
```

File

System

Description

When a Variant (see page 22307) is assigned an integer value greater in value than an LongWord type can hold, it will be set to a varInt64 Variant (see page 22307) type. varInt64 represents a Variant (see page 22307) variable that currently holds an Int64 data value.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.52 System.varInteger Constant

Represents a Variant (see page 22307) that holds Integer data.

Pascal

```
varInteger = $0003;
```

C++

```
varInteger = 0x0003;
```

File

System

Description

To define a Variant (see page 22307) to be a varInteger type, you should use VarAsType to create one. By default, a Variant (see page 22307) with an integer value greater than the Word type capacity, but less than the Int64 type capacity will normally be assigned a varLongWord (see page 22685) type.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.53 System.varLongWord Constant

Represents a Variant (see page 22307) that holds LongWord data.

Pascal

```
varLongWord = $0013;
```

C++

```
varLongWord = 0x0013;
```

File

System

Description

When a Variant (see page 22307) is assigned an integer value greater in value than a Word type can hold, but less than an Int64 type can hold, it will be set to a varLongWord Variant (see page 22307) type. varLongWord represents a Variant (see page 22307) variable that currently holds a LongWord data value.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.54 System.varNull Constant

Represents a Variant (see page 22307) that holds a null value.

Pascal

```
varNull = $0001;
```

C++

```
varNull = 0x0001;
```

File

System

Description

When a Variant (see page 22307) is assigned a null value, it is set to the varNull type.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarIsNull (see page 23660)

VarType (see page 23667)

158.7.55 System.varOleStr Constant

Represents a Variant (see page 22307) that has been assigned a COM interface type string value.

Pascal

```
varOleStr = $0008;
```

C++

```
varOleStr = 0x0008;
```

File

System

Description

When a Variant (see page 22307) is assigned a string value via a COM interface, it is set to the varOleStr type.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.56 System.varShortInt Constant

Represents a Variant (see page 22307) that holds ShortInt data.

Pascal

```
varShortInt = $0010;
```

C++

```
varShortInt = 0x0010;
```

File

System

Description

To define a Variant (see page 22307) to be a varShortInt type, you should use VarAsType to create one. By default, a Variant (see page 22307) with an integer value less than the Word type capacity will normally be assigned a varByte (see page 22681) type.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.57 System.varSingle Constant

Represents a Variant (see page 22307) that holds byte data.

Pascal

```
varSingle = $0004;
```

C++

```
varSingle = 0x0004;
```

File

System

Description

To define a Variant (see page 22307) to be a varSingle type, you should use VarAsType to create one. By default, a Variant (see page 22307) with a floating point value with less than 4 decimal places will be assigned the varCurrency (see page 22681) type. With greater than 4 decimal places, it will be assigned by default the varDouble (see page 22683) type.

Use VarType to determine the variant type.

VarAsType (see page 23650)

VarType (see page 23667)

158.7.58 System.varSmallint Constant

Pascal

```
varSmallint = $0002;
```

C++

```
varSmallint = 0x0002;
```

File

System

Description

This is constant System.varSmallint.

158.7.59 System.varStrArg Constant

Represents a Variant (see page 22307) that has holds a COM compatible string value.

Pascal

```
varStrArg = $0048;
```

C++

```
varStrArg = 0x0048;
```

File

System

Description

In order to use a Variant (see page 22307) with a COM interface, you should create a varStrArg type using VarAsType.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.60 System.varString Constant

Represents a Variant (see page 22307) that holds string data.

Pascal

```
varString = $0100;
```

C++

```
varString = 0x0100;
```

File

System

Description

When a Variant (see page 22307) is assigned a string value, it will be set to a varString Variant (see page 22307) type.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.61 System.varTypeMask Constant

Defines a mask for filtering out the meta data part of a Variant (see page 22307) data type.

Pascal

```
varTypeMask = $0FFF;
```

C++

```
varTypeMask = 0x0FFF;
```

File

System

Description

The VarType routine returns a TVarType (see page 22625) value that describes the current data type used to hold the contents of a Variant (see page 22307) data type. The data type is a 16 bit value, split into a high order 4 bits and a low order 12 bits. The high order bits give a meta data type (varArray (see page 22679) and varByRef (see page 22680)). The low order bits determine the basic data type, such as varDouble (see page 22683), varSmallInt. Use varTypeMask to mask out the meta data so as to be able to determine the basic data type of a Variant (see page 22307).

See Also

TVarType

varArray (see page 22679)

VarAsType (see page 23650)

varByRef (see page 22680)

VarType (see page 23667)

158.7.62 System.varUnknown Constant

Represents a Variant (see page 22307) that holds an unknown value.

Pascal

```
varUnknown = $000D;
```

C++

```
varUnknown = 0x000D;
```

File

System

Description

When a Variant (see page 22307) is assignned a value that is not recognised, it is set to the varUnknown type.

Use VarType to determine the variant type.

See Also

TVarType

VarAsType (see page 23650)

VarType (see page 23667)

158.7.63 System.varVariant Constant

Represents a Variant (see page 22307) data type.

Pascal

```
varVariant = $000C;
```

C++

```
varVariant = 0x000C;
```

File

System

Description

varVariant is principally used when using VarArrayCreate to create an array of Variants (see page 23567). It determines that such an arrray has unspecified Variant (see page 22307) types. Use such an array when element contents may differ.

See Also

TVarType

VarArrayCreate (see page 23644)

VarType (see page 23667)

158.7.64 System.varWord Constant

Represents a Variant (see page 22307) that holds Word data.

Pascal

```
varWord = $0012;
```

C++

```
varWord = 0x0012;
```

File

System

Description

When a Variant (see page 22307) is assigned an integer value greater in value than a Byte type can hold, but less than an LongWord type can hold, it will be set to a varWord Variant (see page 22307) type. varWord represents a Variant (see page 22307) variable that currently holds a Word data value.

Use VarType to determine the variant type.

158.7.65 System.vmtAddRef Constant

Pascal

```
vmtAddRef = 4 deprecated;
```

C++

```
vmtAddRef = 4 deprecated;
```

File

System

Description

This is constant System.vmtAddRef.

158.7.66 System.vmtAfterConstruction Constant

Pascal

```
vmtAfterConstruction = -28 deprecated;
```

C++

```
vmtAfterConstruction = -28 deprecated;
```

File

System

Description

This is constant System.vmtAfterConstruction.

158.7.67 System.vmtAutoTable Constant

Pascal

```
vmtAutoTable = -68;
```

C++

```
vmtAutoTable = -68;
```

File

System

Description

This is constant System.vmtAutoTable.

158.7.68 System.vmtBeforeDestruction Constant

Pascal

```
vmtBeforeDestruction = -24 deprecated;
```

C++

```
vmtBeforeDestruction = -24 deprecated;
```

File

System

Description

This is constant System.vmtBeforeDestruction.

158.7.69 System.vmtClassName Constant

Pascal

```
vmtClassName = -44;
```

C++

```
vmtClassName = -44;
```

File

System

Description

This is constant System.vmtClassName.

158.7.70 System.vmtCreateObject Constant

Pascal

```
vmtCreateObject = 12 deprecated;
```

C++

```
vmtCreateObject = 12 deprecated;
```

File

System

Description

This is constant System.vmtCreateObject.

158.7.71 System.vmtDefaultHandler Constant

Pascal

```
vmtDefaultHandler = -16 deprecated;
```

C++

```
vmtDefaultHandler = -16 deprecated;
```

File

System

Description

This is constant System.vmtDefaultHandler.

158.7.72 System.vmtDestroy Constant

Pascal

```
vmtDestroy = -4 deprecated;
```

C++

```
vmtDestroy = -4 deprecated;
```

File

System

Description

This is constant System.vmtDestroy.

158.7.73 System.vmtDispatch Constant

Pascal

```
vmtDispatch = -20 deprecated;
```

C++

```
vmtDispatch = -20 deprecated;
```

File

System

Description

This is constant System.vmtDispatch.

158.7.74 System.vmtDynamicTable Constant

Pascal

```
vmtDynamicTable = -48;
```

C++

```
vmtDynamicTable = -48;
```

File

System

Description

This is constant System.vmtDynamicTable.

158.7.75 System.vmtFieldTable Constant

Pascal

```
vmtFieldTable = -56;
```

C++

```
vmtFieldTable = -56;
```

File

System

Description

This is constant System.vmtFieldTable.

158.7.76 System.vmtFreeInstance Constant

Pascal

```
vmtFreeInstance = -8 deprecated;
```

C++

```
vmtFreeInstance = -8 deprecated;
```

File

System

Description

This is constant System.vmtFreeInstance.

158.7.77 System.vmtInitTable Constant

Pascal

```
vmtInitTable = -64;
```

C++

```
vmtInitTable = -64;
```

File

System

Description

This is constant System.vmtInitTable.

158.7.78 System.vmtInstanceSize Constant

Pascal

```
vmtInstanceSize = -40;
```

C++

```
vmtInstanceSize = -40;
```

File

System

Description

This is constant System.vmtInstanceSize.

158.7.79 System.vmtIntfTable Constant

Pascal

```
vmtIntfTable = -72;
```

C++

```
vmtIntfTable = -72;
```

File

System

Description

This is constant System.vmtIntfTable.

158.7.80 System.vmtMethodTable Constant

Pascal

```
vmtMethodTable = -52;
```

C++

```
vmtMethodTable = -52;
```

File

System

Description

This is constant System.vmtMethodTable.

158.7.81 System.vmtNewInstance Constant

Pascal

```
vmtNewInstance = -12 deprecated;
```

C++

```
vmtNewInstance = -12 deprecated;
```

File

System

Description

This is constant System.vmtNewInstance.

158.7.82 System.vmtParent Constant

Pascal

```
vmtParent = -36;
```

C++

```
vmtParent = -36;
```

File

System

Description

This is constant System.vmtParent.

158.7.83 System.vmtQueryInterface Constant

Pascal

```
vmtQueryInterface = 0 deprecated;
```

C++

```
vmtQueryInterface = 0 deprecated;
```

File

System

Description

This is constant System.vmtQueryInterface.

158.7.84 System.vmtRelease Constant

Pascal

```
vmtRelease = 8 deprecated;
```

C++

```
vmtRelease = 8 deprecated;
```

File

System

Description

This is constant System.vmtRelease.

158.7.85 System.vmtSafeCallException Constant

Pascal

```
vmtSafeCallException = -32 deprecated;
```

C++

```
vmtSafeCallException = -32 deprecated;
```

File

System

Description

This is constant System.vmtSafeCallException.

158.7.86 System.vmtSelfPtr Constant

Pascal

```
vmtSelfPtr = -76;
```

C++

```
vmtSelfPtr = -76;
```

File

System

Description

This is constant System.vmtSelfPtr.

158.7.87 System.vmtTypeInfo Constant

Pascal

```
vmtTypeInfo = -60;
```

C++

```
vmtTypeInfo = -60;
```

File

System

Description

This is constant System.vmtTypeInfo.

158.7.88 System.vtAnsiString Constant

vtAnsiString defines an AnsiString (see page 22093) TVarData (see page 22571) VType value.

Pascal

```
vtAnsiString = 11;
```

C++

```
vtAnsiString = 11;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.89 System.vtBoolean Constant

vtBoolean defines a Boolean TVarData (see page 22571) VType value.

Pascal

```
vtBoolean = 1;
```

C++

```
vtBoolean = 1;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.90 System.vtChar Constant

vtChar defines a Char TVarData (see page 22571) VType value.

Pascal

```
vtChar = 2;
```

C++

```
vtChar = 2;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.91 System.vtClass Constant

vtClass defines a TClass (see page 22611) TVarData (see page 22571) VType value.

Pascal

```
vtClass = 8;
```

C++

```
vtClass = 8;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.92 System.vtCurrency Constant

vtCurrency defines a Currency (see page 22145) TVarData (see page 22571) VType value.

Pascal

```
vtCurrency = 12;
```

C++

```
vtCurrency = 12;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.93 System.vtExtended Constant

vtExtended defines an Extended TVarData (see page 22571) VType value.

Pascal

```
vtExtended = 3;
```

C++

```
vtExtended = 3;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.94 System.vtInt64 Constant

vtInt64 defines an Int64 TVarData (see page 22571) VType value.

Pascal

```
vtInt64 = 16;
```

C++

```
vtInt64 = 16;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.95 System.vtInteger Constant

vtInteger defines an Integer TVarData (see page 22571) VType value.

Pascal

```
vtInteger = 0;
```

C++

```
vtInteger = 0;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.96 System.vtInterface Constant

vtInterface defines an Interface pointer TVarData (see page 22571) VType value.

Pascal

```
vtInterface = 14;
```

C++

```
vtInterface = 14;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.97 System.vtObject Constant

vtObject defines a TObject (see page 22285) TVarData (see page 22571) VType value.

Pascal

```
vtObject = 7;
```

C++

```
vtObject = 7;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.98 System.vtPChar Constant

vtPChar defines a PChar TVarData (see page 22571) VType value.

Pascal

```
vtPChar = 6;
```

C++

```
vtPChar = 6;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.99 System.vtPointer Constant

vtPointer defines a Pointer TVarData (see page 22571) VType value.

Pascal

```
vtPointer = 5;
```

C++

```
vtPointer = 5;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.100 System.vtPWideChar Constant

vtPWideChar defines a PWideChar TVarData (see page 22571) VType value.

Pascal

```
vtPWideChar = 10;
```

C++

```
vtPWideChar = 10;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.101 System.vtString Constant

vtString defines a Variant (see page 22307) TVarData (see page 22571) VType value.

Pascal

```
vtString = 4;
```

C++

```
vtString = 4;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.102 System.vtVariant Constant

Pascal

```
vtVariant = 13;
```

C++

```
vtVariant = 13;
```

File

System

Description

This is constant System.vtVariant.

158.7.103 System.vtWideChar Constant

vtWideChar defines a WideChar TVarData (see page 22571) VType value.

Pascal

```
vtWideChar = 9;
```

C++

```
vtWideChar = 9;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

158.7.104 System.vtWideString Constant

vtWideString defines a WideString (see page 22377) TVarData (see page 22571) VType value.

Pascal

```
vtWideString = 15;
```

C++

```
vtWideString = 15;
```

File

System

Description

The TVarData (see page 22571) type represents the internal structure of a Variant (see page 22307) variable (on Windows, this is identical to the Variant (see page 22307) type used by COM and the Win32 API).

TVarData.VType defines the type of Variant (see page 22307) it holds.

See Also

TVarData (see page 22571)

TVarRec (see page 22577)

159 SysUtils Namespace

This is namespace SysUtils.

Topics

Name	Description
Classes (see page 22721)	The following table lists classes in this documentation.
Interfaces (see page 22778)	The following table lists interfaces in this documentation.
Functions (see page 22780)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 22996)	The following table lists structs, records, enums in this documentation.
Types (see page 23012)	The following table lists types in this documentation.
Variables (see page 23021)	The following table lists variables in this documentation.
Constants (see page 23038)	The following table lists constants in this documentation.

Classes

	Name	Description
	EAbort (see page 22722)	EAbort is the exception class for errors that should not display an error message dialog box.
	EAbstractError (see page 22722)	EAbstractError is the exception class for attempts to call an abstract method.
	EAccessViolation (see page 22723)	EAccessViolation is the exception class for invalid memory access errors.
	EAssertionFailed (see page 22723)	EAssertionFailed is the exception class for Delphi assertion failure.
	EControlC (see page 22724)	EControlC is the exception class for user interrupts.
	EConvertError (see page 22724)	EConvertError is the exception class for string and object conversion errors.
	EDivByZero (see page 22726)	EDivByZero is the exception class for integer divide-by-zero errors.
	EExternal (see page 22727)	EExternal is the exception class that captures external error information.
	EExternalException (see page 22729)	EExternalException is the exception class for invalid exception codes.
	EHeapException (see page 22730)	EHeapException is the exception class for errors related to heap-allocated memory.
	EInOutError (see page 22732)	EInOutError is the exception class for file input/output errors.
	EIntError (see page 22735)	EIntError is the base class for integer math error exceptions.
	EIntfCastError (see page 22736)	EIntfCastError is the exception class for interface casting errors.
	EIntOverflow (see page 22736)	EIntOverflow is the exception class for integer calculations whose results are too large to fit in the allocated register.
	EInvalidCast (see page 22737)	EInvalidCast is an exception class for typecasting errors.
	EInvalidContainer (see page 22738)	This is class SysUtils.EInvalidContainer.
	EInvalidInsert (see page 22738)	This is class SysUtils.EInvalidInsert.
	EInvalidOp (see page 22738)	EInvalidOp is the exception class for undefined floating-point operations.
	EInvalidPointer (see page 22739)	EInvalidPointer is the exception class for invalid pointer operations.

	EMathError (see page 22739)	EMathError is the base exception class for floating-point math errors.
	EOSError (see page 22740)	EOSError is the exception class for operating system errors.
	EOutOfMemory (see page 22742)	EOutOfMemory is the exception class for unsuccessful attempts to allocate memory.
	EOverflow (see page 22743)	EOverflow is the exception class for floating-point register overflows.
	EPackageError (see page 22744)	EPackageError is the exception class for package-related errors.
	EPrivilege (see page 22744)	EPrivilege is the exception class for processor privilege violations.
	EPropReadOnly (see page 22745)	EPropReadOnly is the exception class for invalid attempts to write to a property using OLE automation.
	EPropWriteOnly (see page 22745)	EPropWriteOnly is the exception class for invalid attempts to read a property using OLE automation.
	ERangeError (see page 22745)	ERangeError is the exception for Delphi range errors.
	ESafecallException (see page 22747)	ESafecallException is the exception for problems with the safecall calling convention.
	EStackOverflow (see page 22747)	EStackOverflow is the exception class for stack overflows.
	EUnderflow (see page 22748)	EUnderflow is the exception class for values that are too small to be represented with a floating-point variable.
	EVariantError (see page 22748)	EVariantError is the exception class for errors involving Variant data types.
	EWin32Error (see page 22749)	EWin32Error is the exception class for Windows errors.
	Exception (see page 22750)	Exception is the base class for all runtime exceptions.
	EZeroDivide (see page 22761)	EZeroDivide is the exception class for floating-point divide-by-zero errors.
	TLanguages (see page 22762)	TLanguages lists all available Windows locales.
	TMultiReadExclusiveWriteSynchronizer (see page 22766)	TMultiReadExclusiveWriteSynchronizer protects memory in a multi-threaded application.
	TSimpleRWSync (see page 22772)	This is class SysUtils.TSimpleRWSync.
	TThreadLocalCounter (see page 22775)	This is class SysUtils.TThreadLocalCounter.

Constants

Name	Description
DateDelta (see page 23039)	Specifies the difference between TDateTime and TTimeStamp (see page 23009) starting values.
DefaultFalseBoolStr (see page 23039)	Specifies the default string representation of the boolean false value.
DefaultTrueBoolStr (see page 23040)	Specifies the default string representation of the boolean true value.
DriveDelim (see page 23041)	Specifies the character used to separate the Windows drive from the path in a file name.
faAnyFile (see page 23041)	Specifies any file type.
faArchive (see page 23042)	Specifies only Windows archived file types.
faDirectory (see page 23042)	Specifies only directory 'file' types.
faHidden (see page 23043)	Specifies only hidden file types.
faReadOnly (see page 23044)	Specifies only read only file types.
faSymLink (see page 23044)	Specifies only symbolic link file types.
faSysFile (see page 23045)	Specifies only system file types.
faVolumeID (see page 23045)	Specifies Volume ID file types.
fmOpenRead (see page 23046)	Specifies a file should be opened for reading only.
fmOpenReadWrite (see page 23047)	Specifies a file should be opened for reading and writing.
fmOpenWrite (see page 23047)	Specifies a file should be opened for writing only.
fmShareCompat (see page 23048)	This is constant SysUtils.fmShareCompat.
fmShareDenyNone (see page 23048)	This is constant SysUtils.fmShareDenyNone.
fmShareDenyRead (see page 23049)	This is constant SysUtils.fmShareDenyRead.
fmShareDenyWrite (see page 23049)	This is constant SysUtils.fmShareDenyWrite.
fmShareExclusive (see page 23049)	This is constant SysUtils.fmShareExclusive.
HoursPerDay (see page 23050)	Specifies the number of hours in a day.
MaxCurrency (see page 23050)	Defines the largest value supported for Currency data types.
MaxDateTime (see page 23051)	Specifies the highest supported TDateTime value.
MaxEraCount (see page 23051)	This is constant SysUtils.MaxEraCount.
MinCurrency (see page 23051)	Defines the largest negative value supported for Currency data types.
MinDateTime (see page 23052)	Specifies the earliest supported TDateTime value.

MinsPerDay (see page 23052)	Specifies the number of minutes in a day.
MinsPerHour (see page 23053)	Specifies the number of minutes in an hour.
MonthDays (see page 23054)	An array specifying how many days are in a month.
MSecsPerDay (see page 23054)	Specifies the number of milliseconds in a day.
MSecsPerSec (see page 23055)	Specifies the number of milliseconds in a second.
PathDelim (see page 23055)	Specifies a path delimiter character.
PathSep (see page 23055)	Specifies the character used to separate a sequence of file or directory names.
pfBCB4Produced (see page 23056)	Indicates that a package was produced by via C++.
pfConsumerBCB (see page 23056)	Indicates that C++ can be a consumer of a package.
pfConsumerCompat (see page 23057)	This is constant SysUtils.pfConsumerCompat.
pfConsumerDelphi (see page 23057)	Indicates that Delphi can be a consumer of a package.
pfConsumerMask (see page 23058)	Indicates the comsumer of a package.
pfDelphi4Produced (see page 23058)	Indicates that a package was produced by Delphi 4 or later.
pfDesignOnly (see page 23059)	Indicates that a package was compiled with {$DESIGNONLY ON}.
pfExeModule (see page 23059)	Indicates that a module is an executable.
pfIgnoreDupUnits (see page 23060)	Indicates that a package was compiled with {$DUPLICATEENABLE ON}.
pfLibraryModule (see page 23060)	Indicates that a module is a library.
pfModuleTypeMask (see page 23060)	Indicates that a package is a module.
pfNeverBuild (see page 23061)	Indicates that a package was compiled with the -z flag.
pfPackageModule (see page 23061)	Indicates that a module is a package.
pfProducerMask (see page 23062)	Indicates the producer of a package.
pfProducerUndefined (see page 23062)	Indicates that a package was produced by an unknown developmemt environment.
pfRunOnly (see page 23063)	Indicates that a package was compiled with {$RUNONLY ON}.
pfV3Produced (see page 23063)	Indicates that a package was produced by Delphi 3 or later.
SecsPerDay (see page 23064)	Specifies the number of seconds in a day.
SecsPerMin (see page 23064)	Specifies the number of seconds in a minute.
SwitchChars (see page 23065)	Specifies the prefix character(s) for program command line arguments.
ufImplicitUnit (see page 23065)	Indicates that a unit was implicitly imported into a package.
ufMainUnit (see page 23066)	Indicates that a unit is the main one in a project.
ufOrgWeakUnit (see page 23066)	This is constant SysUtils.ufOrgWeakUnit.
ufPackageUnit (see page 23067)	Indicates that a unit is a package.
ufWeakPackageUnit (see page 23067)	This is constant SysUtils.ufWeakPackageUnit.
ufWeakUnit (see page 23068)	Indicates that a unit is a weak unit.
UnixDateDelta (see page 23068)	Specifies the difference between TDateTime and Lunix date/time origins.

Functions

	Name	Description
	Abort (see page 22786)	Raises a silent exception.
	AddExitProc (see page 22787)	Adds a procedure to the exit list.
	AddTerminateProc (see page 22787)	Adds a terminate procedure to the system list of termination procedures.
	AdjustLineBreaks (see page 22788)	Adjusts line break characters to reflect Windows or Linux style.
	AnsiCompareFileName (see page 22788)	Compares file names based on the current locale.
	AnsiCompareStr (see page 22789)	Compares strings based on the current locale with case sensitivity.
	AnsiCompareText (see page 22790)	Compares strings based on the current locale without case sensitivity.
	AnsiDequotedStr (see page 22790)	Converts a quoted string into an unquoted string
	AnsiExtractQuotedStr (see page 22791)	Converts a quoted string into an unquoted string.
	AnsiLastChar (see page 22791)	Returns a pointer to the last character in a string.
	AnsiLowerCase (see page 22792)	Returns a string that is a copy of the given string converted to lower case.
	AnsiLowerCaseFileName (see page 22792)	Converts a file name to lower case.
	AnsiPos (see page 22793)	Locates the position of a substring.
	AnsiQuotedStr (see page 22793)	Returns the quoted version of a string.
	AnsiSameStr (see page 22794)	Compares strings based on the current locale with case sensitivity.
	AnsiSameText (see page 22794)	Compares strings based on the current locale without case sensitivity.
	AnsiStrComp (see page 22795)	Compares null-terminated character strings.

	AnsiStrIComp (see page 22795)	Compares null terminated character strings case insensitively.
	AnsiStrLastChar (see page 22796)	Returns a pointer to the last character in a null-terminated string.
	AnsiStrLComp (see page 22796)	Compares the first MaxLen bytes of two null-terminated strings, case-sensitively.
	AnsiStrLIComp (see page 22797)	Compares two strings, case-insensitively, up to the first MaxLen bytes.
	AnsiStrLower (see page 22798)	Converts all characters in a null-terminated string to lower case.
	AnsiStrPos (see page 22798)	Returns a pointer to the first occurrence of a substring.
	AnsiStrRScan (see page 22799)	Returns a pointer to the last occurrence of a specified character in a specified string.
	AnsiStrScan (see page 22799)	Returns a pointer to first occurrence of a character in a string.
	AnsiStrUpper (see page 22800)	Converts all characters in a null-terminated string to upper case.
	AnsiUpperCase (see page 22800)	Converts a string to upper case.
	AnsiUpperCaseFileName (see page 22801)	Converts a file name to upper case.
	AppendStr (see page 22801)	Appends a dynamically allocated string to an existing string.
	AssignStr (see page 22802)	Assigns a new dynamically allocated string to a specified pointer.
	Beep (see page 22802)	Emits a message beep.
	BoolToStr (see page 22804)	Converts a Boolean value to a string.
	ByteToCharIndex (see page 22806)	Returns the position of the character that contains a specified byte in a string.
	ByteToCharLen (see page 22807)	Returns the number of characters fully contained in the first MaxLen bytes of a string.
	ByteType (see page 22807)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	CallTerminateProcs (see page 22808)	Calls all of the functions in the termination procedure list.
	ChangeFileExt (see page 22808)	Changes the extension of a file name.
	ChangeFilePath (see page 22810)	Changes the path of a file name.
	CharLength (see page 22810)	Returns number of bytes used by a character.
	CharToByteIndex (see page 22811)	Returns the 1-based index of the first byte of a specified character in a string.
	CharToByteLen (see page 22811)	Returns the length, in bytes, of the first MaxLen characters of a string.
	CheckWin32Version (see page 22812)	Check to see if you are running on a specific level (or higher) of the Windows 32 bit Operating System (see page 22079).
	CompareMem (see page 22812)	Performs a binary comparison of two memory images.
	CompareStr (see page 22813)	Compares two strings case sensitively.
	CompareStr (see page 22813)	Compares two strings case sensitively.
	CompareText (see page 22814)	Compares two strings by ordinal value without case sensitivity.
	CompareText (see page 22814)	Compares two strings by ordinal value without case sensitivity.
	CreateDir (see page 22817)	Creates a new directory.
	CreateGUID (see page 22819)	Creates a globally unique identifier.
	CurrentYear (see page 22819)	Returns the current year.
	CurrToStr (see page 22819)	Formats a Currency value as a string.
	CurrToStr (see page 22819)	Formats a Currency value as a string.
	CurrToStrF (see page 22820)	Converts a Currency value to a string, using a specified format.
	CurrToStrF (see page 22820)	Converts a Currency value to a string, using a specified format.
	Date (see page 22820)	Returns the current date.
	DateTimeToFileDate (see page 22821)	Converts a TDateTime value to an OS timestamp value.
	DateTimeToStr (see page 22822)	Converts a TDateTime value to a string.
	DateTimeToStr (see page 22822)	Converts a TDateTime value to a string.
	DateTimeToString (see page 22823)	Converts a TDateTime value to a string using a specified Format (see page 22897).
	DateTimeToString (see page 22823)	Converts a TDateTime value to a string using a specified Format (see page 22897).
	DateTimeToSystemTime (see page 22825)	Converts a TDateTime value into the Win32 API's system time type.
	DateTimeToTimeStamp (see page 22825)	Converts a TDateTime value into the corresponding TTimeStamp (see page 23009) value.
	DateToStr (see page 22825)	Converts a TDateTime value to a string.
	DateToStr (see page 22825)	Converts a TDateTime value to a string.
	DayOfWeek (see page 22827)	Returns the day of the week for a specified date.
	DecodeDate (see page 22828)	Returns Year, Month, and Day values for a TDateTime value.

	DecodeDateFully (see page 22829)	Returns Year, Month, and Day, and Day-of-Week values for a TDateTime value.
	DecodeTime (see page 22830)	Breaks a TDateTime value into hours, minutes, seconds, and milliseconds.
	DeleteFile (see page 22831)	Deletes a file from disk.
	DirectoryExists (see page 22832)	Determines whether a specified directory exists.
	DiskFree (see page 22833)	Returns the number of free bytes on a specified drive.
	DiskSize (see page 22835)	Returns the size, in bytes, of a specified drive.
	DisposeStr (see page 22836)	Disposes of a string pointer that was allocated using NewStr (see page 22929).
	EncodeDate (see page 22836)	Returns a TDateTime value that represents a specified Year, Month, and Day.
	EncodeTime (see page 22837)	Returns a TDateTime value for a specified Hour, Min, Sec, and MSec.
	ExceptionErrorMessage (see page 22839)	Formats a standard error message.
	ExcludeTrailingBackslash (see page 22839)	Returns a path name without a trailing delimiter.
	ExcludeTrailingPathDelimiter (see page 22840)	Returns a path name without a trailing delimiter.
	ExpandFileName (see page 22840)	Returns the full path name for a relative file name.
	ExpandFileNameCase (see page 22841)	Returns the full path name for a relative file name on a case-sensitive file system.
	ExpandUNCFileName (see page 22842)	Returns the full path of a file name in UNC format, if appropriate.
	ExtractFileDir (see page 22843)	Extracts the drive and directory parts from FileName.
	ExtractFileDrive (see page 22843)	Returns the drive portion of a file name.
	ExtractFileExt (see page 22844)	Returns the extension portions of a file name.
	ExtractFileName (see page 22844)	Extracts the name and extension parts of a file name.
	ExtractFilePath (see page 22846)	Returns the drive and directory portions of a file name.
	ExtractRelativePath (see page 22848)	Returns a relative path name, relative to a specific base directory.
	ExtractShortPathName (see page 22849)	Converts a file name to the short 8.3 form.
	FileAge (see page 22850)	Returns the OS timestamp of a file.
	FileAge (see page 22850)	Returns the OS timestamp of a file.
	FileClose (see page 22852)	Closes a specified file.
	FileCreate (see page 22855)	Creates a new file.
	FileCreate (see page 22855)	Creates a new file.
	FileDateToDateTime (see page 22858)	Converts an OS timestamp value to TDateTime value.
	FileExists (see page 22860)	Tests if a specified file exists.
	FileGetAttr (see page 22863)	Returns the file attributes of FileName.
	FileGetDate (see page 22866)	Returns an OS timestamp for a specified file.
	FileIsReadOnly (see page 22866)	Reports whether a file is read-only.
	FileOpen (see page 22867)	Opens a specified file using a specified access mode.
	FileRead (see page 22870)	Reads a specified number of bytes from a file.
	FileSearch (see page 22872)	Searches a specified directory path for a file.
	FileSeek (see page 22873)	Repositions read/write point.
	FileSeek (see page 22873)	Repositions read/write point.
	FileSetAttr (see page 22875)	Sets the file attributes of a specified file.
	FileSetDate (see page 22878)	Sets the OS time stamp for a specified file.
	FileSetDate (see page 22878)	Sets the OS time stamp for a specified file.
	FileSetReadOnly (see page 22878)	Sets the file permissions to read-only.
	FileWrite (see page 22879)	Writes the contents of a buffer to the current position in a file.
	FinalizePackage (see page 22882)	Finalizes the specified package (.bpl file).
	FindClose (see page 22882)	Releases memory allocated by FindFirst (see page 22884).
	FindCmdLineSwitch (see page 22884)	Determines whether a string was passed as a command line argument to the application.
	FindCmdLineSwitch (see page 22884)	Determines whether a string was passed as a command line argument to the application.
	FindCmdLineSwitch (see page 22884)	Determines whether a string was passed as a command line argument to the application.
	FindFirst (see page 22884)	Searches for the first instance of a file name with a given set of attributes in a specified directory.
	FindNext (see page 22887)	Returns the next entry matching the name and attributes specified in a previous call to FindFirst (see page 22884).
	FloatToCurr (see page 22889)	Converts a floating-point value to a Currency value.
	FloatToDateTime (see page 22889)	Converts a floating-point value to a TDateTime value.

	FloatToDecimal (see page 22890)	Converts a floating-point value to a decimal representation.
	FloatToStr (see page 22890)	Converts a floating point value to a string.
	FloatToStr (see page 22890)	Converts a floating point value to a string.
	FloatToStrF (see page 22891)	Converts a floating point value to a string, using a specified Format (see page 22897), Precision, and Digits.
	FloatToStrF (see page 22891)	Converts a floating point value to a string, using a specified Format (see page 22897), Precision, and Digits.
	FloatToText (see page 22892)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 22897), Precision and Digits.
	FloatToText (see page 22892)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 22897), Precision and Digits.
	FloatToTextFmt (see page 22893)	Converts a floating-point value to an unterminated character string, using a specified format.
	FloatToTextFmt (see page 22893)	Converts a floating-point value to an unterminated character string, using a specified format.
	FmtLoadStr (see page 22893)	Returns formatted output using a resourced format string.
	FmtStr (see page 22894)	Assembles a formatted string using a format string and an array of arguments.
	FmtStr (see page 22894)	Assembles a formatted string using a format string and an array of arguments.
	ForceDirectories (see page 22895)	Creates a new directory, including the creation of parent directories as needed.
	Format (see page 22897)	Returns a formatted string assembled from a format string and an array of arguments.
	Format (see page 22897)	Returns a formatted string assembled from a format string and an array of arguments.
	FormatBuf (see page 22900)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 22900)	Formats the arguments from an array, placing the result in a buffer.
	FormatCurr (see page 22901)	Formats a Currency object.
	FormatCurr (see page 22901)	Formats a Currency object.
	FormatDateTime (see page 22902)	Formats a TDateTime value.
	FormatDateTime (see page 22902)	Formats a TDateTime value.
	FormatFloat (see page 22904)	Formats a floating point value.
	FormatFloat (see page 22904)	Formats a floating point value.
	FreeAndNil (see page 22907)	Frees an object reference and replaces the reference with nil (Delphi) or NULL (C++).
	GDAL (see page 22909)	Get Delphi Access Licence.
	GetCurrentDir (see page 22910)	Returns the name of the current directory.
	GetEnvironmentVariable (see page 22911)	Retrieves an environment variable value.
	GetFileVersion (see page 22912)	Returns file version.
	GetFormatSettings (see page 22912)	Resets the date and number format parameters to initial values.
	GetLocaleChar (see page 22913)	Retrieves the first character of a localisation value.
	GetLocaleFormatSettings (see page 22913)	Populates a TFormatSettings (see page 23001) data structure.
	GetLocaleStr (see page 22913)	Retrieves a localisation value.
	GetModuleName (see page 22914)	Returns the fully qualified name for a module, given its handle.
	GetPackageDescription (see page 22915)	Returns the description resource from a package.
	GetPackageInfo (see page 22915)	Enumerates all the units and required packages for a package.
	GetTime (see page 22916)	Returns the current time.
	GUIDToString (see page 22916)	Converts a class identifier GUID to a string.
	IncAMonth (see page 22917)	Increments date data by one month.
	IncludeTrailingBackslash (see page 22918)	Ensures path name ends with delimiter
	IncludeTrailingPathDelimiter (see page 22918)	Ensures path name ends with delimiter.
	IncMonth (see page 22919)	Returns a date shifted by a specified number of months.
	InitializePackage (see page 22920)	Validates and initializes a given package.
	InitializePackage (see page 22920)	Validates and initializes a given package.
	IntToHex (see page 22920)	Returns the hex representation of an integer.
	IntToHex (see page 22920)	Returns the hex representation of an integer.
	IntToStr (see page 22921)	Converts an integer to a string.
	IntToStr (see page 22921)	Converts an integer to a string.
	IsAssembly (see page 22922)	Determines whether a dll is an Assembly.

	IsDelimiter (see page 22923)	Indicates whether a specified character in a string matches one of a set of delimiters.
	IsEqualGUID (see page 22923)	Indicates whether two TGUID values are the same.
	IsLeapYear (see page 22924)	Indicates whether a specified year is a leap year.
	IsPathDelimiter (see page 22925)	Indicates whether the byte at a specified position in a string is the path delimiter.
	IsValidIdent (see page 22925)	Determines whether a string conforms to Delphi identifier rules.
	Languages (see page 22926)	Lists the locales for which support is available.
	LastDelimiter (see page 22926)	Returns the byte index of the last character that matches any character in a specified set of delimiters.
	LoadPackage (see page 22927)	Loads a specified package.
	LoadPackage (see page 22927)	Loads a specified package.
	LoadStr (see page 22927)	Loads a string resource from the application's executable file.
	LowerCase (see page 22928)	Converts an ASCII string to lowercase.
	LowerCase (see page 22928)	Converts an ASCII string to lowercase.
	MSecsToTimeStamp (see page 22929)	Converts a specified number of milliseconds into a TTimeStamp (see page 23009) value.
	NewStr (see page 22929)	Allocates a string on the heap.
	NextCharIndex (see page 22930)	Returns the byte index of the next character.
	Now (see page 22930)	Returns the current date and time.
	OutOfMemoryError (see page 22931)	Raises an EOutOfMemory (see page 22742) exception.
	QuotedStr (see page 22931)	Returns the quoted version of a string.
	RaiseLastOSError (see page 22932)	Raises an exception for the last occurring OS or system library error.
	RaiseLastOSError (see page 22932)	Raises an exception for the last occurring OS or system library error.
	RaiseLastWin32Error (see page 22932)	Raises an exception for the last occurring Win32 error.
	RCS (see page 22933)	Check for Delphi Client/Server Licence.
	RemoveDir (see page 22933)	Deletes an existing empty directory.
	RenameFile (see page 22934)	Changes a file name.
	ReplaceDate (see page 22936)	Replaces the date portion of a TDateTime value with a specified date.
	ReplaceTime (see page 22937)	Replaces the time portion of a TDateTime value with a specified time.
	RPR (see page 22938)	Check for Delphi Professional Licence.
	SafeLoadLibrary (see page 22938)	Safe and simple library loading.
	SameFileName (see page 22939)	Compares file names based on the current locale.
	SameStr (see page 22939)	Compares two strings by ordinal value with case sensitivity.
	SameStr (see page 22939)	Compares two strings by ordinal value with case sensitivity.
	SameText (see page 22940)	Compares two strings by ordinal value without case sensitivity.
	SameText (see page 22940)	Compares two strings by ordinal value without case sensitivity.
	SetCurrentDir (see page 22940)	Sets the current directory.
	ShowException (see page 22941)	Displays an exception message with its physical address
	Sleep (see page 22941)	Delay program execution for a specified number of milliseconds.
	StrAlloc (see page 22942)	Allocates a buffer for a null-terminated string and returns a pointer to its first character.
	StrBufSize (see page 22942)	Returns the maximum number of characters that can be stored in a buffer allocated by StrAlloc (see page 22942).
	StrByteType (see page 22943)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	StrCat (see page 22943)	Appends a copy of Source to the end of Dest and returns the concatenated string.
	StrCharLength (see page 22944)	Returns the length, in bytes, of a character.
	StrComp (see page 22945)	Compares two strings with case sensitivity.
	StrCopy (see page 22946)	Copies a null-terminated string.
	StrDispose (see page 22947)	Disposes of a string.
	StrECopy (see page 22948)	Copies null-terminated string.
	StrEnd (see page 22949)	Returns a pointer to the end of a null terminated string.
	StrFmt (see page 22950)	Formats entries in an array.
	StrFmt (see page 22950)	Formats entries in an array.
	StrIComp (see page 22951)	Compares two strings without case sensitivity.
	StringReplace (see page 22951)	Returns a string with occurrences of one substring replaced by another substring.

	StringToGUID (see page 22952)	Converts a string to a GUID.
	StrLCat (see page 22952)	Appends up to a specified maximum number of characters to string.
	StrLComp (see page 22953)	Compares up to a specified maximum number of characters in two strings.
	StrLCopy (see page 22953)	Copies up to a specified maximum number of characters from Source to Dest.
	StrLen (see page 22954)	Returns number of characters in a string excluding the null terminator.
	StrLFmt (see page 22954)	Formats a series of arguments from a specified open array into a buffer.
	StrLFmt (see page 22954)	Formats a series of arguments from a specified open array into a buffer.
	StrLIComp (see page 22955)	Compares strings up to a specified maximum number of characters, without case sensitivity.
	StrLower (see page 22956)	Converts a string to lowercase.
	StrMove (see page 22956)	Copies specified number of characters to string.
	StrNew (see page 22957)	Allocates space on and copies a string to the heap; returning a pointer to the string.
	StrNextChar (see page 22958)	Returns pointer to following character.
	StrPas (see page 22958)	Converts null-terminated string to an AnsiString (long string).
	StrPCopy (see page 22958)	Copies an AnsiString (long string) to a null-terminated string.
	StrPLCopy (see page 22959)	Copies characters from an AnsiString (long string) into a null-terminated string.
	StrPos (see page 22959)	Returns a pointer to the first occurrence of STR2 in STR1.
	StrRScan (see page 22960)	Returns a pointer to the last occurrence of a specified character in a string.
	StrScan (see page 22960)	Returns a pointer to first occurrence of a specified character in a string.
	StrToBool (see page 22961)	Converts a string to a Boolean value.
	StrToBoolDef (see page 22961)	Converts a string to a Boolean value, with error default.
	StrToCurr (see page 22962)	Converts a string to a Currency value.
	StrToCurr (see page 22962)	Converts a string to a Currency value.
	StrToCurrDef (see page 22963)	Converts a string to a Currency value, with error default.
	StrToCurrDef (see page 22963)	Converts a string to a Currency value, with error default.
	StrToDate (see page 22963)	Converts a string to a TDateTime value.
	StrToDate (see page 22963)	Converts a string to a TDateTime value.
	StrToDateDef (see page 22965)	Converts a string to a TDateTime value, with error default.
	StrToDateDef (see page 22965)	Converts a string to a TDateTime value, with error default.
	StrToDateTime (see page 22965)	Converts a string to a TDateTime value.
	StrToDateTime (see page 22965)	Converts a string to a TDateTime value.
	StrToDateTimeDef (see page 22966)	Converts a string to a TDateTime value with error default.
	StrToDateTimeDef (see page 22966)	Converts a string to a TDateTime value with error default.
	StrToFloat (see page 22967)	Converts a given string to a floating-point value.
	StrToFloat (see page 22967)	Converts a given string to a floating-point value.
	StrToFloatDef (see page 22969)	Converts a given string to a floating-point value with error default.
	StrToFloatDef (see page 22969)	Converts a given string to a floating-point value with error default.
	StrToInt (see page 22970)	Converts a string that represents an integer (decimal or hex notation) to a number.
	StrToInt64 (see page 22970)	Converts a string that represents an integer (decimal or hex notation) to a number.
	StrToInt64Def (see page 22971)	Converts a string that represents an integer (decimal or hex notation) to a number.
	StrToIntDef (see page 22971)	Converts a string that represents an integer (decimal or hex notation) to a number with error default.
	StrToTime (see page 22972)	Converts a string to a TDateTime value.
	StrToTime (see page 22972)	Converts a string to a TDateTime value.
	StrToTimeDef (see page 22972)	Converts a string to a TDateTime value with error default.
	StrToTimeDef (see page 22972)	Converts a string to a TDateTime value with error default.
	StrUpper (see page 22973)	Returns a string in upper case.
	Supports (see page 22973)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 22973)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 22973)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 22973)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 22973)	Indicates whether a given object or interface supports a specified interface.

	SysErrorMessage (see page 22974)	Converts OS error codes into strings.
	SystemTimeToDateTime (see page 22974)	Converts a system time value into a TDateTime value.
	TextToFloat (see page 22975)	Converts a null-terminated string to a floating-point value.
	TextToFloat (see page 22975)	Converts a null-terminated string to a floating-point value.
	Time (see page 22976)	Returns the current time.
	TimeStampToDateTime (see page 22976)	Converts a TTimeStamp (see page 23009) value into the corresponding TDateTime value.
	TimeStampToMSecs (see page 22977)	Converts a TTimeStamp (see page 23009) value into an absolute number of milliseconds.
	TimeToStr (see page 22977)	Returns a string that represents a TDateTime value.
	TimeToStr (see page 22977)	Returns a string that represents a TDateTime value.
	Trim (see page 22978)	Trims leading and trailing spaces and control characters from a string.
	Trim (see page 22978)	Trims leading and trailing spaces and control characters from a string.
	TrimLeft (see page 22979)	Trims leading spaces and control characters from a string.
	TrimLeft (see page 22979)	Trims leading spaces and control characters from a string.
	TrimRight (see page 22979)	Trims trailing spaces and control characters from a string.
	TrimRight (see page 22979)	Trims trailing spaces and control characters from a string.
	TryEncodeDate (see page 22980)	Creates a TDateTime value that represents a specified Year, Month, and Day.
	TryEncodeTime (see page 22980)	Creates a TDateTime value for a specified Hour, Min, Sec, and MSec.
	TryFloatToCurr (see page 22981)	Converts a floating-point value to a Currency value.
	TryFloatToDateTime (see page 22982)	Converts a floating-point value to a TDateTime value.
	TryStrToBool (see page 22982)	Converts a string to a Boolean value, with a Boolean success code.
	TryStrToCurr (see page 22983)	Converts a string to a Currency value, with a Boolean success code.
	TryStrToCurr (see page 22983)	Converts a string to a Currency value, with a Boolean success code.
	TryStrToDate (see page 22983)	Converts a string to a TDateTime value, with a Boolean success code.
	TryStrToDate (see page 22983)	Converts a string to a TDateTime value, with a Boolean success code.
	TryStrToDateTime (see page 22984)	Converts a string to a TDateTime value with a Boolean success code.
	TryStrToDateTime (see page 22984)	Converts a string to a TDateTime value with a Boolean success code.
	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToInt (see page 22986)	Converts a string that represents an integer (decimal or hex notation) to a number with Boolean success code.
	TryStrToInt64 (see page 22986)	Converts a string that represents an integer (decimal or hex notation) to a number.
	TryStrToTime (see page 22987)	Converts a string to a TDateTime value with an error default.
	TryStrToTime (see page 22987)	Converts a string to a TDateTime value with an error default.
	UnloadPackage (see page 22987)	Unloads a package.
	UpperCase (see page 22988)	Returns a copy of a string in uppercase.
	UpperCase (see page 22988)	Returns a copy of a string in uppercase.
	WideCompareStr (see page 22989)	Compares Unicode strings based on the current locale with case sensitivity.
	WideCompareText (see page 22990)	Compares Unicode strings based on the current locale without case sensitivity.
	WideFmtStr (see page 22990)	Assembles a formatted Unicode string using a format string and an array of arguments.
	WideFmtStr (see page 22990)	Assembles a formatted Unicode string using a format string and an array of arguments.
	WideFormat (see page 22991)	Returns a formatted Unicode string assembled from a format string and an array of arguments.
	WideFormat (see page 22991)	Returns a formatted Unicode string assembled from a format string and an array of arguments.
	WideFormatBuf (see page 22991)	Formats the arguments from an array, placing the result in a buffer.
	WideFormatBuf (see page 22991)	Formats the arguments from an array, placing the result in a buffer.
	WideLowerCase (see page 22992)	Returns Unicode string converted to lower case.
	WideSameStr (see page 22992)	Compares Unicode strings based on the current locale with case sensitivity.

	WideSameText (see page 22993)	Compares Unicode strings based on the current locale without case sensitivity.
	WideUpperCase (see page 22993)	Returns Unicode string converted to upper case.
	Win32Check (see page 22994)	Checks the return value of a Windows API call and raises an appropriate exception when it indicates failure.
	WrapText (see page 22994)	Splits a string into multiple lines as its length approaches a specified size.
	WrapText (see page 22994)	Splits a string into multiple lines as its length approaches a specified size.

Interfaces

	Name	Description
	IReadWriteSync (see page 22778)	This is class SysUtils.IReadWriteSync.

Structs, Records, Enums

	Name	Description
	Int64Rec (see page 22996)	Int64Rec declares a utility record to provide access to the bytes of an Int64 value.
	LongRec (see page 22997)	LongRec declares a utility record to provide access to the bytes of a LongWord value.
	TExceptionRecord (see page 22997)	TExceptionRecord holds information about an exception in an application.
	TFilenameCaseMatch (see page 22998)	TFilenameCaseMatch indicates how close a match was found to a specified file name.
	TFloatFormat (see page 22999)	TFloatFormat is an enumerated list of formatting codes for float functions.
	TFloatRec (see page 23000)	TFloatRec declares a utility record that provides access to the attributes of a floating point number.
	TFloatValue (see page 23001)	This is record SysUtils.TFloatValue.
	TFormatSettings (see page 23001)	TFormatSettings defines a thread-safe string formatting context.
	TLangRec (see page 23002)	TLangRec declares a record used to describe a Windows locale.
	TLocaleOptions (see page 23003)	TLocaleOptions defines a choice of dependent and independent locale options.
	TMbcsByteType (see page 23004)	TMbcsByteType represents the use of a single byte in a string that uses a multi-byte character set (MBCS).
	TNameType (see page 23005)	This is record SysUtils.TNameType.
	TSearchRec (see page 23005)	TSearchRec defines file information searched for by FindFirst (see page 22884) or FindNext (see page 22887).
	TSysLocale (see page 23008)	TSysLocale represents locale information.
	TThreadInfo (see page 23009)	This is record SysUtils.TThreadInfo.
	TTimeStamp (see page 23009)	TTimeStamp represents time and date values.
	WordRec (see page 23010)	WordRec declares a utility record to store high and low order bytes of a variable.

Types

Name	Description
ExceptClass (see page 23012)	ExceptClass declares an Exception (see page 22750) class.
PByteArray (see page 23013)	PByteArray declares a pointer to an array of Bytes.
PDayTable (see page 23013)	PDayTable is a pointer to a TDayTable (see page 23015) type.
PExceptionRecord (see page 23014)	PExceptionRecord is a pointer to a TExceptionRecord (see page 22997) type.
PThreadInfo (see page 23014)	This is type SysUtils.PThreadInfo.
PWordArray (see page 23014)	PWordArray is a pointer to a TWordArray (see page 23020) type.
TByteArray (see page 23015)	TByteArray declares an array of Bytes.
TBytes (see page 23015)	TBytes declares an array of Bytes.
TDayTable (see page 23015)	TDayTable is used to hold the number of days of each month of a year.
TFileName (see page 23016)	TFileName is a string that represents a file name.
TIntegerSet (see page 23016)	TIntegerSet is used to treat an integer as a set of bits.
TMREWSync (see page 23017)	TMREWSync is a short name equivalent to TMultiReadExclusiveWriteSynchronizer (see page 22766).
TPackageInfoProc (see page 23017)	TPackageInfoProc is a call-back procedure invoked by GetPackageInfo (see page 22915).
TProcedure (see page 23018)	TProcedure declares a procedure.
TReplaceFlags (see page 23018)	TReplaceFlags indicates how to perform a search-and-replace operation
TSysCharSet (see page 23019)	TSysCharSet is a set containing special characters that can be used to parse a string. The elements of the set vary, depending on the type of parsing performed.

TTerminateProc (see page 23019)	TValidatePackageProc (see page 23019) is a call-back function invoked by LoadPackage (see page 22927).
TValidatePackageProc (see page 23019)	This is type SysUtils.TValidatePackageProc.
TWordArray (see page 23020)	TWordArray declares an array of Words.

Variables

Name	Description
CurrencyDecimals (see page 23022)	CurrencyDecimals is the number of digits to the right of the decimal point in a currency amount.
CurrencyFormat (see page 23022)	CurrencyFormat defines the currency symbol placement and separation used in floating-point–to–decimal conversions. Possible values are: 0 = $1 \| 1 = 1$ | 2 = $ 1 | 3 = 1 $
CurrencyString (see page 23023)	CurrencyString defines the currency symbol (or characters) used in floating-point to decimal conversions.
DateSeparator (see page 23023)	DateSeparator is the character used to separate the year, month, and day parts of a date value.
DecimalSeparator (see page 23023)	DecimalSeparator is the character used to separate the integer part from the fractional part of a number. This variable must have a value other than #0.
EmptyStr (see page 23024)	An empty string constant.
EmptyWideStr (see page 23024)	An empty string version of the WideString constant.
EraNames (see page 23024)	Defines the names of calendar eras for East Asian locales.
EraYearOffsets (see page 23025)	Controls (see page 5711) the DateTimeToStr (see page 22822) function (for East Asian locales).
FalseBoolStrs (see page 23025)	Lists strings that can represent the boolean value false.
GetDiskFreeSpaceEx (see page 23026)	This is variable SysUtils.GetDiskFreeSpaceEx.
HexDisplayPrefix (see page 23026)	HexDisplayPrefix contains the prefix to display on hexadecimal values - `$` for Pascal (Delphi) syntax, `0x` for C++ syntax.
LeadBytes (see page 23026)	Lists all values that can be the first byte of a double byte character on the local system.
ListSeparator (see page 23027)	The character used to separate items in a list.
LongDateFormat (see page 23027)	LongDateFormat is the format string used to convert a date value to a long string suitable for display but not for editing.
LongDayNames (see page 23027)	LongDayNames is the array of strings containing long day names. The dddd format specifier in a format string passed to FormatDateTime (see page 22902) causes a long day name to be substituted.
LongMonthNames (see page 23028)	LongMonthNames is the array of strings containing long month names. The mmmm format specifier in a format string passed to FormatDateTime (see page 22902) causes a long month name to be substituted.
LongTimeFormat (see page 23028)	LongTimeFormat is the format string used to convert a time value to a string with hours, minutes, and seconds.
NegCurrFormat (see page 23029)	NegCurrFormat defines the currency format used in floating-point to decimal conversions of negative numbers.
NullStr (see page 23029)	A pointer to an empty string.
NullWideStr (see page 23030)	A pointer to an empty wide string.
ShortDateFormat (see page 23030)	ShortDateFormat is the format string used to convert a date value to a short string suitable for editing.
ShortDayNames (see page 23031)	ShortDayNames is the array of strings containing short day names. The ddd format specifier in a format string passed to FormatDateTime (see page 22902) causes a short day name to be substituted.
ShortMonthNames (see page 23031)	ShortMonthNames is the array of strings containing short month names. The mmm format specifier in a format string passed to FormatDateTime (see page 22902) causes a short month name to be substituted.
ShortTimeFormat (see page 23031)	ShortTimeFormat is the format string used to convert a time value to a short string with only hours and minutes.
SysLocale (see page 23032)	SysLocale holds locale information.
ThousandSeparator (see page 23032)	ThousandSeparator is the character used to separate thousands in numbers with more than three digits to the left of the decimal separator.
TimeAMString (see page 23033)	TimeAMString is the suffix string used for time values between 00:00 and 11:59 in 12-hour clock format.
TimePMString (see page 23033)	TimePMString is the suffix string used for time values between 12:00 and 23:59 in 12-hour clock format.

TimeSeparator (see page 23033)	TimeSeparator is the character used to separate the hour, minute, and second parts of a time value.
TrueBoolStrs (see page 23034)	Lists strings that can represent the boolean value false.
TwoDigitYearCenturyWindow (see page 23034)	Determines what century is added to two-digit years when string dates are converted to numeric dates.
Win32BuildNumber (see page 23035)	Specifies which the build level of the Windows Operating System (see page 22079) operating.
Win32CSDVersion (see page 23035)	Specifies the Win32 latest installed service pack.
Win32MajorVersion (see page 23036)	Specifies which major Windows Operating System (see page 22079) version is operating.
Win32MinorVersion (see page 23036)	Specifies which minor Windows Operating System (see page 22079) version is operating.
Win32Platform (see page 23037)	Specifies the Windows Operating System (see page 22079) platform identifier.

159.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EAbort (see page 22722)	EAbort is the exception class for errors that should not display an error message dialog box.
	EAbstractError (see page 22722)	EAbstractError is the exception class for attempts to call an abstract method.
	EAccessViolation (see page 22723)	EAccessViolation is the exception class for invalid memory access errors.
	EAssertionFailed (see page 22723)	EAssertionFailed is the exception class for Delphi assertion failure.
	EControlC (see page 22724)	EControlC is the exception class for user interrupts.
	EConvertError (see page 22724)	EConvertError is the exception class for string and object conversion errors.
	EDivByZero (see page 22726)	EDivByZero is the exception class for integer divide-by-zero errors.
	EExternal (see page 22727)	EExternal is the exception class that captures external error information.
	EExternalException (see page 22729)	EExternalException is the exception class for invalid exception codes.
	EHeapException (see page 22730)	EHeapException is the exception class for errors related to heap-allocated memory.
	EInOutError (see page 22732)	EInOutError is the exception class for file input/output errors.
	EIntError (see page 22735)	EIntError is the base class for integer math error exceptions.
	EIntfCastError (see page 22736)	EIntfCastError is the exception class for interface casting errors.
	EIntOverflow (see page 22736)	EIntOverflow is the exception class for integer calculations whose results are too large to fit in the allocated register.
	EInvalidCast (see page 22737)	EInvalidCast is an exception class for typecasting errors.
	EInvalidContainer (see page 22738)	This is class SysUtils.EInvalidContainer.
	EInvalidInsert (see page 22738)	This is class SysUtils.EInvalidInsert.
	EInvalidOp (see page 22738)	EInvalidOp is the exception class for undefined floating-point operations.
	EInvalidPointer (see page 22739)	EInvalidPointer is the exception class for invalid pointer operations.
	EMathError (see page 22739)	EMathError is the base exception class for floating-point math errors.
	EOSError (see page 22740)	EOSError is the exception class for operating system errors.
	EOutOfMemory (see page 22742)	EOutOfMemory is the exception class for unsuccessful attempts to allocate memory.
	EOverflow (see page 22743)	EOverflow is the exception class for floating-point register overflows.
	EPackageError (see page 22744)	EPackageError is the exception class for package-related errors.
	EPrivilege (see page 22744)	EPrivilege is the exception class for processor privilege violations.
	EPropReadOnly (see page 22745)	EPropReadOnly is the exception class for invalid attempts to write to a property using OLE automation.
	EPropWriteOnly (see page 22745)	EPropWriteOnly is the exception class for invalid attempts to read a property using OLE automation.
	ERangeError (see page 22745)	ERangeError is the exception for Delphi range errors.
	ESafecallException (see page 22747)	ESafecallException is the exception for problems with the safecall calling convention.
	EStackOverflow (see page 22747)	EStackOverflow is the exception class for stack overflows.
	EUnderflow (see page 22748)	EUnderflow is the exception class for values that are too small to be represented with a floating-point variable.
	EVariantError (see page 22748)	EVariantError is the exception class for errors involving Variant data types.
	EWin32Error (see page 22749)	EWin32Error is the exception class for Windows errors.
	Exception (see page 22750)	Exception is the base class for all runtime exceptions.
	EZeroDivide (see page 22761)	EZeroDivide is the exception class for floating-point divide-by-zero errors.
	TLanguages (see page 22762)	TLanguages lists all available Windows locales.
	TMultiReadExclusiveWriteSynchronizer (see page 22766)	TMultiReadExclusiveWriteSynchronizer protects memory in a multi-threaded application.
	TSimpleRWSync (see page 22772)	This is class SysUtils.TSimpleRWSync.

	TThreadLocalCounter (see page 22775)	This is class SysUtils.TThreadLocalCounter.

159.1.1 EAbort Class

EAbort is the exception class for errors that should not display an error message dialog box.

Class Hierarchy

Pascal

```
EAbort = class(Exception);
```

C++

```
class EAbort : public Exception;
```

File

SysUtils

Description

Use EAbort to raise an exception without displaying an error message in a dialog box. If applications do not trap such "silent" exceptions, the EAbort exception is passed to the HandleException method of the Application object.

The Abort (see page 22786) procedure provides a simple, standard way to raise EAbort.

See Also

Abort (see page 22786)

TApplication (see page 13660)

Application

159.1.2 EAbstractError Class

EAbstractError is the exception class for attempts to call an abstract method.

Class Hierarchy

Pascal

```
EAbstractError = class(Exception);
```

C++

```
class EAbstractError : public Exception;
```

File

SysUtils

Description

EAbstractError is raised when an application tries to call a Delphi abstract method. It is also raised at design time when a component with Delphi abstract method is placed on a form.

Delphi abstract methods are declared with the abstract directive and must be overridden in descendant classes before an instance object can be created.

C++ code can catch this error, but never throws it.

159.1.3 EAccessViolation Class

EAccessViolation is the exception class for invalid memory access errors.

Class Hierarchy

Pascal

```
EAccessViolation = class(EExternal);
```

C++

```
class EAccessViolation : public EExternal;
```

File

SysUtils

Description

EAccessViolation is raised when an application

Dereferences a nil (Delphi) or NULL (C++) pointer.

Writes to memory reserved for executable code.

Attempts to access a memory address for which there is no virtual memory allocated to the application.

Run-time exception information is saved in fields provided by EExternal (see page 22727).

Note: Applications should not raise EAccessViolation directly, but should instead rely on the runtime to raise this exception.

See Also

EExternal (see page 22727)

EOutOfMemory (see page 22742)

EOutOfResources (see page 2702)

159.1.4 EAssertionFailed Class

EAssertionFailed is the exception class for Delphi assertion failure.

Class Hierarchy

Pascal

```
EAssertionFailed = class(Exception);
```

C++

```
class EAssertionFailed : public Exception;
```

File

SysUtils

Description

EAssertionFailed is raised when an assertion fails in Delphi code.

Note: To raise this exception, use the Assert procedure. The exception is raised only in code compiled with the $ASSERTIONS ON directive.

See Also

Assert

159.1.5 EControlC Class

EControlC is the exception class for user interrupts.

Class Hierarchy

Pascal

```
EControlC = class(EExternal);
```

C++

```
class EControlC : public EExternal;
```

File

SysUtils

Description

EControlC is raised when the application is interrupted by the user.

Note: On Windows, a user interrupt can only occur in console applications, when the user presses Ctrl+C.

Note: On Linux, EControlC is raised when the program receives a TERM (15) signal. The TERM signal can be generated by the user typing the interrupt character (normally Ctrl+C) or by another program using the signal system call.

Run-time exception information is saved in fields provided by EExternal (see page 22727).

See Also

EExternal (see page 22727)

159.1.6 EConvertError Class

EConvertError is the exception class for string and object conversion errors.

Class Hierarchy

Pascal

```
EConvertError = class(Exception);
```

C++

```
class EConvertError : public Exception;
```

File

SysUtils

Description

EConvertError is raised when

An application makes an unsuccessful attempt to convert an integer, float, date, or time to a string, or to convert a string to one of these other types.

An application passes an invalid argument to a formatting routine.

An application attempts to assign one type of component derived from TPersistent to another component derived from TPersistent when such an assignment is not possible. For example, EConvertError is raised by the attempted assignment of a TButton control to a TEdit control.

In the examples below, an EConvertError exception is raised on the attempt to convert a String to a TDateTime and the date in the String is invalid. The type of exception and the error message are displayed.

//Delphi example

```
const
  LF = #10;
var
  TempDate: TDateTime;
begin
try
    TempDate := StrToDateTime('99/99/1998');
except
on E: EConvertError do
      ShowMessage(E.ClassName + LF + E.Message);
```

end;

//C++ example

```
  TDateTime TempDate;
try
  {
    TempDate = StrToDateTime("99/99/1998");
  }
catch (EConvertError &E)
  {
    ShowMessage(AnsiString(E.ClassName()) + "\n" + AnsiString(E.Message));
  }
```

159.1.7 EDivByZero Class

EDivByZero is the exception class for integer divide-by-zero errors.

Class Hierarchy

Pascal

```
EDivByZero = class(EIntError);
```

C++

```
class EDivByZero : public EIntError;
```

File

SysUtils

Description

EDivByZero is raised when an application tries to divide an integer by zero.

Run-time exception information is saved in fields provided by EExternal (see page 22727).

Note: Floating-point divide-by-zero errors raise the EZeroDivide (see page 22761) exception.

See Also

EExternal (see page 22727)

EIntOverflow (see page 22736)

ERangeError (see page 22745)

EZeroDivide (see page 22761)

159.1.8 EExternal Class

EExternal is the exception class that captures external error information.

Class Hierarchy

Pascal

```
EExternal = class(Exception);
```

C++

```
class EExternal : public Exception;
```

File

SysUtils

Description

EExternal is the ancestor of all exception classes that represent external run time errors.

Note: Under Windows, EExternal classes represent Win32 exception codes. The ExceptionRecord (see page 22729) member points to a Win32 exception record:

//Delphi syntax

```
type
PExceptionRecord = ^TExceptionRecord;
TExceptionRecord = record
  ExceptionCode: Cardinal;
  ExceptionFlags: Cardinal;
  ExceptionRecord: PExceptionRecord;
  ExceptionAddress: Pointer;
  NumberParameters: Cardinal;
  ExceptionInformation: array[0..14] of Cardinal;
end;
```

ExceptionRecord (see page 22729): PExceptionRecord (see page 23014);

//C++ syntax

```
struct TExceptionRecord;
typedef TExceptionRecord *PExceptionRecord;
struct TExceptionRecord
{
unsigned ExceptionCode;
unsigned ExceptionFlags;
  TExceptionRecord *ExceptionRecord;
void *ExceptionAddress;
unsigned NumberParameters;
```

```
unsigned ExceptionInformation[15];
} ;
```

Note: Under Linux, EExternal classes represent various runtime errors. EExternal has three fields with exception information:

ExceptionAddress, which contains the address of the instruction that caused the error;

AccessAddress, the address that was being accessed when the error occurred;

SignalNumber, for exceptions raised by Linux signals.

See Also

EAccessViolation (see page 22723)

EIntError (see page 22735)

EMathError (see page 22739)

EPrivilege (see page 22744)

EStackOverflow (see page 22747)

159.1.8.1 EExternal Members

The following tables list the members exposed by EExternal.

Public Fields

	Name	Description
	ExceptionRecord (see page 22729)	This is ExceptionRecord, a member of class EExternal.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	Create (see page 22752)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.

	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.

159.1.8.2 EExternal Fields

The fields of the EExternal class are listed here.

Public Fields

	Name	Description
	ExceptionRecord (see page 22729)	This is ExceptionRecord, a member of class EExternal.

159.1.8.2.1 EExternal.ExceptionRecord Field

Pascal

```
ExceptionRecord: PExceptionRecord platform;
```

C++

```
PExceptionRecord platform ExceptionRecord;
```

Description

This is ExceptionRecord, a member of class EExternal.

159.1.9 EExternalException Class

EExternalException is the exception class for invalid exception codes.

Class Hierarchy

Pascal

```
EExternalException = class(EExternal);
```

C++

```
class EExternalException : public EExternal;
```

File

SysUtils

Description

EExternalException is raised when the run time library detects an unrecognized exception code. The run time library recognizes the following exception codes:

STATUS_INTEGER_DIVIDE_BY_ZERO

STATUS_ARRAY_BOUNDS_EXCEEDED

STATUS_FLOAT_OVERFLOW

STATUS_FLOAT_INEXACT_RESULT

STATUS_FLOAT_INVALID_OPERATION

STATUS_FLOAT_STACK_CHECK

STATUS_FLOAT_DIVIDE_BY_ZERO

STATUS_INTEGER_OVERFLOW

STATUS_FLOAT_UNDERFLOW

STATUS_FLOAT_DENORMAL_OPERAND

STATUS_ACCESS_VIOLATION

STATUS_PRIVILEGED_INSTRUCTION

STATUS_CONTROL_C_EXIT

STATUS_STACK_OVERFLOW

Any exception code that is not on the list above raises an EExternalException.

Note: As a descendant of EExternal (see page 22727), EExternalException saves the exception record in its ExceptionRecord (see page 22729) data structure. An exception record is only generated under Windows.

See Also

EExternal (see page 22727)

159.1.10 EHeapException Class

EHeapException is the exception class for errors related to heap-allocated memory.

Class Hierarchy

Pascal

```
EHeapException = class(Exception);
```

C++

```
class EHeapException : public Exception;
```

File

SysUtils

Description

EHeapException's descendants—EOutOfMemory (see page 22742) and EInvalidPointer (see page 22739)—are used to handle failed allocations of dynamic memory and invalid pointer operations.

Note: Memory for these exceptions is pre-allocated whenever an application starts and remains allocated as long as the application is running. Never raise EHeapException or its descendants directly.

See Also

EOutOfMemory (see page 22742)

EInvalidPointer (see page 22739)

159.1.10.1 EHeapException Members

The following tables list the members exposed by EHeapException.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	Create (see page 22752)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22732)	Deallocates the memory occupied by an EHeapException (see page 22730) instance.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.

	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.

159.1.10.2 EHeapException Methods

The methods of the EHeapException class are listed here.

Public Methods

	Name	Description
V	FreeInstance (see page 22732)	Deallocates the memory occupied by an EHeapException (see page 22730) instance.

159.1.10.2.1 EHeapException.FreeInstance Method

Deallocates the memory occupied by an EHeapException (see page 22730) instance.

Pascal

```
procedure FreeInstance; override;
```

C++

```
virtual __fastcall FreeInstance();
```

Description

FreeInstance is called internally when an application shuts down. Do not call this method directly or attempt to create or destroy instances of EHeapException (see page 22730).

159.1.11 EInOutError Class

EInOutError is the exception class for file input/output errors.

Class Hierarchy

Pascal

```
EInOutError = class(Exception);
```

C++

```
class EInOutError : public Exception;
```

File

SysUtils

Description

EInOutError is raised when an file input/output error occurs, provided I/O checking is enabled.

Note: In Delphi code, use the $I+ directive to enable I/O checking. If an I/O error occurs while this directive is disabled, the application must call IOResult to clear the error.

Note: In C++ programs, I/O checking is a project option.

The error code is available in the ErrorCode (see page 22735) class member. Error codes are come in ranges: 0-99 (native OS errors)

Error codes in the range 0-99 represent OS error conditions, which are different for Windows and Linux. Refer to the OS documentation for complete error summaries. The SysErrorMessage (see page 22974) function returns descriptive text for OS errors.

Here are some common OS I/O errors, arranged by rough equivalents in Linux and Windows:

LinuxWindows

Linux		**Windows**	
Error Code	Description	Error Code	Description
2	No such file or directory	2	File not found
3	Path not found		
5	I/O Error		
13	Permission denied	5	Access denied
20	Not a directory		
21	Is a directory		
32	Sharing violation		
Error codes in the range 100 to 149 represent error conditions raised by CLX. Here are the CLX I/O error codes:			

Error code	**Meaning**
100	End of File
101	Disk Full
102	File variable not assigned
103	File not open
104	File not open for input
105	File not open for output
106	Error in formatted input
107	File already open

See Also

IOResult

EStreamError (see page 2704)

SysErrorMessage (see page 22974)

159.1.11.1 EInOutError Members

The following tables list the members exposed by EInOutError.

Public Fields

	Name	Description
	ErrorCode (see page 22735)	This is ErrorCode, a member of class EInOutError.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	Create (see page 22752)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.

	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.

159.1.11.2 EInOutError Fields

The fields of the EInOutError class are listed here.

Public Fields

	Name	Description
	ErrorCode (see page 22735)	This is ErrorCode, a member of class EInOutError.

159.1.11.2.1 EInOutError.ErrorCode Field

Pascal

```
ErrorCode: Integer;
```

C++

```
int ErrorCode;
```

Description

This is ErrorCode, a member of class EInOutError.

159.1.12 EIntError Class

EIntError is the base class for integer math error exceptions.

Class Hierarchy

System::TObject → SysUtils.Exception → SysUtils.EExternal → SysUtils.EIntError

Pascal

```
EIntError = class(EExternal);
```

C++

```
class EIntError : public EExternal;
```

File

SysUtils

Description

EIntError is a generic integer math exception. Although it is never raised in the runtime library, it is the base from which other integer math exceptions descend. These are the integer math exceptions:

Exception (see page 22750)	Meaning
EDivByZero (see page 22726)	An attempt was made to divide by zero
ERangeError (see page 22745)	Number or expression out of range
EIntOverflow (see page 22736)	Integer operation overflowed

Run-time exception information is saved in fields provided by EExternal (see page 22727).

See Also

EDivByZero (see page 22726)

EExternal (see page 22727)

ERangeError (see page 22745)

EIntOverflow (see page 22736)

159.1.13 EIntfCastError Class

EIntfCastError is the exception class for interface casting errors.

Class Hierarchy

Pascal

```
EIntfCastError = class(Exception);
```

C++

```
class EIntfCastError : public Exception;
```

File

SysUtils

Description

EIntfCastError is raised when an illegal cast is attempted on an interface.

See Also

EInvalidCast (see page 22737)

159.1.14 EIntOverflow Class

EIntOverflow is the exception class for integer calculations whose results are too large to fit in the allocated register.

Class Hierarchy

Pascal

```
EIntOverflow = class(EIntError);
```

C++

```
class EIntOverflow : public EIntError;
```

File

SysUtils

Description

EIntOverflow is a occurs when data is lost because an integer result is too large to retain.

Note: In Delphi Code, EIntOverflow is raised only if overflow checking is turned on. To turn on overflow checking, include the $Q+ directive in project source code, or select Project|Options, choose the Compiler tab, and check the Overflow-checking option in the dialog box.

Run-time exception information is saved in fields provided by EExternal (see page 22727).

Note: Floating-point overflows raise the EOverflow (see page 22743) exception.

See Also

EExternal (see page 22727)

ERangeError (see page 22745)

EDivByZero (see page 22726)

EOverflow (see page 22743)

159.1.15 EInvalidCast Class

EInvalidCast is an exception class for typecasting errors.

Class Hierarchy

Pascal

```
EInvalidCast = class(Exception);
```

C++

```
class EInvalidCast : public Exception;
```

File

SysUtils

Description

EInvalidCast is raised when an illegal typecast is attempted.

See Also

EIntfCastError (see page 22736)

Bad

159.1.16 EInvalidContainer Class

Class Hierarchy

Pascal

```
EInvalidContainer = class(Exception);
```

C++

```
class EInvalidContainer : public Exception;
```

File

SysUtils

Description

This is class SysUtils.EInvalidContainer.

159.1.17 EInvalidInsert Class

Class Hierarchy

Pascal

```
EInvalidInsert = class(Exception);
```

C++

```
class EInvalidInsert : public Exception;
```

File

SysUtils

Description

This is class SysUtils.EInvalidInsert.

159.1.18 EInvalidOp Class

EInvalidOp is the exception class for undefined floating-point operations.

Class Hierarchy

Pascal

```
EInvalidOp = class(EMathError);
```

C++

```
class EInvalidOp : public EMathError;
```

File

SysUtils

Description

EInvalidOp is raised when the CPU encounters an undefined instruction, invalid operation, or floating-point stack overflow.

Run-time exception information is saved in fields provided by EExternal (see page 22727).

Note: Do not confuse EInvalidOp with EInvalidOperation, the exception class for invalid component operations.

See Also

EExternal (see page 22727)

EInvalidOperation (see page 2700)

EInvalidArgument (see page 15927)

EOverflow (see page 22743)

EUnderflow (see page 22748)

EZeroDivide (see page 22761)

159.1.19 EInvalidPointer Class

EInvalidPointer is the exception class for invalid pointer operations.

Class Hierarchy

Pascal

```
EInvalidPointer = class(EHeapException);
```

C++

```
class EInvalidPointer : public EHeapException;
```

File

SysUtils

Description

EInvalidPointer is raised when an application attempts an invalid pointer operation. For example, it can occur if an application tries to dispose of the same pointer twice, or refers to a pointer which has already been disposed of.

Note: Never raise an EInvalidPointer exception directly. EInvalidPointer is raised internally by the memory manager.

159.1.20 EMathError Class

EMathError is the base exception class for floating-point math errors.

Class Hierarchy

Pascal

```
EMathError = class(EExternal);
```

C++

```
class EMathError : public EExternal;
```

File

SysUtils

Description

EMathError is the base class for floating-point math exception classes. EMathError itself is never raised.

The following exceptions descend from EMathError:

Exception (see page 22750)	Meaning
EInvalidArgument	Parameter out of range
EInvalidOp (see page 22738)	Processor encountered an undefined instruction
EOverflow (see page 22743)	Floating-point operation produced result too large to store
EUnderflow (see page 22748)	Floating-point operation produced result with no precision
EZeroDivide (see page 22761)	Attempt to divide by zero

Run-time exception information is saved in fields provided by EExternal (see page 22727).

See Also

EExternal (see page 22727)

EInvalidArgument (see page 15927)

EInvalidOp (see page 22738)

EOverflow (see page 22743)

EUnderflow (see page 22748)

EZeroDivide (see page 22761)

159.1.21 EOSError Class

EOSError is the exception class for operating system errors.

Class Hierarchy

Pascal

```
EOSError = class(Exception);
```

C++

```
class EOSError : public Exception;
```

File

SysUtils

Description

EOSError is raised by the RaiseLastOSError (see page 22932) procedure if the operating system returns an error code. The exception dialog contains the error number and the message associated with the error.

Note: EOSError replaces EWin32Error (see page 22749), which is now deprecated.

See Also

RaiseLastOSError (see page 22932)

159.1.21.1 EOSError Members

The following tables list the members exposed by EOSError.

Public Fields

	Name	Description
	ErrorCode (see page 22742)	This is ErrorCode, a member of class EOSError.

Public Methods

	Name	Description
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	Create (see page 22752)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.

	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.

159.1.21.2 EOSError Fields

The fields of the EOSError class are listed here.

Public Fields

	Name	Description
	ErrorCode (see page 22742)	This is ErrorCode, a member of class EOSError.

159.1.21.2.1 EOSError.ErrorCode Field

Pascal

```
ErrorCode: DWORD;
```

C++

```
DWORD ErrorCode;
```

Description

This is ErrorCode, a member of class EOSError.

159.1.22 EOutOfMemory Class

EOutOfMemory is the exception class for unsuccessful attempts to allocate memory.

Class Hierarchy

Pascal

```
EOutOfMemory = class(EHeapException);
```

C++

```
class EOutOfMemory : public EHeapException;
```

File

SysUtils

Description

EOutOfMemory occurs when an application attempts to allocate dynamic memory, but there is not enough free memory in the system to meet the request.

Memory for the EOutOfMemory exception is pre-allocated whenever an application starts and remains allocated as long as the application is running.

Note: Never raise EOutOfMemory directly. Instead, call the global OutOfMemoryError (see page 22931) procedure.

See Also

EOutOfResources (see page 2702)

OutOfMemoryError (see page 22931)

EHeapException (see page 22730)

159.1.23 EOverflow Class

EOverflow is the exception class for floating-point register overflows.

Class Hierarchy

Pascal

```
EOverflow = class(EMathError);
```

C++

```
class EOverflow : public EMathError;
```

File

SysUtils

Description

EOverflow is raised when a calculated result is too large to fit in the floating-point register allocated for it and data is therefore lost.

Run-time exception information is saved in fields provided by EExternal (see page 22727).

Note: Integer register overflows raise the EIntOverflow (see page 22736) exception.

See Also

EExternal (see page 22727)

EInvalidArgument (see page 15927)

EInvalidOp (see page 22738)

EUnderflow (see page 22748)

EZeroDivide (see page 22761)

EIntOverflow (see page 22736)

159.1.24 EPackageError Class

EPackageError is the exception class for package-related errors.

Class Hierarchy

Pascal

```
EPackageError = class(Exception);
```

C++

```
class EPackageError : public Exception;
```

File

SysUtils

Description

EPackageError is raised at design time only, when an error occurs loading or utilizing a package.

159.1.25 EPrivilege Class

EPrivilege is the exception class for processor privilege violations.

Class Hierarchy

Pascal

```
EPrivilege = class(EExternal);
```

C++

```
class EPrivilege : public EExternal;
```

File

SysUtils

Description

EPrivilege is raised when an application tries to execute a processor instruction that is invalid for the current processor privilege level.

Run-time exception information is saved in fields provided by EExternal (see page 22727).

See Also

EExternal (see page 22727)

159.1.26 EPropReadOnly Class

EPropReadOnly is the exception class for invalid attempts to write to a property using OLE automation.

Class Hierarchy

Pascal

```
EPropReadOnly = class(Exception);
```

C++

```
class EPropReadOnly : public Exception;
```

File

SysUtils

Description

EPropReadOnly is raised when an application tries to write to a read-only property using OLE automation.

159.1.27 EPropWriteOnly Class

EPropWriteOnly is the exception class for invalid attempts to read a property using OLE automation.

Class Hierarchy

Pascal

```
EPropWriteOnly = class(Exception);
```

C++

```
class EPropWriteOnly : public Exception;
```

File

SysUtils

Description

EPropWriteOnly is raised when an application tries to read a write-only property using OLE automation.

159.1.28 ERangeError Class

ERangeError is the exception for Delphi range errors.

Class Hierarchy

Pascal

```
ERangeError = class(EIntError);
```

C++

```
class ERangeError : public EIntError;
```

File

SysUtils

Description

ERangeError occurs in Delphi code when range checking is enabled and an ordinal values goes outside its declared range.

Note: Range checking is not a C++ feature. However, ERangeError can occur when C++ code calls Delphi code.

Note: By default, the Delphi compiler disables range checking. The compiler can always detect obvious range errors, which prevents the following code from compiling.

//Delphi subrange example

```
var
  SmallValue: 1..3;
  SevenBits: byte;
begin;
  SmallValue := 4;  //Won't compile: constant expression out of bounds
  SevenBits := 256; //Won't compile: constant expression out of bounds
end;
```

Note: However, the compiler can't anticipate out-of-range values provided at run time:

//Delphi subrange example

```
var
  SmallValue: 1..3;
  SevenBits: byte;
  ThirtyTwoBits: Integer
begin;
  ThirtyTwoBits := 4;
  SmallValue := ThirtyTwoBits; //Assigns 4 to SmallValue (SmallValue is stored as a Byte)
  ThirtyTwoBits := 256;
  SevenBits := ThirtyTwoBits;  //Assigns 0 to ThirtyTwoBits (high-order bits discarded)
end;
```

Note: If range checking is enabled, both out-of-bounds assignments throw ERangeError exceptions. To enable range checking, use the Project option in the IDE or the $R+ directive.

Note: Range checking is considered a debugging feature. It produces bigger and slower executables.

Note: Do not confuse ERangeError with ERangeException, which relates to errors using graduated controls in VisualCLX.

See Also

EExternal (see page 22727)

EIntOverflow (see page 22736)

EDivByZero (see page 22726)

ERangeException

159.1.29 ESafecallException Class

ESafecallException is the exception for problems with the safecall calling convention.

Class Hierarchy

Pascal

```
ESafecallException = class(Exception);
```

C++

```
class ESafecallException : public Exception;
```

File

SysUtils

Description

ESafecallException is raised when the safecall error handler has not been set up and a safecall routine returns a non-0 HResult, or if the safecall error handler does not raise an exception.

If this exception occurs, the Comobj unit is probably missing from the application's uses list (Delphi) or not included in the project source file (C++). You may want to consider removing the safecall calling convention from the routine that gave rise to the exception.

See Also

TComponent (see page 2762)

159.1.30 EStackOverflow Class

EStackOverflow is the exception class for stack overflows.

Class Hierarchy

Pascal

```
EStackOverflow = class(EExternal);
```

C++

```
class EStackOverflow : public EExternal;
```

File

SysUtils

Description

EStackOverflow is raised when the system is unable to allocate necessary stack space. This can happen because of extremely large local variables, deeply recursive routines, or invalid machine-language code.

Run-time exception information is saved in fields provided by EExternal (see page 22727).

See Also

EExternal (see page 22727)

159.1.31 EUnderflow Class

EUnderflow is the exception class for values that are too small to be represented with a floating-point variable.

Class Hierarchy

Pascal

```
EUnderflow = class(EMathError);
```

C++

```
class EUnderflow : public EMathError;
```

File

SysUtils

Description

When a floating-point math operation produces a value that is too small to be represented in a floating-point variable, the result ordinarily becomes zero. However, an application can change the numeric coprocessor's control word to unmask underflow hardware exceptions. In this case, EUnderflow is raised when the processor reports an underflow hardware exception. The control word is reset after the exception.

Run-time exception information is saved in fields provided by EExternal (see page 22727).

See Also

EExternal (see page 22727)

EInvalidArgument (see page 15927)

EInvalidOp (see page 22738)

EOverflow (see page 22743)

EZeroDivide (see page 22761)

159.1.32 EVariantError Class

EVariantError is the exception class for errors involving Variant data types.

Class Hierarchy

Pascal

```
EVariantError = class(Exception);
```

C++

```
class EVariantError : public Exception;
```

File

SysUtils

Description

EVariantError is raised when a variant operation fails. EVariantError has a number of descendant classes which provide more specific information about the error.

See Also

EVariantArrayCreateError (see page 23572)

EVariantArrayLockedError (see page 23573)

EVariantBadIndexError (see page 23574)

EVariantBadVarTypeError (see page 23574)

EVariantDispatchError (see page 23575)

EVariantInvalidArgError (see page 23575)

EVariantInvalidOpError (see page 23577)

EVariantNotImplError (see page 23578)

EVariantOutOfMemoryError (see page 23578)

EVariantOverflowError (see page 23579)

EVariantTypeCastError (see page 23580)

EVariantUnexpectedError (see page 23581)

159.1.33 EWin32Error Class

EWin32Error is the exception class for Windows errors.

Class Hierarchy

Pascal

```
EWin32Error = class(EOSError);
```

C++

```
class EWin32Error : public EOSError;
```

File

SysUtils

Description

EWin32Error is now deprecated in favor of EOSError (see page 22740).

See Also

RaiseLastWin32Error (see page 22932)

EOSError (see page 22740)

159.1.34 Exception Class

Exception is the base class for all runtime exceptions.

Class Hierarchy

Pascal

```
Exception = class(TObject);
```

C++

```
class Exception : public TObject;
```

File

SysUtils

Description

Exception encapsulates the fundamental properties and methods for all exceptions. Use Exception as the base class for creating custom exceptions.

All methods introduced for the Exception object are constructors that provide alternative ways to create exception messages. Some constructors also create help context IDs. Typically, an application calls these constructors dynamically when an exception occurs.

Exception messages can be hard-coded strings, formatted strings, or strings (including formatted strings) loaded from an application resource.

Exceptions are raised when a runtime error occurs in an application, such as attempting to divide by zero. When an exception is raised, typically an exception instance displays a dialog box describing the error condition. If an application does not handle the exception condition, then the default exception handler is called. This handler also displays a dialog box with an OK button that usually permits an application to continue processing when the user clicks OK.

Note: Standard practice is to derive all exception classes from Exception, and specify a name beginning with "E", followed by an abbreviated, descriptive name.

C++ Examples:

```
/*
In addition to displaying the exception message, which
happens by default, the following code shuts down the
application when an exception is not caught and handled.
AppException should be declared a method of TForm1.
*/

#include <System.hpp>
#include <SysUtils.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Application->OnException = AppException;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::AppException(TObject *Sender, Exception *E)
{
  Application->ShowException(E);
```

```
  Application->Terminate();
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  throw(Exception("Hardware error: Divide by 0"));
}
```

159.1.34.1 Exception Members

The following tables list the members exposed by Exception.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22752)	Instantiates an instance of an exception with a simple message string.
	CreateFmt (see page 22754)	Instantiates an instance of an exception with a formatted message string.
	CreateFmtHelp (see page 22755)	Instantiates an instance of an exception with a formatted message string and a help-context ID.
	CreateHelp (see page 22755)	Creates an instance of an exception with a simple message string and a help-context ID.
	CreateRes (see page 22756)	This is the overview for the CreateRes constructor overload.
	CreateResFmt (see page 22756)	This is the overview for the CreateResFmt constructor overload.
	CreateResFmtHelp (see page 22757)	This is the overview for the CreateResFmtHelp constructor overload.
	CreateResHelp (see page 22759)	This is the overview for the CreateResHelp constructor overload.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.

159.1.34.2 Exception.Create Constructor

Instantiates an instance of an exception with a simple message string.

Pascal

```
constructor Create(const Msg: string);
```

C++

```
__fastcall Exception(const AnsiString Msg);
```

Description

Call Create to construct an exception object with a simple message string.

Msg is the string containing the runtime error message to display in the exception dialog box. Msg can be a hard-coded string, or can be a function call that returns a string.

C++ Examples:

```
/*
The following example creates a directory 'C:\temp' if it
does not already exist.
}
*/
#include <Filectrl.hpp>
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (!DirectoryExists("c:\\temp"))
  {
    if (!CreateDir("C:\\temp"))
      throw Exception("Cannot create c:\\temp directory.");
  }
  if (!CreateDir("C:\\temp"))
    throw Exception("The c:\\temp directory already exists.");
}
```

Delphi Examples:

```
{
The following example creates a directory 'C:\temp' if it
does not already exist.
}
uses FileCtrl;
procedure TForm1.Button1Click(Sender: TObject);
begin
  if not SysUtils.DirectoryExists('C:\temp') then
    if not CreateDir('C:\temp') then
      raise Exception.Create('Cannot create C:\temp');
  if not CreateDir('C:\temp') then
    raise Exception.Create('Cannot create C:\temp again!');
end;
{
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
```

```
  file. Additional information is also written to the file so
  that it can be read easily with the FileRead function.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    BackupName: string;
    FileHandle: Integer;
    StringLen: Integer;
    X, Y, I: Integer;
    colCountLength, rowCountLength: Integer;
    Buffer: PChar;
    cellString: string;
  begin
    if SaveDialog1.Execute then
    begin
      if FileExists(SaveDialog1.FileName) then
      begin
        BackupName := SysUtils.ExtractFileName(SaveDialog1.FileName);
        BackupName := ChangeFileExt(BackupName, '.BAK');
        if not RenameFile(SaveDialog1.FileName, BackupName) then
          raise Exception.Create('Unable to create backup file.');
      end;
      FileHandle := FileCreate(SaveDialog1.FileName);
      { Write out the number of rows and columns in the grid. }
      colCountLength := SizeOf(StringGrid1.ColCount);
      FileWrite(FileHandle,
        Pchar(StringGrid1.ColCount), colCountLength);
      rowCountLength := SizeOf(StringGrid1.RowCount);
      FileWrite(FileHandle,
        PChar(StringGrid1.RowCount), rowCountLength);
      for X := 0 to StringGrid1.ColCount - 1 do
      begin
        for Y := 0 to StringGrid1.RowCount - 1 do
        begin
          try
            { Write out the length of each string, followed by the string itself. }
            StringLen := Length(StringGrid1.Cells[X,Y]);
            FileWrite(FileHandle, PChar(StringLen), SizeOf(StringLen));
            GetMem(Buffer, StringLen); { allocate the buffer }
            cellString := StringGrid1.Cells[X,Y];
            for I := 1 to StringLen do
               Buffer[I - 1] := cellString[I];
            FileWrite(FileHandle, Buffer^, StringLen);
          finally
            FreeMem(Buffer, StringLen);
          end;
        end;
      end;
      FileClose(FileHandle);
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    with StringGrid1 do
    begin
      Cells[1,0] := 'Column 1';
      Cells[2,0] := 'Column 2';
      Cells[3,0] := 'Column 3';
      Cells[4,0] := 'Column 4';
      Cells[0,1] := 'Row 1';
      Cells[1,1] := 'Object';
      Cells[2,1] := 'Pascal';
      Cells[3,1] := 'is';
      Cells[4,1] := 'excellent';
      Cells[0,2] := 'Row 2';
```

```
      Cells[1,2] := 'Delphi';
      Cells[2,2] := 'is';
      Cells[4,2] := 'RAD';
    end;
  end;
  {
  In addition to displaying the exception message, which
  happens by default, the following code shuts down the
  application when an exception is not caught and handled.
  AppException should be declared a method of TForm1.
  }
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    Application.OnException := AppException;
  end;
  procedure TForm1.AppException(Sender: TObject; E: Exception);
  begin
    Application.ShowException(E);
    Application.Terminate;
  end;

  procedure TForm1.Button1Click(Sender: TObject);
  begin
    raise EPasswordInvalid.Create('Incorrect password entered');
  end;
```

CreateFmt (see page 22754)

CreateRes (see page 22756)

CreateResFmt (see page 22757)

Message (see page 22760)

159.1.34.3 Exception.CreateFmt Constructor

Instantiates an instance of an exception with a formatted message string.

Pascal

```
constructor CreateFmt(const Msg: string; const Args: array of const);
```

C++

```
__fastcall Exception(const AnsiString Msg, const array of const Args);
```

Description

Call CreateFmt to construct an exception with a formatted message string. Msg is a string constant containing format specifiers to be replaced with values from Args. Args is an array of constants containing values to format according to format specifiers in Msg, and insert into Msg. CreateFmt calls the Format (see page 22897) function to transform Msg with the values in Arg.

CreateResFmt (see page 22757)

CreateResFmtHelp (see page 22758)

Format (see page 22897)

Message (see page 22760)

159.1.34.4 Exception.CreateFmtHelp Constructor

Instantiates an instance of an exception with a formatted message string and a help-context ID.

Pascal

```
constructor CreateFmtHelp(const Msg: string; const Args: array of const; AHelpContext:
Integer);
```

C++

```
__fastcall Exception(const AnsiString Msg, const array of const Args, int AHelpContext);
```

Description

Call CreateFmtHelp to construct an exception with a formatted message string and a help context ID. Msg is a string constant containing format specifiers to be replaced with values from Args. Args is an array of constants containing values to format according to format specifiers in Msg, and insert into Msg. CreateFmt (see page 22754) calls the Format (see page 22897) function to transform Msg with the values in Arg.

AHelpContext is an integer that specifies the context-sensitive help ID for the exception.

See Also

CreateHelp (see page 22755)

CreateResFmtHelp (see page 22758)

Format (see page 22897)

HelpContext (see page 22760)

Message (see page 22760)

159.1.34.5 Exception.CreateHelp Constructor

Creates an instance of an exception with a simple message string and a help- context ID.

Pascal

```
constructor CreateHelp(const Msg: string; AHelpContext: Integer);
```

C++

```
__fastcall Exception(const AnsiString Msg, int AHelpContext);
```

Description

Call CreateHelp to construct an exception with a simple message string and a help-context ID. Msg is the string containing the runtime error message to display in the exception dialog box. Msg can be a hard-coded string, or can be a function call that returns a string.

AHelpContext is an integer that specifies the context-sensitive help ID for the exception.

See Also

HelpContext (see page 22760)

Message (see page 22760)

CreateFmtHelp (see page 22755)

CreateResFmtHelp (see page 22758)

Format (see page 22897)

159.1.34.6 CreateRes Constructor

This is the overview for the CreateRes constructor overload.

Overload List

	Name	Description
	Exception.CreateRes (Integer) (see page 22756)	Creates an instance of an exception with a simple message string that is loaded from the application's resources.
	Exception.CreateRes (PResStringRec) (see page 22756)	Creates an instance of an exception with a simple message string that is loaded from the application's resources.

159.1.34.6.1 Exception.CreateRes Constructor (Integer)

Creates an instance of an exception with a simple message string that is loaded from the application's resources.

Pascal

```
constructor CreateRes(Ident: Integer); overload;
constructor CreateRes(ResStringRec: PResStringRec); overload;
```

C++

```
__fastcall Exception(int Ident);
__fastcall Exception(PResStringRec ResStringRec);
```

Description

Call CreateRes to construct an exception with a simple message string loaded from an application's resources. Resources are bound into the application executable at compile time, but at design time they exist in a separate resource file.

Ident is the unique ID of the resource as specified in the resource file. If Ident is not a valid resource ID, CreateRes creates an empty message string for the exception.

ResStringRec is a pointer to a resource string. This syntax appears as follows:

```
resourcestring sMyNewErrorMessage = 'You shouldn''t have done that';
...
Exception.Create(@sMyNewErrorMessage);
```

See Also

Message (see page 22760)

CreateResFmt (see page 22757)

CreateResFmtHelp (see page 22758)

159.1.34.7 CreateResFmt Constructor

This is the overview for the CreateResFmt constructor overload.

Overload List

	Name	Description
	Exception.CreateResFmt (Integer, array of const) (see page 22757)	Creates an instance of an exception with a message string that is loaded from the application's resources and then formatted.
	Exception.CreateResFmt (PResStringRec, array of const) (see page 22757)	Creates an instance of an exception with a message string that is loaded from the application's resources and then formatted.

159.1.34.7.1 Exception.CreateResFmt Constructor (Integer, array of const)

Creates an instance of an exception with a message string that is loaded from the application's resources and then formatted.

Pascal

```
constructor CreateResFmt(Ident: Integer; const Args: array of const); overload;
constructor CreateResFmt(ResStringRec: PResStringRec; const Args: array of const); overload;
```

C++

```
__fastcall Exception(int Ident, const array of const Args);
__fastcall Exception(PResStringRec ResStringRec, const array of const Args);
```

Description

Call CreateResFmt to construct an exception with a message string loaded from an application's resources and then formatted with additional information. Resources are bound into the application executable at compile time, but at design time they exist in a separate resource file.

Ident is the unique ID of the resource as specified in the resource file. If Ident is not a valid resource ID, CreateResFmt creates an empty message string for the exception.

ResStringRec is a pointer to a resource string. This syntax appears as follows:

```
resourcestring sMyNewErrorMessage = 'Illegal value: %s';
...
Exception.CreateResFmt(@sMyNewErrorMessage, [-1]);
```

Args is an array of constants containing values to:

1Format (see page 22897) according to format specifiers embedded in the string, and

2Insert into the message string.

CreateResFmt calls the Format (see page 22897) function to transform the message string with the values in Arg.

See Also

Message (see page 22760)

CreateRes (see page 22756)

CreateResFmtHelp (see page 22758)

Format (see page 22897)

159.1.34.8 CreateResFmtHelp Constructor

This is the overview for the CreateResFmtHelp constructor overload.

Overload List

	Name	Description
	Exception.CreateResFmtHelp (Integer, array of const, Integer) (see page 22758)	Creates an instance of an exception with a help-context ID and a formatted message string loaded from the application resources
	Exception.CreateResFmtHelp (PResStringRec, array of const, Integer) (see page 22758)	Creates an instance of an exception with a help-context ID and a formatted message string loaded from the application resources

159.1.34.8.1 Exception.CreateResFmtHelp Constructor (Integer, array of const, Integer)

Creates an instance of an exception with a help-context ID and a formatted message string loaded from the application resources

Pascal

```
constructor CreateResFmtHelp(ResStringRec: PResStringRec; const Args: array of const;
AHelpContext: Integer); overload;
constructor CreateResFmtHelp(Ident: Integer; const Args: array of const; AHelpContext:
Integer); overload;
```

C++

```
__fastcall Exception(PResStringRec ResStringRec, const array of const Args, int AHelpContext);
__fastcall Exception(int Ident, const array of const Args, int AHelpContext);
```

Description

Call CreateResFmtHelp to construct an exception with a:

1Message (see page 22760) string loaded from an application's resources and formatted with additional information.

2Help-context ID.

Resources are bound into the application executable at compile time, but at design time they exist in a separate resource file. Ident is the unique ID of the resource as specified in the resource file. If Ident is not a valid resource ID, CreateResFmt (see page 22757) creates an empty message string.

ResStringRec is a pointer to a resource string. This syntax appears as follows:

```
resourcestring sMyNewErrorMessage = 'Illegal value: %s';
const IDH_MYNEWERROR: Integer = 30000;
...
Exception.CreateResFmt(@sMyNewErrorMessage, [-1], IDH_MYNEWERROR);
```

Args is an array of constants containing values to:

1Format (see page 22897) according to format specifiers embedded in the string, and

2Insert into the message string.

CreateResFmtHelp calls the Format (see page 22897) function to transform the message string with the values in Arg.

AHelpContext is an integer that specifies the context-sensitive help ID for the exception.

See Also

HelpContext (see page 22760)

Message (see page 22760)

CreateHelp (see page 22755)

CreateRes (see page 22756)

CreateResHelp (see page 22759)

Format (see page 22897)

159.1.34.9 CreateResHelp Constructor

This is the overview for the CreateResHelp constructor overload.

Overload List

	Name	Description
	Exception.CreateResHelp (Integer, Integer) (see page 22759)	Creates an instance of an exception with a help-context ID and a simple message string that is loaded from the application's resources.
	Exception.CreateResHelp (PResStringRec, Integer) (see page 22759)	Creates an instance of an exception with a help-context ID and a simple message string that is loaded from the application's resources.

159.1.34.9.1 Exception.CreateResHelp Constructor (Integer, Integer)

Creates an instance of an exception with a help-context ID and a simple message string that is loaded from the application's resources.

Pascal

```
constructor CreateResHelp(Ident: Integer; AHelpContext: Integer); overload;
constructor CreateResHelp(ResStringRec: PResStringRec; AHelpContext: Integer); overload;
```

C++

```
__fastcall Exception(int Ident, int AHelpContext);
__fastcall Exception(PResStringRec ResStringRec, int AHelpContext);
```

Description

Call CreateResHelp to construct an exception with a help-context ID and a simple message string loaded from an application's resources. Resources are bound into the application executable at compile time, but at design time they exist in a separate resource file.

Ident is the unique ID of the resource as specified in the resource file. If Ident is not a valid resource ID, CreateResHelp creates an empty message string for the exception.

AHelpContext is an integer that specifies the context-sensitive help ID for the exception.

ResStringRec is a pointer to a resource string. Its syntax appears as follows:

```
resourcestring sMyNewErrorMessage = 'You shouldn''t have done that';
const IDH_MYNEWERROR: Integer = 30000;
...
Exception.Create(@sMyNewErrorMessage, IDH_MYNEWERROR);
```

See Also

HelpContext (see page 22760)

Message (see page 22760)

159.1.34.10 Exception Properties

The properties of the Exception class are listed here.

Public Properties

	Name	Description
	HelpContext (see page 22760)	Indicates the context ID number for context-sensitive online help associated with the exception.
	Message (see page 22760)	Message contains the text string to display in the exception dialog box when the exception is raised.

159.1.34.10.1 Exception.HelpContext Property

Indicates the context ID number for context-sensitive online help associated with the exception.

Pascal

```
property HelpContext: Integer;
```

C++

```
__property int HelpContext;
```

Description

HelpContext provides storage for the help context ID number associated with the exception object. The context ID number determines the contents of the help screen that appears when a user presses F1 in response to an exception error message.

Note: To initialize HelpContext when the Exception (see page 22750) object is instantiated, use the appropriate constructor.

Note: In Delphi code, instantiate the Exception (see page 22750) object with CreateFmtHelp (see page 22755), CreateHelp (see page 22755), CreateResFmtHelp (see page 22758), or CreateResHelp (see page 22759).

Note: In C++ code, use a form of the constructor that takes a help context parameter.

See Also

Create (see page 22752)

CreateFmtHelp (see page 22755)

CreateHelp (see page 22755)

CreateResFmtHelp (see page 22758)

CreateResHelp (see page 22759)

159.1.34.10.2 Exception.Message Property

Message contains the text string to display in the exception dialog box when the exception is raised.

Pascal

```
property Message: string;
```

C++

```
__property AnsiString Message;
```

Description

Message stores the error-message string to display when the exception is raised. All Exception (see page 22750) constructors expect a string parameter to store in Message. Message text can be hard-coded as a parameter to an Exception (see page 22750) constructor, created as dynamic parameter, or loaded from a resource file as a static or dynamically formatted parameter.

159.1.35 EZeroDivide Class

EZeroDivide is the exception class for floating-point divide-by-zero errors.

Class Hierarchy

Pascal

```
EZeroDivide = class(EMathError);
```

C++

```
class EZeroDivide : public EMathError;
```

File

SysUtils

Description

EZeroDivide exception is raised when an application attempts to divide a floating-point value by zero.

Run-time exception information is saved in fields provided by EExternal (see page 22727).

Note: Integer divide-by-zero errors raise the EDivByZero (see page 22726) exception.

See Also

EExternal (see page 22727)

EInvalidArgument (see page 15927)

EInvalidOp (see page 22738)

EOverflow (see page 22743)

EUnderflow (see page 22748)

EDivByZero (see page 22726)

159.1.36 TLanguages Class

TLanguages lists all available Windows locales.

Class Hierarchy

SysUtils.TLanguages

Pascal

```
TLanguages = class;
```

C++

```
class TLanguages;
```

File

SysUtils

Description

The Languages (see page 22926) function returns a TLanguages instance that lists the Windows locales supported by the current system. For each locale, TLanguages indicates the locale ID (see page 22764) (LCID), standard name, and recommended file-name extension. This information is obtained from the operating system; all TLanguages properties are read-only.

See Also

Languages (see page 22926)

159.1.36.1 TLanguages Members

The following tables list the members exposed by TLanguages.

Public Methods

	Name	Description
	Create (see page 22763)	This is Create, a member of class TLanguages.
	IndexOf (see page 22763)	Returns the index of the first locale in the array with the specified LCID.

Public Properties

	Name	Description
R	Count (see page 22764)	Contains the number of locales listed in the TLanguages (see page 22762) object.
R	Ext (see page 22764)	Contains the standard file-name extension at the specified position in the array.
R	ID (see page 22764)	Contains a locale ID as a string.
R	LocaleID (see page 22765)	Contains a locale ID (see page 22764) as an integer.
R	Name (see page 22765)	Contains the locale name at the specified position in the array.
R	NameFromLCID (see page 22766)	Contains the locale name specified by a string representation of a locale ID (see page 22764).

R	NameFromLocaleID (see page 22766)	Contains the locale name specified by an integer locale ID (see page 22764).

159.1.36.2 TLanguages.Create Constructor

Pascal

```
constructor Create;
```

C++

```
__fastcall TLanguages();
```

Description

This is Create, a member of class TLanguages.

159.1.36.3 TLanguages Methods

The methods of the TLanguages class are listed here.

Public Methods

	Name	Description
	IndexOf (see page 22763)	Returns the index of the first locale in the array with the specified LCID.

159.1.36.3.1 TLanguages.IndexOf Method

Returns the index of the first locale in the array with the specified LCID.

Pascal

```
function IndexOf(ID: LCID): Integer;
```

C++

```
__fastcall int IndexOf(LCID ID);
```

Description

Call IndexOf to get the position in the array of a specified locale ID (see page 22764). For example, if U.S. English is the first locale listed in TLanguages (see page 22762), then IndexOf($0409) returns 0.

If the specified LCID is not found, IndexOf returns -1.

See Also

Ext (see page 22764)

ID (see page 22764)

LocaleID (see page 22765)

Name (see page 22765)

159.1.36.4 TLanguages Properties

The properties of the TLanguages class are listed here.

Public Properties

	Name	Description
R	Count (see page 22764)	Contains the number of locales listed in the TLanguages (see page 22762) object.
R	Ext (see page 22764)	Contains the standard file-name extension at the specified position in the array.
R	ID (see page 22764)	Contains a locale ID as a string.
R	LocaleID (see page 22765)	Contains a locale ID (see page 22764) as an integer.
R	Name (see page 22765)	Contains the locale name at the specified position in the array.
R	NameFromLCID (see page 22766)	Contains the locale name specified by a string representation of a locale ID (see page 22764).
R	NameFromLocaleID (see page 22766)	Contains the locale name specified by an integer locale ID (see page 22764).

159.1.36.4.1 TLanguages.Count Property

Contains the number of locales listed in the TLanguages (see page 22762) object.

Pascal

```
property Count: Integer;
```

C++

```
__property int Count;
```

Description

Read Count to determine the number of locales supported by the current system.

See Also

ID (see page 22764)

LocaleID (see page 22765)

IndexOf (see page 22763)

159.1.36.4.2 TLanguages.Ext Property

Contains the standard file-name extension at the specified position in the array.

Pascal

```
property Ext [Index: Integer]: string;
```

C++

```
__property AnsiString Ext[int Index];
```

Description

Read Ext to get the standard three-letter file-name extension for a locale. For example, Ext[IndexOf (see page 22763)($0409)] returns the string ENU.

Ext is a zero-based array.

See Also

IndexOf (see page 22763)

159.1.36.4.3 TLanguages.ID Property

Contains a locale ID as a string.

Pascal

```
property ID [Index: Integer]: string;
```

C++

```
__property AnsiString ID[int Index];
```

Description

Read ID to get the locale ID at a specified position in the array as a string. (To get the same ID as an integer, use the LocaleID (see page 22765) property.) For example, if U.S. English is the first locale listed in TLanguages (see page 22762), then ID[0] returns the string $00000409. You can iterate through the ID array (from 0 to Count (see page 22764) - 1) to determine whether a specific locale is in the array.

See Also

Count (see page 22764)

LocaleID (see page 22765)

159.1.36.4.4 TLanguages.LocaleID Property

Contains a locale ID (see page 22764) as an integer.

Pascal

```
property LocaleID [Index: Integer]: LCID;
```

C++

```
__property LCID LocaleID[int Index];
```

Description

Read LocaleID to get the locale ID (see page 22764) at a specified position in the array as an integer. (To get the same ID (see page 22764) as a string, use the ID (see page 22764) property.) For example, if U.S. English is the first locale listed in TLanguages (see page 22762), then LocaleID[0] returns the integer $409. You can iterate through the LocaleID array (from 0 to Count (see page 22764) - 1) to determine whether a specific locale is in the array.

See Also

Count (see page 22764)

ID (see page 22764)

159.1.36.4.5 TLanguages.Name Property

Contains the locale name at the specified position in the array.

Pascal

```
property Name [Index: Integer]: string;
```

C++

```
__property AnsiString Name[int Index];
```

Description

Read Name to get the standard Windows name for a locale. For example, Name[IndexOf (see page 22763)($0409)] returns the string English (United States).

Name is a zero-based array.

See Also

IndexOf (see page 22763)

NameFromLCID (see page 22766)

NameFromLocaleID (see page 22766)

159.1.36.4.6 TLanguages.NameFromLCID Property

Contains the locale name specified by a string representation of a locale ID (see page 22764).

Pascal

```
property NameFromLCID [const ID: string]: string;
```

C++

```
__property AnsiString NameFromLCID[AnsiString const ID];
```

Description

Read NameFromLCID to get the standard Windows name for a locale using a locale ID (see page 22764) represented by a string.

See Also

Name (see page 22765)

NameFromLocaleID (see page 22766)

159.1.36.4.7 TLanguages.NameFromLocaleID Property

Contains the locale name specified by an integer locale ID (see page 22764).

Pascal

```
property NameFromLocaleID [ID: LCID]: string;
```

C++

```
__property AnsiString NameFromLocaleID[LCID ID];
```

Description

Read NameFromLocaleID to get the standard Windows name for a locale using an integer locale ID (see page 22764). For example, NameFromLCID (see page 22766)[$0409] returns the string English (United States).

See Also

NameFromLCID (see page 22766)

Name (see page 22765)

159.1.37 TMultiReadExclusiveWriteSynchronizer Class

TMultiReadExclusiveWriteSynchronizer protects memory in a multi-threaded application.

Class Hierarchy

Pascal

```
TMultiReadExclusiveWriteSynchronizer = class(TInterfacedObject, IReadWriteSync);
```

C++

```
class TMultiReadExclusiveWriteSynchronizer : public TInterfacedObject, public IReadWriteSync;
```

File

SysUtils

Description

Use TMultiReadExclusiveWriteSynchronizer to guard access to memory in a multi-threaded application. Unlike a critical section, which blocks all other threads from reading or writing its associated memory, TMultiReadExclusiveWriteSynchronizer allows multiple threads to read from the protected memory simultaneously, while ensuring that any thread writing to the memory has exclusive access.

In applications where threads read from an object or variable frequently and only write to it occasionally, using the multi-read exclusive-write synchronizer instead of a critical section can result in considerable performance improvement.

All access to the protected memory must be bracketed by calls to the BeginRead (see page 22769) and EndRead (see page 22770) or BeginWrite (see page 22770) and EndWrite (see page 22771) methods. Any thread that reads from or writes to this memory without using these calls can introduce thread conflicts.

See Also

TCriticalSection (see page 22058)

TThread (see page 3108)

Using the Multi-read Exclusive-write Synchronizer

159.1.37.1 TMultiReadExclusiveWriteSynchronizer Members

The following tables list the members exposed by TMultiReadExclusiveWriteSynchronizer.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginRead (see page 22769)	Allows a thread to read from the protected memory when it is safe to do so.
	BeginWrite (see page 22770)	Allows a thread to write to the protected memory when it is safe to do so.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22769)	Creates and initializes an instance of TMultiReadExclusiveWriteSynchronizer (see page 22766).
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22769)	Destroys an instance of TMultiReadExclusiveWriteSynchronizer (see page 22766).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndRead (see page 22770)	Removes a thread from the internal list of threads that are accessing the protected memory.
	EndWrite (see page 22771)	Allows other threads to access the associated memory.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.
R	RevisionLevel (see page 22771)	Changes revision level of protected memory.

159.1.37.2 TMultiReadExclusiveWriteSynchronizer.Create Constructor

Creates and initializes an instance of TMultiReadExclusiveWriteSynchronizer (see page 22766).

Pascal

```
constructor Create;
```

C++

```
__fastcall TMultiReadExclusiveWriteSynchronizer();
```

Description

Call Create to instantiate TMultiReadExclusiveWriteSynchronizer (see page 22766). The synchronizer must be created in the same thread as the memory it protects, so that it is accessible to all threads that need to access that memory.

159.1.37.3 TMultiReadExclusiveWriteSynchronizer.Destroy Destructor

Destroys an instance of TMultiReadExclusiveWriteSynchronizer (see page 22766).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TMultiReadExclusiveWriteSynchronizer();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TMultiReadExclusiveWriteSynchronizer (see page 22766) reference is not nil, and only then calls Destroy.

See Also

Free (see page 22300)

159.1.37.4 TMultiReadExclusiveWriteSynchronizer Methods

The methods of the TMultiReadExclusiveWriteSynchronizer class are listed here.

Public Methods

	Name	Description
	BeginRead (see page 22769)	Allows a thread to read from the protected memory when it is safe to do so.
	BeginWrite (see page 22770)	Allows a thread to write to the protected memory when it is safe to do so.
	EndRead (see page 22770)	Removes a thread from the internal list of threads that are accessing the protected memory.
	EndWrite (see page 22771)	Allows other threads to access the associated memory.

159.1.37.4.1 TMultiReadExclusiveWriteSynchronizer.BeginRead Method

Allows a thread to read from the protected memory when it is safe to do so.

Pascal

```
procedure BeginRead;
```

C++

```
__fastcall BeginRead();
```

Description

Call BeginRead before reading from the memory protected by the multi-read exclusive-write synchronizer. BeginRead does not return until there are no other threads writing to the memory. After calling BeginRead, other threads can be granted read access to the protected memory by the BeginRead method. However, any thread asking for write permission by calling BeginWrite (see page 22770) must wait until all reading threads have called EndRead (see page 22770).

See Also

EndRead (see page 22770)

BeginWrite (see page 22770)

Using the Multi-read Exclusive-write Synchronizer

159.1.37.4.2 TMultiReadExclusiveWriteSynchronizer.BeginWrite Method

Allows a thread to write to the protected memory when it is safe to do so.

Pascal

```
function BeginWrite: Boolean;
```

C++

```
__fastcall Boolean BeginWrite();
```

Description

BeginWrite obtains an exclusive write lock on the memory protected by the synchronizer object. Call BeginWrite before writing to this memory. BeginWrite does not return until no other threads are reading from or writing to the memory. After a thread calls BeginWrite, any other thread asking to access that memory by calling BeginRead (see page 22769) or BeginWrite must wait until the writing thread calls EndWrite (see page 22771).

Note that a write lock operation is not atomic. Data in protected memory will always be in a consistent state when BeginWrite returns, but is not necessarily in the same state as when BeginWrite was called. As a rule, a thread should always discard previous samples from protected memory after promoting a read lock to a write lock. However, the calling thread can determine whether a state change has occurred by examining return value of BeginWrite: true if protected memory has not be written to by another thread, false if another thread may have modified protected memory.

See Also

EndWrite (see page 22771)

BeginRead (see page 22769)

Using the Multi-read Exclusive-write Synchronizer

159.1.37.4.3 TMultiReadExclusiveWriteSynchronizer.EndRead Method

Removes a thread from the internal list of threads that are accessing the protected memory.

Pascal

```
procedure EndRead;
```

C++

```
__fastcall EndRead();
```

Description

Call EndRead after reading from the memory protected by the multi-read exclusive-write synchronizer. Each call to BeginRead (see page 22769) must be matched by a call to EndRead, or other threads can never return from the BeginWrite (see page 22770) method.

See Also

BeginRead (see page 22769)

BeginWrite (see page 22770)

Using the Multi-read Exclusive-write Synchronizer

159.1.37.4.4 TMultiReadExclusiveWriteSynchronizer.EndWrite Method

Allows other threads to access the associated memory.

Pascal

```
procedure EndWrite;
```

C++

```
__fastcall EndWrite();
```

Description

Call EndWrite after writing to the memory that is protected by the multi-read exclusive-write synchronizer. Each call to BeginWrite (see page 22770) must be matched by a call to EndWrite, or other threads can never return from the BeginRead (see page 22769) or BeginWrite (see page 22770) methods.

See Also

BeginWrite (see page 22770)

Using the Multi-read Exclusive-write Synchronizer

159.1.37.5 TMultiReadExclusiveWriteSynchronizer Properties

The properties of the TMultiReadExclusiveWriteSynchronizer class are listed here.

Public Properties

	Name	Description
R	RevisionLevel (see page 22771)	Changes revision level of protected memory.

159.1.37.5.1 TMultiReadExclusiveWriteSynchronizer.RevisionLevel Property

Changes revision level of protected memory.

Pascal

```
property RevisionLevel: Cardinal;
```

C++

```
__property unsigned RevisionLevel;
```

Description

RevisionLevel changes each time a write lock is granted. This property should be used for identity comparisons only, not for determining revision sequence.

159.1.38 TSimpleRWSync Class

Class Hierarchy

Pascal

```
TSimpleRWSync = class(TInterfacedObject, IReadWriteSync);
```

C++

```
class TSimpleRWSync : public TInterfacedObject, public IReadWriteSync;
```

File

SysUtils

Description

This is class SysUtils.TSimpleRWSync.

159.1.38.1 TSimpleRWSync Members

The following tables list the members exposed by TSimpleRWSync.

Protected Data Members

	Name	Description
	FRefCount (see page 22278)	This is FRefCount, a member of class TInterfacedObject.

Protected Methods

	Name	Description
	_AddRef (see page 22278)	Implements the IInterface (see page 22396) System::TInterfacedObject::_AddRef method.
	_Release (see page 22279)	Implements the IInterface (see page 22396) System::TInterfacedObject::_Release method.
	QueryInterface (see page 22280)	Implements the IInterface (see page 22396) System::TInterfacedObject::QueryInterface method.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22279)	Responds after the last constructor executes.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22279)	Checks that the reference count is zero before allowing the interfaced object to be destroyed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginRead (see page 22774)	This is BeginRead, a member of class TSimpleRWSync.

	BeginWrite (see page 22775)	This is BeginWrite, a member of class TSimpleRWSync.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 22773)	Constructs an object and initializes its data before the object is first used.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22774)	Disposes of an object instance.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndRead (see page 22775)	This is EndRead, a member of class TSimpleRWSync.
	EndWrite (see page 22775)	This is EndWrite, a member of class TSimpleRWSync.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22280)	Allocates memory for each instance of an interfaced object.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Public Properties

	Name	Description
R	RefCount (see page 22281)	Indicates the number of interface pointers currently dependent upon the object.

159.1.38.2 TSimpleRWSync.Create Constructor

Constructs an object and initializes its data before the object is first used.

Pascal

```
constructor Create;
```

C++

```
__fastcall TSimpleRWSync();
```

Description

System::TObject::Create constructs an object. The purpose, size, and behavior of objects differ greatly. The System::TObject::Create constructor defined by System::TObject::TObject allocates memory but does not initialize data.

Descendant objects usually define a constructor that creates the particular kind of object and initializes its data.

Note: If an exception escapes from a constructor, the object's destructor is called to clean up the failed instance.

See Also

System::TObject::Destroy (see page 22287)

System::TObject::Free (see page 22300)

159.1.38.3 TSimpleRWSync.Destroy Destructor

Disposes of an object instance.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TSimpleRWSync();
```

Description

Do not call System::TObject::Destroy directly. Call System::TObject::Free instead. Free verifies that the object reference is not nil before calling System::TObject::Destroy.

The System::TObject::Destroy method defined by System::TObject::TObject deallocates memory. Descendant objects usually define a destructor that is customized for that particular kind of object.

When declaring a System::TObject::Destroy method in a descendant, always add the override directive to the declaration and call the inherited System::TObject::Destroy as the last statement in the overriding method. Since System::TObject::Destroy is a virtual method, overriding it ensures that the proper inherited behavior occurs.

Note: If an exception escapes from the constructor, the destructor is called to destroy the partially constructed object instance that failed to initialize completely. Therefore, destructors should check that allocated resources, such as handles, were actually allocated before trying to release them, since their value might be zero.

System::TObject::Destroy should be implemented so that it calls System::TObject::Free on all subobjects created within the object's constructor (that is, allocated by the constructor). Unlike System::TObject::Destroy, System::TObject::Free provides a safeguard when destroying objects that are nil.

See Also

System::TObject::Free (see page 22300)

159.1.38.4 TSimpleRWSync Methods

The methods of the TSimpleRWSync class are listed here.

Public Methods

	Name	Description
	BeginRead (see page 22774)	This is BeginRead, a member of class TSimpleRWSync.
	BeginWrite (see page 22775)	This is BeginWrite, a member of class TSimpleRWSync.
	EndRead (see page 22775)	This is EndRead, a member of class TSimpleRWSync.
	EndWrite (see page 22775)	This is EndWrite, a member of class TSimpleRWSync.

159.1.38.4.1 TSimpleRWSync.BeginRead Method

Pascal

```
procedure BeginRead;
```

C++

```
__fastcall BeginRead();
```

Description

This is BeginRead, a member of class TSimpleRWSync.

159.1.38.4.2 TSimpleRWSync.BeginWrite Method

Pascal

```
function BeginWrite: Boolean;
```

C++

```
__fastcall Boolean BeginWrite();
```

Description

This is BeginWrite, a member of class TSimpleRWSync.

159.1.38.4.3 TSimpleRWSync.EndRead Method

Pascal

```
procedure EndRead;
```

C++

```
__fastcall EndRead();
```

Description

This is EndRead, a member of class TSimpleRWSync.

159.1.38.4.4 TSimpleRWSync.EndWrite Method

Pascal

```
procedure EndWrite;
```

C++

```
__fastcall EndWrite();
```

Description

This is EndWrite, a member of class TSimpleRWSync.

159.1.39 TThreadLocalCounter Class

Class Hierarchy

SysUtils.TThreadLocalCounter

Pascal

```
TThreadLocalCounter = class;
```

C++

```
class TThreadLocalCounter;
```

File

SysUtils

Description

This is class SysUtils.TThreadLocalCounter.

159.1.39.1 TThreadLocalCounter Members

The following tables list the members exposed by TThreadLocalCounter.

Public Methods

	Name	Description
	Close (see page 22776)	This is Close, a member of class TThreadLocalCounter.
	Delete (see page 22777)	This is Delete, a member of class TThreadLocalCounter.
V	Destroy (see page 22776)	This is Destroy, a member of class TThreadLocalCounter.
	Open (see page 22777)	This is Open, a member of class TThreadLocalCounter.

159.1.39.2 TThreadLocalCounter.Destroy Destructor

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TThreadLocalCounter();
```

Description

This is Destroy, a member of class TThreadLocalCounter.

159.1.39.3 TThreadLocalCounter Methods

The methods of the TThreadLocalCounter class are listed here.

Public Methods

	Name	Description
	Close (see page 22776)	This is Close, a member of class TThreadLocalCounter.
	Delete (see page 22777)	This is Delete, a member of class TThreadLocalCounter.
	Open (see page 22777)	This is Open, a member of class TThreadLocalCounter.

159.1.39.3.1 TThreadLocalCounter.Close Method

Pascal

```
procedure Close(var Thread: PThreadInfo);
```

C++

```
__fastcall Close(PThreadInfo Thread);
```

Description

This is Close, a member of class TThreadLocalCounter.

159.1.39.3.2 TThreadLocalCounter.Delete Method

Pascal

```
procedure Delete(var Thread: PThreadInfo);
```

C++

```
__fastcall Delete(PThreadInfo Thread);
```

Description

This is Delete, a member of class TThreadLocalCounter.

159.1.39.3.3 TThreadLocalCounter.Open Method

Pascal

```
procedure Open(var Thread: PThreadInfo);
```

C++

```
__fastcall Open(PThreadInfo Thread);
```

Description

This is Open, a member of class TThreadLocalCounter.

159.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IReadWriteSync (see page 22778)	This is class SysUtils.IReadWriteSync.

159.2.1 IReadWriteSync Interface

Class Hierarchy

SysUtils.IReadWriteSync

Pascal

```
IReadWriteSync = interface;
```

C++

```
__interface IReadWriteSync;
```

File

SysUtils

Description

This is class SysUtils.IReadWriteSync.

159.2.1.1 IReadWriteSync Members

The following tables list the members exposed by IReadWriteSync.

Public Methods

	Name	Description
	BeginRead (see page 22779)	This is BeginRead, a member of class IReadWriteSync.
	BeginWrite (see page 22779)	This is BeginWrite, a member of class IReadWriteSync.
	EndRead (see page 22779)	This is EndRead, a member of class IReadWriteSync.
	EndWrite (see page 22779)	This is EndWrite, a member of class IReadWriteSync.

159.2.1.2 IReadWriteSync Methods

The methods of the IReadWriteSync class are listed here.

Public Methods

	Name	Description
	BeginRead (see page 22779)	This is BeginRead, a member of class IReadWriteSync.
	BeginWrite (see page 22779)	This is BeginWrite, a member of class IReadWriteSync.
	EndRead (see page 22779)	This is EndRead, a member of class IReadWriteSync.

	EndWrite (see page 22779)	This is EndWrite, a member of class IReadWriteSync.

159.2.1.2.1 IReadWriteSync.BeginRead Method

Pascal

```
procedure BeginRead;
```

C++

```
__fastcall BeginRead();
```

Description

This is BeginRead, a member of class IReadWriteSync.

159.2.1.2.2 IReadWriteSync.BeginWrite Method

Pascal

```
function BeginWrite: Boolean;
```

C++

```
__fastcall Boolean BeginWrite();
```

Description

This is BeginWrite, a member of class IReadWriteSync.

159.2.1.2.3 IReadWriteSync.EndRead Method

Pascal

```
procedure EndRead;
```

C++

```
__fastcall EndRead();
```

Description

This is EndRead, a member of class IReadWriteSync.

159.2.1.2.4 IReadWriteSync.EndWrite Method

Pascal

```
procedure EndWrite;
```

C++

```
__fastcall EndWrite();
```

Description

This is EndWrite, a member of class IReadWriteSync.

159.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	Abort (see page 22786)	Raises a silent exception.
	AddExitProc (see page 22787)	Adds a procedure to the exit list.
	AddTerminateProc (see page 22787)	Adds a terminate procedure to the system list of termination procedures.
	AdjustLineBreaks (see page 22788)	Adjusts line break characters to reflect Windows or Linux style.
	AnsiCompareFileName (see page 22788)	Compares file names based on the current locale.
	AnsiCompareStr (see page 22789)	Compares strings based on the current locale with case sensitivity.
	AnsiCompareText (see page 22790)	Compares strings based on the current locale without case sensitivity.
	AnsiDequotedStr (see page 22790)	Converts a quoted string into an unquoted string
	AnsiExtractQuotedStr (see page 22791)	Converts a quoted string into an unquoted string.
	AnsiLastChar (see page 22791)	Returns a pointer to the last character in a string.
	AnsiLowerCase (see page 22792)	Returns a string that is a copy of the given string converted to lower case.
	AnsiLowerCaseFileName (see page 22792)	Converts a file name to lower case.
	AnsiPos (see page 22793)	Locates the position of a substring.
	AnsiQuotedStr (see page 22793)	Returns the quoted version of a string.
	AnsiSameStr (see page 22794)	Compares strings based on the current locale with case sensitivity.
	AnsiSameText (see page 22794)	Compares strings based on the current locale without case sensitivity.
	AnsiStrComp (see page 22795)	Compares null-terminated character strings.
	AnsiStrIComp (see page 22795)	Compares null terminated character strings case insensitively.
	AnsiStrLastChar (see page 22796)	Returns a pointer to the last character in a null-terminated string.
	AnsiStrLComp (see page 22796)	Compares the first MaxLen bytes of two null-terminated strings, case-sensitively.
	AnsiStrLIComp (see page 22797)	Compares two strings, case-insensitively, up to the first MaxLen bytes.
	AnsiStrLower (see page 22798)	Converts all characters in a null-terminated string to lower case.
	AnsiStrPos (see page 22798)	Returns a pointer to the first occurrence of a substring.
	AnsiStrRScan (see page 22799)	Returns a pointer to the last occurrence of a specified character in a specified string.
	AnsiStrScan (see page 22799)	Returns a pointer to first occurrence of a character in a string.
	AnsiStrUpper (see page 22800)	Converts all characters in a null-terminated string to upper case.
	AnsiUpperCase (see page 22800)	Converts a string to upper case.
	AnsiUpperCaseFileName (see page 22801)	Converts a file name to upper case.
	AppendStr (see page 22801)	Appends a dynamically allocated string to an existing string.
	AssignStr (see page 22802)	Assigns a new dynamically allocated string to a specified pointer.
	Beep (see page 22802)	Emits a message beep.
	BoolToStr (see page 22804)	Converts a Boolean value to a string.
	ByteToCharIndex (see page 22806)	Returns the position of the character that contains a specified byte in a string.
	ByteToCharLen (see page 22807)	Returns the number of characters fully contained in the first MaxLen bytes of a string.
	ByteType (see page 22807)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	CallTerminateProcs (see page 22808)	Calls all of the functions in the termination procedure list.
	ChangeFileExt (see page 22808)	Changes the extension of a file name.
	ChangeFilePath (see page 22810)	Changes the path of a file name.
	CharLength (see page 22810)	Returns number of bytes used by a character.
	CharToByteIndex (see page 22811)	Returns the 1-based index of the first byte of a specified character in a string.
	CharToByteLen (see page 22811)	Returns the length, in bytes, of the first MaxLen characters of a string.
	CheckWin32Version (see page 22812)	Check to see if you are running on a specific level (or higher) of the Windows 32 bit Operating System (see page 22079).

	CompareMem (see page 22812)	Performs a binary comparison of two memory images.
	CompareStr (see page 22813)	Compares two strings case sensitively.
	CompareStr (see page 22813)	Compares two strings case sensitively.
	CompareText (see page 22814)	Compares two strings by ordinal value without case sensitivity.
	CompareText (see page 22814)	Compares two strings by ordinal value without case sensitivity.
	CreateDir (see page 22817)	Creates a new directory.
	CreateGUID (see page 22819)	Creates a globally unique identifier.
	CurrentYear (see page 22819)	Returns the current year.
	CurrToStr (see page 22819)	Formats a Currency value as a string.
	CurrToStr (see page 22819)	Formats a Currency value as a string.
	CurrToStrF (see page 22820)	Converts a Currency value to a string, using a specified format.
	CurrToStrF (see page 22820)	Converts a Currency value to a string, using a specified format.
	Date (see page 22820)	Returns the current date.
	DateTimeToFileDate (see page 22821)	Converts a TDateTime value to an OS timestamp value.
	DateTimeToStr (see page 22822)	Converts a TDateTime value to a string.
	DateTimeToStr (see page 22822)	Converts a TDateTime value to a string.
	DateTimeToString (see page 22823)	Converts a TDateTime value to a string using a specified Format (see page 22897).
	DateTimeToString (see page 22823)	Converts a TDateTime value to a string using a specified Format (see page 22897).
	DateTimeToSystemTime (see page 22825)	Converts a TDateTime value into the Win32 API's system time type.
	DateTimeToTimeStamp (see page 22825)	Converts a TDateTime value into the corresponding TTimeStamp (see page 23009) value.
	DateToStr (see page 22825)	Converts a TDateTime value to a string.
	DateToStr (see page 22825)	Converts a TDateTime value to a string.
	DayOfWeek (see page 22827)	Returns the day of the week for a specified date.
	DecodeDate (see page 22828)	Returns Year, Month, and Day values for a TDateTime value.
	DecodeDateFully (see page 22829)	Returns Year, Month, and Day, and Day-of-Week values for a TDateTime value.
	DecodeTime (see page 22830)	Breaks a TDateTime value into hours, minutes, seconds, and milliseconds.
	DeleteFile (see page 22831)	Deletes a file from disk.
	DirectoryExists (see page 22832)	Determines whether a specified directory exists.
	DiskFree (see page 22833)	Returns the number of free bytes on a specified drive.
	DiskSize (see page 22835)	Returns the size, in bytes, of a specified drive.
	DisposeStr (see page 22836)	Disposes of a string pointer that was allocated using NewStr (see page 22929).
	EncodeDate (see page 22836)	Returns a TDateTime value that represents a specified Year, Month, and Day.
	EncodeTime (see page 22837)	Returns a TDateTime value for a specified Hour, Min, Sec, and MSec.
	ExceptionErrorMessage (see page 22839)	Formats a standard error message.
	ExcludeTrailingBackslash (see page 22839)	Returns a path name without a trailing delimiter.
	ExcludeTrailingPathDelimiter (see page 22840)	Returns a path name without a trailing delimiter.
	ExpandFileName (see page 22840)	Returns the full path name for a relative file name.
	ExpandFileNameCase (see page 22841)	Returns the full path name for a relative file name on a case-sensitive file system.
	ExpandUNCFileName (see page 22842)	Returns the full path of a file name in UNC format, if appropriate.
	ExtractFileDir (see page 22843)	Extracts the drive and directory parts from FileName.
	ExtractFileDrive (see page 22843)	Returns the drive portion of a file name.
	ExtractFileExt (see page 22844)	Returns the extension portions of a file name.
	ExtractFileName (see page 22844)	Extracts the name and extension parts of a file name.
	ExtractFilePath (see page 22846)	Returns the drive and directory portions of a file name.
	ExtractRelativePath (see page 22848)	Returns a relative path name, relative to a specific base directory.
	ExtractShortPathName (see page 22849)	Converts a file name to the short 8.3 form.
	FileAge (see page 22850)	Returns the OS timestamp of a file.
	FileAge (see page 22850)	Returns the OS timestamp of a file.
	FileClose (see page 22852)	Closes a specified file.
	FileCreate (see page 22855)	Creates a new file.
	FileCreate (see page 22855)	Creates a new file.
	FileDateToDateTime (see page 22858)	Converts an OS timestamp value to TDateTime value.

	FileExists (see page 22860)	Tests if a specified file exists.
	FileGetAttr (see page 22863)	Returns the file attributes of FileName.
	FileGetDate (see page 22866)	Returns an OS timestamp for a specified file.
	FileIsReadOnly (see page 22866)	Reports whether a file is read-only.
	FileOpen (see page 22867)	Opens a specified file using a specified access mode.
	FileRead (see page 22870)	Reads a specified number of bytes from a file.
	FileSearch (see page 22872)	Searches a specified directory path for a file.
	FileSeek (see page 22873)	Repositions read/write point.
	FileSeek (see page 22873)	Repositions read/write point.
	FileSetAttr (see page 22875)	Sets the file attributes of a specified file.
	FileSetDate (see page 22878)	Sets the OS time stamp for a specified file.
	FileSetDate (see page 22878)	Sets the OS time stamp for a specified file.
	FileSetReadOnly (see page 22878)	Sets the file permissions to read-only.
	FileWrite (see page 22879)	Writes the contents of a buffer to the current position in a file.
	FinalizePackage (see page 22882)	Finalizes the specified package (.bpl file).
	FindClose (see page 22882)	Releases memory allocated by FindFirst (see page 22884).
	FindCmdLineSwitch (see page 22884)	Determines whether a string was passed as a command line argument to the application.
	FindCmdLineSwitch (see page 22884)	Determines whether a string was passed as a command line argument to the application.
	FindCmdLineSwitch (see page 22884)	Determines whether a string was passed as a command line argument to the application.
	FindFirst (see page 22884)	Searches for the first instance of a file name with a given set of attributes in a specified directory.
	FindNext (see page 22887)	Returns the next entry matching the name and attributes specified in a previous call to FindFirst (see page 22884).
	FloatToCurr (see page 22889)	Converts a floating-point value to a Currency value.
	FloatToDateTime (see page 22889)	Converts a floating-point value to a TDateTime value.
	FloatToDecimal (see page 22890)	Converts a floating-point value to a decimal representation.
	FloatToStr (see page 22890)	Converts a floating point value to a string.
	FloatToStr (see page 22890)	Converts a floating point value to a string.
	FloatToStrF (see page 22891)	Converts a floating point value to a string, using a specified Format (see page 22897), Precision, and Digits.
	FloatToStrF (see page 22891)	Converts a floating point value to a string, using a specified Format (see page 22897), Precision, and Digits.
	FloatToText (see page 22892)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 22897), Precision and Digits.
	FloatToText (see page 22892)	Converts a floating-point value to an unterminated character string, using a specified Format (see page 22897), Precision and Digits.
	FloatToTextFmt (see page 22893)	Converts a floating-point value to an unterminated character string, using a specified format.
	FloatToTextFmt (see page 22893)	Converts a floating-point value to an unterminated character string, using a specified format.
	FmtLoadStr (see page 22893)	Returns formatted output using a resourced format string.
	FmtStr (see page 22894)	Assembles a formatted string using a format string and an array of arguments.
	FmtStr (see page 22894)	Assembles a formatted string using a format string and an array of arguments.
	ForceDirectories (see page 22895)	Creates a new directory, including the creation of parent directories as needed.
	Format (see page 22897)	Returns a formatted string assembled from a format string and an array of arguments.
	Format (see page 22897)	Returns a formatted string assembled from a format string and an array of arguments.
	FormatBuf (see page 22900)	Formats the arguments from an array, placing the result in a buffer.
	FormatBuf (see page 22900)	Formats the arguments from an array, placing the result in a buffer.
	FormatCurr (see page 22901)	Formats a Currency object.
	FormatCurr (see page 22901)	Formats a Currency object.
	FormatDateTime (see page 22902)	Formats a TDateTime value.
	FormatDateTime (see page 22902)	Formats a TDateTime value.
	FormatFloat (see page 22904)	Formats a floating point value.

	FormatFloat (see page 22904)	Formats a floating point value.
	FreeAndNil (see page 22907)	Frees an object reference and replaces the reference with nil (Delphi) or NULL (C++).
	GDAL (see page 22909)	Get Delphi Access Licence.
	GetCurrentDir (see page 22910)	Returns the name of the current directory.
	GetEnvironmentVariable (see page 22911)	Retrieves an environment variable value.
	GetFileVersion (see page 22912)	Returns file version.
	GetFormatSettings (see page 22912)	Resets the date and number format parameters to initial values.
	GetLocaleChar (see page 22913)	Retrieves the first character of a localisation value.
	GetLocaleFormatSettings (see page 22913)	Populates a TFormatSettings (see page 23001) data structure.
	GetLocaleStr (see page 22913)	Retrieves a localisation value.
	GetModuleName (see page 22914)	Returns the fully qualified name for a module, given its handle.
	GetPackageDescription (see page 22915)	Returns the description resource from a package.
	GetPackageInfo (see page 22915)	Enumerates all the units and required packages for a package.
	GetTime (see page 22916)	Returns the current time.
	GUIDToString (see page 22916)	Converts a class identifier GUID to a string.
	IncAMonth (see page 22917)	Increments date data by one month.
	IncludeTrailingBackslash (see page 22918)	Ensures path name ends with delimiter
	IncludeTrailingPathDelimiter (see page 22918)	Ensures path name ends with delimiter.
	IncMonth (see page 22919)	Returns a date shifted by a specified number of months.
	InitializePackage (see page 22920)	Validates and initializes a given package.
	InitializePackage (see page 22920)	Validates and initializes a given package.
	IntToHex (see page 22920)	Returns the hex representation of an integer.
	IntToHex (see page 22920)	Returns the hex representation of an integer.
	IntToStr (see page 22921)	Converts an integer to a string.
	IntToStr (see page 22921)	Converts an integer to a string.
	IsAssembly (see page 22922)	Determines whether a dll is an Assembly.
	IsDelimiter (see page 22923)	Indicates whether a specified character in a string matches one of a set of delimiters.
	IsEqualGUID (see page 22923)	Indicates whether two TGUID values are the same.
	IsLeapYear (see page 22924)	Indicates whether a specified year is a leap year.
	IsPathDelimiter (see page 22925)	Indicates whether the byte at a specified position in a string is the path delimiter.
	IsValidIdent (see page 22925)	Determines whether a string conforms to Delphi identifier rules.
	Languages (see page 22926)	Lists the locales for which support is available.
	LastDelimiter (see page 22926)	Returns the byte index of the last character that matches any character in a specified set of delimiters.
	LoadPackage (see page 22927)	Loads a specified package.
	LoadPackage (see page 22927)	Loads a specified package.
	LoadStr (see page 22927)	Loads a string resource from the application's executable file.
	LowerCase (see page 22928)	Converts an ASCII string to lowercase.
	LowerCase (see page 22928)	Converts an ASCII string to lowercase.
	MSecsToTimeStamp (see page 22929)	Converts a specified number of milliseconds into a TTimeStamp (see page 23009) value.
	NewStr (see page 22929)	Allocates a string on the heap.
	NextCharIndex (see page 22930)	Returns the byte index of the next character.
	Now (see page 22930)	Returns the current date and time.
	OutOfMemoryError (see page 22931)	Raises an EOutOfMemory (see page 22742) exception.
	QuotedStr (see page 22931)	Returns the quoted version of a string.
	RaiseLastOSError (see page 22932)	Raises an exception for the last occurring OS or system library error.
	RaiseLastOSError (see page 22932)	Raises an exception for the last occurring OS or system library error.
	RaiseLastWin32Error (see page 22932)	Raises an exception for the last occurring Win32 error.
	RCS (see page 22933)	Check for Delphi Client/Server Licence.
	RemoveDir (see page 22933)	Deletes an existing empty directory.
	RenameFile (see page 22934)	Changes a file name.
	ReplaceDate (see page 22936)	Replaces the date portion of a TDateTime value with a specified date.
	ReplaceTime (see page 22937)	Replaces the time portion of a TDateTime value with a specified time.

	RPR (see page 22938)	Check for Delphi Professional Licence.
	SafeLoadLibrary (see page 22938)	Safe and simple library loading.
	SameFileName (see page 22939)	Compares file names based on the current locale.
	SameStr (see page 22939)	Compares two strings by ordinal value with case sensitivity.
	SameStr (see page 22939)	Compares two strings by ordinal value with case sensitivity.
	SameText (see page 22940)	Compares two strings by ordinal value without case sensitivity.
	SameText (see page 22940)	Compares two strings by ordinal value without case sensitivity.
	SetCurrentDir (see page 22940)	Sets the current directory.
	ShowException (see page 22941)	Displays an exception message with its physical address
	Sleep (see page 22941)	Delay program execution for a specified number of milliseconds.
	StrAlloc (see page 22942)	Allocates a buffer for a null-terminated string and returns a pointer to its first character.
	StrBufSize (see page 22942)	Returns the maximum number of characters that can be stored in a buffer allocated by StrAlloc (see page 22942).
	StrByteType (see page 22943)	Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.
	StrCat (see page 22943)	Appends a copy of Source to the end of Dest and returns the concatenated string.
	StrCharLength (see page 22944)	Returns the length, in bytes, of a character.
	StrComp (see page 22945)	Compares two strings with case sensitivity.
	StrCopy (see page 22946)	Copies a null-terminated string.
	StrDispose (see page 22947)	Disposes of a string.
	StrECopy (see page 22948)	Copies null-terminated string.
	StrEnd (see page 22949)	Returns a pointer to the end of a null terminated string.
	StrFmt (see page 22950)	Formats entries in an array.
	StrFmt (see page 22950)	Formats entries in an array.
	StrIComp (see page 22951)	Compares two strings without case sensitivity.
	StringReplace (see page 22951)	Returns a string with occurrences of one substring replaced by another substring.
	StringToGUID (see page 22952)	Converts a string to a GUID.
	StrLCat (see page 22952)	Appends up to a specified maximum number of characters to string.
	StrLComp (see page 22953)	Compares up to a specified maximum number of characters in two strings.
	StrLCopy (see page 22953)	Copies up to a specified maximum number of characters from Source to Dest.
	StrLen (see page 22954)	Returns number of characters in a string excluding the null terminator.
	StrLFmt (see page 22954)	Formats a series of arguments from a specified open array into a buffer.
	StrLFmt (see page 22954)	Formats a series of arguments from a specified open array into a buffer.
	StrLIComp (see page 22955)	Compares strings up to a specified maximum number of characters, without case sensitivity.
	StrLower (see page 22956)	Converts a string to lowercase.
	StrMove (see page 22956)	Copies specified number of characters to string.
	StrNew (see page 22957)	Allocates space on and copies a string to the heap; returning a pointer to the string.
	StrNextChar (see page 22958)	Returns pointer to following character.
	StrPas (see page 22958)	Converts null-terminated string to an AnsiString (long string).
	StrPCopy (see page 22958)	Copies an AnsiString (long string) to a null-terminated string.
	StrPLCopy (see page 22959)	Copies characters from an AnsiString (long string) into a null-terminated string.
	StrPos (see page 22959)	Returns a pointer to the first occurrence of STR2 in STR1.
	StrRScan (see page 22960)	Returns a pointer to the last occurrence of a specified character in a string.
	StrScan (see page 22960)	Returns a pointer to first occurrence of a specified character in a string.
	StrToBool (see page 22961)	Converts a string to a Boolean value.
	StrToBoolDef (see page 22961)	Converts a string to a Boolean value, with error default.
	StrToCurr (see page 22962)	Converts a string to a Currency value.
	StrToCurr (see page 22962)	Converts a string to a Currency value.
	StrToCurrDef (see page 22963)	Converts a string to a Currency value, with error default.
	StrToCurrDef (see page 22963)	Converts a string to a Currency value, with error default.
	StrToDate (see page 22963)	Converts a string to a TDateTime value.
	StrToDate (see page 22963)	Converts a string to a TDateTime value.
	StrToDateDef (see page 22965)	Converts a string to a TDateTime value, with error default.

	StrToDateDef (see page 22965)	Converts a string to a TDateTime value, with error default.
	StrToDateTime (see page 22965)	Converts a string to a TDateTime value.
	StrToDateTime (see page 22965)	Converts a string to a TDateTime value.
	StrToDateTimeDef (see page 22966)	Converts a string to a TDateTime value with error default.
	StrToDateTimeDef (see page 22966)	Converts a string to a TDateTime value with error default.
	StrToFloat (see page 22967)	Converts a given string to a floating-point value.
	StrToFloat (see page 22967)	Converts a given string to a floating-point value.
	StrToFloatDef (see page 22969)	Converts a given string to a floating-point value with error default.
	StrToFloatDef (see page 22969)	Converts a given string to a floating-point value with error default.
	StrToInt (see page 22970)	Converts a string that represents an integer (decimal or hex notation) to a number.
	StrToInt64 (see page 22970)	Converts a string that represents an integer (decimal or hex notation) to a number.
	StrToInt64Def (see page 22971)	Converts a string that represents an integer (decimal or hex notation) to a number.
	StrToIntDef (see page 22971)	Converts a string that represents an integer (decimal or hex notation) to a number with error default.
	StrToTime (see page 22972)	Converts a string to a TDateTime value.
	StrToTime (see page 22972)	Converts a string to a TDateTime value.
	StrToTimeDef (see page 22972)	Converts a string to a TDateTime value with error default.
	StrToTimeDef (see page 22972)	Converts a string to a TDateTime value with error default.
	StrUpper (see page 22973)	Returns a string in upper case.
	Supports (see page 22973)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 22973)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 22973)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 22973)	Indicates whether a given object or interface supports a specified interface.
	Supports (see page 22973)	Indicates whether a given object or interface supports a specified interface.
	SysErrorMessage (see page 22974)	Converts OS error codes into strings.
	SystemTimeToDateTime (see page 22974)	Converts a system time value into a TDateTime value.
	TextToFloat (see page 22975)	Converts a null-terminated string to a floating-point value.
	TextToFloat (see page 22975)	Converts a null-terminated string to a floating-point value.
	Time (see page 22976)	Returns the current time.
	TimeStampToDateTime (see page 22976)	Converts a TTimeStamp (see page 23009) value into the corresponding TDateTime value.
	TimeStampToMSecs (see page 22977)	Converts a TTimeStamp (see page 23009) value into an absolute number of milliseconds.
	TimeToStr (see page 22977)	Returns a string that represents a TDateTime value.
	TimeToStr (see page 22977)	Returns a string that represents a TDateTime value.
	Trim (see page 22978)	Trims leading and trailing spaces and control characters from a string.
	Trim (see page 22978)	Trims leading and trailing spaces and control characters from a string.
	TrimLeft (see page 22979)	Trims leading spaces and control characters from a string.
	TrimLeft (see page 22979)	Trims leading spaces and control characters from a string.
	TrimRight (see page 22979)	Trims trailing spaces and control characters from a string.
	TrimRight (see page 22979)	Trims trailing spaces and control characters from a string.
	TryEncodeDate (see page 22980)	Creates a TDateTime value that represents a specified Year, Month, and Day.
	TryEncodeTime (see page 22980)	Creates a TDateTime value for a specified Hour, Min, Sec, and MSec.
	TryFloatToCurr (see page 22981)	Converts a floating-point value to a Currency value.
	TryFloatToDateTime (see page 22982)	Converts a floating-point value to a TDateTime value.
	TryStrToBool (see page 22982)	Converts a string to a Boolean value, with a Boolean success code.
	TryStrToCurr (see page 22983)	Converts a string to a Currency value, with a Boolean success code.
	TryStrToCurr (see page 22983)	Converts a string to a Currency value, with a Boolean success code.
	TryStrToDate (see page 22983)	Converts a string to a TDateTime value, with a Boolean success code.
	TryStrToDate (see page 22983)	Converts a string to a TDateTime value, with a Boolean success code.
	TryStrToDateTime (see page 22984)	Converts a string to a TDateTime value with a Boolean success code.
	TryStrToDateTime (see page 22984)	Converts a string to a TDateTime value with a Boolean success code.
	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.

	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToFloat (see page 22985)	Converts a given string to a floating-point value with a boolean success code.
	TryStrToInt (see page 22986)	Converts a string that represents an integer (decimal or hex notation) to a number with Boolean success code.
	TryStrToInt64 (see page 22986)	Converts a string that represents an integer (decimal or hex notation) to a number.
	TryStrToTime (see page 22987)	Converts a string to a TDateTime value with an error default.
	TryStrToTime (see page 22987)	Converts a string to a TDateTime value with an error default.
	UnloadPackage (see page 22987)	Unloads a package.
	UpperCase (see page 22988)	Returns a copy of a string in uppercase.
	UpperCase (see page 22988)	Returns a copy of a string in uppercase.
	WideCompareStr (see page 22989)	Compares Unicode strings based on the current locale with case sensitivity.
	WideCompareText (see page 22990)	Compares Unicode strings based on the current locale without case sensitivity.
	WideFmtStr (see page 22990)	Assembles a formatted Unicode string using a format string and an array of arguments.
	WideFmtStr (see page 22990)	Assembles a formatted Unicode string using a format string and an array of arguments.
	WideFormat (see page 22991)	Returns a formatted Unicode string assembled from a format string and an array of arguments.
	WideFormat (see page 22991)	Returns a formatted Unicode string assembled from a format string and an array of arguments.
	WideFormatBuf (see page 22991)	Formats the arguments from an array, placing the result in a buffer.
	WideFormatBuf (see page 22991)	Formats the arguments from an array, placing the result in a buffer.
	WideLowerCase (see page 22992)	Returns Unicode string converted to lower case.
	WideSameStr (see page 22992)	Compares Unicode strings based on the current locale with case sensitivity.
	WideSameText (see page 22993)	Compares Unicode strings based on the current locale without case sensitivity.
	WideUpperCase (see page 22993)	Returns Unicode string converted to upper case.
	Win32Check (see page 22994)	Checks the return value of a Windows API call and raises an appropriate exception when it indicates failure.
	WrapText (see page 22994)	Splits a string into multiple lines as its length approaches a specified size.
	WrapText (see page 22994)	Splits a string into multiple lines as its length approaches a specified size.

159.3.1 SysUtils.Abort Function

Raises a silent exception.

Pascal

```
procedure Abort;
```

C++

```
Abort();
```

File

SysUtils

Description

Use Abort to escape from an execution path without reporting an error.

Abort raises a special "silent exception" (EAbort (see page 22722)), which operates like any other exception, but does not display an error message to the end user. Abort redirects execution to the end of the last exception block.

Delphi Examples:

```
{
This example checks for a valid entry in a TDBEdit control
and calls the Abort procedure if the control is empty; Abort
cancels the post before it happens.
}
procedure TForm1.ClientDataSet1BeforePost(DataSet: TDataSet);
begin
  if DBEdit1.Text = '' then
    Abort;
  DataSet.Fields[2].AsString := DBEdit1.Text;
end;
```

See Also

EAbort (see page 22722)

159.3.2 SysUtils.AddExitProc Function

Adds a procedure to the exit list.

Pascal

```
procedure AddExitProc(Proc: TProcedure);
```

C++

```
AddExitProc(TProcedure Proc);
```

File

SysUtils

Description

AddExitProc adds Proc to the Delphi exit procedure list, so that Proc is automatically executed when the application terminates. AddExitProc is not compatible with CLX package support and is provided for backward compatibility only. Do not use AddExitProc in new applications.

159.3.3 SysUtils.AddTerminateProc Function

Adds a terminate procedure to the system list of termination procedures.

Pascal

```
procedure AddTerminateProc(TermProc: TTerminateProc);
```

C++

```
AddTerminateProc(TTerminateProc TermProc);
```

File

SysUtils

Description

Call AddTerminateProc in Delphi code to add a procedure that is called when the application is about to terminate. The run time library calls all termination procedures before the application terminates. The supplied termination procedure (TermProc) should return true if the application can safely terminate or false if the application cannot safely terminate. If any termination procedure returns false, the application does not terminate.

See Also

CallTerminateProcs (see page 22808)

159.3.4 SysUtils.AdjustLineBreaks Function

Adjusts line break characters to reflect Windows or Linux style.

Pascal

```
function AdjustLineBreaks(const S: string; Style: TTextLineBreakStyle = tlbsCRLF): string;
```

C++

```
AnsiString AdjustLineBreaks(const AnsiString S, TTextLineBreakStyle Style = tlbsCRLF);
```

File

SysUtils

Description

AdjustLineBreaks returns a text string with its line breaks adjusted to fit a specified style.

S is the string to convert.

Style indicates whether line breaks should all be Windows-style line breaks with a carriage return and linefeed (tlbsCRLF), or Linux-style breaks with a single linefeed character (tlbsLF). If Style is omitted, the style for the compile target is used.

See Also

TrimLeft (see page 22979)

TrimRight (see page 22979)

159.3.5 SysUtils.AnsiCompareFileName Function

Compares file names based on the current locale.

Pascal

```
function AnsiCompareFileName(const S1: string; const S2: string): Integer;
```

C++

```
int AnsiCompareFileName(const AnsiString S1, const AnsiString S2);
```

File

SysUtils

Description

AnsiCompareFileName compares two file names. The current locale controls the compare operation. Comparison is case-insensitive under Windows, case-sensitive under Linux.

The return value is:

Condition	Return Value
S1 > S2	> 0

S1 < S2	< 0
S1 = S2	= 0

AnsiCompareFileName supports the idiosyncrasies of MS-DOS file names that use Zenkaku Moji, a character encoding used in some Asian locales. Under Windows locales that do not use MBCS, AnsiCompareFileName is identical to AnsiCompareText (see page 22790). Under Linux, AnsiCompareFileName is identical to AnsiCompareStr (see page 22789).

See Also

SameFileName (see page 22939)

AnsiCompareText (see page 22790)

159.3.6 SysUtils.AnsiCompareStr Function

Compares strings based on the current locale with case sensitivity.

Pascal

```
function AnsiCompareStr(const S1: string; const S2: string): Integer;
```

C++

```
int AnsiCompareStr(const AnsiString S1, const AnsiString S2);
```

File

SysUtils

Description

AnsiCompareStr compares S1 to S2, with case sensitivity. The compare operation is controlled by the current locale. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

Note: Most locales consider lowercase characters to be less than the corresponding uppercase characters. This is in contrast to ASCII order, in which lowercase characters are greater than uppercase characters. Thus, setting S1 to 'a' and S2 to 'A' causees AnsiCompareStr to return a value less than zero, while CompareStr (see page 22813), with the same arguments, returns a value greater than zero.

See Also

AnsiCompareText (see page 22790)

AnsiStrComp (see page 22795)

AnsiSameStr (see page 22794)

159.3.7 SysUtils.AnsiCompareText Function

Compares strings based on the current locale without case sensitivity.

Pascal

```
function AnsiCompareText(const S1: string; const S2: string): Integer;
```

C++

```
int AnsiCompareText(const AnsiString S1, const AnsiString S2);
```

File

SysUtils

Description

AnsiCompareText compares S1 to S2, without case sensitivity. The compare operation is controlled by the current locale. AnsiCompareText returns a value less than 0 if S1 < S2, a value greater than 0 if S1 > S2, and returns 0 if S1 = S2.

See Also

AnsiCompareStr (see page 22789)

AnsiStrIComp (see page 22795)

AnsiSameText (see page 22794)

159.3.8 SysUtils.AnsiDequotedStr Function

Converts a quoted string into an unquoted string

Pascal

```
function AnsiDequotedStr(const S: string; AQuote: Char): string;
```

C++

```
AnsiString AnsiDequotedStr(const AnsiString S, Char AQuote);
```

File

SysUtils

Description

AnsiDequotedStr removes the quote characters from the beginning and end of a quoted string, and reduces pairs of quote characters within the string to a single quote character. The AQuote parameter defines what character to use as a quote character. If the S parameter does not begin and end with the quote character, AnsiDequotedStr returns S unchanged.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiQuotedStr (see page 22793)

AnsiExtractQuotedStr (see page 22791)

159.3.9 SysUtils.AnsiExtractQuotedStr Function

Converts a quoted string into an unquoted string.

Pascal

```
function AnsiExtractQuotedStr(var Src: PChar; Quote: Char): string;
```

C++

```
AnsiString AnsiExtractQuotedStr(const char * Src, Char Quote);
```

File

SysUtils

Description

AnsiExtractQuotedStr removes the quote characters from the beginning and end of a quoted string, and reduces pairs of quote characters within the string to a single quote character. The Quote parameter defines what character to use as a quote character. If the first character in Src is not the value of the Quote parameter, AnsiExtractQuotedStr returns an empty string.

The function copies characters from Src to the result string until the second solitary quote character or the first null character in Src. The Src parameter is updated to point to the first character following the quoted string. If Src does not contain a matching end quote character, the Src parameter is updated to point to the terminating null character.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiQuotedStr (see page 22793)

159.3.10 SysUtils.AnsiLastChar Function

Returns a pointer to the last character in a string.

Pascal

```
function AnsiLastChar(const S: string): PChar;
```

C++

```
const char * AnsiLastChar(const AnsiString S);
```

File

SysUtils

Description

Call AnsiLastChar to obtain the last character in a string. This function supports multi-byte character sets (MBCS).

See Also

AnsiStrLastChar (see page 22796)

AnsiStrRScan (see page 22799)

159.3.11 SysUtils.AnsiLowerCase Function

Returns a string that is a copy of the given string converted to lower case.

Pascal

```
function AnsiLowerCase(const S: string): string;
```

C++

```
AnsiString AnsiLowerCase(const AnsiString S);
```

File

SysUtils

Description

AnsiLowerCase returns a string that is a copy of the given string converted to lower case. The conversion uses the current locale. This function supports multi-byte character sets (MBCS).

See Also

AnsiLowerCaseFileName (see page 22792)

AnsiUpperCase (see page 22800)

LowerCase (see page 22928)

159.3.12 SysUtils.AnsiLowerCaseFileName Function

Converts a file name to lower case.

Pascal

```
function AnsiLowerCaseFileName(const S: string): string;
```

C++

```
AnsiString AnsiLowerCaseFileName(const AnsiString S);
```

File

SysUtils

Description

AnsiLowerCaseFileName returns a string that is a copy of S converted to lower case. The conversion uses the current locale.

Note: On Windows, AnsiLowerCaseFileName supports lowercase conversion idiosyncrasies of file names in Asian locales (Zenkaku).

On Linux, or in locales that do not use multi byte character systems (MBCS), AnsiLowerCaseFileName is identical to AnsiLowerCase (see page 22792).

See Also

AnsiLowerCase (see page 22792)

AnsiUpperCaseFileName (see page 22801)

159.3.13 SysUtils.AnsiPos Function

Locates the position of a substring.

Pascal

```
function AnsiPos(const Substr: string; const S: string): Integer;
```

C++

```
int AnsiPos(const AnsiString Substr, const AnsiString S);
```

File

SysUtils

Description

Call AnsiPos to obtain the byte offset of the Substr parameter, as it appears in the string S. For example, if Substr is the string "AB", and S is the string "ABCDE", AnsiPos returns 1. If Substr does not appear in S, AnsiPos returns 0.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiStrPos (see page 22798)

159.3.14 SysUtils.AnsiQuotedStr Function

Returns the quoted version of a string.

Pascal

```
function AnsiQuotedStr(const S: string; Quote: Char): string;
```

C++

```
AnsiString AnsiQuotedStr(const AnsiString S, Char Quote);
```

File

SysUtils

Description

Use AnsiQuotedStr to convert a string (S) to a quoted string, using the provided Quote character. A Quote character is inserted at the beginning and end of S, and each Quote character in the string is doubled.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiExtractQuotedStr (see page 22791)

QuotedStr (see page 22931)

159.3.15 SysUtils.AnsiSameStr Function

Compares strings based on the current locale with case sensitivity.

Pascal

```
function AnsiSameStr(const S1: string; const S2: string): Boolean;
```

C++

```
Boolean AnsiSameStr(const AnsiString S1, const AnsiString S2);
```

File

SysUtils

Description

AnsiSameStr compares S1 to S2, with case sensitivity. The compare operation is controlled by the current locale. The return value is true if the two strings have the same value, false otherwise.

See Also

AnsiSameText (see page 22794)

AnsiCompareStr (see page 22789)

AnsiSameCaption (see page 16186)

159.3.16 SysUtils.AnsiSameText Function

Compares strings based on the current locale without case sensitivity.

Pascal

```
function AnsiSameText(const S1: string; const S2: string): Boolean;
```

C++

```
Boolean AnsiSameText(const AnsiString S1, const AnsiString S2);
```

File

SysUtils

Description

AnsiSameText compares S1 to S2, without case sensitivity. The compare operation is controlled by the current locale. The return value is true if the two strings have the same value, false otherwise.

See Also

AnsiSameStr (see page 22794)

AnsiCompareText (see page 22790)

AnsiSameCaption (see page 16186)

159.3.17 SysUtils.AnsiStrComp Function

Compares null-terminated character strings.

Pascal

```
function AnsiStrComp(S1: PChar; S2: PChar): Integer;
```

C++

```
int AnsiStrComp(const char * S1, const char * S2);
```

File

SysUtils

Description

AnsiStrComp compares S1 to S2, with case sensitivity. The compare operation is controlled by the current locale. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

Note: Most locales consider lowercase characters to be less than the corresponding uppercase characters. This is in contrast to ASCII order, in which lowercase characters are greater than uppercase characters.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiCompareStr (see page 22789)

AnsiStrIComp (see page 22795)

AnsiStrLComp (see page 22796)

159.3.18 SysUtils.AnsiStrIComp Function

Compares null terminated character strings case insensitively.

Pascal

```
function AnsiStrIComp(S1: PChar; S2: PChar): Integer;
```

C++

```
int AnsiStrIComp(const char * S1, const char * S2);
```

File

SysUtils

Description

AnsiStrIComp compares S1 to S2, without case sensitivity. The compare operation is controlled by the current locale. The return value is the same as for CompareStr (see page 22813).

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiCompareText (see page 22790)

AnsiStrComp (see page 22795)

159.3.19 SysUtils.AnsiStrLastChar Function

Returns a pointer to the last character in a null-terminated string.

Pascal

```
function AnsiStrLastChar(P: PChar): PChar;
```

C++

```
const char * AnsiStrLastChar(const char * P);
```

File

SysUtils

Description

Call AnsiStrLastChar to obtain a pointer to the last full character in a null-terminated sequence. When working with multi-byte character sets (MBCS), the last character will not be the same as the last char value if the last two bytes represent a single double byte character.

See Also

AnsiLastChar (see page 22791)

159.3.20 SysUtils.AnsiStrLComp Function

Compares the first MaxLen bytes of two null-terminated strings, case-sensitively.

Pascal

```
function AnsiStrLComp(S1: PChar; S2: PChar; MaxLen: Cardinal): Integer;
```

C++

```
int AnsiStrLComp(const char * S1, const char * S2, unsigned MaxLen);
```

File

SysUtils

Description

AnsiStrLComp compares S1 to S2, with case sensitivity. If S1 or S2 is longer than MaxLen bytes, AnsiStrLComp only compares the first MaxLen bytes. The compare operation is controlled by the current locale. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2 (up to MaxLen characters)	= 0

Note: This function supports multi-byte character sets (MBCS).

Note: AnsiStrLComp can continue the comparison beyond a null terminating character if S1 and S2 are equal up to a null character and the null character occurs before MaxLen bytes.

Note: Most locales consider lowercase characters to come before corresponding uppercase characters. This is in contrast to ASCII order, in which lowercase characters come after uppercase characters.

See Also

AnsiStrComp (see page 22795)

AnsiStrLIComp (see page 22797)

StrLComp (see page 22953)

159.3.21 SysUtils.AnsiStrLIComp Function

Compares two strings, case-insensitively, up to the first MaxLen bytes.

Pascal

```
function AnsiStrLIComp(S1: PChar; S2: PChar; MaxLen: Cardinal): Integer;
```

C++

```
int AnsiStrLIComp(const char * S1, const char * S2, unsigned MaxLen);
```

File

SysUtils

Description

AnsiStrLIComp compares S1 to S2, without case sensitivity. If S1 or S2 is longer than MaxLen characters, AnsiStrLIComp only compares up to the first MaxLen characters. The compare operation is controlled by the current locale. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2 (up to MaxLen characters)	= 0

Note: This function supports multi-byte character sets (MBCS).

Note: AnsiStrLIComp can continue the comparison beyond a null terminating character if S1 and S2 are equal up to a null character and the null character occurs before MaxLen bytes.

See Also

AnsiStrIComp (see page 22795)

AnsiStrLComp (see page 22796)

StrLIComp (see page 22955)

159.3.22 SysUtils.AnsiStrLower Function

Converts all characters in a null-terminated string to lower case.

Pascal

```
function AnsiStrLower(Str: PChar): PChar;
```

C++

```
const char * AnsiStrLower(const char * Str);
```

File

SysUtils

Description

AnsiStrLower returns a null-terminated character sequence where all characters are lower case. The conversion uses the current locale.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiLowerCase (see page 22792)

AnsiLowerCaseFileName (see page 22792)

AnsiStrUpper (see page 22800)

159.3.23 SysUtils.AnsiStrPos Function

Returns a pointer to the first occurrence of a substring.

Pascal

```
function AnsiStrPos(Str: PChar; SubStr: PChar): PChar;
```

C++

```
const char * AnsiStrPos(const char * Str, const char * SubStr);
```

File

SysUtils

Description

Call AnsiStrPos to locate the first occurrence of SubStr in Str. If SubStr does not occur in Str, AnsiStrPos returns nil (Delphi) or NULL (C++).

Unlike the StrPos (see page 22959) function, AnsiStrPos works with multi-byte characters sets (MBCS).

See Also

AnsiPos (see page 22793)

StrPos (see page 22959)

159.3.24 SysUtils.AnsiStrRScan Function

Returns a pointer to the last occurrence of a specified character in a specified string.

Pascal

```
function AnsiStrRScan(Str: PChar; Chr: Char): PChar;
```

C++

```
const char * AnsiStrRScan(const char * Str, Char Chr);
```

File

SysUtils

Description

Call AnsiStrRScan to obtain a pointer to the last occurrence of Chr in Str. If Chr does not occur in Str, AnsiStrRScan returns nil (Delphi) or NULL (C++). The null terminator is considered to be part of the string.

Unlike the StrRScan (see page 22960) function, AnsiStrRScan works with multi-byte character systems (MBCS).

See Also

AnsiStrScan (see page 22799)

StrRScan (see page 22960)

159.3.25 SysUtils.AnsiStrScan Function

Returns a pointer to first occurrence of a character in a string.

Pascal

```
function AnsiStrScan(Str: PChar; Chr: Char): PChar;
```

C++

```
const char * AnsiStrScan(const char * Str, Char Chr);
```

File

SysUtils

Description

Call AnsiStrScan to obtain a pointer to the first occurrence of Chr in Str. If Chr does not occur in Str, AnsiStrScan returns nil (Delphi) or NULL (C++). The null terminator is considered to be part of the string.

Unlike the StrScan (see page 22960) function, AnsiStrScan works with multi-byte character systems (MBCS).

See Also

AnsiStrRScan (see page 22799)

StrScan (see page 22960)

159.3.26 SysUtils.AnsiStrUpper Function

Converts all characters in a null-terminated string to upper case.

Pascal

```
function AnsiStrUpper(Str: PChar): PChar;
```

C++

```
const char * AnsiStrUpper(const char * Str);
```

File

SysUtils

Description

AnsiStrUpper returns a null-terminated string where all characters are upper case. The conversion uses the current locale.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiUpperCase (see page 22800)

AnsiUpperCaseFileName (see page 22801)

AnsiStrLower (see page 22798)

159.3.27 SysUtils.AnsiUpperCase Function

Converts a string to upper case.

Pascal

```
function AnsiUpperCase(const S: string): string;
```

C++

```
AnsiString AnsiUpperCase(const AnsiString S);
```

File

SysUtils

Description

AnsiUpperCase returns a string that is a copy of S, converted to upper case. The conversion uses the current locale.

Note: This function supports multi-byte character sets (MBCS).

See Also

AnsiLowerCase (see page 22792)

UpperCase (see page 22988)

159.3.28 SysUtils.AnsiUpperCaseFileName Function

Converts a file name to upper case.

Pascal

```
function AnsiUpperCaseFileName(const S: string): string;
```

C++

```
AnsiString AnsiUpperCaseFileName(const AnsiString S);
```

File

SysUtils

Description

AnsiUpperCaseFileName returns a string that is a copy of S converted to upper case. The conversion uses the current locale.

Note: On Windows, AnsiUpperCaseFileName supports uppercase conversion idiosyncrasies of file names in Asian locales (Zenkaku).

On Linux or in locales that do not use multi byte character systems (MBCS), AnsiUpperCaseFileName is identical to AnsiUpperCase (see page 22800).

See Also

AnsiLowerCaseFileName (see page 22792)

AnsiUpperCase (see page 22800)

159.3.29 SysUtils.AppendStr Function

Appends a dynamically allocated string to an existing string.

Pascal

```
procedure AppendStr(var Dest: string; const S: string); deprecated;
```

C++

```
AppendStr(AnsiString Dest, const AnsiString S);
```

File

SysUtils

Description

AppendStr appends S to the end of Dest. It is provided for backwards compatibility only. Use the + operator instead:

Dest := Dest + S;

Dest = Dest + S;

159.3.30 SysUtils.AssignStr Function

Assigns a new dynamically allocated string to a specified pointer.

Pascal

```
procedure AssignStr(var P: PString; const S: string); deprecated;
```

C++

```
AssignStr(PString P, const AnsiString S);
```

File

SysUtils

Description

Do not use AssignStr in new applications. It is provided for backward compatibility only.

See Also

DisposeStr (see page 22836)

159.3.31 SysUtils.Beep Function

Emits a message beep.

Pascal

```
procedure Beep;
```

C++

```
Beep();
```

File

SysUtils

Description

Beep generates a conventional message beep.

Note: On Windows, Beep calls the Windows API MessageBeep.

Note: On Linux, to minimize library dependencies in the run time library, the SysUtils (see page 22709) version of Beep has limited Linux functionality. For cross-platform GUI applications, use the QControls version of Beep instead.

C++ Examples:

```
/*
This example requires a TRichEdit, a TButton, and a
TFindDialog.  Clicking the button click will display a Find
Dialog to the right of the edit control.  Filling in the
"Find what" text and pressing the Find Next button will
select the first matching string in the Rich Edit control
that follows the previous selection.
```

```
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FindDialog1->Position = Point(RichEdit1->Left + RichEdit1->Width, RichEdit1->Top);
  FindDialog1->Execute();
}

void __fastcall TForm1::FindDialog1Find(TObject *Sender)
{
  int FoundAt, StartPos, ToEnd;
  TSearchTypes mySearchTypes;
  // begin the search after the current selection
  // if there is one
  // otherwise, begin at the start of the text
  if (FindDialog1->Options.Contains(frMatchCase))
    mySearchTypes << stMatchCase;
  if (FindDialog1->Options.Contains(frWholeWord))
    mySearchTypes << stWholeWord;
  if (RichEdit1->SelLength)
    StartPos = RichEdit1->SelStart + RichEdit1->SelLength;
  else
    StartPos = 0;
  // ToEnd is the length from StartPos
  // to the end of the text in the rich edit control
  ToEnd = RichEdit1->Text.Length() - StartPos;
  FoundAt = RichEdit1->FindText(FindDialog1->FindText, StartPos, ToEnd, mySearchTypes);
  if (FoundAt != -1)
  {
    RichEdit1->SetFocus();
    RichEdit1->SelStart = FoundAt;
    RichEdit1->SelLength = FindDialog1->FindText.Length();
  }
  else Beep();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  RichEdit1->PlainText = False;
  RichEdit1->Lines->LoadFromFile("../Overview.RTF");  // starts in Debug
  RichEdit1->ScrollBars = ssVertical;
}
```

Delphi Examples:

```
{
This example requires a TRichEdit, a TButton, and a
TFindDialog.  Clicking the button click will display a Find
Dialog to the right of the edit control.  Filling in the
"Find what" text and pressing the Find Next button will
select the first matching string in the Rich Edit control
that follows the previous selection.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  FindDialog1.Position :=
    Point(RichEdit1.Left + RichEdit1.Width, RichEdit1.Top);
  FindDialog1.Execute;
end;

procedure TForm1.FindDialog1Find(Sender: TObject);
var
  FoundAt: LongInt;
  StartPos, ToEnd: Integer;
  mySearchTypes : TSearchTypes;
  myFindOptions : TFindOptions;
begin
  with RichEdit1 do
```

```
    begin
      if frMatchCase in FindDialog1.Options then
         mySearchTypes := mySearchTypes + [stMatchCase];
      if frWholeWord in FindDialog1.Options then
         mySearchTypes := mySearchTypes + [stWholeWord];
      { begin the search after the current selection if there is one }
      { otherwise, begin at the start of the text }
      if SelLength <> 0 then
        StartPos := SelStart + SelLength
      else
        StartPos := 0;
      { ToEnd is the length from StartPos to the end of the
        text in the rich edit control }
      ToEnd := Length(Text) - StartPos;
      FoundAt :=
        FindText(FindDialog1.FindText, StartPos, ToEnd, mySearchTypes);
      if FoundAt <> -1 then
      begin
        SetFocus;
        SelStart := FoundAt;
        SelLength := Length(FindDialog1.FindText);
      end
      else Beep;
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  const Path = 'OverView.RTF';
  begin
    RichEdit1.PlainText := False;
    RichEdit1.Lines.LoadFromFile(Path);
    RichEdit1.ScrollBars := ssVertical;
  end;
  {
  The following example beeps once for each "beep" passed in
  on the command line.  The example terminates the application
  if  "exit" is passed in on the command line.  Build the
  project to generate a .exe file and then execute that file
  from a command line: "ParamCount_proj beep beep exit".
  }
  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  begin
  //  Use print statements since you can't use the debugger.
  //  MessageDlg(
  //    'System ParamCount = ' + IntToStr(System.ParamCount),
  //    mtConfirmation, [mbOK], 0);
    for i := 1 to System.ParamCount do
    begin
      if LowerCase(ParamStr(i)) = 'beep' then
        Beep
      else if LowerCase(ParamStr(i)) = 'exit' then
        Application.Terminate;
      Sleep(250);
    end;
  end;
```

159.3.32 SysUtils.BoolToStr Function

Converts a Boolean value to a string.

Pascal

```
function BoolToStr(B: Boolean; UseBoolStrs: Boolean = False): string;
```

C++

```
AnsiString BoolToStr(Boolean B, Boolean UseBoolStrs = False);
```

File

SysUtils

Description

BoolToStr converts the given Boolean value to a string as follows:

Value of B	Value of UseBoolStrs	Value of returned string
true	false	'-1'
true	true	The first string in TrueBoolStrs (see page 23034) (default 'True');
false	false	'0'
false	true	The first string in FalseBoolStrs (see page 23025) (default 'False');

Note: The TrueBoolStrs (see page 23034) and FalseBoolStrs (see page 23025) variables are undefined when an application starts. Any use of StrToBool (see page 22961), BoolToStr or TryStrToBool (see page 22982) will cause these variables to be initialised with the default values above.

C++ Examples:

```
/*
This example requires that a memo and a TApplicationEvent be
added to the form.  Change the Windows Locale by using the
Regional and Language Options in the Windows Control Panel.
*/
void __fastcall TForm1::ApplicationEvents1SettingChange(TObject *Sender, int Flag, const
AnsiString Section, int &Result)
{
  Memo1->Lines->BeginUpdate();
  try
  {
//    char buffer[64];
    AnsiString buffer;
    buffer.sprintf("Section = %s", Section.c_str());
    Memo1->Lines->Add(buffer);
    buffer.sprintf("Flag = %8x", Flag);
    Memo1->Lines->Add(buffer);
    if (strcmp(Section.c_str(), "intl") == 0)
    {
      buffer.sprintf("DefaultLCID = %8x", SysLocale.DefaultLCID);
      Memo1->Lines->Add(buffer);
      buffer.sprintf("PriLangID = %8x", SysLocale.PriLangID);
      Memo1->Lines->Add(buffer);
      buffer.sprintf("SubLangID = %8x", SysLocale.SubLangID);
      Memo1->Lines->Add(buffer);
      buffer.sprintf("FarEast = %s", BoolToStr(SysLocale.FarEast, true));
      Memo1->Lines->Add(buffer);
      buffer.sprintf("MiddleEast = %s", BoolToStr(SysLocale.MiddleEast, true));
      Memo1->Lines->Add(buffer);
      Memo1->Lines->Add("");
    }
  }
  __finally
  {
```

```
    Memo1->Lines->EndUpdate();
  }
}
```

Delphi Examples:

```
{
This example requires that a memo and a TApplicationEvent be
added to the form.  Change the Windows Locale by using the
Regional and Language Options in the Windows Control Panel.
}
procedure TForm1.ApplicationEvents1SettingChange(Sender: TObject; Flag: Integer; const
Section: string; var Result: Integer);
begin
  Memo1.Lines.BeginUpdate;
  try
    Memo1.Lines.Add(Format('Section  = %s', [Section]));
    Memo1.Lines.Add(Format('Flags  = %.8x', [Flag]));
    if AnsiSameStr(Section, 'intl') then
    with SysLocale do
    begin
      Memo1.Lines.Add(Format('DefaultLCID  = %.8x', [DefaultLCID]));
      Memo1.Lines.Add(Format('PriLangID  = %.8x', [PriLangID]));
      Memo1.Lines.Add(Format('SubLangID  = %.8x', [SubLangID]));
      Memo1.Lines.Add(Format('FarEast  = %s', [BoolToStr(FarEast, True)]));
      Memo1.Lines.Add(Format('MiddleEast  = %s', [BoolToStr(MiddleEast, True)]));
    end;
    Memo1.Lines.Add('');
  finally
    Memo1.Lines.EndUpdate;
  end;
//  Result:= 0;
end;
```

FalseBoolStrs (see page 23025)

159.3.33 SysUtils.ByteToCharIndex Function

Returns the position of the character that contains a specified byte in a string.

Pascal

```
function ByteToCharIndex(const S: string; Index: Integer): Integer;
```

C++

```
int ByteToCharIndex(const AnsiString S, int Index);
```

File

SysUtils

Description

Call ByteToCharIndex to determine which character contains a particular byte in a string, where 1 specifies the first byte, 2 specifies the second byte, and so on. If the Index parameter specifies a byte that is not in the AnsiString (Index < 0 or Index > Length(S)), ByteToCharIndex returns 0.

If the system does not use a multi-byte character system (MBCS), ByteToCharIndex simply returns the value of Index, because there is a 1:1 correspondence between bytes and characters. Otherwise, ByteToCharIndex returns the position of the character, where 1 specifies the first character, 2 specifies the second character, and so on.

For example, if an AnsiString contains two characters, a single-byte character followed by a double byte character, then ByteToCharIndex returns 1 when Index is 1, it returns 2 when Index is 2 or 3, and it returns 0 for any other value of Index.

See Also

ByteToCharLen (see page 22807)

CharToByteIndex (see page 22811)

159.3.34 SysUtils.ByteToCharLen Function

Returns the number of characters fully contained in the first MaxLen bytes of a string.

Pascal

```
function ByteToCharLen(const S: string; MaxLen: Integer): Integer;
```

C++

```
int ByteToCharLen(const AnsiString S, int MaxLen);
```

File

SysUtils

Description

Call ByteToCharLen to determine the number of characters represented by a portion of a string. ByteToCharLen counts characters until it reaches MaxLen bytes or the end of the string, whichever comes first.

When working with multi-byte character systems (MBCS), the value returned by ByteToCharLen may be less than MaxLen or the length of the string.

Note: ByteToCharLen will count a partial character if it appears as the last of the first MaxLen bytes.

See Also

ByteToCharIndex (see page 22806)

CharToByteIndex (see page 22811)

CharToByteLen (see page 22811)

159.3.35 SysUtils.ByteType Function

Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.

Pascal

```
function ByteType(const S: string; Index: Integer): TMbcsByteType;
```

C++

```
TMbcsByteType ByteType(const AnsiString S, int Index);
```

File

SysUtils

Description

Call ByteType to determine whether a specified byte in a string is a single-byte character, the first byte of a multibyte character, or one of the trailing bytes.

AnsiString is the string that contains the byte in question.

Index identifies the byte for which you want to know the byte type. Bytes are numbered from 1.

If the system is not using a multi-byte character system (MBCS), ByteType always returns mbSingleByte. Otherwise, ByteType returns mbSingleByte if the indicated byte represents a complete character in S, mbLeadByte if it represents the first byte of a double byte character, and mbTrailByte if it represents a subsequent byte of a multibyte character.

Note: No checking is done to ensure that Index is less than the length of S. It is the caller's responsibility to ensure that Index is not out of bounds.

See Also

LeadBytes (see page 23026)

StrByteType (see page 22943)

159.3.36 SysUtils.CallTerminateProcs Function

Calls all of the functions in the termination procedure list.

Pascal

```
function CallTerminateProcs: Boolean;
```

C++

```
Boolean CallTerminateProcs();
```

File

SysUtils

Description

CallTerminateProcs is called internally when an application is about to terminate. It returns true only if all of the functions in the application's terminate procedure list return true. Do not call this function directly. Its use is automatic in Delphi application.

See Also

AddTerminateProc (see page 22787)

159.3.37 SysUtils.ChangeFileExt Function

Changes the extension of a file name.

Pascal

```
function ChangeFileExt(const FileName: string; const Extension: string): string;
```

C++

```
AnsiString ChangeFileExt(const AnsiString FileName, const AnsiString Extension);
```

File

SysUtils

Description

ChangeFileExt takes the file name passed in FileName and changes the extension of the file name to the extension passed in Extension. Extension specifies the new extension, including the initial dot character.

ChangeFileExt does not rename the actual file, it just creates a new file name string.

Note: This function works with multi-byte character sets (MBCS).

C++ Examples:

```
/*
This example converts a specified icon to a bitmap. To run
this example, add an image, a button, and an Open dialog to
a form. Name the button ConvertIcon2Bitmap, and add the
following code as its OnClick event handler.
*/
void __fastcall TForm1::ConvertIcon2BitmapClick(TObject *Sender)
{
  OpenDialog1->DefaultExt = ".ICO";
  OpenDialog1->Filter = "icons (*.ico)|*.ICO";
  OpenDialog1->Options << ofOverwritePrompt << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    TIcon *pi = new TIcon();
    try
    {
      AnsiString as;
      pi->LoadFromFile(OpenDialog1->FileName);
      as = ChangeFileExt(OpenDialog1->FileName,".BMP");
      Image1->Width = pi->Width;
      Image1->Height = pi->Height;
      Image1->Canvas->Draw(0,0,pi);
      Image1->Picture->SaveToFile(as);
      ShowMessage(OpenDialog1->FileName + " Saved to " + as);
    }
    __finally
    {
      delete pi;
    }
  }
}
```

Delphi Examples:

```
{
This example converts a specified icon to a bitmap. To run
this example, add an image, a button, and an Open dialog to
a form. Name the button ConvertIcon2Bitmap, and add the
following code as its OnClick event handler.
}
procedure TForm1.ConvertIcon2BitmapClick(Sender: TObject);
var
  s : string;
  Icon: TIcon;
begin
  OpenDialog1.DefaultExt := '.ICO';
```

```
    OpenDialog1.Filter := 'icons (*.ico)|*.ICO';
    OpenDialog1.Options := [ofOverwritePrompt, ofFileMustExist, ofHideReadOnly ];
    if OpenDialog1.Execute then
    begin
      Icon := TIcon.Create;
      try
        Icon.Loadfromfile(OpenDialog1.FileName);
        s:= ChangeFileExt(OpenDialog1.FileName,'.BMP');
        Image1.Width := Icon.Width;
        Image1.Height := Icon.Height;
        Image1.Canvas.Draw(0,0,Icon);
        Image1.Picture.SaveToFile(s);
        ShowMessage(OpenDialog1.FileName + ' Saved to ' + s);
      finally
        Icon.Free;
      end;
    end;
  end;
```

See Also

ExtractFileExt (see page 22844)

159.3.38 SysUtils.ChangeFilePath Function

Changes the path of a file name.

Pascal

```
function ChangeFilePath(const FileName: string; const Path: string): string;
```

C++

```
AnsiString ChangeFilePath(const AnsiString FileName, const AnsiString Path);
```

File

SysUtils

Description

ChangeFilePath replaces the drive and directory parts of the passed FileName with the passed Path value. If Path is not blank, it must specify a drive (terminated by a colon) and/or a directory (terminated by a backslash).

ChangeFilePath does not rename the actual file, it just creates a new file name string.

Note: This function works with multi-byte character sets (MBCS).

See Also

ExtractFilePath (see page 22846)

159.3.39 SysUtils.CharLength Function

Returns number of bytes used by a character.

Pascal

```
function CharLength(const S: String; Index: Integer): Integer;
```

C++

```
int CharLength(const AnsiString S, int Index);
```

File

SysUtils

Description

Call CharLength to determine the size in bytes of the character located in S at Index.

If the system is not using a multi-byte character system (MBCS), CharLength always returns 1.

159.3.40 SysUtils.CharToByteIndex Function

Returns the 1-based index of the first byte of a specified character in a string.

Pascal

```
function CharToByteIndex(const S: string; Index: Integer): Integer;
```

C++

```
int CharToByteIndex(const AnsiString S, int Index);
```

File

SysUtils

Description

Call CharToByteIndex to obtain the byte offset for the character at a specified position in the string S, where 1 specifies the first character, 2 specifies the second character, and so on. CharToByteIndex returns zero if Index is out of range (Index <= 0 or S contains fewer than Index characters). If the Index parameter indicates a double-byte character, CharToByteIndex returns the offset of the first byte.

If the system is not using a multi-byte character system (MBCS), CharToByteIndex returns the value of Index, because there is a 1:1 correspondence between bytes and characters.

See Also

ByteToCharIndex (see page 22806)

CharToByteLen (see page 22811)

159.3.41 SysUtils.CharToByteLen Function

Returns the length, in bytes, of the first MaxLen characters of a string.

Pascal

```
function CharToByteLen(const S: string; MaxLen: Integer): Integer;
```

C++

```
int CharToByteLen(const AnsiString S, int MaxLen);
```

File

SysUtils

Description

Call CharToByteLen to convert the length of a string in characters to the corresponding length in bytes. CharToByteLen returns the number of bytes required by the first MaxLen characters of S. If S contains fewer than MaxLen characters, CharToByteLen returns the byte length of S.

If the system is not using a multi-byte character system (MBCS), CharToByteLen returns the length of S or MaxLen, whichever is smaller.

See Also

ByteToCharLen (see page 22807)

CharToByteIndex (see page 22811)

159.3.42 SysUtils.CheckWin32Version Function

Check to see if you are running on a specific level (or higher) of the Windows 32 bit Operating System (see page 22079).

Pascal

```
function CheckWin32Version(AMajor: Integer; AMinor: Integer = 0): Boolean;
```

C++

```
Boolean CheckWin32Version(int AMajor, int AMinor = 0);
```

File

SysUtils

Description

The Windows Operating System (see page 22079) Major.Minor version number is compared with the passed AMajor and AMinor values. AMinor defaults to 0 if not supplied.

CheckWin32Version Returns true if the Windows OS Major.Minor version number is >= the passed AMajor.AMinor value.

Note: Prior to Delphi 7, this routine returned a different result.

See Also

Win32MajorVersion (see page 23036)Win32MinorVersion (see page 23036)

159.3.43 SysUtils.CompareMem Function

Performs a binary comparison of two memory images.

Pascal

```
function CompareMem(P1: Pointer; P2: Pointer; Length: Integer): Boolean;
```

C++

```
Boolean CompareMem(void * P1, void * P2, int Length);
```

File

SysUtils

Description

CompareMem performs a binary compare of Length bytes of memory referenced by P1 to that of P2. CompareMem returns true if the memory referenced by P1 is identical to that of P2.

See Also

CompareStr (see page 22813)

CompareText (see page 22814)

CollectionsEqual (see page 3220)

159.3.44 SysUtils.CompareStr Function

Compares two strings case sensitively.

Pascal

```
function CompareStr(const S1: string; const S2: string): Integer; overload;
function CompareStr(const S1: string; const S2: string; LocaleOptions: TLocaleOptions):
Integer; overload;
```

C++

```
int CompareStr(const AnsiString S1, const AnsiString S2);
int CompareStr(const AnsiString S1, const AnsiString S2, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

CompareStr compares S1 to S2, with case-sensitivity. The return value is less than 0 if S1 is less than S2, 0 if S1 equals S2, or greater than 0 if S1 is greater than S2. The compare operation is based on the 8-bit ordinal value of each character and is not affected by the current locale.

C++ Examples:

```
/*
The following code compares String1, 'STEVE', to String2,
'STEVe'. Note that CompareStr returns a number less than 0
because the value of 'e' is greater than the value of 'E'.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString String1 = "STEVE";
  AnsiString String2 = "Steve";
  int I = CompareStr(String1, String2);  // the value of I is < 0
  Edit1->Text = IntToStr(I);
  if (I != 0)
    ShowMessage ("The strings are not equal");
}
```

Delphi Examples:

```
{
The following code compares String1, 'STEVE', to String2,
'STEVe'. Note that CompareStr returns a number less than 0
because the value of 'e' is greater than the value of 'E'.
}
procedure TForm1.Button1Click(Sender: TObject);
var
```

```
    String1, String2 : string;
    I : Integer;
  begin
    String1 := 'STEVE';
    String2 := 'STEVe';
    I := SysUtils.CompareStr(String1, String2);  { the value of I is < 0 }
    Edit1.Text := InttoStr(I);
    if I <> 0 then
      MessageDlg('The strings are not equal', mtWarning, [mbOK], 0)
  end;
```

See Also

CompareText (see page 22814)

AnsiCompareStr (see page 22789)

159.3.45 SysUtils.CompareText Function

Compares two strings by ordinal value without case sensitivity.

Pascal

```
function CompareText(const S1: string; const S2: string): Integer; overload;
function CompareText(const S1: string; const S2: string; LocaleOptions: TLocaleOptions):
Integer; overload;
```

C++

```
int CompareText(const AnsiString S1, const AnsiString S2);
int CompareText(const AnsiString S1, const AnsiString S2, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

CompareText compares S1 and S2 and returns 0 if they are equal. If S1 is greater than S2, CompareText returns an integer greater than 0. If S1 is less than S2, CompareText returns an integer less than 0. CompareText is not case sensitive and is not affected by the current locale.

C++ Examples:

```
/*
The following code orders a list view in reverse
alphabetical order on the click of a button. The callback
function CustomSortProc calls the global CompareText
function and negates its return value.
*/
int __stdcall CustomSortProc(long Item1, long Item2, long ParamSort)
{
  return -CompareText(((TListItem *)Item1)->Caption,
                      ((TListItem *)Item2)->Caption);
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ListView1->CustomSort(CustomSortProc, 0);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TListItem *ListItem;
```

```
  ListView1->ViewStyle = vsList;
  ListItem = ListView1->Items->Add();
  ListItem->Caption = "Apples";
  ListItem = ListView1->Items->Add();
  ListItem->Caption = "Oranges";
  ListItem = ListView1->Items->Add();
  ListItem->Caption = "Pears";
}
/*
This example shows how to use the OnColumnClick and
OnCompare events of a list view to let users sort the
columns in a report-style list view by clicking on the
column headers. This requires a global variable to keep
track of the column that was clicked.  The OnColumnClick
event handler sets the global variable to indicate the
column to sort and calls AlphaSort:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TListItem *Item;
  TListColumn *Column;
  const char imagenames[3][20] = {
    "C++ Image", "Borland Image", "Delphi Image"};
  const char Col2Array[3][40] = {
    "Documentation for the C++ icon.",
    "Borland icon.", "Delphi icon."
    };
  // Create a ListView item for each image in the ImageList
  ListView1->SmallImages = ImageList1;
  ListView1->LargeImages = ImageList1;
  for (int i = 0; i < ImageList1->Count; i++)
  {
    Item = ListView1->Items->Add();
    Item->Caption = imagenames[i];
    Item->ImageIndex = i;
    Item->SubItems->Add(Col2Array[i]);
  }
  // Create two columns to show during viewing as vsReport
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 1";
  Column->Width = 200;
  Column = ListView1->Columns->Add();
  Column->Caption = "Column 2";
  Column->Width = 200;
  ListView1->ViewStyle = vsReport;
}

int ColumnToSort = 0;

/*
The OnColumnClick event handler sets the global variable to
indicate the column to sort and calls AlphaSort:
*/

void __fastcall TForm1::ListView1ColumnClick(TObject *Sender,
      TListColumn *Column)
{
  ColumnToSort = Column->Index;
  ((TCustomListView *)Sender)->AlphaSort();
}

/*
The OnCompare event handler causes the list view to sort on
the selected column:
*/
```

```
void __fastcall TForm1::ListView1Compare(TObject *Sender, TListItem *Item1,
      TListItem *Item2, int Data, int &Compare)
{
  if (ColumnToSort == 0)
    Compare = CompareText(Item1->Caption,Item2->Caption);
  else
  {
    int ix = ColumnToSort - 1;
    Compare =
      CompareText(Item1->SubItems->Strings[ix], Item2->SubItems->Strings[ix]);
  }
}
```

Delphi Examples:

```
{
The following code orders a list view in reverse
alphabetical order on the click of a button. The callback
function CustomSortProc calls the global CompareText
function and negates its return value.
}
function CustomSortProc(Item1, Item2: TListItem; ParamSort: integer): integer; stdcall;
begin
  Result := -CompareText(Item1.Caption,Item2.Caption);
end;
procedure TForm1.Button1Click(Sender: TObject);
begin
  ListView1.CustomSort(@CustomSortProc, 0);
end;

procedure TForm1.FormCreate(Sender: TObject);
var ListItem : TListItem;
begin
  ListView1.ViewStyle := vsList;
  ListItem := ListView1.Items.Add;
  ListItem.Caption := 'Apples';
  ListItem := ListView1.Items.Add;
  ListItem.Caption := 'Oranges';
  ListItem := ListView1.Items.Add;
  ListItem.Caption := 'Pears';
end;
{
This example shows how to use the OnColumnClick and
OnCompare events of a list view to let users sort the
columns in a report-style list view by clicking on the
column headers. This requires a global variable to keep
track of the column that was clicked.  The OnColumnClick
event handler sets the global variable to indicate the
column to sort and calls AlphaSort:
}
var ColumnToSort: Integer;

procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
  ListItem: TListItem;
  NewColumn: TListColumn;
const
  imagenames: Array[0..2] of string = ('C++ Image', 'Borland Image', 'Delphi Image');
begin
  Col2Array[0]:= 'Documentation for the C++ icon.';
  Col2Array[1]:= 'Borland icon.';
  Col2Array[2]:= 'Delphi icon.';
  // Create a ListView item for each image in the ImageList
  with ListView1 do
  begin
    SmallImages := ImageList1;
```

```
      LargeImages := ImageList1;
      for I := 0 to ImageList1.Count - 1 do
      begin
        ListItem := Items.Add;
        Listitem.Caption := imagenames[I];
        ListItem.ImageIndex := I;
        Listitem.SubItems.Add(Col2Array[I]);
      end;
      // Create two columns to show during viewing as vsReport
      NewColumn := Columns.Add;
      NewColumn.Caption := 'Column 1';
      NewColumn.Width := 200;
      NewColumn := Columns.Add;
      NewColumn.Caption := 'Column 2';
      NewColumn.Width := 200;
      ListView1.ViewStyle := vsReport;
    end;
  end;

  procedure TForm1.ListView1ColumnClick(Sender: TObject; Column: TListColumn);
  begin
    ColumnToSort := Column.Index;
    (Sender as TCustomListView).AlphaSort;
  end;

  {
  The OnCompare event handler causes the list view to sort on
  the selected column:
  }
  procedure TForm1.ListView1Compare(Sender: TObject; Item1, Item2: TListItem; Data: Integer; var
  Compare: Integer);
  var
    ix: Integer;
  begin
    if ColumnToSort = 0 then
      Compare := CompareText(Item1.Caption,Item2.Caption)
    else begin
     ix := ColumnToSort - 1;
     Compare := CompareText(Item1.SubItems[ix],Item2.SubItems[ix]);
    end;
  end;
  {
  Note:   This OnCompare event handler uses the global
  CompareText function. An application may want to use
  AnsiCompareText, CompareStr, or AnsiCompareStr instead,
  depending on whether the comparison should be case-sensitive
  and whether the locale should be considered.
  }
```

CompareStr (see page 22813)

AnsiCompareText (see page 22790)

CompareMem (see page 22812)

SameText (see page 22940)

159.3.46 SysUtils.CreateDir Function

Creates a new directory.

Pascal

```
function CreateDir(const Dir: string): Boolean;
```

C++

```
Boolean CreateDir(const AnsiString Dir);
```

File

SysUtils

Description

CreateDir creates a new directory. The return value is true if a new directory was successfully created, or false if an error occurred.

C++ Examples:

```
/*
The following example creates a directory 'C:\temp' if it
does not already exist.
}
*/
#include <Filectrl.hpp>
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (!DirectoryExists("c:\\temp"))
  {
    if (!CreateDir("C:\\temp"))
      throw Exception("Cannot create c:\\temp directory.");
  }
  if (!CreateDir("C:\\temp"))
    throw Exception("The c:\\temp directory already exists.");
}
```

Delphi Examples:

```
{
The following example creates a directory 'C:\temp' if it
does not already exist.
}
uses FileCtrl;
procedure TForm1.Button1Click(Sender: TObject);
begin
  if not SysUtils.DirectoryExists('C:\temp') then
    if not CreateDir('C:\temp') then
      raise Exception.Create('Cannot create C:\temp');
  if not CreateDir('C:\temp') then
    raise Exception.Create('Cannot create C:\temp again!');
end;
```

RemoveDir (see page 22933)

SetCurrentDir (see page 22940)

ForceDirectories (see page 22895)

159.3.47 SysUtils.CreateGUID Function

Creates a globally unique identifier.

Pascal

```
function CreateGUID(out Guid: TGUID): HResult; stdcall;
```

C++

```
__stdcall HRESULT CreateGUID(TGUID Guid);
```

File

SysUtils

Description

CreateGUID sets Guid to a new-created Globally Unique Identifier.

Note: Under Windows, CreateGUID calls the Windows API CoCreateGUID.

Note: Under Linux, CreateGUID calls uuid_generate_time.

159.3.48 SysUtils.CurrentYear Function

Returns the current year.

Pascal

```
function CurrentYear: Word;
```

C++

```
Word CurrentYear();
```

File

SysUtils

Description

CurrentYear returns the current year on the Gregorian calendar. The value returned is the complete four-digit year.

159.3.49 SysUtils.CurrToStr Function

Formats a Currency value as a string.

Pascal

```
function CurrToStr(Value: Currency): string; overload;
function CurrToStr(Value: Currency; const FormatSettings: TFormatSettings): string; overload;
```

C++

```
AnsiString CurrToStr(Currency Value);
AnsiString CurrToStr(Currency Value, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

CurrToStr converts the Currency value given by Value to its string representation. The conversion uses the ffGeneral floating point conversion rules.

The first form of CurrToStr is not thread-safe, because it uses localization information contained in global variables. The second form of CurrToStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of CurrToStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.50 SysUtils.CurrToStrF Function

Converts a Currency value to a string, using a specified format.

Pascal

```
function CurrToStrF(Value: Currency; Format: TFloatFormat; Digits: Integer): string; overload;
function CurrToStrF(Value: Currency; Format: TFloatFormat; Digits: Integer; const
FormatSettings: TFormatSettings): string; overload;
```

C++

```
AnsiString CurrToStrF(Currency Value, TFloatFormat Format, int Digits);
AnsiString CurrToStrF(Currency Value, TFloatFormat Format, int Digits, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

CurrToStrF converts the Currency value given by Value to its string representation using the indicated float format convention. A call to CurrToStrF corresponds to a call to FloatToStrF (see page 22891) with an implied precision of 19 digits.

The first form of CurrToStrF is not thread-safe, because it uses localization information contained in global variables. The second form of CurrToStrF, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of CurrToStrF, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.51 SysUtils.Date Function

Returns the current date.

Pascal

```
function Date: TDateTime;
```

C++

```
TDateTime Date();
```

File

SysUtils

Description

Use Date to obtain the current local date as a TDateTime value. The time portion of the value is 0 (midnight).

C++ Examples:

```
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date is displayed in the
caption of the label:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = DateToStr(Date());
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, the current date is displayed in the
caption of the label:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := 'Today is  ' + SysUtils.DateToStr(Date);
end;
```

159.3.52 SysUtils.DateTimeToFileDate Function

Converts a TDateTime value to an OS timestamp value.

Pascal

```
function DateTimeToFileDate(DateTime: TDateTime): Integer;
```

C++

```
int DateTimeToFileDate(TDateTime DateTime);
```

File

SysUtils

Description

A timestamp is a signed 32-bit integer, used by the Operating System (see page 22079) to record information such as the date

and time a file was modified. The precise format of a timestamp depends on the OS. Use DateTimeToFileDate to convert a TDateTime value to an OS timestamp value.

DateTimeToFileDate is particularly useful for converting the Time (see page 22976) field of the TSearchRec (see page 23005) type used by the FindFirst (see page 22884) and FindNext (see page 22887) functions.

See Also

FileDateToDateTime (see page 22858)

FindFirst (see page 22884)

FindNext (see page 22887)

TSearchRec (see page 23005)

159.3.53 SysUtils.DateTimeToStr Function

Converts a TDateTime value to a string.

Pascal

```
function DateTimeToStr(const DateTime: TDateTime): string; overload;
function DateTimeToStr(const DateTime: TDateTime; const FormatSettings: TFormatSettings):
string; overload;
```

C++

```
AnsiString DateTimeToStr(const TDateTime DateTime);
AnsiString DateTimeToStr(const TDateTime DateTime, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

The first form of DateTimeToStr is not thread-safe, because it uses localization information contained in global variables. The second form of DateTimeToStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of DateTimeToStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

C++ Examples:

```
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date and time is
converted to a string and displayed as the caption of the
label:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = DateTimeToStr(Now());
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, the current date and time is
converted to a string and displayed as the caption of the
label:
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
begin
  Label1.Caption := SysUtils.DateTimeToStr(Now);
end;
```

159.3.54 SysUtils.DateTimeToString Function

Converts a TDateTime value to a string using a specified Format (see page 22897).

Pascal

```
procedure DateTimeToString(var Result: string; const Format: string; DateTime: TDateTime);
overload;
procedure DateTimeToString(var Result: string; const Format: string; DateTime: TDateTime;
const FormatSettings: TFormatSettings); overload;
```

C++

```
DateTimeToString(AnsiString Result, const AnsiString Format, TDateTime DateTime);
DateTimeToString(AnsiString Result, const AnsiString Format, TDateTime DateTime, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

DateTimeToString converts the TDateTime value given by DateTime using the format string given by Format (see page 22897) into the string variable given by Result. See the table below for information about the supported format strings.

The first form of DateTimeToString is not thread-safe, because it uses localization information contained in global variables. The second form of DateTimeToString, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of DateTimeToString, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

Date (see page 22820) Time (see page 22976) Format (see page 22897) Strings are composed from specifiers that represent values to be inserted into the formatted string. Some specifiers (such as "d"), simply format numbers or strings. Other specifiers (such as "/") refer to locale-specific strings from global variables.

In the following table, specifiers are given in lower case. Case is ignored in formats, except for the "am/pm" and "a/p" specifiers.

Specifier	Displays
c	Displays the date using the format given by the ShortDateFormat (see page 23030) global variable, followed by the time using the format given by the LongTimeFormat (see page 23028) global variable. The time is not displayed if the date-time value indicates midnight precisely.
d	Displays the day as a number without a leading zero (1-31).
dd	Displays the day as a number with a leading zero (01-31).
ddd	Displays the day as an abbreviation (Sun-Sat) using the strings given by the ShortDayNames (see page 23031) global variable.
dddd	Displays the day as a full name (Sunday-Saturday) using the strings given by the LongDayNames (see page 23027) global variable.
ddddd	Displays the date using the format given by the ShortDateFormat (see page 23030) global variable.
dddddd	Displays the date using the format given by the LongDateFormat (see page 23027) global variable.
e	(Windows only) Displays the year in the current period/era as a number without a leading zero (Japanese, Korean and Taiwanese locales only).

ee	(Windows only) Displays the year in the current period/era as a number with a leading zero (Japanese, Korean and Taiwanese locales only).
g	(Windows only) Displays the period/era as an abbreviation (Japanese and Taiwanese locales only).
gg	(Windows only) Displays the period/era as a full name. (Japanese and Taiwanese locales only).
m	Displays the month as a number without a leading zero (1-12). If the m specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mm	Displays the month as a number with a leading zero (01-12). If the mm specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mmm	Displays the month as an abbreviation (Jan-Dec) using the strings given by the ShortMonthNames (see page 23031) global variable.
mmmm	Displays the month as a full name (January-December) using the strings given by the LongMonthNames (see page 23028) global variable.
yy	Displays the year as a two-digit number (00-99).
yyyy	Displays the year as a four-digit number (0000-9999).
h	Displays the hour without a leading zero (0-23).
hh	Displays the hour with a leading zero (00-23).
n	Displays the minute without a leading zero (0-59).
nn	Displays the minute with a leading zero (00-59).
s	Displays the second without a leading zero (0-59).
ss	Displays the second with a leading zero (00-59).
z	Displays the millisecond without a leading zero (0-999).
zzz	Displays the millisecond with a leading zero (000-999).
t	Displays the time using the format given by the ShortTimeFormat (see page 23031) global variable.
tt\	Displays the time using the format given by the LongTimeFormat (see page 23028) global variable.
am/pm	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'am' for any hour before noon, and 'pm' for any hour after noon. The am/pm specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
a/p	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'a' for any hour before noon, and 'p' for any hour after noon. The a/p specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
ampm	Uses the 12-hour clock for the preceding h or hh specifier, and displays the contents of the TimeAMString (see page 23033) global variable for any hour before noon, and the contents of the TimePMString (see page 23033) global variable for any hour after noon.
/	Displays the date separator character given by the DateSeparator (see page 23023) global variable.
:	Displays the time separator character given by the TimeSeparator (see page 23033) global variable.
'xx'/"xx"	Characters enclosed in single or double quotes are displayed as-is, and do not affect formatting.

DateTimeToStr (see page 22822)

GetLocaleFormatSettings (see page 22913)

159.3.55 SysUtils.DateTimeToSystemTime Function

Converts a TDateTime value into the Win32 API's system time type.

Pascal

```
procedure DateTimeToSystemTime(const DateTime: TDateTime; var SystemTime: TSystemTime);
```

C++

```
DateTimeToSystemTime(const TDateTime DateTime, TSystemTime SystemTime);
```

File

SysUtils

Description

Use DateTimeToSystemTime to convert a TDateTime value into a TSystemTime (Delphi) or _SYSTEMTIME (C++) value. This procedure is primarily used to convert TDateTime values for making a Windows API call.

See Also

SystemTimeToDateTime (see page 22974)

159.3.56 SysUtils.DateTimeToTimeStamp Function

Converts a TDateTime value into the corresponding TTimeStamp (see page 23009) value.

Pascal

```
function DateTimeToTimeStamp(DateTime: TDateTime): TTimeStamp;
```

C++

```
TTimeStamp DateTimeToTimeStamp(TDateTime DateTime);
```

File

SysUtils

Description

Call DateTimeToTimeStamp to convert a TDateTime value into a TTimeStamp (see page 23009) value.

See Also

TimeStampToDateTime (see page 22976)

159.3.57 SysUtils.DateToStr Function

Converts a TDateTime value to a string.

Pascal

```
function DateToStr(const DateTime: TDateTime): string; overload;
function DateToStr(const DateTime: TDateTime; const FormatSettings: TFormatSettings): string;
overload;
```

C++

```
AnsiString DateToStr(const TDateTime DateTime);
AnsiString DateToStr(const TDateTime DateTime, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Use DateToStr to obtain a string representation of a date value that can be used for display purposes.

The first form of DateToStr is not thread-safe, because it uses localization information contained in global variables. The second form of DateToStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of DateToStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

C++ Examples:

```
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date is displayed in the
caption of the label:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = DateToStr(Date());
}
/*
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TDateTime dt;
  try
  {
    dt = EncodeDate((Word)StrToInt(Edit1->Text), (Word)StrToInt(Edit2->Text),
(Word)StrToInt(Edit3->Text));
    Label1->Caption = DateToStr(dt);
  }
  catch(...)
  {
    ShowMessage("Invalid day, month, or year.");
  }
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, the current date is displayed in the
caption of the label:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := 'Today is  ' + SysUtils.DateToStr(Date);
end;
{
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
```

```
AnsiString that is displayed in the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyDate: TDateTime;
begin
  MyDate := SysUtils.EncodeDate(StrToInt(Edit1.Text), StrToInt(Edit2.Text),
StrToInt(Edit3.Text));
  Label1.Caption := DateToStr(MyDate);
end;
```

159.3.58 SysUtils.DayOfWeek Function

Returns the day of the week for a specified date.

Pascal

```
function DayOfWeek(const DateTime: TDateTime): Word;
```

C++

```
Word DayOfWeek(const TDateTime DateTime);
```

File

SysUtils

Description

DayOfWeek returns the day of the week of the specified date as an integer between 1 and 7, where Sunday is the first day of the week and Saturday is the seventh.

Note: DayOfWeek is not compliant with the ISO 8601 standard, which defines Monday as the first day of the week. For an ISO 8601 compliant version, use the DayOfTheWeek function instead.

C++ Examples:

```
/*
This example uses an edit box and a button on a form. When
the user enters a date in the edit box in the format
associated with the current locale (for example MM/DD/YY
format in the US), the string entered is converted to a
TDateTime value. This value is used to indicate the day of
the week the date represents.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char days[7][10] = {"Sunday", "Monday", "Tuesday", "Wednesday", "Thursday", "Friday",
"Saturday" };
  TDateTime dtDate = StrToDate(Edit1->Text);
  ShowMessage(Edit1->Text + AnsiString(" is a ") + days[dtDate.DayOfWeek() - 1]);
}
```

Delphi Examples:

```
{
This example uses an edit box and a button on a form. When
the user enters a date in the edit box in the format
associated with the current locale (for example MM/DD/YY
format in the US), the string entered is converted to a
TDateTime value. This value is used to indicate the day of
the week the date represents.
}
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  ADate: TDateTime;
  days: array[1..7] of string;
begin
  days[1] := 'Sunday';
  days[2] := 'Monday';
  days[3] := 'Tuesday';
  days[4] := 'Wednesday';
  days[5] := 'Thursday';
  days[6] := 'Friday';
  days[7] := 'Saturday';
  ADate := StrToDate(Edit1.Text);
  ShowMessage(Edit1.Text + ' is a ' + days[SysUtils.DayOfWeek(ADate)]);
end;
```

See Also

Date (see page 22820)

DayOfTheMonth (see page 6618)

DayOfTheYear (see page 6620)

DayOfTheWeek (see page 6619)

159.3.59 SysUtils.DecodeDate Function

Returns Year, Month, and Day values for a TDateTime value.

Pascal

```
procedure DecodeDate(const DateTime: TDateTime; var Year: Word; var Month: Word; var Day:
Word);
```

C++

```
DecodeDate(const TDateTime DateTime, Word Year, Word Month, Word Day);
```

File

SysUtils

Description

The DecodeDate procedure breaks the value specified as the Date (see page 22820) parameter into Year, Month, and Day values. If the given TDateTime value has a negative (BC) year, the year, month, and day return parameters are all set to zero.

C++ Examples:

```
/*
This example uses a button and two labels on a form. When
the user clicks the button, the current date and time are
reported in the captions of the two labels.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Word Year, Month, Day, Hour, Min, Sec, MSec;
  TDateTime dtPresent = Now();
  DecodeDate(dtPresent, Year, Month, Day);
  Label1->Caption = AnsiString("Today is Day ") + IntToStr(Day) + AnsiString(" of Month ") +
IntToStr(Month) + AnsiString(" of Year ") + IntToStr(Year);
  DecodeTime(dtPresent, Hour, Min, Sec, MSec);
```

```
  Label2->Caption = AnsiString("The time is Minute ") + IntToStr(Min) + AnsiString(" of Hour
") + IntToStr(Hour);
}
```

Delphi Examples:

```
{
This example uses a button and two labels on a form. When
the user clicks the button, the current date and time are
reported in the captions of the two labels.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Present: TDateTime;
  Year, Month, Day, Hour, Min, Sec, MSec: Word;
 begin
  Present:= Now;
  SysUtils.DecodeDate(Present, Year, Month, Day);
  Label1.Caption := 'Today is Day ' + IntToStr(Day) + ' of Month '
    + IntToStr(Month) + ' of Year ' + IntToStr(Year);
  SysUtils.DecodeTime(Present, Hour, Min, Sec, MSec);
  Label2.Caption := 'The time is Minute ' + IntToStr(Min) + ' of Hour '
    + IntToStr(Hour);
end;
```

See Also

DecodeDateFully (see page 22829)

MonthOf (see page 6670)

DecodeDateTime (see page 6626)

159.3.60 SysUtils.DecodeDateFully Function

Returns Year, Month, and Day, and Day-of-Week values for a TDateTime value.

Pascal

```
function DecodeDateFully(const DateTime: TDateTime; var Year: Word; var Month: Word; var Day:
Word; var DOW: Word): Boolean;
```

C++

```
Boolean DecodeDateFully(const TDateTime DateTime, Word Year, Word Month, Word Day, Word DOW);
```

File

SysUtils

Description

DecodeDateFully procedure breaks the value specified as the Date (see page 22820) parameter into Year, Month, Day, and DOW values. If Year is a leap year, the function return value is True; otherwise the function return value is false. If the given TDateTime value has a negative (BC) year, the return parameters are all set to zero.

See Also

DecodeDate (see page 22828)

DecodeTime (see page 22830)

DayOf (see page 6618)

YearOf (see page 6714)

MonthOf (see page 6670)

DecodeDateTime (see page 6626)

159.3.61 SysUtils.DecodeTime Function

Breaks a TDateTime value into hours, minutes, seconds, and milliseconds.

Pascal

```
procedure DecodeTime(const DateTime: TDateTime; var Hour: Word; var Min: Word; var Sec: Word;
var MSec: Word);
```

C++

```
DecodeTime(const TDateTime DateTime, Word Hour, Word Min, Word Sec, Word MSec);
```

File

SysUtils

Description

DecodeTime breaks the object specified as the Time (see page 22976) parameter into hours, minutes, seconds, and milliseconds.

C++ Examples:

```
/*
This example uses a button and two labels on a form. When
the user clicks the button, the current date and time are
reported in the captions of the two labels.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Word Year, Month, Day, Hour, Min, Sec, MSec;
  TDateTime dtPresent = Now();
  DecodeDate(dtPresent, Year, Month, Day);
  Label1->Caption = AnsiString("Today is Day ") + IntToStr(Day) + AnsiString(" of Month ") +
IntToStr(Month) + AnsiString(" of Year ") + IntToStr(Year);
  DecodeTime(dtPresent, Hour, Min, Sec, MSec);
  Label2->Caption = AnsiString("The time is Minute ") + IntToStr(Min) + AnsiString(" of Hour
") + IntToStr(Hour);
}
```

Delphi Examples:

```
{
This example uses a button and two labels on a form. When
the user clicks the button, the current date and time are
reported in the captions of the two labels.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Present: TDateTime;
  Year, Month, Day, Hour, Min, Sec, MSec: Word;
 begin
  Present:= Now;
  SysUtils.DecodeDate(Present, Year, Month, Day);
```

```
  Label1.Caption := 'Today is Day ' + IntToStr(Day) + ' of Month '
    + IntToStr(Month) + ' of Year ' + IntToStr(Year);
  SysUtils.DecodeTime(Present, Hour, Min, Sec, MSec);
  Label2.Caption := 'The time is Minute ' + IntToStr(Min) + ' of Hour '
    + IntToStr(Hour);
end;
```

159.3.62 SysUtils.DeleteFile Function

Deletes a file from disk.

Pascal

```
function DeleteFile(const FileName: string): Boolean;
```

C++

```
Boolean DeleteFile(const AnsiString FileName);
```

File

SysUtils

Description

DeleteFile deletes the file named by FileName from the disk. If the file cannot be deleted or does not exist, the function returns false.

C++ Examples:

```
/*
The following code prompts for confirmation before deleting
a file.  Create a file and then click on the button to select
the file with a TOpenDialog.  Click Yes to delete it.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  OpenDialog1->Title = "Delete File";
  if (OpenDialog1->Execute())
  {
    if (FileExists(OpenDialog1->FileName))
    {
      if (MessageDlg(
        ("Do you really want to delete " + ExtractFileName(OpenDialog1->FileName) + "?"),
        mtConfirmation,
        TMsgDlgButtons() << mbYes << mbNo,
        0,
```

```
        mbNo) == mrYes)
        DeleteFile(OpenDialog1->FileName);
    }
    else
      MessageDlg(("File " + ExtractFileName(OpenDialog1->FileName) + " does not exist."),
mtConfirmation, TMsgDlgButtons() << mbOK, 0);
  }
}
/*
Click the button to open a TOpenDialog, then select a file
to delete.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  OpenDialog1->Title = "Delete File";
  if (OpenDialog1->Execute())
  {
    if (FileExists(OpenDialog1->FileName))
      DeleteFile(OpenDialog1->FileName);
  }
}
```

Delphi Examples:

```
{
The following code prompts for confirmation before deleting
a file.  Create a file and then enter the path and file name
in the textfields.  Click the button to delete it.
}
procedure TForm1.Button1Click(Sender: TObject);
var FileName: string;
begin
  Filename:= Edit1.Text;
  if SysUtils.FileExists(FileName) then
  begin
    if MessageDlg(('Do you really want to delete ' + ExtractFileName(FileName) + '?'),
mtConfirmation, [mbYes, mbNo], 0, mbNo) = IDYes then
      DeleteFile(FileName);
  end
  else
    MessageDlg(('File ' + ExtractFileName(FileName) + ' does not exist.'), mtConfirmation,
[mbOK], 0);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Edit2.Text:= ExtractFilePath(Application.ExeName);
end;
```

159.3.63 SysUtils.DirectoryExists Function

Determines whether a specified directory exists.

Pascal

```
function DirectoryExists(const Directory: string): Boolean;
```

C++

```
Boolean DirectoryExists(const AnsiString Directory);
```

File

SysUtils

Description

Call DirectoryExists to determine whether the directory specified by the **Directory** parameter exists. If the directory exists, the function returns true. If the directory does not exist, the function returns false.

If a full path name is entered, DirectoryExists searches for the directory along the designated path. Otherwise, the **Directory** parameter is interpreted as a relative path name from the current directory.

Note: The FileCtrl (see page 13311) unit (Windows only) also contains a DirectoryExists function. However, the FileCtrl (see page 13311) version is deprecated, and the SysUtils (see page 22709) version preferred, even if the code does not need to be cross-platform.

C++ Examples:

```
/*
The following example creates a directory 'C:\temp' if it
does not already exist.
}
*/
#include <Filectrl.hpp>
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (!DirectoryExists("c:\\temp"))
  {
    if (!CreateDir("C:\\temp"))
      throw Exception("Cannot create c:\\temp directory.");
  }
  if (!CreateDir("C:\\temp"))
    throw Exception("The c:\\temp directory already exists.");
}
```

Delphi Examples:

```
{
The following example creates a directory 'C:\temp' if it
does not already exist.
}
uses FileCtrl;
procedure TForm1.Button1Click(Sender: TObject);
begin
  if not SysUtils.DirectoryExists('C:\temp') then
    if not CreateDir('C:\temp') then
      raise Exception.Create('Cannot create C:\temp');
  if not CreateDir('C:\temp') then
    raise Exception.Create('Cannot create C:\temp again!');
end;
```

FileExists

159.3.64 SysUtils.DiskFree Function

Returns the number of free bytes on a specified drive.

Pascal

```
function DiskFree(Drive: Byte): Int64;
```

C++

```
Int64 DiskFree(Byte Drive);
```

File

SysUtils

Description

DiskFree returns the number of free bytes on the specified drive, where 0 = Current, 1 = A, 2 = B, and so on.

DiskFree returns -1 if the drive number is invalid.

Note: DiskFree is only available on Windows.

C++ Examples:

```
/*
This example uses a form with a label on it. When the
following code executes, it displays a message in the label
indicating the number of KB free, and what percentage of the
entire disk space that represents.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  __int64 AmtFree = DiskFree(0);
  __int64 Total = DiskSize(0);
  AnsiString S;
  S.sprintf("%I64d percent of the space on drive 0 is free: %I64d KB", AmtFree*100/Total,
AmtFree/1024 );
  Label1->Caption = S;
}
```

Delphi Examples:

```
{
This example uses a form with a label on it. When the
following code executes, it displays a message in the label
indicating the number of KB free, and what percentage of the
entire disk space that represents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S: string;
  AmtFree: Int64;
  Total:   Int64;
begin
  AmtFree := SysUtils.DiskFree(0);
  Total := DiskSize(0);
  S := IntToStr((AmtFree  * 100) div Total) + ' percent of the space on drive 0 is free: ' +
IntToStr(AmtFree div 1024) + ' Kbytes free. ';
  Label1.Caption := S;
end;
{
The following example displays in a dialog the disk free
space of the current drive with commas as thousand separators.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ShowMessage(FormatFloat('#,##0 bytes', DiskFree(0)));
end;
```

See Also

DiskSize (see page 22835)

159.3.65 SysUtils.DiskSize Function

Returns the size, in bytes, of a specified drive.

Pascal

```
function DiskSize(Drive: Byte): Int64;
```

C++

```
Int64 DiskSize(Byte Drive);
```

File

SysUtils

Description

DiskSize returns the size in bytes of the specified drive, where 0 = Current, 1 = A, 2 = B, etc. DiskSize returns -1 if the drive number is invalid.

Note: DiskSize is only available on Windows.

C++ Examples:

```
/*
This example uses a form with a label on it. When the
following code executes, it displays a message in the label
indicating the number of KB free, and what percentage of the
entire disk space that represents.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  __int64 AmtFree = DiskFree(0);
  __int64 Total = DiskSize(0);
  AnsiString S;
  S.sprintf("%I64d percent of the space on drive 0 is free: %I64d KB", AmtFree*100/Total,
AmtFree/1024 );
  Label1->Caption = S;
}
```

Delphi Examples:

```
{
This example uses a form with a label on it. When the
following code executes, it displays a message in the label
indicating the number of KB free, and what percentage of the
entire disk space that represents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  S: string;
  AmtFree: Int64;
  Total:   Int64;
begin
  AmtFree := SysUtils.DiskFree(0);
  Total := DiskSize(0);
  S := IntToStr((AmtFree  * 100) div Total) + ' percent of the space on drive 0 is free: ' +
IntToStr(AmtFree div 1024) + ' Kbytes free. ';
  Label1.Caption := S;
end;
```

See Also

DiskFree (see page 22833)

159.3.66 SysUtils.DisposeStr Function

Disposes of a string pointer that was allocated using NewStr (see page 22929).

Pascal

```
procedure DisposeStr(P: PString); deprecated;
```

C++

```
DisposeStr(PString P);
```

File

SysUtils

Description

DisposeStr is only provided for backward compatibility with existing code that allocated a string using NewStr (see page 22929). Both DisposeStr and NewStr (see page 22929) are obsolete.

See Also

NewStr (see page 22929)

159.3.67 SysUtils.EncodeDate Function

Returns a TDateTime value that represents a specified Year, Month, and Day.

Pascal

```
function EncodeDate(Year: Word; Month: Word; Day: Word): TDateTime;
```

C++

```
TDateTime EncodeDate(Word Year, Word Month, Word Day);
```

File

SysUtils

Description

EncodeDate returns a TDateTime value from the values specified as the Year, Month, and Day parameters.

The year must be between 1 and 9999.

Valid Month values are 1 through 12.

Valid Day values are 1 through 28, 29, 30, or 31, depending on the Month value. For example, the possible Day values for month 2 (February) are 1 through 28 or 1 through 29, depending on whether or not the Year value specifies a leap year.

If the specified values are not within range, EncodeDate raises an EConvertError (see page 22724) exception.

C++ Examples:

```
/*
This example uses three edit controls, a label, and a button
```

```
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TDateTime dt;
  try
  {
    dt = EncodeDate((Word)StrToInt(Edit1->Text), (Word)StrToInt(Edit2->Text),
(Word)StrToInt(Edit3->Text));
    Label1->Caption = DateToStr(dt);
  }
  catch(...)
  {
    ShowMessage("Invalid day, month, or year.");
  }
}
```

Delphi Examples:

```
{
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyDate: TDateTime;
begin
  MyDate := SysUtils.EncodeDate(StrToInt(Edit1.Text), StrToInt(Edit2.Text),
StrToInt(Edit3.Text));
  Label1.Caption := DateToStr(MyDate);
end;
```

See Also

DateToStr (see page 22825)

DecodeDate (see page 22828)

EncodeTime (see page 22837)

EncodeDateTime (see page 6630)

TryEncodeDate (see page 22980)

159.3.68 SysUtils.EncodeTime Function

Returns a TDateTime value for a specified Hour, Min, Sec, and MSec.

Pascal

```
function EncodeTime(Hour: Word; Min: Word; Sec: Word; MSec: Word): TDateTime;
```

C++

```
TDateTime EncodeTime(Word Hour, Word Min, Word Sec, Word MSec);
```

File

SysUtils

Description

EncodeTime encodes the given hour, minute, second, and millisecond into a TDateTime value.

Valid Hour values are 0 through 23.

Valid Min and Sec values are 0 through 59.

Valid MSec values are 0 through 999.

If the specified values are not within range, EncodeTime raises an EConvertError (see page 22724) exception.

The resulting value is a number between 0 and 1 (inclusive) that indicates the fractional part of a day given by the specified time or (if 1.0) midnight on the following day. The value 0 corresponds to midnight, 0.5 corresponds to noon, 0.75 corresponds to 6:00 pm, and so on.

C++ Examples:

```
/*
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TDateTime dt;
  try
  {
    dt = EncodeTime((Word)StrToInt(Edit1->Text), (Word)StrToInt(Edit2->Text),
(Word)StrToInt(Edit3->Text), (Word)StrToInt(Edit4->Text));
    Label1->Caption = TimeToStr(dt);
  }
  catch(...)
  {
    ShowMessage("Invalid hour, minute, second, or millisecond.");
  }
}
```

Delphi Examples:

```
{
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyDate: TDateTime;
begin
  MyDate := SysUtils.EncodeTime(StrToInt(Edit1.Text), StrToInt(Edit2.Text),
StrToInt(Edit3.Text), StrToInt(Edit4.Text));
  Label1.Caption := TimeToStr(MyDate);
end;
```

EncodeDate (see page 22836)

EConvertError (see page 22724)

EncodeDateTime (see page 6630)

159.3.69 SysUtils.ExceptionErrorMessage Function

Formats a standard error message.

Pascal

```
function ExceptionErrorMessage(ExceptObject: TObject; ExceptAddr: Pointer; Buffer: PChar;
Size: Integer): Integer;
```

C++

```
int ExceptionErrorMessage(TObject * ExceptObject, void * ExceptAddr, const char * Buffer, int
Size);
```

File

SysUtils

Description

Call ExceptionErrorMessage to assemble an error message that indicates the object associated with the current exception and the location at which the exception was raised. The assembled message is written into the buffer provided by the Buffer parameter. Specify the size of this buffer using the Size parameter.

ExceptionErrorMessage returns the number of bytes in the assembled error message.

See Also

ExceptAddr (see page 22452)

ExceptObject (see page 22452)

ShowException (see page 22941)

159.3.70 SysUtils.ExcludeTrailingBackslash Function

Returns a path name without a trailing delimiter.

Pascal

```
function ExcludeTrailingBackslash(const S: string): string; platform;
```

C++

```
AnsiString ExcludeTrailingBackslash(const AnsiString S);
```

File

SysUtils

Description

ExcludeTrailingBackslash returns S with any trailing path delimiter ('\' on Windows, '/' on Linux) removed. This function is included for backward compatibility only. New programs should use ExcludeTrailingPathDelimiter (see page 22840).

Note: ExcludeTrailingBackslash works with multibyte character sets.

See Also

IncludeTrailingBackslash (see page 22918)

IsPathDelimiter (see page 22925)

ExcludeTrailingPathDelimiter (see page 22840)

159.3.71 SysUtils.ExcludeTrailingPathDelimiter Function

Returns a path name without a trailing delimiter.

Pascal

```
function ExcludeTrailingPathDelimiter(const S: string): string;
```

C++

```
AnsiString ExcludeTrailingPathDelimiter(const AnsiString S);
```

File

SysUtils

Description

ExcludeTrailingPathDelimiter returns S with any trailing path delimiter ('\' on Windows, '/' on Linux) removed. If the last character in S is a delimiter, the return value is S with the last character removed. Otherwise, S is returned unchanged.

Note: ExcludeTrailingPathDelimiter works with multibyte character sets.

See Also

IncludeTrailingPathDelimiter (see page 22918)

IsPathDelimiter (see page 22925)

159.3.72 SysUtils.ExpandFileName Function

Returns the full path name for a relative file name.

Pascal

```
function ExpandFileName(const FileName: string): string;
```

C++

```
AnsiString ExpandFileName(const AnsiString FileName);
```

File

SysUtils

Description

ExpandFileName converts the relative file name into a fully qualified path name. ExpandFileName does not verify that the resulting fully qualified path name refers to an existing file, or even that the resulting path exists.

Note: ExpandFileName does not support UNC format. To expand to a UNC file name, use ExpandUNCFileName (see page 22842).

C++ Examples:

```
/*
The following example uses a listbox, an edit control, and a
button on a form. When the button is clicked, the filename
```

```
specified in the edit control is expanded to a fully
qualified filename and added to the list box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ListBox1->Items->Add(ExpandFileName(Edit1->Text));
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Label2->Caption = ExtractFilePath(Application->ExeName);
}
```

Delphi Examples:

```
{
The following example uses a listbox, an edit control, and a
button on a form. When the button is clicked, the filename
specified in the edit control is expanded to a fully
qualified filename and added to the list box.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ListBox1.Items.Add(SysUtils.ExpandFileName(Edit1.Text));
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Label2.Caption := ExtractFilePath(Application.ExeName);
end;
```

See Also

ExtractFileName (see page 22844)

ExpandUNCFileName (see page 22842)

ExpandFileNameCase (see page 22841)

159.3.73 SysUtils.ExpandFileNameCase Function

Returns the full path name for a relative file name on a case-sensitive file system.

Pascal

```
function ExpandFileNameCase(const FileName: string; out MatchFound: TFilenameCaseMatch):
string;
```

C++

```
AnsiString ExpandFileNameCase(const AnsiString FileName, TFilenameCaseMatch MatchFound);
```

File

SysUtils

Description

ExpandFileNameCase expands a relative file name into a fully qualified path name, then attempts to find the file or a close case-insensitive match. This is useful when converting file name data from case-insensitive conventions (Windows) to case-sensitive conventions (Linux). It is also useful for validating file names entered by users unfamiliar with Linux conventions.

FileName is the relative file name to expand.

MatchFound indicates what match, if any, was found for FileName.

The return value is the fully qualified path name generated by ExpandFileNameCase. Its relationship to FileName depends on the value of MatchFound, as indicated in the following table:

MatchFound	Return value
mkNone	The fully qualified path name, as returned by ExpandFileName (see page 22840).
mkExactMatch	The fully qualified path name for the single case-sensitive match to FileName. This is the same value as the one returned when MatchFound is mkNone.
mkSingleMatch	(Linux only.) The fully qualified path name for the single file that matches FileName case-insensitively.
mkAmbiguous	(Linux only.) The fully qualified path name for one of the case-insensitve matches to FileName. This path name is not the same as the specified file, and not necessarily the closest match.

Note: ExpandFileNameCase is much slower than ExpandFileName (see page 22840), particularly when the specified file name is ambiguous or does not match an actual file.

See Also

ExpandFileName (see page 22840)

159.3.74 SysUtils.ExpandUNCFileName Function

Returns the full path of a file name in UNC format, if appropriate.

Pascal

```
function ExpandUNCFileName(const FileName: string): string;
```

C++

```
AnsiString ExpandUNCFileName(const AnsiString FileName);
```

File

SysUtils

Description

ExpandUNCFileName returns the fully-qualified file name for a specified file name.

Note: On Windows, ExpandUNCFileName returns a fully qualified path name using Universal Naming Convention for network files. For files on local disks, ExpandUNCFileName is equivalent to ExpandFileName (see page 22840). In a UNC file name, the drive prefix is replaced with the name of the network resource to which the drive is mapped. For example, if the working directory is J:\ourdir and drive J is mapped to \\ourserver\ourshare, ExpandUNCFileName('ourfile') returns "\\ourserver\ourshare\ourdir\ourfile".

Note: On Linux, ExpandUNCFileName is always equivalent to ExpandFileName (see page 22840).

See Also

ExpandFileName (see page 22840)

ExtractFileDrive (see page 22843)

159.3.75 SysUtils.ExtractFileDir Function

Extracts the drive and directory parts from FileName.

Pascal

```
function ExtractFileDir(const FileName: string): string;
```

C++

```
AnsiString ExtractFileDir(const AnsiString FileName);
```

File

SysUtils

Description

The resulting string is a directory name suitable for passing to the CreateDir (see page 22817), GetCurrentDir (see page 22910), RemoveDir (see page 22933), and SetCurrentDir (see page 22940) functions. This string is empty if FileName contains no drive and directory parts.

Note: This function works for multi-byte character systems (MBCS).

See Also

CreateDir (see page 22817)

GetCurrentDir (see page 22910)

RemoveDir (see page 22933)

SetCurrentDir (see page 22940)

159.3.76 SysUtils.ExtractFileDrive Function

Returns the drive portion of a file name.

Pascal

```
function ExtractFileDrive(const FileName: string): string;
```

C++

```
AnsiString ExtractFileDrive(const AnsiString FileName);
```

File

SysUtils

Description

Note: On Windows, ExtractFileDrive returns a string containing the drive portion of a fully qualified path name for the file passed in the FileName. For file names with drive letters, the result is in the form '"<drive>"'. For file names with a UNC path the result is in the form '"\\<servername>\<sharename>"'. If the given path contains neither style of path prefix, the result is an empty string.

Note: On Linux, ExtractFileDrive always returns a zero-length string.

See Also

ExpandFileName (see page 22840)

ExpandUNCFileName (see page 22842)

159.3.77 SysUtils.ExtractFileExt Function

Returns the extension portions of a file name.

Pascal

```
function ExtractFileExt(const FileName: string): string;
```

C++

```
AnsiString ExtractFileExt(const AnsiString FileName);
```

File

SysUtils

Description

Use ExtractFileExt to obtain the extension from a file name. For example, the following code returns the extension of the file name specified by a variable named MyFileName:

MyFilesExtension := ExtractFileExt(MyFileName); // Delphi

MyFilesExtension = ExtractFileExt(MyFileName); // C++

The resulting string includes the period character that separates the name and extension parts. This string is empty if the given file name has no extension.

Note: This function works for multi-byte character systems (MBCS).

See Also

ExtractFileName (see page 22844)

159.3.78 SysUtils.ExtractFileName Function

Extracts the name and extension parts of a file name.

Pascal

```
function ExtractFileName(const FileName: string): string;
```

C++

```
AnsiString ExtractFileName(const AnsiString FileName);
```

File

SysUtils

Description

The resulting string is the rightmost characters of FileName, starting with the first character after the colon or backslash that separates the path information from the name and extension. The resulting string is equal to FileName if FileName contains no drive and directory parts.

Note: This function works for multi-byte character systems (MBCS).

Delphi Examples:

```
{
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  BackupName: string;
  FileHandle: Integer;
  StringLen: Integer;
  X, Y, I: Integer;
  colCountLength, rowCountLength: Integer;
  Buffer: PChar;
  cellString: string;
begin
  if SaveDialog1.Execute then
  begin
    if FileExists(SaveDialog1.FileName) then
    begin
      BackupName := SysUtils.ExtractFileName(SaveDialog1.FileName);
      BackupName := ChangeFileExt(BackupName, '.BAK');
      if not RenameFile(SaveDialog1.FileName, BackupName) then
        raise Exception.Create('Unable to create backup file.');
    end;
    FileHandle := FileCreate(SaveDialog1.FileName);
    { Write out the number of rows and columns in the grid. }
    colCountLength := SizeOf(StringGrid1.ColCount);
    FileWrite(FileHandle,
      Pchar(StringGrid1.ColCount), colCountLength);
    rowCountLength := SizeOf(StringGrid1.RowCount);
    FileWrite(FileHandle,
      PChar(StringGrid1.RowCount), rowCountLength);
    for X := 0 to StringGrid1.ColCount - 1 do
    begin
      for Y := 0 to StringGrid1.RowCount - 1 do
      begin
        try
          { Write out the length of each string, followed by the string itself. }
          StringLen := Length(StringGrid1.Cells[X,Y]);
          FileWrite(FileHandle, PChar(StringLen), SizeOf(StringLen));
          GetMem(Buffer, StringLen); { allocate the buffer }
          cellString := StringGrid1.Cells[X,Y];
          for I := 1 to StringLen do
             Buffer[I - 1] := cellString[I];
          FileWrite(FileHandle, Buffer^, StringLen);
        finally
          FreeMem(Buffer, StringLen);
        end;
      end;
    end;
    FileClose(FileHandle);
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  with StringGrid1 do
```

```
  begin
    Cells[1,0] := 'Column 1';
    Cells[2,0] := 'Column 2';
    Cells[3,0] := 'Column 3';
    Cells[4,0] := 'Column 4';
    Cells[0,1] := 'Row 1';
    Cells[1,1] := 'Object';
    Cells[2,1] := 'Pascal';
    Cells[3,1] := 'is';
    Cells[4,1] := 'excellent';
    Cells[0,2] := 'Row 2';
    Cells[1,2] := 'Delphi';
    Cells[2,2] := 'is';
    Cells[4,2] := 'RAD';
  end;
end;
```

See Also

ExpandFileName (see page 22840)

ExtractFilePath (see page 22846)

159.3.79 SysUtils.ExtractFilePath Function

Returns the drive and directory portions of a file name.

Pascal

```
function ExtractFilePath(const FileName: string): string;
```

C++

```
AnsiString ExtractFilePath(const AnsiString FileName);
```

File

SysUtils

Description

The resulting string is the leftmost characters of FileName, up to and including the colon or backslash that separates the path information from the name and extension. The resulting string is empty if FileName contains no drive and directory parts.

This function works for multi-byte character systems (MBCS).

C++ Examples:

```
/*
This example copies a specified old file to a new file.  Add
a TSaveDialog to the form.  Also add two TEdits, two TLabels
and a TButton with the OnClick event named Save1Click. Files
can be saved to and from the app directory by using relative
paths.
*/
void __fastcall TForm1::Save1Click(TObject *Sender)
{

ExtractFileName (see page 22844)

159.3.80 SysUtils.ExtractRelativePath Function

Returns a relative path name, relative to a specific base directory.

Pascal

```
function ExtractRelativePath(const BaseName: string; const DestName: string): string;
```

C++

```
AnsiString ExtractRelativePath(const AnsiString BaseName, const AnsiString DestName);
```

File

SysUtils

Description

Call ExtractRelativePath to convert a fully qualified path name into a relative path name. The `DestName` parameter specifies file name (including path) to be converted. `BaseName` is the fully qualified name of the base directory to which the returned path name should be relative. `BaseName` may or may not include a file name, but it must include the final path delimiter.

Note: If you send it what should be a directory without the trailing backslash (c:\foo

instead of `c:\foo\`), the function treats `foo` as a file and returns undesirable results. You should correctly call it like this:

```
ExtractRelativePath('c:\foo\', 'c:\bar\')
```

so that it would return

```
'..\bar\'
```

.

```
ExtractRelativePath('c:\foo\', 'c:\bar')
```

would return the incorrect result, probably like

```
'..'
```

.

159.3.81 SysUtils.ExtractShortPathName Function

Converts a file name to the short 8.3 form.

Pascal

```
function ExtractShortPathName(const FileName: string): string;
```

C++

```
AnsiString ExtractShortPathName(const AnsiString FileName);
```

File

SysUtils

Description

ExtractShortPathName converts the file name, FileName, to the short 8.3 form. ExtractShortPathName returns an empty string if the file or directory does not exist.

The first parameter, FileName, can be a full path name. For example, ExtractShortPathName would convert the full path name:

C:\Program Files\MyCompany\MyApp\MyApp.exe

to the short form:

C:\Progra~1\MyComp~1\MyApp\MyApp.exe

Note: ExtractShortPathName is only available on Windows.

ExpandUNCFileName (see page 22842)

159.3.82 SysUtils.FileAge Function

Returns the OS timestamp of a file.

Pascal

```
function FileAge(const FileName: string): Integer; overload; deprecated;
function FileAge(const FileName: string; out FileDateTime: TDateTime): Boolean; overload;
```

C++

```
int FileAge(const AnsiString FileName);
Boolean FileAge(const AnsiString FileName, TDateTime FileDateTime);
```

File

SysUtils

Description

Call FileAge to obtain the OS timestamp of the file specified by FileName. The return value can be converted to a TDateTime object using the FileDateToDateTime (see page 22858) function. The return value is -1 if the file does not exist.

Note: :Under Linux, -1 is a valid timestamp. Use FileExists (see page 22860) to verify that the file does not exist.

C++ Examples:

```
/*
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings:
*/
#include "fattrdlg.h"

void __fastcall TForm1::FileListMouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{

  unsigned short  Attributes;
  unsigned short  NewAttributes;

  FileAttrDlg->FileDirName->Caption = FileList->Items->Strings[FileList->ItemIndex];
  FileAttrDlg->FilePathName->Caption = FileList->Directory;
  FileAttrDlg->ChangeDate->Caption =
DateTimeToStr(FileDateToDateTime(FileAge(FileList->FileName)));
  Attributes = FileGetAttr(FileList->Items->Strings[FileList->ItemIndex]);
  FileAttrDlg->ReadOnly->Checked = Attributes & faReadOnly;
  FileAttrDlg->Archive->Checked = Attributes & faArchive;
```

```
  FileAttrDlg->System->Checked = Attributes & faSysFile;
  FileAttrDlg->Hidden->Checked = Attributes & faHidden;
  if (FileAttrDlg->ShowModal()!= mrCancel){
     NewAttributes = Attributes;
     if (FileAttrDlg->ReadOnly->Checked)
       NewAttributes = NewAttributes | faReadOnly;
     else
        NewAttributes = NewAttributes & ~faReadOnly;

     if (FileAttrDlg->Archive->Checked)
       NewAttributes = NewAttributes | faArchive;
     else
       NewAttributes = NewAttributes & ~faArchive;

     if (FileAttrDlg->System->Checked)
       NewAttributes = NewAttributes | faSysFile;
     else
       NewAttributes = NewAttributes & ~faSysFile;

     if (FileAttrDlg->Hidden->Checked)
       NewAttributes = NewAttributes | faHidden;
     else
       NewAttributes = NewAttributes  & ~faHidden;
     if (NewAttributes != Attributes)
       FileSetAttr(FileAttrDlg->FileDirName->Caption, NewAttributes);
  }
}
```

Delphi Examples:

```
{
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings:
}
procedure TForm1.FileListMouseUp(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
var
  Attributes, NewAttributes: Word;
begin
  with FileAttrForm do
  begin
    FileDirName.Caption := FileList.Items[FileList.ItemIndex];
    { set box caption }
    FilePathName.Caption := FileList.Directory;
    { show directory name }
    ChangeDate.Caption := DateTimeToStr(FileDateToDateTime(FileAge(FileList.FileName)));
    Attributes := SysUtils.FileGetAttr(FileDirName.Caption);
    { read file attributes }
    ReadOnly.Checked := (Attributes and SysUtils.faReadOnly) = faReadOnly;
    Archive.Checked := (Attributes and faArchive) = faArchive;
    System.Checked := (Attributes and faSysFile) = faSysFile;
    Hidden.Checked := (Attributes and faHidden) = faHidden;
    if ShowModal <> id_Cancel then    { execute dialog box }
    begin
      NewAttributes := Attributes;
      { start with original attributes }
      if ReadOnly.Checked then
        NewAttributes := NewAttributes or SysUtils.faReadOnly
      else
        NewAttributes := NewAttributes and not SysUtils.faReadOnly;
      if Archive.Checked then
        NewAttributes := NewAttributes or faArchive
      else
```

```
          NewAttributes := NewAttributes and not faArchive;
        if System.Checked then
          NewAttributes := NewAttributes or faSysFile
        else
          NewAttributes := NewAttributes and not faSysFile;
        if Hidden.Checked then
          NewAttributes := NewAttributes or faHidden
        else
          NewAttributes := NewAttributes and not faHidden;
        if NewAttributes <> Attributes then { if anything changed... }
          FileSetAttr(FileDirName.Caption, NewAttributes);
           { ...write the new values }
      end;
    end;
  end;
```

159.3.83 SysUtils.FileClose Function

Closes a specified file.

Pascal

```
procedure FileClose(Handle: Integer);
```

C++

```
FileClose(int Handle);
```

File

SysUtils

Description

FileClose closes a file given its handle. The handle is obtained when the file is opened using FileOpen (see page 22867) or FileCreate (see page 22855).

Note: : When working with Delphi language file variables, use the CloseFile procedure instead.

C++ Examples:

```
/*
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
*/

#include <dir.h>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char szFileName[MAXFILE+4];
```

```
  int iFileHandle;
  int iLength;
  if (SaveDialog1->Execute())
  {
    if (FileExists(SaveDialog1->FileName))
    {
      fnsplit(SaveDialog1->FileName.c_str(), 0, 0, szFileName, 0);
      strcat(szFileName, ".BAK");
      RenameFile(SaveDialog1->FileName, szFileName);
    }
    iFileHandle = FileCreate(SaveDialog1->FileName);
    // Write out the number of rows and columns in the grid.
    FileWrite(iFileHandle, (char*)&(StringGrid1->ColCount), sizeof(StringGrid1->ColCount));
    FileWrite(iFileHandle, (char*)&(StringGrid1->RowCount), sizeof(StringGrid1->RowCount));
    for (int x=0;x<StringGrid1->ColCount;x++)
    {
      for (int y=0;y<StringGrid1->RowCount;y++)
      {
        // Write out the length of each string, followed by the string itself.
        iLength = StringGrid1->Cells[x][y].Length();
        FileWrite(iFileHandle, (char*)&iLength, sizeof(iLength));
        FileWrite(iFileHandle, StringGrid1->Cells[x][y].c_str(),
StringGrid1->Cells[x][y].Length());
      }
    }
    FileClose(iFileHandle);
  }
}
//---------------------------------------------------------------------------
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  StringGrid1->Cells[1][0] = "Column 1";
  StringGrid1->Cells[2][0] = "Column 2";
  StringGrid1->Cells[3][0] = "Column 3";
  StringGrid1->Cells[4][0] = "Column 4";
  StringGrid1->Cells[0][1] = "Row 1";
  StringGrid1->Cells[1][1] = "Object";
  StringGrid1->Cells[2][1] = "Pascal";
  StringGrid1->Cells[3][1] = "is";
  StringGrid1->Cells[4][1] = "excellent";

159.3.84 SysUtils.FileCreate Function

Creates a new file.

Pascal

```
function FileCreate(const FileName: string): Integer; overload;
function FileCreate(const FileName: string; Rights: Integer): Integer; overload;
```

C++

```
int FileCreate(const AnsiString FileName);
int FileCreate(const AnsiString FileName, int Rights);
```

File

SysUtils

Description

FileCreate creates a new file with the specified name. If the return value is positive, the function was successful and the value is the file handle of the new file. A return value of -1 indicates that an error occurred.

Note: On Windows, the FileAccessRights variable and Rights parameter are ignored.

Note: On Linux, a file has a set of permission bits controlling access to the file. The first form of FileCreate takes the permission bits from the global FileAccessRights variable. The second form takes the permission bits from the Rights parameter. In either case, the permission bits are masked by the current process's umask value.

C++ Examples:

```
/*
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
*/

#include <dir.h>

159.3.85 SysUtils.FileDateToDateTime Function

Converts an OS timestamp value to TDateTime value.

Pascal

```
function FileDateToDateTime(FileDate: Integer): TDateTime;
```

C++

```
TDateTime FileDateToDateTime(int FileDate);
```

File

SysUtils

Description

A timestamp is a signed 32-bit integer, used by the OS to record information such as the date and time a file was modified. The precise format of a timestamp depends on the OS. Use FileDateToDateTime to convert a timestamp to a TDateTime value.

You may need to use FileDateToDateTime to convert the Time (see page 22976) field of the TSearchRec (see page 23005) type used by the FindFirst (see page 22884) and FindNext (see page 22887) functions.

C++ Examples:

```
/*
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
```

```
changed settings:
*/
#include "fattrdlg.h"

void __fastcall TForm1::FileListMouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{

  unsigned short  Attributes;
  unsigned short  NewAttributes;

  FileAttrDlg->FileDirName->Caption = FileList->Items->Strings[FileList->ItemIndex];
  FileAttrDlg->FilePathName->Caption = FileList->Directory;
  FileAttrDlg->ChangeDate->Caption =
DateTimeToStr(FileDateToDateTime(FileAge(FileList->FileName)));
  Attributes = FileGetAttr(FileList->Items->Strings[FileList->ItemIndex]);
  FileAttrDlg->ReadOnly->Checked = Attributes & faReadOnly;
  FileAttrDlg->Archive->Checked = Attributes & faArchive;
  FileAttrDlg->System->Checked = Attributes & faSysFile;
  FileAttrDlg->Hidden->Checked = Attributes & faHidden;
  if (FileAttrDlg->ShowModal()!= mrCancel){
     NewAttributes = Attributes;
     if (FileAttrDlg->ReadOnly->Checked)
       NewAttributes = NewAttributes | faReadOnly;
     else
        NewAttributes = NewAttributes & ~faReadOnly;

     if (FileAttrDlg->Archive->Checked)
       NewAttributes = NewAttributes | faArchive;
     else
       NewAttributes = NewAttributes & ~faArchive;

     if (FileAttrDlg->System->Checked)
       NewAttributes = NewAttributes | faSysFile;
     else
       NewAttributes = NewAttributes & ~faSysFile;

     if (FileAttrDlg->Hidden->Checked)
       NewAttributes = NewAttributes | faHidden;
     else
       NewAttributes = NewAttributes  & ~faHidden;
     if (NewAttributes != Attributes)
       FileSetAttr(FileAttrDlg->FileDirName->Caption, NewAttributes);
  }
}
```

Delphi Examples:

```
{
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings:

159.3.86 SysUtils.FileExists Function

Tests if a specified file exists.

Pascal

```
function FileExists(const FileName: string): Boolean;
```

C++

```
Boolean FileExists(const AnsiString FileName);
```

File

SysUtils

Description

FileExists returns true if the file specified by FileName exists. If the file does not exist, FileExists returns false.

C++ Examples:

```
/*
```

```
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
*/

#include <dir.h>

159.3.87 SysUtils.FileGetAttr Function

Returns the file attributes of FileName.

Pascal

```
function FileGetAttr(const FileName: string): Integer; platform;
```

C++

```
int FileGetAttr(const AnsiString FileName);
```

File

SysUtils

Description

FileGetAttr returns the attributes of the file as a string of bits. This value is the same as the Attr field of a TSearchRec (see page 23005) type. Check for individual attributes with code such as the following:

Attrs := FileGetAttr('MyFile.sys');

```
if Attrs and faHidden <> 0 then
  FileSetAttr('MyFile.sys', Attrs – faHidden);
```

int Attrs = FileGetAttr("MyFile.sys");

```
if (Attrs & faHidden)
  FileSetAttr("MyFile.sys", Attrs & !faHidden);
```

A return value of -1 indicates that an error occurred.

Note: See TSearchRec (see page 23005) for a description of the individual attribute constants.

Note: FileGetAttr is Windows-only.

C++ Examples:

```
/*
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings:
*/
#include "fattrdlg.h"

void __fastcall TForm1::FileListMouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{

  unsigned short  Attributes;
  unsigned short  NewAttributes;

  FileAttrDlg->FileDirName->Caption = FileList->Items->Strings[FileList->ItemIndex];
  FileAttrDlg->FilePathName->Caption = FileList->Directory;
  FileAttrDlg->ChangeDate->Caption =
DateTimeToStr(FileDateToDateTime(FileAge(FileList->FileName)));
  Attributes = FileGetAttr(FileList->Items->Strings[FileList->ItemIndex]);
  FileAttrDlg->ReadOnly->Checked = Attributes & faReadOnly;
  FileAttrDlg->Archive->Checked = Attributes & faArchive;
  FileAttrDlg->System->Checked = Attributes & faSysFile;
  FileAttrDlg->Hidden->Checked = Attributes & faHidden;
  if (FileAttrDlg->ShowModal()!= mrCancel){
     NewAttributes = Attributes;
     if (FileAttrDlg->ReadOnly->Checked)
       NewAttributes = NewAttributes | faReadOnly;
```

```
      else
         NewAttributes = NewAttributes & ~faReadOnly;

      if (FileAttrDlg->Archive->Checked)
        NewAttributes = NewAttributes | faArchive;
      else
        NewAttributes = NewAttributes & ~faArchive;

      if (FileAttrDlg->System->Checked)
        NewAttributes = NewAttributes | faSysFile;
      else
        NewAttributes = NewAttributes & ~faSysFile;

      if (FileAttrDlg->Hidden->Checked)
        NewAttributes = NewAttributes | faHidden;
      else
        NewAttributes = NewAttributes  & ~faHidden;
      if (NewAttributes != Attributes)
        FileSetAttr(FileAttrDlg->FileDirName->Caption, NewAttributes);
  }
}
```

Delphi Examples:

```
{
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings:
}
procedure TForm1.FileListMouseUp(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
var
  Attributes, NewAttributes: Word;
begin
  with FileAttrForm do
  begin
    FileDirName.Caption := FileList.Items[FileList.ItemIndex];
    { set box caption }
    FilePathName.Caption := FileList.Directory;
    { show directory name }
    ChangeDate.Caption := DateTimeToStr(FileDateToDateTime(FileAge(FileList.FileName)));
    Attributes := SysUtils.FileGetAttr(FileDirName.Caption);
    { read file attributes }
    ReadOnly.Checked := (Attributes and SysUtils.faReadOnly) = faReadOnly;
    Archive.Checked := (Attributes and faArchive) = faArchive;
    System.Checked := (Attributes and faSysFile) = faSysFile;
    Hidden.Checked := (Attributes and faHidden) = faHidden;
    if ShowModal <> id_Cancel then    { execute dialog box }
    begin
      NewAttributes := Attributes;
      { start with original attributes }
      if ReadOnly.Checked then
        NewAttributes := NewAttributes or SysUtils.faReadOnly
      else
        NewAttributes := NewAttributes and not SysUtils.faReadOnly;
      if Archive.Checked then
        NewAttributes := NewAttributes or faArchive
      else
        NewAttributes := NewAttributes and not faArchive;
      if System.Checked then
        NewAttributes := NewAttributes or faSysFile
      else
        NewAttributes := NewAttributes and not faSysFile;
      if Hidden.Checked then
```

```
          NewAttributes := NewAttributes or faHidden
        else
          NewAttributes := NewAttributes and not faHidden;
        if NewAttributes <> Attributes then { if anything changed... }
          FileSetAttr(FileDirName.Caption, NewAttributes);
           { ...write the new values }
      end;
    end;
  end;
```

See Also

FileSetAttr (see page 22875)

159.3.88 SysUtils.FileGetDate Function

Returns an OS timestamp for a specified file.

Pascal

```
function FileGetDate(Handle: Integer): Integer;
```

C++

```
int FileGetDate(int Handle);
```

File

SysUtils

Description

Use FileGetDate to determine the timestamp of a file given its handle. The return value is -1 if the handle is invalid. The FileDateToDateTime (see page 22858) function can be used to convert the returned value to a TDateTime value.

Note: :FileGetDate uses a file handle rather than a native Delphi file variable. To obtain the timestamp of a file that has not been opened using the FileOpen (see page 22867) or FileCreate (see page 22855) method, use the FileAge (see page 22850) function instead.

Note: :Under Linux, -1 is a valid timestamp. Use FileExists (see page 22860) to verify that the file does not exist.

See Also

FileSetDate (see page 22878)

FileDateToDateTime (see page 22858)

FileAge (see page 22850)

FileExists (see page 22860)

159.3.89 SysUtils.FileIsReadOnly Function

Reports whether a file is read-only.

Pascal

```
function FileIsReadOnly(const FileName: string): Boolean;
```

C++

```
Boolean FileIsReadOnly(const AnsiString FileName);
```

File

SysUtils

Description

FileIsReadOnly returns **True** if FileName can be found and opened, but the current process does not have permission to write to it.

Note: On Windows XP, FileIsReadOnly returns **True** if the file does **not** exist.

159.3.90 SysUtils.FileOpen Function

Opens a specified file using a specified access mode.

Pascal

```
function FileOpen(const FileName: string; Mode: LongWord): Integer;
```

C++

```
int FileOpen(const AnsiString FileName, LongWord Mode);
```

File

SysUtils

Description

Use FileOpen to open a file and obtain a file handle. The access mode value is constructed by or-ing one of the fmOpen constants with one of the fmShare constants defined in File open mode constants. If the return value is 0 or greater, the function was successful and the value is the file handle of the opened file. A return value of -1 indicates that an error occurred.

Note: Use of the non-native Delphi language file handlers such as FileOpen is not encouraged. These routines map to system routines and return OS file handles, not normal Delphi file variables. These are low-level file access routines. For normal file operations use AssignFile, Rewrite, and Reset instead.

C++ Examples:

```
/*
The following example uses a button, a string grid, and an
Open dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the specified file is opened, read into a buffer, and closed.
Then the buffer is displayed in two columns of the string
grid. The first column contains the character values in the
buffer. The second column contains the numeric values of the
characters in the buffer.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int iFileHandle;
  int iFileLength;
  int iBytesRead;
  char *pszBuffer;
  if (OpenDialog1->Execute())
  {
```

```
    try
    {
      iFileHandle = FileOpen(OpenDialog1->FileName, fmOpenRead);
      iFileLength = FileSeek(iFileHandle,0,2);
      FileSeek(iFileHandle,0,0);
      pszBuffer = PChar(AllocMem(iFileLength+1));
//    pszBuffer = new char[iFileLength+1];
      iBytesRead = FileRead(iFileHandle, pszBuffer, iFileLength);
      FileClose(iFileHandle);
      for (int i=0;i<iBytesRead;i++)
      {
        StringGrid1->RowCount += 1;
        StringGrid1->Cells[1][i+1] = pszBuffer[i];
        StringGrid1->Cells[2][i+1] = IntToStr((int)pszBuffer[i]);
      }
      delete [] pszBuffer;
    }
    catch(...)
    {
      Application->MessageBox("Can't perform one of the following file operations: Open, Seek,
Read, Close.", "File Error", IDOK);
    }
  }
}
```

Delphi Examples:

```
{
This example uses a file listbox and a regular listbox on a
form. The following routine scans through the files listed
in the file listbox and lists the sizes of any selected
files to the regular list box.  To exercise the error
condition create a file in the Debug directory, start this
application and then delete the file.  Now try to list the
size of the deleted file.  Set the MultiSelect and
ExtendedSelect properties on the FileListBox.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  F: File;
  i, filehandle: Integer;
begin
  for i := 0 to (FileListBox1.Items.Count - 1) do begin
  try
    if FileListBox1.Selected[i] then
    begin
      if not FileExists(FileListBox1.Items.Strings[i]) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' not found', mtError, [mbOk], 0);
        Continue;
      end;
      filehandle:=  FileOpen(FileListBox1.Items.Strings[i], 1);
      if (filehandle = -1) then
      begin
        MessageDlg('File: ' + FileListBox1.Items.Strings[i] +
                   ' cannot be opened with access mode 1.', mtError, [mbOk], 0);
        Continue;
      end
      else
        FileClose(filehandle);

      AssignFile(F, FileListBox1.Items.Strings[i]);
      Reset(F, 1);
      ListBox1.Items.Add(
        FileListBox1.Items.Strings[i] + ': ' + IntToStr(FileSize(F)));
      CloseFile(F);
```

```
    end;
   finally
   { do something here }
   end;
  end;
end;
{
This example requires a TEdit, a button and a string grid.
Enter the file name in the TEdit and click the button to open
that file.  Notice that the file cannot be read.  Remove the
fmOpenWrite and the fmShareDenyNone access and the string
grid loads fine.
}

159.3.91 SysUtils.FileRead Function

Reads a specified number of bytes from a file.

Pascal

```
function FileRead(Handle: Integer; var Buffer; Count: LongWord): Integer;
```

C++

```
int FileRead(int Handle,  Buffer, LongWord Count);
```

File

SysUtils

Description

FileRead reads Count bytes from the file specified by Handle into the buffer. The Count parameter indicates the size, in bytes, of the buffer. The function result is the actual number of bytes read, which may be less than Count. The Handle that is passed to FileRead must be opened with FileOpen (see page 22867) or FileCreate (see page 22855).

Note: :In Delphi, do not mix routines that take or return file handles with those that use Delphi language file variables (typically seen as var F). To read from a file specified by a Delphi file variable, use the BlockRead procedure or the Read procedure instead.

C++ Examples:

```
/*
```

```

159.3.92 SysUtils.FileSearch Function

Searches a specified directory path for a file.

Pascal

```
function FileSearch(const Name: string; const DirList: string): string;
```

C++

```
AnsiString FileSearch(const AnsiString Name, const AnsiString DirList);
```

File

SysUtils

Description

FileSearch searches through the directories passed in DirList for a file named Name. DirList is a list of path names delimited by semicolons on Windows, colons on Linux). If FileSearch locates a file matching Name, it returns a string specifying a path name for that file. If no matching file exists, FileSearch returns an empty string.

C++ Examples:

```
/*
The following example uses an edit control and a button on a
form. When the button is clicked, the current directory is
searched for the filename specified in the edit control. A
message box indicates whether the file is found.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString asFileName = FileSearch(Edit1->Text, GetCurrentDir());
```

```
  if (asFileName.IsEmpty())
    ShowMessage(AnsiString("Couldn't find ") + Edit1->Text + ".");
  else
    ShowMessage(AnsiString("Found ") + asFileName + ".");
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Label2->Caption = GetCurrentDir();
}
```

Delphi Examples:

```
{
The following example uses an edit control and a button on a
form. When the button is clicked, the current directory is
searched for the filename specified in the edit control. A
message box indicates whether the file is found.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  FileToFind: string;
begin
  FileToFind := SysUtils.FileSearch(Edit1.Text, GetCurrentDir);
  if FileToFind = '' then
    ShowMessage('Couldn''t find ' + Edit1.Text + '.')
  else
    ShowMessage('Found ' + FileToFind + '.');
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Label2.Caption := GetCurrentDir;
end;
```

FileExists (see page 22860)

159.3.93 SysUtils.FileSeek Function

Repositions read/write point.

Pascal

```
function FileSeek(Handle: Integer; Offset: Integer; Origin: Integer): Integer; overload;
function FileSeek(Handle: Integer; const Offset: Int64; Origin: Integer): Int64; overload;
```

C++

```
int FileSeek(int Handle, int Offset, int Origin);
Int64 FileSeek(int Handle, const Int64 Offset, int Origin);
```

File

SysUtils

Description

Use FileSeek to reposition the read/write point in a file that was opened with FileOpen (see page 22867) or FileCreate (see page 22855). Handle is the file handle that was returned by FileOpen (see page 22867) or FileCreate (see page 22855).

Offset specifies the number of bytes from Origin where the file pointer should be positioned. Origin is a code with three possible values, denoting the beginning of the file, the end of the file, and the current position of the file pointer.

Origin	Action
0	The file pointer is positioned Offset bytes from the beginning of the file.
1	The file pointer is positioned Offset bytes from its current position.
2	The file pointer is positioned Offset bytes from the end of the file.

If FileSeek is successful, it returns the new position of the file pointer; otherwise, it returns -1.

Note: :Do not mix routines that take or return file handles with those that use Delphi language file variables (typically seen as var F). To move the file pointer in a file specified by a Delphi file variable, use the Seek procedure instead.

C++ Examples:

```
/*
The following example uses a button, a string grid, and an
Open dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the specified file is opened, read into a buffer, and closed.
Then the buffer is displayed in two columns of the string
grid. The first column contains the character values in the
buffer. The second column contains the numeric values of the
characters in the buffer.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int iFileHandle;
  int iFileLength;
  int iBytesRead;
  char *pszBuffer;
  if (OpenDialog1->Execute())
  {
    try
    {
      iFileHandle = FileOpen(OpenDialog1->FileName, fmOpenRead);
      iFileLength = FileSeek(iFileHandle,0,2);
      FileSeek(iFileHandle,0,0);
      pszBuffer = PChar(AllocMem(iFileLength+1));
//    pszBuffer = new char[iFileLength+1];
      iBytesRead = FileRead(iFileHandle, pszBuffer, iFileLength);
      FileClose(iFileHandle);
      for (int i=0;i<iBytesRead;i++)
      {
        StringGrid1->RowCount += 1;
        StringGrid1->Cells[1][i+1] = pszBuffer[i];
        StringGrid1->Cells[2][i+1] = IntToStr((int)pszBuffer[i]);
      }
      delete [] pszBuffer;
    }
    catch(...)
    {
      Application->MessageBox("Can't perform one of the following file operations: Open, Seek,
Read, Close.", "File Error", IDOK);
    }
  }
}
```

Delphi Examples:

```
{
The following example uses a button, a string grid, and an
Open dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
```

```
  the specified file is opened, read into a buffer, and closed.
  Then the buffer is displayed in two columns of the string
  grid. The first column contains the character values in the
  buffer. The second column contains the numeric values of the
  characters in the buffer.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    iFileHandle: Integer;
    iFileLength: Integer;
    iBytesRead: Integer;
    Buffer: PChar;
    i: Integer;
  begin
    if OpenDialog1.Execute then
    begin
      try
        iFileHandle := SysUtils.FileOpen(OpenDialog1.FileName, fmOpenRead);
        iFileLength := SysUtils.FileSeek(iFileHandle,0,2);
        FileSeek(iFileHandle,0,0);
        Buffer := PChar(System.AllocMem(iFileLength + 1));
        iBytesRead := SysUtils.FileRead(iFileHandle, Buffer^, iFileLength);
        FileClose(iFileHandle);
        for i := 0 to iBytesRead-1 do
        begin
          StringGrid1.RowCount := StringGrid1.RowCount + 1;
          StringGrid1.Cells[1,i+1] := Buffer[i];
          StringGrid1.Cells[2,i+1] := IntToStr(Integer(Buffer[i]));
        end;
      finally
        FreeMem(Buffer);
      end;
    end;
  end;
```

159.3.94 SysUtils.FileSetAttr Function

Sets the file attributes of a specified file.

Pascal

```
function FileSetAttr(const FileName: string; Attr: Integer): Integer; platform;
```

C++

```
int FileSetAttr(const AnsiString FileName, int Attr);
```

File

SysUtils

Description

FileSetAttr sets the file attributes of the file given by FileName to the value given by Attr. The value of Attr is formed by combining the appropriate file attribute constants, as in the following:

```
FileSetAttr('MyFile.sys', faReadOnly or faSysFile); // Delphi
FileSetAttr("MyFile.sys", faReadOnly | faSysFile); // C++
```

FileSetAttr returns zero if the function was successful. Otherwise the return value is an error code.

Note: See TSearchRec (see page 23005) for a description of the file attribute constants.

Note: FileSetAttr is only available on Windows.

C++ Examples:

```
/*
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings:
*/
#include "fattrdlg.h"

void __fastcall TForm1::FileListMouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{

  unsigned short  Attributes;
  unsigned short  NewAttributes;

  FileAttrDlg->FileDirName->Caption = FileList->Items->Strings[FileList->ItemIndex];
  FileAttrDlg->FilePathName->Caption = FileList->Directory;
  FileAttrDlg->ChangeDate->Caption =
DateTimeToStr(FileDateToDateTime(FileAge(FileList->FileName)));
  Attributes = FileGetAttr(FileList->Items->Strings[FileList->ItemIndex]);
  FileAttrDlg->ReadOnly->Checked = Attributes & faReadOnly;
  FileAttrDlg->Archive->Checked = Attributes & faArchive;
  FileAttrDlg->System->Checked = Attributes & faSysFile;
  FileAttrDlg->Hidden->Checked = Attributes & faHidden;
  if (FileAttrDlg->ShowModal()!= mrCancel){
     NewAttributes = Attributes;
     if (FileAttrDlg->ReadOnly->Checked)
       NewAttributes = NewAttributes | faReadOnly;
     else
        NewAttributes = NewAttributes & ~faReadOnly;

     if (FileAttrDlg->Archive->Checked)
       NewAttributes = NewAttributes | faArchive;
     else
       NewAttributes = NewAttributes & ~faArchive;

     if (FileAttrDlg->System->Checked)
       NewAttributes = NewAttributes | faSysFile;
     else
       NewAttributes = NewAttributes & ~faSysFile;

     if (FileAttrDlg->Hidden->Checked)
       NewAttributes = NewAttributes | faHidden;
     else
       NewAttributes = NewAttributes  & ~faHidden;
```

```
      if (NewAttributes != Attributes)
        FileSetAttr(FileAttrDlg->FileDirName->Caption, NewAttributes);
    }
  }
```

Delphi Examples:

```
{
The following code reads a file's attributes into a set
variable, sets the check boxes in a file-attribute dialog
box to represent the current attributes, then executes the
dialog box. If the user changes and accepts any dialog box
settings, the code sets the file attributes to match the
changed settings:
}
procedure TForm1.FileListMouseUp(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
var
  Attributes, NewAttributes: Word;
begin
  with FileAttrForm do
  begin
    FileDirName.Caption := FileList.Items[FileList.ItemIndex];
    { set box caption }
    FilePathName.Caption := FileList.Directory;
    { show directory name }
    ChangeDate.Caption := DateTimeToStr(FileDateToDateTime(FileAge(FileList.FileName)));
    Attributes := SysUtils.FileGetAttr(FileDirName.Caption);
    { read file attributes }
    ReadOnly.Checked := (Attributes and SysUtils.faReadOnly) = faReadOnly;
    Archive.Checked := (Attributes and faArchive) = faArchive;
    System.Checked := (Attributes and faSysFile) = faSysFile;
    Hidden.Checked := (Attributes and faHidden) = faHidden;
    if ShowModal <> id_Cancel then    { execute dialog box }
    begin
      NewAttributes := Attributes;
      { start with original attributes }
      if ReadOnly.Checked then
        NewAttributes := NewAttributes or SysUtils.faReadOnly
      else
        NewAttributes := NewAttributes and not SysUtils.faReadOnly;
      if Archive.Checked then
        NewAttributes := NewAttributes or faArchive
      else
        NewAttributes := NewAttributes and not faArchive;
      if System.Checked then
        NewAttributes := NewAttributes or faSysFile
      else
        NewAttributes := NewAttributes and not faSysFile;
      if Hidden.Checked then
        NewAttributes := NewAttributes or faHidden
      else
        NewAttributes := NewAttributes and not faHidden;
      if NewAttributes <> Attributes then { if anything changed... }
        FileSetAttr(FileDirName.Caption, NewAttributes);
         { ...write the new values }
    end;
  end;
end;
```

159.3.95 SysUtils.FileSetDate Function

Sets the OS time stamp for a specified file.

Pascal

```
function FileSetDate(const FileName: string; Age: Integer): Integer; overload;
function FileSetDate(Handle: Integer; Age: Integer): Integer; overload; platform;
```

C++

```
int FileSetDate(const AnsiString FileName, int Age);
int FileSetDate(int Handle, int Age);
```

File

SysUtils

Description

FileSetDate sets the OS timestamp of the specified file to the value given by Age. The DateTimeToFileDate (see page 22821) function can be used to convert a TDateTime value to a OS timestamp.

Handle is the Windows file handle of the file to alter. This syntax is only available on Windows.

FileName is the name of the file to alter.

Age is the timestamp to apply to the specified file.

The return value is zero if the function was successful. Otherwise the return value is an error code.

See Also

FileCreate (see page 22855)

FileGetDate (see page 22866)

FileOpen (see page 22867)

DateTimeToFileDate (see page 22821)

159.3.96 SysUtils.FileSetReadOnly Function

Sets the file permissions to read-only.

Pascal

```
function FileSetReadOnly(const FileName: string; ReadOnly: Boolean): Boolean;
```

C++

```
Boolean FileSetReadOnly(const AnsiString FileName, Boolean ReadOnly);
```

File

SysUtils

Description

FileSetReadOnly attempts to set the read-only status of the specified file.

FileName is the name of the file to alter.

ReadOnly indicates the status to assign to the file.

FileSetReadOnly returns true if the operation was successful and false if an error occurred.

Note: On Windows, the ReadOnly parameter is assigned to the file's read-only flag.

Note: On Linux, the inverse of the ReadOnly parameter is assigned to the file's user write, group write, and other write permission bits. The active user must have permission to perform these operations.

FileSetReadOnly is designed to support cross-platform code. To manipulate permissions more specifically than FileSetReadOnly allows, use platform-specific functions.

159.3.97 SysUtils.FileWrite Function

Writes the contents of a buffer to the current position in a file.

Pascal

```
function FileWrite(Handle: Integer; const Buffer; Count: LongWord): Integer;
```

C++

```
int FileWrite(int Handle, const  Buffer, LongWord Count);
```

File

SysUtils

Description

FileWrite writes Count bytes to the file given by Handle from the buffer specified by Buffer. Handle is a file handle returned by the FileOpen (see page 22867) or FileCreate (see page 22855) method.

The return value is the number of bytes actually written, or -1 if an error occurred.

Note: :Do not mix routines that take or return file handles with those that use Delphi language file variables (typically seen as var F). To write to a file specified by a Delphi file variable, use Write, Writeln, or BlockWrite instead.

C++ Examples:

```
/*
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
*/

#include <dir.h>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char szFileName[MAXFILE+4];
  int iFileHandle;
  int iLength;
  if (SaveDialog1->Execute())
  {
    if (FileExists(SaveDialog1->FileName))
```

```
    {
      fnsplit(SaveDialog1->FileName.c_str(), 0, 0, szFileName, 0);
      strcat(szFileName, ".BAK");
      RenameFile(SaveDialog1->FileName, szFileName);
    }
    iFileHandle = FileCreate(SaveDialog1->FileName);
    // Write out the number of rows and columns in the grid.
    FileWrite(iFileHandle, (char*)&(StringGrid1->ColCount), sizeof(StringGrid1->ColCount));
    FileWrite(iFileHandle, (char*)&(StringGrid1->RowCount), sizeof(StringGrid1->RowCount));
    for (int x=0;x<StringGrid1->ColCount;x++)
    {
      for (int y=0;y<StringGrid1->RowCount;y++)
      {
        // Write out the length of each string, followed by the string itself.
        iLength = StringGrid1->Cells[x][y].Length();
        FileWrite(iFileHandle, (char*)&iLength, sizeof(iLength));
        FileWrite(iFileHandle, StringGrid1->Cells[x][y].c_str(),
StringGrid1->Cells[x][y].Length());
      }
    }
    FileClose(iFileHandle);
  }
}
//---------------------------------------------------------------------------

159.3.98 SysUtils.FinalizePackage Function

Finalizes the specified package (.bpl file).

Pascal

```
procedure FinalizePackage(Module: HMODULE);
```

C++

```
FinalizePackage(HMODULE Module);
```

File

SysUtils

Description

Most applications do not need to call FinalizePackage, because UnloadPackage (see page 22987) calls FinalizePackage internally. FinalizePackage executes any finalization code in the specified package.

See Also

UnloadPackage (see page 22987)

159.3.99 SysUtils.FindClose Function

Releases memory allocated by FindFirst (see page 22884).

Pascal

```
procedure FindClose(var F: TSearchRec);
```

C++

```
FindClose(TSearchRec F);
```

File

SysUtils

Description

FindClose terminates a FindFirst (see page 22884)/FindNext (see page 22887) sequence.

C++ Examples:

```
/*
The following example uses an edit control, a button, a
string grid, and seven check boxes. The check boxes
correspond to the seven possible file attributes. When the
button is clicked, the path specified in the edit control is
searched for files matching the checked file attributes. The
names and sizes of the matching files are inserted into the
string grid.  The Path constant parameter is the directory
and file name mask, including wildcard characters. For
example, '.\test\*.*' specifies all files in the current
directory).
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TSearchRec sr;
```

```
  int iAttributes = 0;
  StringGrid1->RowCount = 1;
  iAttributes |= faReadOnly * CheckBox1->Checked;
  iAttributes |= faHidden * CheckBox2->Checked;
  iAttributes |= faSysFile * CheckBox3->Checked;
  iAttributes |= faVolumeID * CheckBox4->Checked;
  iAttributes |= faDirectory * CheckBox5->Checked;
  iAttributes |= faArchive * CheckBox6->Checked;
  iAttributes |= faAnyFile * CheckBox7->Checked;
  StringGrid1->RowCount = 0;
  if (FindFirst(Edit1->Text, iAttributes, sr) == 0)
  {

159.3.100 SysUtils.FindCmdLineSwitch Function

Determines whether a string was passed as a command line argument to the application.

Pascal

```
function FindCmdLineSwitch(const Switch: string; const Chars: TSysCharSet; IgnoreCase:
Boolean): Boolean; overload;
function FindCmdLineSwitch(const Switch: string): Boolean; overload;
function FindCmdLineSwitch(const Switch: string; IgnoreCase: Boolean): Boolean; overload;
```

C++

```
Boolean FindCmdLineSwitch(const AnsiString Switch, const TSysCharSet Chars, Boolean
IgnoreCase);
Boolean FindCmdLineSwitch(const AnsiString Switch);
Boolean FindCmdLineSwitch(const AnsiString Switch, Boolean IgnoreCase);
```

File

SysUtils

Description

FindCmdLineSwitch determines whether a string represents a command-line switch, based on the first character of the string.

Switch is a command line parameter, typically provided by the ParamStr function.

Chars is the set of characters that distinguish switches from other parameters. If SwitchChars (see page 23065) is omitted, it defaults to '/' and '-' on Windows, and to '-' on Linux.

IgnoreCase determines whether case-insensitive character matching is used. The default is true on Windows, false on Linux.

ParamCount (see page 22495)

ParamStr (see page 22496)

159.3.101 SysUtils.FindFirst Function

Searches for the first instance of a file name with a given set of attributes in a specified directory.

Pascal

```
function FindFirst(const Path: string; Attr: Integer; var F: TSearchRec): Integer;
```

C++

```
int FindFirst(const AnsiString Path, int Attr, TSearchRec F);
```

File

SysUtils

Description

FindFirst searches the directory specified by Path for the first file that matches the file name implied by Path and the attributes specified by the Attr parameter. The result is returned in the F parameter. Use the fields of this search record to extract the information needed. FindFirst returns 0 if a file was successfully located, otherwise, it returns an error code.

The Path constant parameter is the directory and file name mask, including wildcard characters. For example, '.\test*.*' specifies all files in the test subdirectory.

The Attr parameter specifies the special files to include in addition to all normal files. Choose from these file attribute constants when specifying the Attr parameter:

Constant	Description
faReadOnly (see page 23044)	Read-only files
faHidden (see page 23043)	Hidden files
faSysFile (see page 23045)	System (see page 22079) files
faVolumeID (see page 23045)	Volume ID files
faDirectory (see page 23042)	Directory files
faArchive (see page 23042)	Archive files
faAnyFile (see page 23041)	Any file

Attributes can be combined by adding (Delphi) or or-ing (C++) their constants or values. For example, to search for read-only and hidden files in addition to normal files, pass (faReadOnly (see page 23044) + faHidden (see page 23043)) in Delphi or (faReadOnly (see page 23044) | faHidden (see page 23043)) in C++ as the Attr parameter. To include only normal files, pass zero for the Attr parameter.

Note: FindFirst allocates resources (memory) which must be released by calling FindClose (see page 22882).

Note: Some of the file attribute constants are not valid on all platforms. For example, faVolumeID (see page 23045) and faArchive (see page 23042) will not work on Linux.

C++ Examples:

```
/*
The following example uses an edit control, a button, a
string grid, and seven check boxes. The check boxes
correspond to the seven possible file attributes. When the
button is clicked, the path specified in the edit control is
searched for files matching the checked file attributes. The
names and sizes of the matching files are inserted into the
string grid.  The Path constant parameter is the directory
and file name mask, including wildcard characters. For
example, '.\test\*.*' specifies all files in the current
directory).
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TSearchRec sr;
```

```
  int iAttributes = 0;
  StringGrid1->RowCount = 1;
  iAttributes |= faReadOnly * CheckBox1->Checked;
  iAttributes |= faHidden * CheckBox2->Checked;
  iAttributes |= faSysFile * CheckBox3->Checked;
  iAttributes |= faVolumeID * CheckBox4->Checked;
  iAttributes |= faDirectory * CheckBox5->Checked;
  iAttributes |= faArchive * CheckBox6->Checked;
  iAttributes |= faAnyFile * CheckBox7->Checked;
  StringGrid1->RowCount = 0;
  if (FindFirst(Edit1->Text, iAttributes, sr) == 0)
  {
    do
    {
      if ((sr.Attr & iAttributes) == sr.Attr)
      {
        StringGrid1->RowCount = StringGrid1->RowCount + 1;
        StringGrid1->Cells[1][StringGrid1->RowCount-1] = sr.Name;
        StringGrid1->Cells[2][StringGrid1->RowCount-1] = IntToStr(sr.Size);
      }
    } while (FindNext(sr) == 0);
    FindClose(sr);
  }
}
```

Delphi Examples:

```
{
The following example uses an edit control, a button, a
string grid, and seven check boxes. The check boxes
correspond to the seven possible file attributes. When the
button is clicked, the path specified in the edit control is
searched for files matching the checked file attributes. The
names and sizes of the matching files are inserted into the
string grid.  The Path constant parameter is the directory
and file name mask, including wildcard characters. For
example, '.\test\*.*' specifies all files in the current
directory).

FindNext (see page 22887)

159.3.102 SysUtils.FindNext Function

Returns the next entry matching the name and attributes specified in a previous call to FindFirst (see page 22884).

Pascal

```
function FindNext(var F: TSearchRec): Integer;
```

C++

```
int FindNext(TSearchRec F);
```

File

SysUtils

Description

FindNext returns the next entry that matches the name and attributes specified in a previous call to FindFirst (see page 22884). The search record must be one that was passed to FindFirst (see page 22884). The return value is zero if the function was successful. Otherwise the return value is an error code.

C++ Examples:

```
/*
The following example uses an edit control, a button, a
string grid, and seven check boxes. The check boxes
correspond to the seven possible file attributes. When the
button is clicked, the path specified in the edit control is
searched for files matching the checked file attributes. The
names and sizes of the matching files are inserted into the
string grid.  The Path constant parameter is the directory
and file name mask, including wildcard characters. For
example, '.\test\*.*' specifies all files in the current
directory).
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TSearchRec sr;
  int iAttributes = 0;
  StringGrid1->RowCount = 1;
  iAttributes |= faReadOnly * CheckBox1->Checked;
  iAttributes |= faHidden * CheckBox2->Checked;
  iAttributes |= faSysFile * CheckBox3->Checked;
  iAttributes |= faVolumeID * CheckBox4->Checked;

159.3.103 SysUtils.FloatToCurr Function

Converts a floating-point value to a Currency value.

Pascal

```
function FloatToCurr(const Value: Extended): Currency;
```

C++

```
Currency FloatToCurr(const Extended Value);
```

File

SysUtils

Description

FloatToCurr returns the Currency value equivalent to Value. If Value is not within the valid range for a Currency value, FloatToCurr raises an EConvertError (see page 22724) exception.

See Also

TryFloatToCurr (see page 22981)

Double

159.3.104 SysUtils.FloatToDateTime Function

Converts a floating-point value to a TDateTime value.

Pascal

```
function FloatToDateTime(const Value: Extended): TDateTime;
```

C++

```
TDateTime FloatToDateTime(const Extended Value);
```

File

SysUtils

Description

FloatToDateTime returns the TDateTime value equivalent to Value. If Value is not within the valid range for TDateTime, FloatToDateTime raises an EConvertError (see page 22724) exception.

See Also

TryFloatToDateTime (see page 22982)

MinDateTime (see page 23052)

EConvertError (see page 22724)

159.3.105 SysUtils.FloatToDecimal Function

Converts a floating-point value to a decimal representation.

Pascal

```
procedure FloatToDecimal(var Result: TFloatRec; const Value; ValueType: TFloatValue;
Precision: Integer; Decimals: Integer);
```

C++

```
FloatToDecimal(TFloatRec Result, const  Value, TFloatValue ValueType, int Precision, int
Decimals);
```

File

SysUtils

Description

FloatToDecimal converts a floating-point value to a decimal representation that is suited for further formatting.

The Value parameter must be a variable of type Extended or Currency, as indicated by the ValueType parameter.

For values of type Extended, the Precision parameter specifies the requested number of significant digits in the result--the allowed range is 1..18. For values of type Currency, the Precision parameter is ignored, and the implied precision of the conversion is 19 digits.

The Decimals parameter specifies the requested maximum number of digits to the left of the decimal point in the result. Precision and Decimals together control how the result is rounded. To produce a result that always has a given number of significant digits regardless of the magnitude of the number, specify 9999 for the Decimals parameter.

159.3.106 SysUtils.FloatToStr Function

Converts a floating point value to a string.

Pascal

```
function FloatToStr(Value: Extended): string; overload;
function FloatToStr(Value: Extended; const FormatSettings: TFormatSettings): string; overload;
```

C++

```
AnsiString FloatToStr(Extended Value);
AnsiString FloatToStr(Extended Value, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

FloatToStr converts the floating-point value given by Value to its string representation. The conversion uses general number format with 15 significant digits.

For greater control over the formatting of the string, use the FloatToStrF (see page 22891) function.

The first form of FloatToStr is not thread-safe, because it uses localization information contained in global variables. The second

form of FloatToStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FloatToStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

Delphi Examples:

```
{
This example displays the compiler version number in the
text field.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Edit1.Text := FloatToStr(System.CompilerVersion);
end;
{
This example shows how to use the ArcTan and FloatToStr
functions.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ex : Extended;
  mystring : String;
begin
  ex := 16 * ArcTan(1/5) - 4 * ArcTan(1/239); // Machin's formula
  mystring := FloatToStr(ex);
  Edit2.Text := mystring;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  ex : Extended;
  myString : String;
begin
  ex := Pi;
  mystring := FloatToStr(ex);
  Edit1.Text := mystring;
end;
```

FloatToStrF (see page 22891)

FloatToText (see page 22892)

GetLocaleFormatSettings (see page 22913)

159.3.107 SysUtils.FloatToStrF Function

Converts a floating point value to a string, using a specified Format (see page 22897), Precision, and Digits.

Pascal

```
function FloatToStrF(Value: Extended; Format: TFloatFormat; Precision: Integer; Digits:
Integer): string; overload;
function FloatToStrF(Value: Extended; Format: TFloatFormat; Precision: Integer; Digits:
Integer; const FormatSettings: TFormatSettings): string; overload;
```

C++

```
AnsiString FloatToStrF(Extended Value, TFloatFormat Format, int Precision, int Digits);
AnsiString FloatToStrF(Extended Value, TFloatFormat Format, int Precision, int Digits, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

FloatToStrF converts the floating-point value given by Value to its string representation.

The Value parameter is the value to convert.

The Precision parameter specifies the precision of the given value. It should be 7 or less for values of type Single, 15 or less for values of type Double, and 18 or less for values of type Extended.

The Digits and Format (see page 22897) parameters together control how the value is formatted into a string. For details, see the description of TFloatFormat (see page 22999).

If the given value is a NAN (not-a-number), the resulting string is 'NAN'. If the given value is positive infinity, the resulting string is 'INF'. If the given value is negative infinity, the resulting string is '-INF'.

The first form of FloatToStrF is not thread-safe, because it uses localization information contained in global variables. The second form of FloatToStrF, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FloatToStrF, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.108 SysUtils.FloatToText Function

Converts a floating-point value to an unterminated character string, using a specified Format (see page 22897), Precision and Digits.

Pascal

```
function FloatToText(BufferArg: PChar; const Value; ValueType: TFloatValue; Format:
TFloatFormat; Precision: Integer; Digits: Integer): Integer; overload;
function FloatToText(BufferArg: PChar; const Value; ValueType: TFloatValue; Format:
TFloatFormat; Precision: Integer; Digits: Integer; const FormatSettings: TFormatSettings):
Integer; overload;
```

C++

```
int FloatToText(const char * BufferArg, const  Value, TFloatValue ValueType, TFloatFormat
Format, int Precision, int Digits);
int FloatToText(const char * BufferArg, const  Value, TFloatValue ValueType, TFloatFormat
Format, int Precision, int Digits, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

FloatToText converts the given floating-point value to its decimal representation using the specified format, precision, and digits. The Value parameter must be a variable of type Extended or Currency, as indicated by the ValueType parameter. The resulting string of characters is stored in the given buffer, and the returned value is the number of characters stored. The resulting string is not null-terminated.

The first form of FloatToText is not thread-safe, because it uses localization information contained in global variables. The second form of FloatToText, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FloatToText, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

See Also

FloatToStrF (see page 22891)

GetLocaleFormatSettings (see page 22913)

159.3.109 SysUtils.FloatToTextFmt Function

Converts a floating-point value to an unterminated character string, using a specified format.

Pascal

```
function FloatToTextFmt(Buf: PChar; const Value; ValueType: TFloatValue; Format: PChar):
Integer; overload;
function FloatToTextFmt(Buf: PChar; const Value; ValueType: TFloatValue; Format: PChar; const
FormatSettings: TFormatSettings): Integer; overload;
```

C++

```
int FloatToTextFmt(const char * Buf, const  Value, TFloatValue ValueType, const char * Format);
int FloatToTextFmt(const char * Buf, const  Value, TFloatValue ValueType, const char * Format,
const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Use FloatToTextFmt to format a floating-point value using a format string rather than using a predefined format. To use a predefined format, use the FloatToText (see page 22892) or FloatToStrF (see page 22891) function instead.

The Value parameter must be a variable of type Extended or Currency, as indicated by the ValueType parameter. The resulting string of characters is stored in the given buffer, and the returned value is the number of characters stored. The resulting string is not null-terminated.

Formats supported are described as part of the FormatFloat (see page 22904) function.

The first form of FloatToTextFmt is not thread-safe, because it uses localization information contained in global variables. The second form of FloatToTextFmt, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FloatToTextFmt, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

See Also

FormatFloat (see page 22904)

FloatToText (see page 22892)

GetLocaleFormatSettings (see page 22913)

159.3.110 SysUtils.FmtLoadStr Function

Returns formatted output using a resourced format string.

Pascal

```
function FmtLoadStr(Ident: Integer; const Args: array of const): string;
```

C++

```
AnsiString FmtLoadStr(int Ident, const array of const Args);
```

File

SysUtils

Description

FmtLoadStr loads a string from a program's resource string table and uses that string, plus an array of arguments, as a parameter to Format (see page 22897).

Ident is the string resource ID of the desired format string.

Args is an array of arguments that replace the format specifiers in the string Ident designates.

Note: Args_Size is the index of the last element in the Args array (one less than the number of arguments).

FmtLoadStr returns the resourced string with the arguments applied. This is the same value that would result from calling Format (see page 22897), using the resourced string and the specified arguments.

See Also

Format (see page 22897)

159.3.111 SysUtils.FmtStr Function

Assembles a formatted string using a format string and an array of arguments.

Pascal

```
procedure FmtStr(var Result: string; const Format: string; const Args: array of const);
overload;
procedure FmtStr(var Result: string; const Format: string; const Args: array of const; const
FormatSettings: TFormatSettings); overload;
```

C++

```
FmtStr(AnsiString Result, const AnsiString Format, const array of const Args);
FmtStr(AnsiString Result, const AnsiString Format, const array of const Args, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

This function formats the series of arguments in the specified open (untyped) array.

StrResult returns the results of the operation.

Format (see page 22897) is the format string that determines how to generate StrResult. For information on the format strings, see Format (see page 22897) Strings.

Args is an array of arguments that replace the format specifiers in Format (see page 22897).

Note: Args_Size specifies the index of the last element of Args (one less than the number of elements).

The first form of FmtStr is not thread-safe, because it uses localization information contained in global variables. The second

form of FmtStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FmtStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.112 SysUtils.ForceDirectories Function

Creates a new directory, including the creation of parent directories as needed.

Pascal

```
function ForceDirectories(Dir: string): Boolean;
```

C++

```
Boolean ForceDirectories(AnsiString Dir);
```

File

SysUtils

Description

ForceDirectories creates a new directory as specified in Dir, which must be a fully-qualified path name. If the directories given in the path do not yet exist, ForceDirectories attempts to create them.

ForceDirectories returns true if it successfully creates all necessary directories, false if it could not create a needed directory.

Warning: Important:Do not call ForceDirectories with an empty string. Doing so causes ForceDirectories to raise an exception.

Note: The FileCtrl (see page 13311) unit (Windows only) also contains a ForceDirectories function. However, the FileCtrl (see page 13311) version is deprecated, and the SysUtils (see page 22709) version preferred, even if the code does not need to be cross-platform.

C++ Examples:

```
/*
The following sample code sets the directory of
DirectoryListBox1 to c:\\WINDOWS when the form is created.
When Button1 is pressed, a subdirectory called
c:\\WINDOWS\\mytemp is added, but note that it is not updated
in DirectoryListBox1 until Button2 is pressed and Update is
called.
Note: A EInOutError will occur if you add a directory that
already exists.  Also, you must add the new directory to
your current directory to see the magic happen.  Also,
capitalization matters in C++ and the file spearators must
```

```
be "\\".
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  ForceDirectories(Edit1->Text);
}

void __fastcall TForm1::Button2Click(TObject *Sender)
{
  DirectoryListBox1->Update();
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  DirectoryListBox1->Directory = "c:\\WINDOWS";
}
/*
This example uses a label and a button on a form. When the
user clicks the button, all the directories along the
specified path that don't exist are created. The results are
reported in the caption of the label:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString Dir = "C:\\Apps\\Sales\\Local";
  if (ForceDirectories(Dir))
    Label1->Caption = Dir + " was created";
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, all the directories along the
specified path that don't exist are created. The results are
reported in the caption of the label:
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Dir: string;
begin
  Dir := 'C:\APPS\SALES\LOCAL';
  if SysUtils.ForceDirectories(Dir) then
    Label1.Caption := Dir + ' was created'
end;
```

159.3.113 SysUtils.Format Function

Returns a formatted string assembled from a format string and an array of arguments.

Pascal

```
function Format(const Format: string; const Args: array of const): string; overload;
function Format(const Format: string; const Args: array of const; const FormatSettings:
TFormatSettings): string; overload;
```

C++

```
AnsiString Format(const AnsiString Format, const array of const Args);
AnsiString Format(const AnsiString Format, const array of const Args, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

The Format function formats the series of arguments in an open (untyped) array.

Format is the format string. For information on the format strings, see Format Strings, described in this topic.

Args is an array of arguments to apply to the format specifiers in Format. For C++, Args_Size specifies the index of the last element of Args (one less than the number of elements).

Format returns the results of applying the arguments in Args to the format string Format.

Two syntax forms are given for Format. The first form of Format is not thread-safe, because it uses localization information contained in global variables. The second form of Format, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of Format, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

Format Strings

Format strings specify required formats to general-purpose formatting routines. Format strings passed to the string formatting routines contain two types of objects -- literal characters and format specifiers. Literal characters are copied verbatim to the resulting string. Format specifiers fetch arguments from the argument list and apply formatting to them.

Format specifiers have the following form:

```
"%" [index ":"] ["-"] [width] ["." prec] type
```

A format specifier begins with a % character. After the % come the following elements, in this order:

An optional argument zero-offset index specifier (that is, the first item has index 0), `[index ":"]`

An optional left justification indicator, `["-"]`

An optional width specifier, `[width]`

An optional precision specifier, `["." prec]`

The conversion type character, `type`

The following table summarizes the possible values for type:

Value	Meaning
d	Decimal. The argument must be an integer value. The value is converted to a string of decimal digits. If the format string contains a precision specifier, it indicates that the resulting string must contain at least the specified number of digits; if the value has less digits, the resulting string is left-padded with zeros.
u	Unsigned decimal. Similar to 'd' but no sign is output.
e	Scientific. The argument must be a floating-point value. The value is converted to a string of the form "-d.ddd...E+ddd". The resulting string starts with a minus sign if the number is negative. One digit always precedes the decimal point. The total number of digits in the resulting string (including the one before the decimal point) is given by the precision specifier in the format string—a default precision of 15 is assumed if no precision specifier is present. The "E" exponent character in the resulting string is always followed by a plus or minus sign and at least three digits.
f	Fixed. The argument must be a floating-point value. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative. The number of digits after the decimal point is given by the precision specifier in the format string—a default of 2 decimal digits is assumed if no precision specifier is present.
g	General. The argument must be a floating-point value. The value is converted to the shortest possible decimal string using fixed or scientific format. The number of significant digits in the resulting string is given by the precision specifier in the format string—a default precision of 15 is assumed if no precision specifier is present. Trailing zeros are removed from the resulting string, and a decimal point appears only if necessary. The resulting string uses fixed point format if the number of digits to the left of the decimal point in the value is less than or equal to the specified precision, and if the value is greater than or equal to 0.00001. Otherwise the resulting string uses scientific format.
n	Number. The argument must be a floating-point value. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The "n" format corresponds to the "f" format, except that the resulting string contains thousand separators.
m	Money. The argument must be a floating-point value. The value is converted to a string that represents a currency amount. The conversion is controlled by the CurrencyString (see page 23023), CurrencyFormat (see page 23022), NegCurrFormat (see page 23029), ThousandSeparator (see page 23032), DecimalSeparator (see page 23023), and CurrencyDecimals (see page 23022) global variables or their equivalent in a TFormatSettings (see page 23001) data structure. If the format string contains a precision specifier, it overrides the value given by the CurrencyDecimals (see page 23022) global variable or its TFormatSettings (see page 23001) equivalent.
p	Pointer. The argument must be a pointer value. The value is converted to an 8 character string that represents the pointers value in hexadecimal.
s	String. The argument must be a character, a string, or a PChar value. The string or character is inserted in place of the format specifier. The precision specifier, if present in the format string, specifies the maximum length of the resulting string. If the argument is a string that is longer than this maximum, the string is truncated.
x	Hexadecimal. The argument must be an integer value. The value is converted to a string of hexadecimal digits. If the format string contains a precision specifier, it indicates that the resulting string must contain at least the specified number of digits; if the value has fewer digits, the resulting string is left-padded with zeros.

Conversion characters may be specified in uppercase as well as in lowercase—both produce the same results.

For all floating-point formats, the actual characters used as decimal and thousand separators are obtained from the DecimalSeparator (see page 23023) and ThousandSeparator (see page 32032) global variables or their TFormatSettings (see page 23001) equivalent.

Index, width, and precision specifiers can be specified directly using decimal digit string (for example "%10d"), or indirectly using an asterisk character (for example "%*.*f"). When using an asterisk, the next argument in the argument list (which must be an integer value) becomes the value that is actually used. For example,

```
Format ('%*.*f', [8, 2, 123.456]);
```

is equivalent to

```
Format ('%8.2f', [123.456]);
```

Similarly:

```
TVarRec args[3] = {8,2,123.456};
Format ("%*.*f", args, 2);
```

is equivalent to

```
TVarRec args[1] = {123.456};
Format ("%8.2f", args, 0);
```

A width specifier sets the minimum field width for a conversion. If the resulting string is shorter than the minimum field width, it is padded with blanks to increase the field width. The default is to right-justify the result by adding blanks in front of the value, but if the format specifier contains a left-justification indicator (a "-" character preceding the width specifier), the result is left-justified by adding blanks after the value.

An index specifier sets the current argument list index to the specified value. The index of the first argument in the argument list is 0. Using index specifiers, it is possible to format the same argument multiple times. For example "Format('%d %d %0:d %1:d', [10, 20])" produces the string '10 20 10 20'.

Note: Setting the index specifier affects all subsequent formatting. That is, Format('%d %d %d %0:d %d', [1, 2, 3, 4]) returns '1 2 3 1 2', not '1 2 3 1 4'. To get the latter result, you must use Format('%d %d %d %0:d %3:d', [1, 2, 3, 4])

C++ Examples:

```
/*
This example copies a specified old file to a new file.  Add
a TSaveDialog to the form.  Also add two TEdits, two TLabels
and a TButton with the OnClick event named Save1Click. Files
can be saved to and from the app directory by using relative
paths.
*/
void __fastcall TForm1::Save1Click(TObject *Sender)
{
  AnsiString NewFileName =
    ExtractFilePath(Application->ExeName) +
    ExtractFileName(Edit1->Text);
  AnsiString OldFileName =
    ExtractFilePath(Application->ExeName) +
    ExtractFileName(Edit2->Text);
  AnsiString Msg = Format("Copy %s to %s", ARRAYOFCONST((OldFileName, NewFileName)));
  if (MessageDlg(Msg, mtCustom, TMsgDlgButtons() << mbOK << mbCancel, 0) == mrOk)
  {
    TFileStream *OldFile = new TFileStream(OldFileName, fmOpenRead);
    try
    {
      TFileStream *NewFile = new TFileStream(NewFileName, fmCreate);
      try
      {
        NewFile->CopyFrom(OldFile, OldFile->Size);
      }
      __finally
      {
        FreeAndNil(&NewFile);
      }
    }
    __finally
    {
      FreeAndNil(&OldFile);
    }
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Label3->Caption = "Current directory: " + ExtractFilePath(Application->ExeName);
}
```

Delphi Examples:

```
{
This example copies a specified old file to a new file.  Add
a TSaveDialog to the form.  Also add two TEdits, two TLabels
and a TButton with the OnClick event named Save1Click. Files
can be saved to and from the app directory by using relative
paths.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  Label3.Caption:= 'Current directory: ' + ExtractFilePath(Application.ExeName);
end;

procedure TForm1.Save1Click(Sender: TObject);
var
  NewFileName, OldFileName: string;
  Msg: string;
  NewFile: TFileStream;
  OldFile: TFileStream;
begin
  NewFileName :=
    ExtractFilePath(Application.ExeName) +
    ExtractFileName(Edit1.Text);
  OldFileName :=
    ExtractFilePath(Application.ExeName) +
    ExtractFileName(Edit2.Text);
  Msg := Format('Copy %s to %s?', [OldFileName, NewFileName]);
  if MessageDlg(Msg, mtCustom, mbOKCancel, 0) = mrOK then
  begin
    OldFile := TFileStream.Create(
      OldFileName, fmOpenRead or fmShareDenyWrite);
    try
      NewFile := TFileStream.Create(
        NewFileName, fmCreate or fmShareDenyRead);
      try
        NewFile.CopyFrom(OldFile, OldFile.Size);
      finally
        FreeAndNil(NewFile);
      end;
    finally
      FreeAndNil(OldFile);
    end;
  end;
end;
```

159.3.114 SysUtils.FormatBuf Function

Formats the arguments from an array, placing the result in a buffer.

Pascal

```
function FormatBuf(var Buffer; BufLen: Cardinal; const Format; FmtLen: Cardinal; const Args:
array of const): Cardinal; overload;
function FormatBuf(var Buffer; BufLen: Cardinal; const Format; FmtLen: Cardinal; const Args:
array of const; const FormatSettings: TFormatSettings): Cardinal; overload;
```

C++

```
unsigned FormatBuf( Buffer, unsigned BufLen, const  Format, unsigned FmtLen, const array of
const Args);
unsigned FormatBuf( Buffer, unsigned BufLen, const  Format, unsigned FmtLen, const array of
```

```
const Args, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

This function formats the series of arguments in the specified open array into a text buffer.

Buffer is the text buffer that receives the results.

BufLen is the number of bytes in Buffer.

Format (see page 22897) is the format string that determines how arguments are formatted. For information on the format strings, see Format (see page 22897) Strings.

FmtLen is the number of bytes in Format (see page 22897).

Args are the arguments that replace the format specifiers in Format (see page 22897).

Note: Args_Size is the index of the last element in Args (one less than the number of arguments).

FormatBuf function returns the length, in bytes, of the resulting string.

The first form of FormatBuf is not thread-safe, because it uses localization information contained in global variables. The second form of FormatBuf, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FormatBuf, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

See Also

GetLocaleFormatSettings (see page 22913)

159.3.115 SysUtils.FormatCurr Function

Formats a Currency object.

Pascal

```
function FormatCurr(const Format: string; Value: Currency): string; overload;
function FormatCurr(const Format: string; Value: Currency; const FormatSettings:
TFormatSettings): string; overload;
```

C++

```
AnsiString FormatCurr(const AnsiString Format, Currency Value);
AnsiString FormatCurr(const AnsiString Format, Currency Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

FormatCurr formats the Currency object given by Value using the format string given by Format (see page 22897).

For information on the format strings, see Format (see page 22897) Strings.

The first form of FormatCurr is not thread-safe, because it uses localization information contained in global variables. The second form of FormatCurr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FormatCurr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.116 SysUtils.FormatDateTime Function

Formats a TDateTime value.

Pascal

```
function FormatDateTime(const Format: string; DateTime: TDateTime): string; overload;
function FormatDateTime(const Format: string; DateTime: TDateTime; const FormatSettings:
TFormatSettings): string; overload;
```

C++

```
AnsiString FormatDateTime(const AnsiString Format, TDateTime DateTime);
AnsiString FormatDateTime(const AnsiString Format, TDateTime DateTime, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

FormatDateTime formats the TDateTime value given by DateTime using the format given by Format (see page 22897). See the table below for information about the supported format strings.

If the string specified by the Format (see page 22897) parameter is empty, the TDateTime value is formatted as if a 'c' format specifier had been given.

The first form of FormatDateTime is not thread-safe, because it uses localization information contained in global variables. The second form of FormatDateTime, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FormatDateTime, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

Date (see page 22820) Time (see page 22976) Format (see page 22897) Strings are composed from specifiers that represent values to be inserted into the formatted string. Some specifiers (such as "d"), simply format numbers or strings. Other specifiers (such as "/") refer to locale-specific strings from global variables.

In the following table, specifiers are given in lower case. Case is ignored in formats, except for the "am/pm" and "a/p" specifiers.

Specifier	Displays
c	Displays the date using the format given by the ShortDateFormat (see page 23030) global variable, followed by the time using the format given by the LongTimeFormat (see page 23028) global variable. The time is not displayed if the date-time value indicates midnight precisely.
d	Displays the day as a number without a leading zero (1-31).
dd	Displays the day as a number with a leading zero (01-31).

ddd	Displays the day as an abbreviation (Sun-Sat) using the strings given by the ShortDayNames (see page 23031) global variable.
dddd	Displays the day as a full name (Sunday-Saturday) using the strings given by the LongDayNames (see page 23027) global variable.
ddddd	Displays the date using the format given by the ShortDateFormat (see page 23030) global variable.
dddddd	Displays the date using the format given by the LongDateFormat (see page 23027) global variable.
e	(Windows only) Displays the year in the current period/era as a number without a leading zero (Japanese, Korean and Taiwanese locales only).
ee	(Windows only) Displays the year in the current period/era as a number with a leading zero (Japanese, Korean and Taiwanese locales only).
g	(Windows only) Displays the period/era as an abbreviation (Japanese and Taiwanese locales only).
gg	(Windows only) Displays the period/era as a full name. (Japanese and Taiwanese locales only).
m	Displays the month as a number without a leading zero (1-12). If the m specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mm	Displays the month as a number with a leading zero (01-12). If the mm specifier immediately follows an h or hh specifier, the minute rather than the month is displayed.
mmm	Displays the month as an abbreviation (Jan-Dec) using the strings given by the ShortMonthNames (see page 23031) global variable.
mmmm	Displays the month as a full name (January-December) using the strings given by the LongMonthNames (see page 23028) global variable.
yy	Displays the year as a two-digit number (00-99).
yyyy	Displays the year as a four-digit number (0000-9999).
h	Displays the hour without a leading zero (0-23).
hh	Displays the hour with a leading zero (00-23).
n	Displays the minute without a leading zero (0-59).
nn	Displays the minute with a leading zero (00-59).
s	Displays the second without a leading zero (0-59).
ss	Displays the second with a leading zero (00-59).
z	Displays the millisecond without a leading zero (0-999).
zzz	Displays the millisecond with a leading zero (000-999).
t	Displays the time using the format given by the ShortTimeFormat (see page 23031) global variable.
tt\	Displays the time using the format given by the LongTimeFormat (see page 23028) global variable.
am/pm	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'am' for any hour before noon, and 'pm' for any hour after noon. The am/pm specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
a/p	Uses the 12-hour clock for the preceding h or hh specifier, and displays 'a' for any hour before noon, and 'p' for any hour after noon. The a/p specifier can use lower, upper, or mixed case, and the result is displayed accordingly.
ampm	Uses the 12-hour clock for the preceding h or hh specifier, and displays the contents of the TimeAMString (see page 23033) global variable for any hour before noon, and the contents of the TimePMString (see page 23033) global variable for any hour after noon.
/	Displays the date separator character given by the DateSeparator (see page 23023) global variable.
:	Displays the time separator character given by the TimeSeparator (see page 23033) global variable.
'xx'/"xx"	Characters enclosed in single or double quotes are displayed as-is, and do not affect formatting.

C++ Examples:

```
/*
The following example uses FormatDateTime to set the string
variable S to a sentence indicating a meeting time in 3
hours. The sentence has the form "The meeting is on
Wednesday, February 15, 1995 at 2:30 PM."
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString S = "The meeting is on ";
  S = S + FormatDateTime("dddd, mmmm d, yyyy ' at ' hh:mm AM/PM", Now() + 0.125);
  Label1->Caption = S;
}
```

Delphi Examples:

```
{
The following example uses FormatDateTime to set the string
variable S to a sentence indicating a meeting time in 3
hours. The sentence has the form "The meeting is on
Wednesday, February 15, 1995 at 2:30 PM."
}
procedure TForm1.Button1Click(Sender: TObject);
var S : string;
begin
  S := SysUtils.FormatDateTime(
    '"The meeting is on " dddd, mmmm d, yyyy, " at " hh:mm AM/PM', Now + 0.125);
  Label1.Caption := S;
end;
```

159.3.117 SysUtils.FormatFloat Function

Formats a floating point value.

Pascal

```
function FormatFloat(const Format: string; Value: Extended): string; overload;
function FormatFloat(const Format: string; Value: Extended; const FormatSettings:
TFormatSettings): string; overload;
```

C++

```
AnsiString FormatFloat(const AnsiString Format, Extended Value);
AnsiString FormatFloat(const AnsiString Format, Extended Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

FormatFloat formats the floating-point value given by Value using the format string given by Format (see page 22897). The following format specifiers are supported in the format string:

Specifier	Represents
0	Digit place holder. If the value being formatted has a digit in the position where the '0' appears in the format string, then that digit is copied to the output string. Otherwise, a '0' is stored in that position in the output string.
#	Digit placeholder. If the value being formatted has a digit in the position where the '#' appears in the format string, then that digit is copied to the output string. Otherwise, nothing is stored in that position in the output string.

.	Decimal point. The first '.' character in the format string determines the location of the decimal separator in the formatted value; any additional '.' characters are ignored. The actual character used as a the decimal separator in the output string is determined by the DecimalSeparator (see page 23023) global variable or its TFormatSettings (see page 23001) equivalent.
,	Thousand separator. If the format string contains one or more ',' characters, the output will have thousand separators inserted between each group of three digits to the left of the decimal point. The placement and number of ',' characters in the format string does not affect the output, except to indicate that thousand separators are wanted. The actual character used as a the thousand separator in the output is determined by the ThousandSeparator (see page 23032) global variable or its TFormatSettings (see page 23001) equivalent.
E+	Scientific notation. If any of the strings 'E+', 'E-', 'e+', or 'e-' are contained in the format string, the number is formatted using scientific notation. A group of up to four '0' characters can immediately follow the 'E+', 'E-', 'e+', or 'e-' to determine the minimum number of digits in the exponent. The 'E+' and 'e+' formats cause a plus sign to be output for positive exponents and a minus sign to be output for negative exponents. The 'E-' and 'e-' formats output a sign character only for negative exponents.
'xx'/"xx"	Characters enclosed in single or double quotes are output as-is, and do not affect formatting.
;	Separates sections for positive, negative, and zero numbers in the format string.

The locations of the leftmost '0' before the decimal point in the format string and the rightmost '0' after the decimal point in the format string determine the range of digits that are always present in the output string.

The number being formatted is always rounded to as many decimal places as there are digit placeholders ('0' or '#') to the right of the decimal point. If the format string contains no decimal point, the value being formatted is rounded to the nearest whole number.

If the number being formatted has more digits to the left of the decimal separator than there are digit placeholders to the left of the '.' character in the format string, the extra digits are output before the first digit placeholder.

To allow different formats for positive, negative, and zero values, the format string can contain between one and three sections separated by semicolons.

One section: The format string applies to all values.

Two sections: The first section applies to positive values and zeros, and the second section applies to negative values.

Three sections: The first section applies to positive values, the second applies to negative values, and the third applies to zeros.

If the section for negative values or the section for zero values is empty, that is if there is nothing between the semicolons that delimit the section, the section for positive values is used instead.

If the section for positive values is empty, or if the entire format string is empty, the value is formatted using general floating-point formatting with 15 significant digits, corresponding to a call to FloatToStrF (see page 22891) with the ffGeneral format. General floating-point formatting is also used if the value has more than 18 digits to the left of the decimal point and the format string does not specify scientific notation.

The first form of FormatFloat is not thread-safe, because it uses localization information contained in global variables. The second form of FormatFloat, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of FormatFloat, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

C++ Examples:

```
/*
The following example uses two buttons, a string grid, and
text edit on a form. When the conversion button is clicked,
the values across the top of the string grid are converted
using the formats along the left side.  Select a cell and
use the Alter Cell button and text edit to change the
values converted and the conversion formats.
```

```
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int x = 1; x < StringGrid1->ColCount; x++)
  {
    for (int y = 1; y < StringGrid1->RowCount; y++)
    {
      StringGrid1->Cells[x][y] = FormatFloat(
      StringGrid1->Cells[0][y], StrToFloat(StringGrid1->Cells[x][0]));
    }
  }
}

int currCellCol, currCellRow;

void __fastcall TForm1::StringGrid1MouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  StringGrid1->MouseToCell(X, Y, currCellCol, currCellRow);
}

// Alter Cell
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  StringGrid1->Cells[currCellCol][currCellRow] = Edit1->Text;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  StringGrid1->Cells[1][0] = "1234";
  StringGrid1->Cells[2][0] = "-1234";
  StringGrid1->Cells[3][0] = "0.5";
  StringGrid1->Cells[4][0] = "0";
  StringGrid1->Cells[0][1] = "";
  StringGrid1->Cells[0][2] = "0";
  StringGrid1->Cells[0][3] = "0.00";
  StringGrid1->Cells[0][4] = "#.##";
  StringGrid1->Cells[0][5] = "#,##0.00";
  StringGrid1->Cells[0][6] = "#,##0.00;(#,##0.00)";
  StringGrid1->Cells[0][7] = "#,##0.00;;Zero";
  StringGrid1->Cells[0][8] = "0.000E+00";
  StringGrid1->Cells[0][9] = "#.###E-0";
}
```

Delphi Examples:

```
{
The following example uses two buttons, a string grid, and
text edit on a form. When the conversion button is clicked,
the values across the top of the string grid are converted
using the formats along the left side.  Select a cell and
use the Alter Cell button and text edit to change the
values converted and the conversion formats.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  X, Y, I: Integer;
begin
  for X := 1 to StringGrid1.ColCount - 1 do
  begin
    for Y := 0 to StringGrid1.RowCount - 1 do
    begin
      StringGrid1.Cells[X,Y] := SysUtils.FormatFloat(
        StringGrid1.Cells[0,Y], StrToFloat(StringGrid1.Cells[X,0]));
    end;
  end;
```

```
end;

var currCellCol, currCellRow: Integer;

// Alter Cell
procedure TForm1.Button2Click(Sender: TObject);
begin
  StringGrid1.Cells[currCellCol,currCellRow] := Edit1.Text;
end;

procedure TForm1.StringGrid1MouseUp(Sender: TObject; Button: TMouseButton;
  Shift: TShiftState; X, Y: Integer);
begin
  StringGrid1.MouseToCell(X, Y, &currCellCol, &currCellRow);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  StringGrid1.Cells[1,0] := '1234';
  StringGrid1.Cells[2,0] := '-1234';
  StringGrid1.Cells[3,0] := '0.5';
  StringGrid1.Cells[4,0] := '0';
  StringGrid1.Cells[0,1] := '';
  StringGrid1.Cells[0,2] := '0';
  StringGrid1.Cells[0,3] := '0.00';
  StringGrid1.Cells[0,4] := '#.##';
  StringGrid1.Cells[0,5] := '#,##0.00';
  StringGrid1.Cells[0,6] := '#,##0.00;(#,##0.00)';
  StringGrid1.Cells[0,7] := '#,##0.00;;Zero';
  StringGrid1.Cells[0,8] := '0.000E+00';
  StringGrid1.Cells[0,9] := '#.###E-0';
end;
{
The following example displays in a dialog the disk free
space of the current drive with commas as thousand separators.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  ShowMessage(FormatFloat('#,##0 bytes', DiskFree(0)));
end;
```

159.3.118 SysUtils.FreeAndNil Function

Frees an object reference and replaces the reference with nil (Delphi) or NULL (C++).

Pascal

```
procedure FreeAndNil(var Obj);
```

C++

```
FreeAndNil( Obj);
```

File

SysUtils

Description

Use FreeAndNil to ensure that a variable is nil (Delphi) or NULL (C++) after you free the object it references. Pass any variable that represents an object as the Obj parameter.

Warning: Obj must be an instance of a TObject descendant.

C++ Examples:

```
/*
This code displays a Save Picture dialog box with the
TBitmap default extension that is added automatically to
files that are given no extension. Confirm that the
bitmap file has been saved under the filename and path
specified.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  AnsiString NewFileName, OldFileName;
  TFileStream *NewFile, *OldFile;
  SavePictureDialog1->DefaultExt = GraphicExtension(__classid(Graphics::TBitmap));
  SavePictureDialog1->Filter = GraphicFilter(__classid(Graphics::TBitmap));
  OldFileName = "factory.bmp";
  if (SavePictureDialog1->Execute())
  {
    NewFileName = SavePictureDialog1->FileName;
    OldFile = new TFileStream(OldFileName, (fmOpenRead | fmShareDenyWrite));
    try
    {
      NewFile = new TFileStream(NewFileName, (fmCreate | fmShareDenyRead));
      try
      {
        NewFile->CopyFrom(OldFile, OldFile->Size);
      }
      __finally
      {
        FreeAndNil(&NewFile);
      };
    }
    __finally
    {
      FreeAndNil(&OldFile);
    };
  };
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Image1->Picture->LoadFromFile("../factory.bmp");
}
```

Delphi Examples:

```
{
This code displays a Save Picture dialog box with the
TBitmap default extension that is added automatically to
files that are given no extension. Confirm that the
bitmap file has been saved under the filename and path
specified.
}
procedure TForm1.Button1Click(Sender: TObject);
```

```
var NewFileName, OldFileName: string;
    NewFile, OldFile: TFileStream;
begin
  SavePictureDialog1.DefaultExt := GraphicExtension(TBitmap);
  SavePictureDialog1.Filter := GraphicFilter(TBitmap);
  OldFileName := 'factory.bmp';
  if SavePictureDialog1.Execute then
  begin
    NewFileName := SavePictureDialog1.FileName;
    OldFile := TFileStream.Create(
      OldFileName, fmOpenRead or fmShareDenyWrite);
    try
      NewFile := TFileStream.Create(
        NewFileName, fmCreate or fmShareDenyRead);
      try
        NewFile.CopyFrom(OldFile, OldFile.Size);
      finally
        FreeAndNil(NewFile);
      end;
    finally
      FreeAndNil(OldFile);
    end;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  Image1.Picture.LoadFromFile('factory.bmp');
end;
```

TObject

159.3.119 SysUtils.GDAL Function

Get Delphi Access Licence.

Pascal

```
function GDAL: LongWord;
```

C++

```
LongWord GDAL();
```

File

SysUtils

Description

GDAL retreives the access licences resource. It checks if it is valid, if not an Access Licence Violation exception with the message 'Application is not licenced to use this feature' is raised.

The returned value is the decrypted first Access Licence (AL1).

RCS (see page 22933)

RPR (see page 22938)

159.3.120 SysUtils.GetCurrentDir Function

Returns the name of the current directory.

Pascal

```
function GetCurrentDir: string;
```

C++

```
AnsiString GetCurrentDir();
```

File

SysUtils

Description

GetCurrentDir returns the fully qualified name of the current directory.

Delphi Examples:

```
{
This example shows how to change and display the current
directory through text.  This example requires that a drive
combo box, a file list box, and a directory list box are on
a form. Add this code as the OnChange event handler for the
drive combo box and the OnChange event handler for the
directory list box.  When the user changes the drive using
the combo box, the directory list box and file list box will
update to reflect the new drive and the current directory on
that drive.  When the user double clicks on a directory in
the file list box will update to reflect the new directory.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  System.ChDir(Edit1.Text);
  if IOResult <> 0 then
    MessageDlg('Cannot find directory', mtWarning, [mbOk], 0);
  Edit2.Text := GetCurrentDir;
  FileListBox1.Directory := GetCurrentDir;
  DirectoryListBox1.Directory := GetCurrentDir;
end;

procedure TForm1.DirectoryListBox1Change(Sender: TObject);
begin
  FileListBox1.Directory := DirectoryListBox1.Directory;
  Edit2.Text := GetCurrentDir;
end;

procedure TForm1.DriveComboBox1Change(Sender: TObject);
begin
  DirectoryListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Drive := DriveComboBox1.Drive;
  FileListBox1.Directory := DirectoryListBox1.Directory;
  Edit2.Text := GetCurrentDir;
end;
```

RemoveDir (see page 22933)

SetCurrentDir (see page 22940)

159.3.121 SysUtils.GetEnvironmentVariable Function

Retrieves an environment variable value.

Pascal

```
function GetEnvironmentVariable(const Name: string): string; overload;
```

C++

```
AnsiString GetEnvironmentVariable(const AnsiString Name);
```

File

SysUtils

Description

Call GetEnvironmentVariable to retrieve the value of an environment variable, passed as `Name`, for the current process.

Note:

The case of the specified environment variable `Name` is ignored.

The following table defines the standard environment variables for Microsoft Windows.

Environment variable name	Environment value
ALLUSERSPROFILE	Generic user profile.
APPDATA	Path of the application data folder.
CLIENTNAME	Name of Client machine.
COMMONPROGRAMFILES	Path of common program files folder.
COMPUTERNAME	Name of Computer code is running on.
COMSPEC	Path of the cmd.exe program.
HOMEDRIVE	Current home drive designation, such as 'C:'
HOMEPATH	Path to current location for document storage.
LOGONSERVER	
NUMBER_OF_PROCESSORS	Number of processors on current machine.
OS	Base name of the Operating System (see page 22079). Note that Windows XP is given as Windows_NT.
PATH	The current program path.
PATHEXT	
PROCESSOR_ARCHITECTURE	Type of CPU architecture. For example, X86 for Intel Pentium processors.
PROCESSOR_IDENTIFIER	
PROCESSOR_LEVEL	More detailed description of the CPU architecture.
PROCESSOR_REVISION	Processor revision level.
PROGRAMFILES	Path of the program files folder.

SESSIONNAME	Name of the current OS session.
SYSTEMDRIVE	Drive the OS operates from.
SYSTEMROOT	
TEMP	Path of the temporary files folder.
TMP	
USERDOMAIN	
USERNAME	Name of the current user.
USERPROFILE	Path of the folder holding the current user's information.
WINDIR	Path of the Windows folder.

159.3.122 SysUtils.GetFileVersion Function

Returns file version.

Pascal

```
function GetFileVersion(const AFileName: string): Cardinal;
```

C++

```
unsigned GetFileVersion(const AnsiString AFileName);
```

File

SysUtils

Description

GetFileVersion returns the most significant 32 bits of a file binary version number. AFileName specifies the name of the file, which is searched using the same path as the LoadLibrary function.

GetFileVersion is only available on Windows and must not be used in cross-platform code.

159.3.123 SysUtils.GetFormatSettings Function

Resets the date and number format parameters to initial values.

Pascal

```
procedure GetFormatSettings;
```

C++

```
GetFormatSettings();
```

File

SysUtils

Description

GetFormatSettings resets all date and number format variables to their initial values.

Note: On Windows, GetFormatSettings is called automatically in response to WM_WININICHANGE messages.

159.3.124 SysUtils.GetLocaleChar Function

Retrieves the first character of a localisation value.

Pascal

```
function GetLocaleChar(Locale: Integer; LocaleType: Integer; Default: Char): Char; platform;
```

C++

```
Char GetLocaleChar(int Locale, int LocaleType, Char Default);
```

File

SysUtils

Description

GetLocaleChar retrieves the first character of the passed LocaleType value, or the passed Default value if not found. The actual value is determined by the location specified by Locale. For example, on Windows, $0809 is the Locale for United Kingdom English, and $0409 is the Locale for US English. For the LOCALE_SCURRENCY LocaleType, these locales would yield '£' and '$' respectively.

Note: This is an OS specific function.

See Also

GetLocaleStr (see page 22913)

159.3.125 SysUtils.GetLocaleFormatSettings Function

Populates a TFormatSettings (see page 23001) data structure.

Pascal

```
procedure GetLocaleFormatSettings(LCID: Integer; var FormatSettings: TFormatSettings);
```

C++

```
GetLocaleFormatSettings(int LCID, TFormatSettings FormatSettings);
```

File

SysUtils

Description

GetLocaleFormatSettings populates FormatSettings based on the Windows locale ID specified in LCID. A TFormatSettings (see page 23001) data structure must be initialized by a call to GetLocaleFormatSettings before it can be used with any string formatting routines.

159.3.126 SysUtils.GetLocaleStr Function

Retrieves a localisation value.

Pascal

```
function GetLocaleStr(Locale: Integer; LocaleType: Integer; const Default: string): string;
platform;
```

C++

```
AnsiString GetLocaleStr(int Locale, int LocaleType, const AnsiString Default);
```

File

SysUtils

Description

GetLocaleStr retrieves the passed LocaleType value, or the passed Default value if not found. The actual value is determined by the location specified by Locale. For example, on Windows, $040c is the Locale for France French, and $0409 is the Locale for US English. For the LOCALE_SMONTHNAME1 LocaleType, these locales would yield 'janvier' and 'January' respectively.

Note: This is an OS specific function.

See Also

GetLocaleChar (see page 22913)

159.3.127 SysUtils.GetModuleName Function

Returns the fully qualified name for a module, given its handle.

Pascal

```
function GetModuleName(Module: HMODULE): string;
```

C++

```
AnsiString GetModuleName(HMODULE Module);
```

File

SysUtils

Description

Call GetModuleName to obtain the fully qualified name of a module, given its handle.

Module is the handle of the module whose file name is required.

Warning: :On Linux, GetModuleName is not always successful. Depending on the way the application is called, the presence of the /proc file system, and other factors, there are times when GetModuleName may return a name that is not fully qualified or in some cases, no file name at all. Be sure to check the results of this function before using the returned value.

C++ Examples:

```
/*
This example requires a button and a label.  When the user clicks
the button, the GetModuleName function retieves the path and name
of the project executable using the file handle HInstance.
*/
AnsiString __fastcall GetUsersFileName(void)
{
  return GetModuleName(unsigned(HInstance));
}
```

```
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = GetUsersFileName();
}
```

Delphi Examples:

```
{
This example requires a button and a label.  When the user clicks
the button, the GetModuleName function retieves the path and name
of the project executable using the file handle HInstance.
}
function GetUsersFileName: string;
begin
  Result := SysUtils.GetModuleName(HInstance);
end;

procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := GetUsersFileName;
end;
```

159.3.128 SysUtils.GetPackageDescription Function

Returns the description resource from a package.

Pascal

```
function GetPackageDescription(ModuleName: PChar): string;
```

C++

```
AnsiString GetPackageDescription(const char * ModuleName);
```

File

SysUtils

Description

Call GetPackageDescription to obtain the description stored with the named package. If the package does not have a description resource, GetPackageDescription returns an empty string.

See Also

GetPackageInfo (see page 22915)

159.3.129 SysUtils.GetPackageInfo Function

Enumerates all the units and required packages for a package.

Pascal

```
procedure GetPackageInfo(Module: HMODULE; Param: Pointer; var Flags: Integer; InfoProc:
TPackageInfoProc);
```

C++

```
GetPackageInfo(HMODULE Module, void * Param, int Flags, TPackageInfoProc InfoProc);
```

File

SysUtils

Description

Call GetPackageInfo to process the information in a package's information table. The InfoProc callback is called for every unit included in the package and for every package required by the package. Module is the module handle for the package. GetPackageInfo passes any application-supplied information passed in the Param parameter to the InfoProc callback. The package's information flags are passed to the InfoProc and returned in the Flags parameter.

See Also

LoadPackage (see page 22927)

GetPackageDescription (see page 22915)

159.3.130 SysUtils.GetTime Function

Returns the current time.

Pascal

```
function GetTime: TDateTime;
```

C++

```
TDateTime GetTime();
```

File

SysUtils

Description

GetTime and Time (see page 22976) return the current time as a TDateTime value. The two functions are completely equivalent.

Note: Time (see page 22976) clashes with an Xlib function of the same name. Use GetTime in Linux and cross-platform code.

See Also

Time (see page 22976)

Date (see page 22820)

DecodeTime (see page 22830)

Now (see page 22930)

TimeToStr (see page 22977)

159.3.131 SysUtils.GUIDToString Function

Converts a class identifier GUID to a string.

Pascal

```
function GUIDToString(const GUID: TGUID): string;
```

C++

```
AnsiString GUIDToString(const TGUID GUID);
```

File

SysUtils

Description

GUIDToString converts a GUID into a string of printable characters. Each GUID always converts to a unique string.

If GUIDToString succeeds it returns a string for the requested GUID. If GUIDToString fails, it raises EConvertError (see page 22724).

Delphi Examples:

```
{
OleCheck, GuidToString example
The following example manufactures a GUID and displays it in a dialog box after translating it
to a string.
}
uses ActiveX, ComObj;
procedure TForm1.Button1Click(Sender: TObject);
var
  G: TGUID;
begin
  OleCheck(CoCreateGuid(G));
  ShowMessage(SysUtils.GuidToString(G));
end;
```

See Also

StringToGUID (see page 22952)

EConvertError (see page 22724)

159.3.132 SysUtils.IncAMonth Function

Increments date data by one month.

Pascal

```
procedure IncAMonth(var Year: Word; var Month: Word; var Day: Word; NumberOfMonths: Integer =
1);
```

C++

```
IncAMonth(Word Year, Word Month, Word Day, int NumberOfMonths = 1);
```

File

SysUtils

Description

IncAMonth modifies Year, Month, and Day parameters so the date they describe is incremented by NumberOfMonths months. NumberOfMonths can be negative, to return a date N months previous.

If the input day of month is greater than the last day of the resulting month, the day is set to the last day of the resulting month.

See Also

IncMonth (see page 22919)

DecodeDate (see page 22828)

EncodeDate (see page 22836)

ReplaceDate (see page 22936)

IncDay (see page 6643)

IncHour (see page 6644)

IncMilliSecond (see page 6645)

IncMinute (see page 6645)

IncSecond (see page 6646)

IncWeek (see page 6647)

IncYear (see page 6647)

159.3.133 SysUtils.IncludeTrailingBackslash Function

Ensures path name ends with delimiter

Pascal

```
function IncludeTrailingBackslash(const S: string): string; platform;
```

C++

```
AnsiString IncludeTrailingBackslash(const AnsiString S);
```

File

SysUtils

Description

IncludeTrailingBackslash ensures that a path name ends with a trailing path delimiter ('\" on Windows, '/' on Linux). This function is included for backward-compatibility only. New programs should use IncludeTrailingPathDelimiter (see page 22918).

Note: IncludeTrailingBackslash works with multibyte character sets.

See Also

ExcludeTrailingBackslash (see page 22839)

IsPathDelimiter (see page 22925)

159.3.134 SysUtils.IncludeTrailingPathDelimiter Function

Ensures path name ends with delimiter.

Pascal

```
function IncludeTrailingPathDelimiter(const S: string): string;
```

C++

```
AnsiString IncludeTrailingPathDelimiter(const AnsiString S);
```

File

SysUtils

Description

IncludeTrailingPathDelimiter ensures that a path name ends with a trailing path delimiter ('\" on Windows, '/' on Linux). If S already ends with a trailing delimiter character, it is returned unchanged; otherwise S with appended delimiter character is returned.

Note: IncludeTrailingPathDelimiter works with multibyte character sets.

See Also

ExcludeTrailingPathDelimiter (see page 22840)

IsPathDelimiter (see page 22925)

159.3.135 SysUtils.IncMonth Function

Returns a date shifted by a specified number of months.

Pascal

```
function IncMonth(const DateTime: TDateTime; NumberOfMonths: Integer = 1): TDateTime;
```

C++

```
TDateTime IncMonth(const TDateTime DateTime, int NumberOfMonths = 1);
```

File

SysUtils

Description

IncMonth returns the value of the Date (see page 22820) parameter, incremented by NumberOfMonths months. NumberOfMonths can be negative, to return a date N months previous.

If the input day of month is greater than the last day of the resulting month, the day is set to the last day of the resulting month. The time of day specified by the Date (see page 22820) parameter is copied to the result.

See Also

IncAMonth (see page 22917)

DecodeDate (see page 22828)

EncodeDate (see page 22836)

ReplaceDate (see page 22936)

IncDay (see page 6643)

IncHour (see page 6644)

IncMilliSecond (see page 6645)

IncMinute (see page 6645)

IncSecond (see page 6646)

IncWeek (see page 6647)

IncYear (see page 6647)

159.3.136 SysUtils.InitializePackage Function

Validates and initializes a given package.

Pascal

```
procedure InitializePackage(Module: HMODULE); overload;
procedure InitializePackage(Module: HMODULE; AValidatePackage: TValidatePackageProc); overload;
```

C++

```
InitializePackage(HMODULE Module);
InitializePackage(HMODULE Module, TValidatePackageProc AValidatePackage);
```

File

SysUtils

Description

InitializePackage checks for duplicate units in a package and calls the initialization blocks of the contained units.

Note: InitializePackage is called internally by the LoadPackage (see page 22927) function.

See Also

LoadPackage (see page 22927)

159.3.137 SysUtils.IntToHex Function

Returns the hex representation of an integer.

Pascal

```
function IntToHex(Value: Integer; Digits: Integer): string; overload;
function IntToHex(Value: Int64; Digits: Integer): string; overload;
```

C++

```
AnsiString IntToHex(int Value, int Digits);
AnsiString IntToHex(Int64 Value, int Digits);
```

File

SysUtils

Description

IntToHex converts a number into a string containing the number's hexadecimal (base 16) representation. Value is the number to convert. Digits indicates the minimum number of hexadecimal digits to return.

C++ Examples:

```
/*
The following example uses an edit control, a button, and a
label on a form. When the button is clicked, the hexadecimal
value of each character in the edit control is displayed in
the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = "";
```

```
    for (int i = 1; i <= Edit1->Text.Length(); i++)
    {
      try
      {
        Label1->Caption =
          Label1->Caption +
          IntToHex(Byte(Edit1->Text[i]),2) + ' ';
      }
      catch (...)
      {
        Beep();
      }
    }
  }
```

Delphi Examples:

```
{
The following example uses an edit control, a button, and a
label on a form. When the button is clicked, the hexadecimal
value of each character in the edit control is displayed in
the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  i: Integer;
begin
  Label1.Caption := '';
  for i := 1 to Length(Edit1.Text) do
  begin
    try
      Label1.Caption :=
        Label1.Caption +
        SysUtils.IntToHex(Byte(Edit1.Text[i]),2) + ' ';
    except
      Beep;
    end;
  end;
end;
```

See Also

IntToStr (see page 22921)

159.3.138 SysUtils.IntToStr Function

Converts an integer to a string.

Pascal

```
function IntToStr(Value: Integer): string; overload;
function IntToStr(Value: Int64): string; overload;
```

C++

```
AnsiString IntToStr(int Value);
AnsiString IntToStr(Int64 Value);
```

File

SysUtils

Description

IntToStr converts an integer into a string containing the decimal representation of that number.

C++ Examples:

```
/*
The following example uses two edit controls, a button, and
a label on a form. When the button is clicked, the integers
in the edit controls are multiplied together and the result
is displayed in the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  try
  {
    Label1->Caption = IntToStr(StrToInt(Edit1->Text) * StrToInt(Edit2->Text));
  }
  catch(...)
  {
    ShowMessage("You must specify integer values. Please try again.");
  }
}
```

Delphi Examples:

```
{
The following example uses two edit controls, a button, and
a label on a form. When the button is clicked, the integers
in the edit controls are multiplied together and the result
is displayed in the label.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  try
    Label1.Caption :=
      SysUtils.IntToStr(StrToInt(Edit1.Text) * StrToInt(Edit2.Text));
  except
    ShowMessage('You must specify integer values. Please try again.');
  end;
end;
```

See Also

IntToHex (see page 22920)

StrToIntDef (see page 22971)

FloatToStr (see page 22890)

DateToStr (see page 22825)

TimeToStr (see page 22977)

159.3.139 SysUtils.IsAssembly Function

Determines whether a dll is an Assembly.

Pascal

```
function IsAssembly(const FileName: string): Boolean;
```

C++

```
Boolean IsAssembly(const AnsiString FileName);
```

File

SysUtils

Description

Call IsAssembly to determine whether the passed FileName is that of a .Net Assembly or a traditional WIN32 DLL. The result is true if FileName is an Assembly.

159.3.140 SysUtils.IsDelimiter Function

Indicates whether a specified character in a string matches one of a set of delimiters.

Pascal

```
function IsDelimiter(const Delimiters: string; const S: string; Index: Integer): Boolean;
```

C++

```
Boolean IsDelimiter(const AnsiString Delimiters, const AnsiString S, int Index);
```

File

SysUtils

Description

Call IsDelimiter to determine whether the character at byte offset Index in the string S is one of the delimiters in the string Delimiters. Index is the index of the byte in question, where 1 is the first byte of the string, 2 is the second byte, and so on.

When working with a multi-byte character system (MBCS), IsDelimiter checks to make sure the indicated byte is not part of a double byte character. The delimiters in the Delimiters parameter must all be single byte characters.

See Also

AnsiStrRScan (see page 22799)

AnsiStrScan (see page 22799)

IsPathDelimiter (see page 22925)

LastDelimiter (see page 22926)

159.3.141 SysUtils.IsEqualGUID Function

Indicates whether two TGUID values are the same.

Pascal

```
function IsEqualGUID(const guid1: TGUID; const guid2: TGUID): Boolean; stdcall;
```

C++

```
__stdcall Boolean IsEqualGUID(const TGUID guid1, const TGUID guid2);
```

File

SysUtils

Description

IsEqualGUID returns true if the TGUID values are equal.

159.3.142 SysUtils.IsLeapYear Function

Indicates whether a specified year is a leap year.

Pascal

```
function IsLeapYear(Year: Word): Boolean;
```

C++

```
Boolean IsLeapYear(Word Year);
```

File

SysUtils

Description

Call IsLeapYear to determine whether the year specified by the Year parameter is a leap year. Year specifies the calendar year.

Use YearOf to obtain the value of Year for IsLeapYear from a TDateTime value.

C++ Examples:

```
/*
This example requires a button and a text edit. When the
user presses the button a message indicates if the year
specified in the text edit is a leap year.
*/
bool __fastcall IsThisLeapYear(int year)
{
  return IsLeapYear(year);
}

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  int year = StrToInt(Edit1->Text);
  if (IsThisLeapYear(year))
    ShowMessage(Edit1->Text + " is a leap year.");
  else
    ShowMessage(Edit1->Text + " is not a leap year.");
}
```

Delphi Examples:

```
{
This example requires a button and a text edit. When the
user presses the button a message indicates if the year
specified in the text edit is a leap year.
}
function IsThisLeapYear(year : Word): Boolean;
begin
  Result := IsLeapYear(year);
end;

procedure TForm1.Button1Click(Sender: TObject);
var
  year : integer;
begin
  year := StrToInt(Edit1.Text);
```

```
  if (IsThisLeapYear(year)) then
    ShowMessage(Edit1.Text + ' is a leap year.')
  else
    ShowMessage(Edit1.Text + ' is not a leap year.');
end;
```

See Also

Date (see page 22820)

YearOf (see page 6714)

IsInLeapYear (see page 6650)

159.3.143 SysUtils.IsPathDelimiter Function

Indicates whether the byte at a specified position in a string is the path delimiter.

Pascal

```
function IsPathDelimiter(const S: string; Index: Integer): Boolean;
```

C++

```
Boolean IsPathDelimiter(const AnsiString S, int Index);
```

File

SysUtils

Description

Call IsPathDelimiter to determine whether a position in the string S contains the path delimiter character ('/' on Linux, '\' on Windows). Positions are numbered from 1.

When working with a multi-byte character system (MBCS), IsPathDelimiter distinguishes between a true delimiter character, and the byte of the same value that can appear as the second byte of a double byte character.

To test for more characters than just the delimiter, use IsDelimiter (see page 22923).

See Also

IsDelimiter (see page 22923)

LastDelimiter (see page 22926)

159.3.144 SysUtils.IsValidIdent Function

Determines whether a string conforms to Delphi identifier rules.

Pascal

```
function IsValidIdent(const Ident: string; AllowDots: Boolean = False): Boolean;
```

C++

```
Boolean IsValidIdent(const AnsiString Ident, Boolean AllowDots = False);
```

File

SysUtils

Description

Call IsValidIdent to determine whether the passed Ident is valid for use as an identifier, such as the name of a component.

An identifier is a sequence of letters, digits or underscores. Only the first 63 characters are used uniquely. Letters are limited to A-Z and a-z, although the case is ignored. The first character cannot be a digit.

159.3.145 SysUtils.Languages Function

Lists the locales for which support is available.

Pascal

```
function Languages: TLanguages;
```

C++

```
TLanguages Languages();
```

File

SysUtils

Description

Use the value returned by Languages to obtain information about the locales that the system supports. This function is only available on Windows.

See Also

TSysLocale (see page 23008)

159.3.146 SysUtils.LastDelimiter Function

Returns the byte index of the last character that matches any character in a specified set of delimiters.

Pascal

```
function LastDelimiter(const Delimiters: string; const S: string): Integer;
```

C++

```
int LastDelimiter(const AnsiString Delimiters, const AnsiString S);
```

File

SysUtils

Description

Call LastDelimiter to locate the last delimiter in a specified string.

Delimiters is a string where each character is a valid delimiter.

S is the string to search for delimiters.

For example, the line

MyIndex := LastDelimiter('\.:','c:\filename.ext'); // Delphi

MyIndex = LastDelimiter("\\.:","c:\\filename.ext"); // C++

sets MyIndex to 12.

When working with multi-byte character sets (MBCS), S may contain double byte characters, but the delimiters listed in the Delimiters parameter must all be single byte non-null characters.

See Also

IsDelimiter (see page 22923)

AnsiStrRScan (see page 22799)

159.3.147 SysUtils.LoadPackage Function

Loads a specified package.

Pascal

```
function LoadPackage(const Name: string): HMODULE; overload;
function LoadPackage(const Name: string; AValidatePackage: TValidatePackageProc): HMODULE;
overload;
```

C++

```
HMODULE LoadPackage(const AnsiString Name);
HMODULE LoadPackage(const AnsiString Name, TValidatePackageProc AValidatePackage);
```

File

SysUtils

Description

LoadPackage loads the package specified by the Name parameter, checks for duplicate units, and calls the initialization blocks of all units contained in the package.

See Also

UnloadPackage (see page 22987)

159.3.148 SysUtils.LoadStr Function

Loads a string resource from the application's executable file.

Pascal

```
function LoadStr(Ident: Integer): string;
```

C++

```
AnsiString LoadStr(int Ident);
```

File

SysUtils

Description

LoadStr loads the string resource given by Ident from the application's executable file or shared library. If the string resource does not exist, LoadStr returns an empty string.

Moving display strings into string resources makes an application easier to localize without rewriting the program.

Note: :LoadStr is provided primarily for backward compatibility. To isolate string resources in Delphi, use the resourcestring keyword in new applications.

159.3.149 SysUtils.LowerCase Function

Converts an ASCII string to lowercase.

Pascal

```
function LowerCase(const S: string): string; overload;
function LowerCase(const S: string; LocaleOptions: TLocaleOptions): string; overload;
```

C++

```
AnsiString LowerCase(const AnsiString S);
AnsiString LowerCase(const AnsiString S, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

LowerCase returns a string with the same text as the string passed in S, but with all letters converted to lowercase. The conversion affects only 7-bit ASCII characters between 'A' and 'Z'. To convert 8-bit international characters, use AnsiLowerCase (see page 22792).

C++ Examples:

```
/*
This example uses an edit control, a label, and a button on a
form. When the user clicks the button, the label shows the text of
the edit control in lower case.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = LowerCase(Edit1->Text);
}
```

Delphi Examples:

```
{
This example uses an edit control, a label, and a button on a
form. When the user clicks the button, the label shows the text of
the edit control in lower case.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := SysUtils.LowerCase(Edit1.Text);
end;
{
The following example beeps once for each "beep" passed in
on the command line.  The example terminates the application
if  "exit" is passed in on the command line.  Build the
project to generate a .exe file and then execute that file
from a command line: "ParamCount_proj beep beep exit".
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
//  Use print statements since you can't use the debugger.
//  MessageDlg(
//    'System ParamCount = ' + IntToStr(System.ParamCount),
```

```
//    mtConfirmation, [mbOK], 0);
  for i := 1 to System.ParamCount do
  begin
    if LowerCase(ParamStr(i)) = 'beep' then
      Beep
    else if LowerCase(ParamStr(i)) = 'exit' then
      Application.Terminate;
    Sleep(250);
  end;
end;
```

See Also

AnsiLowerCase (see page 22792)

UpperCase (see page 22988)

159.3.150 SysUtils.MSecsToTimeStamp Function

Converts a specified number of milliseconds into a TTimeStamp (see page 23009) value.

Pascal

```
function MSecsToTimeStamp(MSecs: Comp): TTimeStamp;
```

C++

```
TTimeStamp MSecsToTimeStamp(Comp MSecs);
```

File

SysUtils

Description

Call MSecsToTimeStamp to convert MSecs, a number of milliseconds, into the number of days represented, plus the number of milliseconds remaining. The days and milliseconds are expressed as a TTimeStamp (see page 23009) value, where the Date (see page 22820) field is the number of days and the Time (see page 22976) field is the remainder in milliseconds.

See Also

TimeStampToMSecs (see page 22977)

TTimeStamp (see page 23009)

159.3.151 SysUtils.NewStr Function

Allocates a string on the heap.

Pascal

```
function NewStr(const S: string): PString; deprecated;
```

C++

```
PString NewStr(const AnsiString S);
```

File

SysUtils

Description

NewStr allocates a new string on the heap. Do not use NewStr in new applications. This function is provided for backward compatibility only.

159.3.152 SysUtils.NextCharIndex Function

Returns the byte index of the next character.

Pascal

```
function NextCharIndex(const S: String; Index: Integer): Integer;
```

C++

```
int NextCharIndex(const AnsiString S, int Index);
```

File

SysUtils

Description

NextCharIndex returns the byte index of the first byte of the character following the character starting at S[Index].

159.3.153 SysUtils.Now Function

Returns the current date and time.

Pascal

```
function Now: TDateTime;
```

C++

```
TDateTime Now();
```

File

SysUtils

Description

Returns the current date and time, corresponding to the sum of the value returned by the global Date (see page 22820) and Time (see page 22976) functions.

Note: Although TDateTime values can represent milliseconds, Now is accurate only to the nearest second.

C++ Examples:

```
/*
This example uses a label and a button on a form. When the
user clicks the button, the current date and time is
converted to a string and displayed as the caption of the
label:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->Caption = DateTimeToStr(Now());
```

```
}
```

Delphi Examples:

```
{
This example uses a label and a button on a form. When the
user clicks the button, the current date and time is
converted to a string and displayed as the caption of the
label:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.Caption := SysUtils.DateTimeToStr(Now);
end;
```

See Also

Date (see page 22820)

DateTimeToStr (see page 22822)

Time (see page 22976)

159.3.154 SysUtils.OutOfMemoryError Function

Raises an EOutOfMemory (see page 22742) exception.

Pascal

```
procedure OutOfMemoryError;
```

C++

```
OutOfMemoryError();
```

File

SysUtils

Description

Call OutOfMemoryError to raise the EOutOfMemory (see page 22742) exception. OutOfMemoryError runs without allocating additional memory.

See Also

EOutOfMemory (see page 22742)

159.3.155 SysUtils.QuotedStr Function

Returns the quoted version of a string.

Pascal

```
function QuotedStr(const S: string): string;
```

C++

```
AnsiString QuotedStr(const AnsiString S);
```

File

SysUtils

Description

Use QuotedStr to convert the string S to a quoted string. A single quote character (') is inserted at the beginning and end of S, and each single quote character in the string is repeated.

Note: When working with multi-byte character systems (MBCS), use AnsiQuotedStr (see page 22793) instead.

159.3.156 SysUtils.RaiseLastOSError Function

Raises an exception for the last occurring OS or system library error.

Pascal

```
procedure RaiseLastOSError; overload;
procedure RaiseLastOSError(LastError: Integer); overload;
```

C++

```
RaiseLastOSError();
RaiseLastOSError(int LastError);
```

File

SysUtils

Description

Call RaiseLastOSError to raise an EOSError (see page 22740) exception for the last OS API call that failed. RaiseLastOSError retrieves the code for the last occurring API call error, if any. If this belongs to a previously occurring error, RaiseLastOSError raises an EOSError (see page 22740) exception with the error code and message associated with that error.

See Also

EOSError (see page 22740)

159.3.157 SysUtils.RaiseLastWin32Error Function

Raises an exception for the last occurring Win32 error.

Pascal

```
procedure RaiseLastWin32Error; deprecated;
```

C++

```
RaiseLastWin32Error();
```

File

SysUtils

Description

Call RaiseLastWin32Error to raise an EWin32Error (see page 22749) exception for the last Windows API call that failed. RaiseLastWin32Error retrieves the code for the last occurring Win32 error, if any. If Windows returns a previously occurring error code, RaiseLastWin32Error raises an EWin32Error (see page 22749) exception with the error code and message associated with that error.

Note: RaiseLastWin32Error is a deprecated Windows-only procedure. New applications should use RaiseLastOSError (see page 22932) instead.

See Also

EWin32Error (see page 22749)

Win32Check (see page 22994)

RaiseLastOSError (see page 22932)

159.3.158 SysUtils.RCS Function

Check for Delphi Client/Server Licence.

Pascal

```
procedure RCS;
```

C++

```
RCS();
```

File

SysUtils

Description

RCS is used by VCL components to check whether there is a Client/Server licence, raising an exception of not.

See Also

GDAL (see page 22909)

RPR (see page 22938)

159.3.159 SysUtils.RemoveDir Function

Deletes an existing empty directory.

Pascal

```
function RemoveDir(const Dir: string): Boolean;
```

C++

```
Boolean RemoveDir(const AnsiString Dir);
```

File

SysUtils

Description

Call RemoveDir to remove the directory specified by the Dir parameter. The return value is true if a new directory was successfully deleted, false if an error occurred. The directory must be empty before it can be successfully deleted.

See Also

ExtractFileDir (see page 22843)

GetCurrentDir (see page 22910)

SetCurrentDir (see page 22940)

159.3.160 SysUtils.RenameFile Function

Changes a file name.

Pascal

```
function RenameFile(const OldName: string; const NewName: string): Boolean;
```

C++

```
Boolean RenameFile(const AnsiString OldName, const AnsiString NewName);
```

File

SysUtils

Description

RenameFile attempts to change the name of the file specified by OldFile to NewFile. If the operation succeeds, RenameFile returns true. If RenameFile cannot rename the file (for example, if the application does not have permission to modify the file), it returns false.

Note: If NewFile represents the name of an existing file, RenameFile behaves differently under Windows and Linux. Under Windows, the rename operation fails. Under Linux, RenameFile silently removes the other file.

C++ Examples:

```
/*
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
*/

#include <dir.h>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char szFileName[MAXFILE+4];
  int iFileHandle;
  int iLength;
  if (SaveDialog1->Execute())
  {
    if (FileExists(SaveDialog1->FileName))
    {
      fnsplit(SaveDialog1->FileName.c_str(), 0, 0, szFileName, 0);
      strcat(szFileName, ".BAK");
      RenameFile(SaveDialog1->FileName, szFileName);
    }
    iFileHandle = FileCreate(SaveDialog1->FileName);
    // Write out the number of rows and columns in the grid.
    FileWrite(iFileHandle, (char*)&(StringGrid1->ColCount), sizeof(StringGrid1->ColCount));
    FileWrite(iFileHandle, (char*)&(StringGrid1->RowCount), sizeof(StringGrid1->RowCount));
    for (int x=0;x<StringGrid1->ColCount;x++)
    {
      for (int y=0;y<StringGrid1->RowCount;y++)
      {
        // Write out the length of each string, followed by the string itself.
        iLength = StringGrid1->Cells[x][y].Length();
```

```
        FileWrite(iFileHandle, (char*)&iLength, sizeof(iLength));
        FileWrite(iFileHandle, StringGrid1->Cells[x][y].c_str(),
StringGrid1->Cells[x][y].Length());
      }
    }
    FileClose(iFileHandle);
  }
}
//---------------------------------------------------------------------------
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  StringGrid1->Cells[1][0] = "Column 1";
  StringGrid1->Cells[2][0] = "Column 2";
  StringGrid1->Cells[3][0] = "Column 3";
  StringGrid1->Cells[4][0] = "Column 4";
  StringGrid1->Cells[0][1] = "Row 1";
  StringGrid1->Cells[1][1] = "Object";
  StringGrid1->Cells[2][1] = "Pascal";
  StringGrid1->Cells[3][1] = "is";
  StringGrid1->Cells[4][1] = "excellent";
  StringGrid1->Cells[0][2] = "Row 2";
  StringGrid1->Cells[1][2] = "Delphi";
  StringGrid1->Cells[2][2] = "is";
  StringGrid1->Cells[4][2] = "RAD";
};
```

Delphi Examples:

```
{
The following example uses a button, a string grid, and a
Save dialog box on a form. When the button is clicked, the
user is prompted for a filename. When the user clicks OK,
the contents of the string grid are written to the specified
file. Additional information is also written to the file so
that it can be read easily with the FileRead function.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  BackupName: string;
  FileHandle: Integer;
  StringLen: Integer;
  X, Y, I: Integer;
  colCountLength, rowCountLength: Integer;
  Buffer: PChar;
  cellString: string;
begin
  if SaveDialog1.Execute then
  begin
    if FileExists(SaveDialog1.FileName) then
    begin
      BackupName := SysUtils.ExtractFileName(SaveDialog1.FileName);
      BackupName := ChangeFileExt(BackupName, '.BAK');
      if not RenameFile(SaveDialog1.FileName, BackupName) then
        raise Exception.Create('Unable to create backup file.');
    end;
    FileHandle := FileCreate(SaveDialog1.FileName);
    { Write out the number of rows and columns in the grid. }
    colCountLength := SizeOf(StringGrid1.ColCount);
    FileWrite(FileHandle,
      Pchar(StringGrid1.ColCount), colCountLength);
    rowCountLength := SizeOf(StringGrid1.RowCount);
    FileWrite(FileHandle,
      PChar(StringGrid1.RowCount), rowCountLength);
    for X := 0 to StringGrid1.ColCount - 1 do
    begin
      for Y := 0 to StringGrid1.RowCount - 1 do
      begin
```

```
          try
            { Write out the length of each string, followed by the string itself. }
            StringLen := Length(StringGrid1.Cells[X,Y]);
            FileWrite(FileHandle, PChar(StringLen), SizeOf(StringLen));
            GetMem(Buffer, StringLen); { allocate the buffer }
            cellString := StringGrid1.Cells[X,Y];
            for I := 1 to StringLen do
               Buffer[I - 1] := cellString[I];
            FileWrite(FileHandle, Buffer^, StringLen);
          finally
            FreeMem(Buffer, StringLen);
          end;
        end;
      end;
      FileClose(FileHandle);
    end;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    with StringGrid1 do
    begin
      Cells[1,0] := 'Column 1';
      Cells[2,0] := 'Column 2';
      Cells[3,0] := 'Column 3';
      Cells[4,0] := 'Column 4';
      Cells[0,1] := 'Row 1';
      Cells[1,1] := 'Object';
      Cells[2,1] := 'Pascal';
      Cells[3,1] := 'is';
      Cells[4,1] := 'excellent';
      Cells[0,2] := 'Row 2';
      Cells[1,2] := 'Delphi';
      Cells[2,2] := 'is';
      Cells[4,2] := 'RAD';
    end;
  end;
```

DeleteFile (see page 22831)

Rename (see page 22510)

159.3.161 SysUtils.ReplaceDate Function

Replaces the date portion of a TDateTime value with a specified date.

Pascal

```
procedure ReplaceDate(var DateTime: TDateTime; const NewDate: TDateTime);
```

C++

```
ReplaceDate(TDateTime DateTime, const TDateTime NewDate);
```

File

SysUtils

Description

ReplaceDate changes the value of the DateTime parameter so that it has the same date as the NewDate parameter. The time portion of DateTime remains the same. ReplaceDate makes any necessary adjustments for negative dates (before 1900).

See Also

DecodeDate (see page 22828)

EncodeDate (see page 22836)

ReplaceTime (see page 22937)

RecodeDateYear

RecodeDate (see page 6673)

159.3.162 SysUtils.ReplaceTime Function

Replaces the time portion of a TDateTime value with a specified time.

Pascal

```
procedure ReplaceTime(var DateTime: TDateTime; const NewTime: TDateTime);
```

C++

```
ReplaceTime(TDateTime DateTime, const TDateTime NewTime);
```

File

SysUtils

Description

ReplaceTime changes the value of the DateTime parameter so that it has the same time as the NewTime parameter. The date portion of DateTime remains the same. ReplaceTime makes any necessary adjustments for negative dates. (before 1900)

See Also

159.3.163 SysUtils.RPR Function

Check for Delphi Professional Licence.

Pascal

```
procedure RPR;
```

C++

```
RPR();
```

File

SysUtils

Description

RPR is used by VCL components to check whether there is a Professional licence, raising an exception of not.

See Also

GDAL (see page 22909)

RCS (see page 22933)

159.3.164 SysUtils.SafeLoadLibrary Function

Safe and simple library loading.

Pascal

```
function SafeLoadLibrary(const FileName: string; ErrorMode: UINT = SEM_NOOPENFILEERRORBOX):
HMODULE;
```

C++

```
HMODULE SafeLoadLibrary(const AnsiString FileName, UINT ErrorMode = SEM_NOOPENFILEERRORBOX);
```

File

SysUtils

Description

SafeLoadLibrary loads a Windows DLL or Linux shared object file, as specified by Filename. SafeLoadLibrary preserves the current FPU control word, preventing library initialization code from permanently overwriting precision and exception masks.

Note: On Windows, SafeLoadLibrary temporarily sets the system error mode to ErrorMode. The default, SEM_NOOPENFILEERRORBOX, suppresses error dialogs. The previous error mode is restored before SafeLoadLibrary exits. For a list of error modes, refer to SetErrorMode in the Microsoft documentation.

Note: On Linux, the Dummy argument is ignored.

See Also

LoadPackage (see page 22927)

159.3.165 SysUtils.SameFileName Function

Compares file names based on the current locale.

Pascal

```
function SameFileName(const S1: string; const S2: string): Boolean;
```

C++

```
Boolean SameFileName(const AnsiString S1, const AnsiString S2);
```

File

SysUtils

Description

SameFileName compares two file names in the same way as AnsiCompareFileName (see page 22788). SameFileName returns true if the file names match, false otherwise. Like AnsiCompareFileName (see page 22788), SameFileName supports locales and MBCS strings; see the AnsiCompareFileName (see page 22788) topic for more details.

See Also

AnsiCompareText (see page 22790)

159.3.166 SysUtils.SameStr Function

Compares two strings by ordinal value with case sensitivity.

Pascal

```
function SameStr(const S1: string; const S2: string): Boolean; overload;
function SameStr(const S1: string; const S2: string; LocaleOptions: TLocaleOptions): Boolean;
overload;
```

C++

```
Boolean SameStr(const AnsiString S1, const AnsiString S2);
Boolean SameStr(const AnsiString S1, const AnsiString S2, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

SameStr compares S1 and S2 and returns true if they are identical. SameStr is case sensitive and is not affected by the current locale.

See Also

SameText (see page 22940)

CompareStr (see page 22813)

CompareText (see page 22814)

AnsicompareStr

AnsicompareText

CompareMem (see page 22812)

159.3.167 SysUtils.SameText Function

Compares two strings by ordinal value without case sensitivity.

Pascal

```
function SameText(const S1: string; const S2: string): Boolean; overload;
function SameText(const S1: string; const S2: string; LocaleOptions: TLocaleOptions): Boolean;
overload;
```

C++

```
Boolean SameText(const AnsiString S1, const AnsiString S2);
Boolean SameText(const AnsiString S1, const AnsiString S2, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

SameText compares S1 and S2 and returns true if they are equal. SameText is not case sensitive and is not affected by the current locale.

See Also

CompareStr (see page 22813)

AnsiCompareText (see page 22790)

CompareMem (see page 22812)

CompareText (see page 22814)

159.3.168 SysUtils.SetCurrentDir Function

Sets the current directory.

Pascal

```
function SetCurrentDir(const Dir: string): Boolean;
```

C++

```
Boolean SetCurrentDir(const AnsiString Dir);
```

File

SysUtils

Description

The SetCurrentDir function sets the current directory. The return value is true if the current directory was successfully changed, or false if an error occurred.

See Also

ChDir (see page 22429)

CreateDir (see page 22817)

ExtractFileDir (see page 22843)

GetCurrentDir (see page 22910)

RemoveDir (see page 22933)

159.3.169 SysUtils.ShowException Function

Displays an exception message with its physical address

Pascal

```
procedure ShowException(ExceptObject: TObject; ExceptAddr: Pointer);
```

C++

```
ShowException(TObject * ExceptObject, void * ExceptAddr);
```

File

SysUtils

Description

ShowException displays the message associated with an exception, together with the exception's physical address. The exception's address can be used with Search | Find Error menu command to find the statement that raised the exception.

See Also

ExceptionErrorMessage (see page 22839)

ExceptObject (see page 22452)

ExceptAddr (see page 22452)

159.3.170 SysUtils.Sleep Function

Delay program execution for a specified number of milliseconds.

Pascal

```
procedure Sleep(milliseconds: Cardinal); stdcall;
```

C++

```
__stdcall Sleep(unsigned milliseconds);
```

File

SysUtils

Description

Sleep pauses program executions as specified by the milliseconds parameter. Under Windows, Sleep is just a link to the Sleep function in the system API.

159.3.171 SysUtils.StrAlloc Function

Allocates a buffer for a null-terminated string and returns a pointer to its first character.

Pascal

```
function StrAlloc(Size: Cardinal): PChar;
```

C++

```
const char * StrAlloc(unsigned Size);
```

File

SysUtils

Description

StrAlloc allocates a buffer for a null-terminated string with a maximum length of Size - 1 (1 byte must be reserved for the termination character). The result points to the location where the first character of the string is to be stored. A 32-bit number giving the total amount of memory allocated is stored in the four bytes preceding the first character; it is equal to Size + 4. If space for a string is allocated with StrAlloc, it should be deallocated via StrDispose (see page 22947).

Because AnsiStrings (long strings) are implicitly null terminated and dynamically allocated, the use of StrAlloc is deprecated.

See Also

StrDispose (see page 22947)

StrNew (see page 22957)

StrBufSize (see page 22942)

159.3.172 SysUtils.StrBufSize Function

Returns the maximum number of characters that can be stored in a buffer allocated by StrAlloc (see page 22942).

Pascal

```
function StrBufSize(const Str: PChar): Cardinal;
```

C++

```
unsigned StrBufSize(const const char * Str);
```

File

SysUtils

Description

StrBufSize returns the number of bytes in Str, including the byte for the termination character.

Note: NoteIf Str does not point to a string buffer allocated by StrAlloc (see page 22942) or StrNew (see page 22957), no error message is returned, and the result is unpredictable.

See Also

StrAlloc (see page 22942)

StrNew (see page 22957)

159.3.173 SysUtils.StrByteType Function

Indicates whether a byte in a string is a single byte character, the first byte of a double byte character, or the second byte of a double byte character.

Pascal

```
function StrByteType(Str: PChar; Index: Cardinal): TMbcsByteType;
```

C++

```
TMbcsByteType StrByteType(const char * Str, unsigned Index);
```

File

SysUtils

Description

Call StrByteType to determine the type of the byte specified by the Index parameter, where 0 specifies the first byte in the string Str, 1 specifies the second byte, and so on.

If the system is not using a multi-byte character system (MBCS), StrByteType always returns mbSingleByte. Otherwise, StrByteType returns mbSingleByte if the indicated byte represents a complete character in Str, mbLeadByte if it represents the first byte of a double byte character, and mbTrailByte if it represents the second byte of a double byte character.

Note: No checking is done to ensure that Index is less than the length of Str. It is the caller's responsibility to ensure that Index is not out of bounds.

See Also

ByteType (see page 22807)

LeadBytes (see page 23026)

159.3.174 SysUtils.StrCat Function

Appends a copy of Source to the end of Dest and returns the concatenated string.

Pascal

```
function StrCat(Dest: PChar; const Source: PChar): PChar;
```

C++

```
const char * StrCat(const char * Dest, const const char * Source);
```

File

SysUtils

Description

Use StrCat to concatenate Source to the end of Dest. StrCat does not perform any length checking. The destination buffer must

have room for at least StrLen (see page 22954)(Dest)+StrLen (see page 22954)(Source)+1 characters.

To check length, use the StrLCat (see page 22952) function.

C++ Examples:

```
/*
The following example uses an edit control, a label, and a button
on a form. When the button is clicked, the label's caption and the
edit control's text are combined in a buffer. Then the buffer is
displayed in the label's caption.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char* szBuffer = new char[Label1->Caption.Length() + Edit1->Text.Length() + 1];
  // The following 2 lines are used in VCL applications
  StrCopy(szBuffer, Label1->Caption.c_str());
  StrCat(szBuffer, Edit1->Text.c_str());
  Label1->Caption = szBuffer;
  Edit1->Clear();
  delete [] szBuffer;
}
```

Delphi Examples:

```
{
The following example uses an edit control, a label, and a button
on a form. When the button is clicked, the label's caption and the
edit control's text are combined in a buffer. Then the buffer is
displayed in the label's caption.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
begin
  GetMem(Buffer,Length(Label1.Caption) + Length(Edit1.Text) + 1);
  StrCopy(Buffer, PChar(Label1.Caption));
  SysUtils.StrCat(Buffer, PChar(Edit1.Text));
  Label1.Caption := Buffer;
  Edit1.Clear;
  FreeMem(Buffer);
end;
```

See Also

StrLCat (see page 22952)

StrLen (see page 22954)

159.3.175 SysUtils.StrCharLength Function

Returns the length, in bytes, of a character.

Pascal

```
function StrCharLength(const Str: PChar): Integer;
```

C++

```
int StrCharLength(const const char * Str);
```

File

SysUtils

Description

StrCharLength returns the size, in bytes, of the first character in Str. This value can be 1 or 2 under Windows, 1 to 6 under Linux.

See Also

ByteType (see page 22807)

LeadBytes (see page 23026)

159.3.176 SysUtils.StrComp Function

Compares two strings with case sensitivity.

Pascal

```
function StrComp(const Str1: PChar; const Str2: PChar): Integer;
```

C++

```
int StrComp(const const char * Str1, const const char * Str2);
```

File

SysUtils

Description

Call StrComp to compare two null-terminated strings, with case sensitivity. The return value is indicated in the following table:

Return value	Condition
<0	Str1 sorts before Str2
=0	Str1is the same as Str2
>0	Str1 sorts after Str2

Note: When working with International characters, use AnsiStrComp (see page 22795) instead.

C++ Examples:

```
/*
The following example uses two edit controls and a button on
a form. When the button is clicked, the text in the edit
controls is compared.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char* szResult = new char[Edit1->Text.Length() + Edit2->Text.Length() + 20];
  int iResult = StrComp(Edit1->Text.c_str(), Edit2->Text.c_str());
  StrCopy(szResult, Edit1->Text.c_str());
  if (iResult < 0)
    StrCat(szResult, " is less than ");
  else if (iResult > 0)
    StrCat(szResult, " is greater than ");
  else
    StrCat(szResult, " is equal to ");

  StrCat(szResult, Edit2->Text.c_str());
  ShowMessage(AnsiString(szResult));
  delete [] szResult;
```

```
}
```

Delphi Examples:

```
{
The following example uses two edit controls and a button on
a form. When the button is clicked, the text in the edit
controls is compared.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Msg: string;
  CompResult: Integer;
begin
  Msg := Edit1.Text;
  CompResult := SysUtils.StrComp(PChar(Edit1.Text), PChar(Edit2.Text));
  if CompResult < 0 then
    Msg := Msg + ' is less than '
  else if CompResult > 0 then
    Msg := Msg + ' is greater than '
  else
    Msg := Msg + ' is equal to ';
  Msg := Msg + Edit2.Text;
  ShowMessage(Msg);
end;
```

See Also

AnsiStrComp (see page 22795)

StrIComp (see page 22951)

StrLComp (see page 22953)

StrLIComp (see page 22955)

159.3.177 SysUtils.StrCopy Function

Copies a null-terminated string.

Pascal

```
function StrCopy(Dest: PChar; const Source: PChar): PChar;
```

C++

```
const char * StrCopy(const char * Dest, const const char * Source);
```

File

SysUtils

Description

Use StrCopy to copy Source to Dest. StrCopy returns Dest.

StrCpy does not perform any length checking. The destination buffer must have room for at least StrLen (see page 22954)(Source)+1 characters.

For length checking, use the StrLCopy (see page 22953) function.

C++ Examples:

```
/*
The following example uses an edit control, a label, and a button
```

```
on a form. When the button is clicked, the label's caption and the
edit control's text are combined in a buffer. Then the buffer is
displayed in the label's caption.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char* szBuffer = new char[Label1->Caption.Length() + Edit1->Text.Length() + 1];
  // The following 2 lines are used in VCL applications
  StrCopy(szBuffer, Label1->Caption.c_str());
  StrCat(szBuffer, Edit1->Text.c_str());
  Label1->Caption = szBuffer;
  Edit1->Clear();
  delete [] szBuffer;
}
```

Delphi Examples:

```
{
The following example uses an edit control, a label, and a button
on a form. When the button is clicked, the label's caption and the
edit control's text are combined in a buffer. Then the buffer is
displayed in the label's caption.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Buffer: PChar;
begin
  GetMem(Buffer,Length(Label1.Caption) + Length(Edit1.Text) + 1);
  StrCopy(Buffer, PChar(Label1.Caption));
  SysUtils.StrCat(Buffer, PChar(Edit1.Text));
  Label1.Caption := Buffer;
  Edit1.Clear;
  FreeMem(Buffer);
end;
```

See Also

StrECopy (see page 22948)

StrLCopy (see page 22953)

159.3.178 SysUtils.StrDispose Function

Disposes of a string.

Pascal

```
procedure StrDispose(Str: PChar);
```

C++

```
StrDispose(const char * Str);
```

File

SysUtils

Description

StrDispose is provided for backward compatibility. StrDispose disposes of a string on a heap that was previously allocated with StrAlloc (see page 22942) or StrNew (see page 22957).

If Str is nil (Delphi) or NULL (C++), StrDispose does nothing.

C++ Examples:

```
/*
This example uses an edit control and a button on a form.
When the button is clicked, memory is allocated for a copy
of the text in the edit control, the text is displayed in a
message box, and then the memory is deallocated.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // Allocate memory.
  char* psz = StrNew(Edit1->Text.c_str());
  Application->MessageBox(psz, "StrNew, StrDispose example", MB_OK);
  // Deallocate memory.
  StrDispose(psz);
}
```

Delphi Examples:

```
{
This example uses an edit control and a button on a form.
When the button is clicked, memory is allocated for a copy
of the text in the edit control, the text is displayed in a
message box, and then the memory is deallocated.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Temp: PChar;
begin
  // Allocate memory.
  Temp := StrNew(PChar(Edit1.Text));
  Application.MessageBox(Temp, 'StrNew, StrDispose example', MB_OK);
  // Deallocate memory.
  SysUtils.StrDispose(Temp);
end;
```

See Also

StrAlloc (see page 22942)

StrNew (see page 22957)

159.3.179 SysUtils.StrECopy Function

Copies null-terminated string.

Pascal

```
function StrECopy(Dest: PChar; const Source: PChar): PChar;
```

C++

```
const char * StrECopy(const char * Dest, const const char * Source);
```

File

SysUtils

Description

StrECopy copies Source to Dest and returns StrEnd (see page 22949)(Dest).

StrECopy does not perform any length checking. The destination buffer must have room for at least StrLen (see page 22954)(Source)+1 characters.

Nested calls to StrECopy to concatenate a sequence of strings run more efficiently than multiple calls to StrCat (see page 22943).

C++ Examples:

```
/*
The following example uses an edit control, a label, and a
button on a form. When the button is clicked, the edit
control’s text is appended to a static buffer. Then the
buffer is displayed in the label’s caption.
*/
const static int MAX_LENGTH = 15;
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  static char szBuffer[MAX_LENGTH];
  static char* pszBuffer = szBuffer;

  if (StrLen(pszBuffer) + StrLen(Edit1->Text.c_str()) < MAX_LENGTH)
    pszBuffer = StrECopy(pszBuffer, Edit1->Text.c_str());
  else
    ShowMessage("Can't fit new string in allocated memory space.");
  Label1->Caption = szBuffer;
}
```

Delphi Examples:

```
{
This example uses a button on a form.  Since StrECopy returns
the destination char array, nested calls are possible and
actually more efficient than repeated calls.  StrECopy does
no bounds checking. When the button is clicked, the inline
text is appended to a static buffer. Then the buffer is
displayed in the form's canvas.
}

procedure TForm1.Button1Click(Sender: TObject);
const
  Turbo: PChar = 'Object';
  Pascal: PChar = 'Pascal';
 var
  S: array[0..15] of Char;
begin
  StrECopy(StrECopy(StrECopy(S, Turbo), ' '), Pascal);
  Canvas.TextOut(10, 10, string(S));
end;
```

See Also

StrCat (see page 22943)

StrCopy (see page 22946)

StrEnd (see page 22949)

StrLen (see page 22954)

159.3.180 SysUtils.StrEnd Function

Returns a pointer to the end of a null terminated string.

Pascal

```
function StrEnd(const Str: PChar): PChar;
```

C++

```
const char * StrEnd(const const char * Str);
```

File

SysUtils

Description

StrEnd returns a pointer to the null character at the end of Str.

See Also

AnsiStrLastChar (see page 22796)

StrLen (see page 22954)

159.3.181 SysUtils.StrFmt Function

Formats entries in an array.

Pascal

```
function StrFmt(Buffer: PChar; Format: PChar; const Args: array of const): PChar; overload;
function StrFmt(Buffer: PChar; Format: PChar; const Args: array of const; const
FormatSettings: TFormatSettings): PChar; overload;
```

C++

```
const char * StrFmt(const char * Buffer, const char * Format, const array of const Args);
const char * StrFmt(const char * Buffer, const char * Format, const array of const Args, const
TFormatSettings FormatSettings);
```

File

SysUtils

Description

StrFmt formats the series of arguments from an open array into a buffer.

Buffer is a buffer that receives the results.

Format (see page 22897) is a null-terminated format string that indicates how to generate the results. For more information about how the result is formatted, see Format (see page 22897) Strings.

Args is an array of arguments that replace the format specifiers in Format (see page 22897).

Note: Args_Size gives the index of the last argument (one less than the number of elements in Args).

StrFmt returns a pointer to the destination buffer.

The first form of StrFmt is not thread-safe, because it uses localization information contained in global variables. The second form of StrFmt, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrFmt, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

See Also

Format (see page 22897)

GetLocaleFormatSettings (see page 22913)

159.3.182 SysUtils.StrIComp Function

Compares two strings without case sensitivity.

Pascal

```
function StrIComp(const Str1: PChar; const Str2: PChar): Integer;
```

C++

```
int StrIComp(const const char * Str1, const const char * Str2);
```

File

SysUtils

Description

Call StrIComp to compare two strings without case sensitivity. StrIComp returns a value greater than 0 if Str1 > Str2, less than 0 if Str1 < Str2, and returns 0 if the strings are equal except for differences in case.

When working with international characters, use AnsiStrIComp (see page 22795) instead.

See Also

AnsiStrIComp (see page 22795)

StrComp (see page 22945)

StrLComp (see page 22953)

StrLIComp (see page 22955)

159.3.183 SysUtils.StringReplace Function

Returns a string with occurrences of one substring replaced by another substring.

Pascal

```
function StringReplace(const S: string; const OldPattern: string; const NewPattern: string;
Flags: TReplaceFlags): string;
```

C++

```
AnsiString StringReplace(const AnsiString S, const AnsiString OldPattern, const AnsiString
NewPattern, TReplaceFlags Flags);
```

File

SysUtils

Description

StringReplace replaces occurrences of the substring specified by OldPattern with the substring specified by NewPattern. StringReplace assumes that the source string may contain Multibyte characters.

S is the source string, whose substrings are changed.

OldPattern is the substring to locate and replace with NewPattern.

NewPattern is the substring to substitute for occurrences of OldPattern.

Flags is a set of flags that govern how StringReplace locates and replaces occurrences of OldPattern. If Flags does not include rfReplaceAll, StringReplace only replaces the first occurrence of OldPattern in S. Otherwise, StringReplace replaces all instances of OldPattern with NewPattern. If the Flags parameter includes rfIgnoreCase, the comparison operation is case insensitive.

159.3.184 SysUtils.StringToGUID Function

Converts a string to a GUID.

Pascal

```
function StringToGUID(const S: string): TGUID;
```

C++

```
TGUID StringToGUID(const AnsiString S);
```

File

SysUtils

Description

StringToGUID converts the string representation of a GUID, S, into an equivalent TGUID data structure.

If StringToGUID succeeds it returns the requested GUID. If StringToGUID fails an EConvertError (see page 22724) exception is raised.

See Also

GUIDToString (see page 22916)

159.3.185 SysUtils.StrLCat Function

Appends up to a specified maximum number of characters to string.

Pascal

```
function StrLCat(Dest: PChar; const Source: PChar; MaxLen: Cardinal): PChar;
```

C++

```
const char * StrLCat(const char * Dest, const const char * Source, unsigned MaxLen);
```

File

SysUtils

Description

StrLCat appends at most MaxLen - StrLen (see page 22954)(Dest) characters from Source to the end of Dest and returns Dest. That is, MaxLen indicates the maximum length that is allowed in the result string.

See Also

SizeOf (see page 22528)

StrCat (see page 22943)

StrLen (see page 22954)

159.3.186 SysUtils.StrLComp Function

Compares up to a specified maximum number of characters in two strings.

Pascal

```
function StrLComp(const Str1: PChar; const Str2: PChar; MaxLen: Cardinal): Integer;
```

C++

```
int StrLComp(const const char * Str1, const const char * Str2, unsigned MaxLen);
```

File

SysUtils

Description

StrLComp compares Str1 to Str2, up to a maximum length of MaxLen characters. The return value is indicated in the following table:

Return value	Condition
<0	Str1sorts before Str2
=0	Str1is the same as Str2
>0	Str1 sorts after Str2

Note: When working with international characters, use AnsiStrLComp (see page 22796) instead.

See Also

AnsiStrLComp (see page 22796)

StrComp (see page 22945)

StrIComp (see page 22951)

StrLIComp (see page 22955)

159.3.187 SysUtils.StrLCopy Function

Copies up to a specified maximum number of characters from Source to Dest.

Pascal

```
function StrLCopy(Dest: PChar; const Source: PChar; MaxLen: Cardinal): PChar;
```

C++

```
const char * StrLCopy(const char * Dest, const const char * Source, unsigned MaxLen);
```

File

SysUtils

Description

StrLCopy copies at most MaxLen characters from Source to Dest, then adds a null terminator to Dest and returns Dest. The SizeOf standard function (Delphi) or the sizeof operator (C++) can be used to determine the MaxLen parameter. Usually MaxLen

equals SizeOf(Dest)-1.

Note: StrLCopy copies a null terminator as well as MaxLen characters. Be sure that Dest is large enough to accommodate the null terminator at the end.

See Also

SizeOf (see page 22528)

StrCopy (see page 22946)

StrLen (see page 22954)

159.3.188 SysUtils.StrLen Function

Returns number of characters in a string excluding the null terminator.

Pascal

```
function StrLen(const Str: PChar): Cardinal;
```

C++

```
unsigned StrLen(const const char * Str);
```

File

SysUtils

Description

StrLen returns the number of characters in Str, not counting the null terminator.

See Also

StrEnd (see page 22949)

159.3.189 SysUtils.StrLFmt Function

Formats a series of arguments from a specified open array into a buffer.

Pascal

```
function StrLFmt(Buffer: PChar; MaxBufLen: Cardinal; Format: PChar; const Args: array of
const): PChar; overload;
function StrLFmt(Buffer: PChar; MaxBufLen: Cardinal; Format: PChar; const Args: array of
const; const FormatSettings: TFormatSettings): PChar; overload;
```

C++

```
const char * StrLFmt(const char * Buffer, unsigned MaxBufLen, const char * Format, const array
of const Args);
const char * StrLFmt(const char * Buffer, unsigned MaxBufLen, const char * Format, const array
of const Args, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

StrLFmt formats the series of arguments in and open array and writes the results to a buffer.

Buffer is the buffer that receives the results.

MaxLen is the maximum number of bytes that can be written to Buffer. This value does not include the terminating null character.

Format (see page 22897) is the format string that governs the operation.

Args is an array of arguments that replace the format specifiers in Format (see page 22897).

Note: Args_Size is the index of the last argument in Args (one less than the number of arguments).

StrLFmt returns a pointer to the destination buffer.

The first form of StrLFmt is not thread-safe, because it uses localization information contained in global variables. The second form of StrLFmt, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrLFmt, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

See Also

FormatBuf (see page 22900)

StrFmt (see page 22950)

FmtStr (see page 22894)

GetLocaleFormatSettings (see page 22913)

159.3.190 SysUtils.StrLIComp Function

Compares strings up to a specified maximum number of characters, without case sensitivity.

Pascal

```
function StrLIComp(const Str1: PChar; const Str2: PChar; MaxLen: Cardinal): Integer;
```

C++

```
int StrLIComp(const const char * Str1, const const char * Str2, unsigned MaxLen);
```

File

SysUtils

Description

StrLIComp compares Str1 to Str2, up to a maximum length of MaxLen characters, without case sensitivity. The return value is indicated in the following table:

Return value	Condition
<0	Str1 sorts before Str2
=0	Str1is the same as Str2
>0	Str1 sorts after Str2

Note: When working with international characters, use AnsiStrLIComp (see page 22797) instead.

See Also

AnsiStrLIComp (see page 22797)

StrComp (see page 22945)

StrIComp (see page 22951)

StrLComp (see page 22953)

159.3.191 SysUtils.StrLower Function

Converts a string to lowercase.

Pascal

```
function StrLower(Str: PChar): PChar;
```

C++

```
const char * StrLower(const char * Str);
```

File

SysUtils

Description

StrLower converts Str to lowercase and returns Str.

Note: If the source string contains international characters, use AnsiStrLower (see page 22798) instead. If the source string is an AnsiString (long string), use LowerCase (see page 22928) (or AnsiLowerCase (see page 22792)) instead.

See Also

AnsiLowerCase (see page 22792)

AnsiStrLower (see page 22798)

LowerCase (see page 22928)

StrUpper (see page 22973)

159.3.192 SysUtils.StrMove Function

Copies specified number of characters to string.

Pascal

```
function StrMove(Dest: PChar; const Source: PChar; Count: Cardinal): PChar;
```

C++

```
const char * StrMove(const char * Dest, const const char * Source, unsigned Count);
```

File

SysUtils

Description

StrMove copies exactly Count characters from Source to Dest and returns Dest. Source and Dest can overlap.

See Also

Move (see page 22490)

159.3.193 SysUtils.StrNew Function

Allocates space on and copies a string to the heap; returning a pointer to the string.

Pascal

```
function StrNew(const Str: PChar): PChar;
```

C++

```
const char * StrNew(const const char * Str);
```

File

SysUtils

Description

StrNew allocates a copy of Str on the heap.

If Str is nil (Delphi) or NULL (C++) or points to an empty string, StrNew returns a pointer to a new empty string.

Otherwise, StrNew makes a duplicate of Str, obtaining space with a call to StrAlloc (see page 22942), and returns a pointer to the duplicated string.

The allocated space is the length of Str + 5 bytes.

C++ Examples:

```
/*
This example uses an edit control and a button on a form.
When the button is clicked, memory is allocated for a copy
of the text in the edit control, the text is displayed in a
message box, and then the memory is deallocated.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  // Allocate memory.
  char* psz = StrNew(Edit1->Text.c_str());
  Application->MessageBox(psz, "StrNew, StrDispose example", MB_OK);
  // Deallocate memory.
  StrDispose(psz);
}
```

Delphi Examples:

```
{
This example uses an edit control and a button on a form.
When the button is clicked, memory is allocated for a copy
of the text in the edit control, the text is displayed in a
message box, and then the memory is deallocated.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  Temp: PChar;
begin
  // Allocate memory.
  Temp := StrNew(PChar(Edit1.Text));
  Application.MessageBox(Temp, 'StrNew, StrDispose example', MB_OK);
  // Deallocate memory.
  SysUtils.StrDispose(Temp);
end;
```

See Also

GetMem (see page 22469)

StrDispose (see page 22947)

StrAlloc (see page 22942)

159.3.194 SysUtils.StrNextChar Function

Returns pointer to following character.

Pascal

```
function StrNextChar(const Str: PChar): PChar;
```

C++

```
const char * StrNextChar(const const char * Str);
```

File

SysUtils

Description

Note: StrNextChar returns a pointer to the second character in Str, allowing for multi-byte characters.

159.3.195 SysUtils.StrPas Function

Converts null-terminated string to an AnsiString (long string).

Pascal

```
function StrPas(const Str: PChar): string;
```

C++

```
AnsiString StrPas(const const char * Str);
```

File

SysUtils

Description

This function is provided for backwards compatibility only. To convert a null terminated string to an AnsiString or native Delphi language string, use a typecast or an assignment.

See Also

StrPCopy (see page 22958)

159.3.196 SysUtils.StrPCopy Function

Copies an AnsiString (long string) to a null-terminated string.

Pascal

```
function StrPCopy(Dest: PChar; const Source: string): PChar;
```

C++

```
const char * StrPCopy(const char * Dest, const AnsiString Source);
```

File

SysUtils

Description

StrPCopy copies Source into a null-terminated string Dest. It returns a pointer to Dest.

StrPCopy does not perform any length checking.

The destination buffer must have room for at least Length(Source)+1 characters.

See Also

StrCopy (see page 22946)

159.3.197 SysUtils.StrPLCopy Function

Copies characters from an AnsiString (long string) into a null-terminated string.

Pascal

```
function StrPLCopy(Dest: PChar; const Source: string; MaxLen: Cardinal): PChar;
```

C++

```
const char * StrPLCopy(const char * Dest, const AnsiString Source, unsigned MaxLen);
```

File

SysUtils

Description

StrPLCopy copies up to a maximum of MaxLen characters from Source into the null-terminated string Dest. StrPLCopy returns a pointer to Dest.

Note: Dest should point to a location with room for MaxLen + 1 characters, including the null terminator.

159.3.198 SysUtils.StrPos Function

Returns a pointer to the first occurrence of STR2 in STR1.

Pascal

```
function StrPos(const Str1: PChar; const Str2: PChar): PChar;
```

C++

```
const char * StrPos(const const char * Str1, const const char * Str2);
```

File

SysUtils

Description

StrPos returns a pointer to the first occurrence of Str2 in Str1. If Str2 does not occur in Str1, StrPos returns nil (Delphi) or NULL (C++).

Note: If the source string contains international characters, use AnsiStrPos (see page 22798) instead.

See Also

AnsiStrPos (see page 22798)

159.3.199 SysUtils.StrRScan Function

Returns a pointer to the last occurrence of a specified character in a string.

Pascal

```
function StrRScan(const Str: PChar; Chr: Char): PChar;
```

C++

```
const char * StrRScan(const const char * Str, Char Chr);
```

File

SysUtils

Description

StrRScan returns a pointer to the last occurrence of Chr in Str.

If Chr does not occur in Str, StrRScan returns nil (Delphi) or NULL (C++). The null terminator is considered to be part of the string.

Note: If the source string contains international characters, use AnsiStrRScan (see page 22799) instead.

See Also

AnsiStrRScan (see page 22799)

StrScan (see page 22960)

159.3.200 SysUtils.StrScan Function

Returns a pointer to first occurrence of a specified character in a string.

Pascal

```
function StrScan(const Str: PChar; Chr: Char): PChar;
```

C++

```
const char * StrScan(const const char * Str, Char Chr);
```

File

SysUtils

Description

StrScan returns a pointer to the first occurrence of Chr in Str. If Chr does not occur in Str, StrScan returns nil (Delphi) or NULL

(C++). The null terminator is considered to be part of the string.

Note: If the source string contains international characters, use AnsiStrScan (see page 22799) instead.

See Also

AnsiStrScan (see page 22799)

StrRScan (see page 22960)

159.3.201 SysUtils.StrToBool Function

Converts a string to a Boolean value.

Pascal

```
function StrToBool(const S: string): Boolean;
```

C++

```
Boolean StrToBool(const AnsiString S);
```

File

SysUtils

Description

StrToBool converts the string specified by S to a Boolean. If S can be converted to a number, StrToBool returns false if that number is 0, true otherwise. If S can't be converted to a number, StrToBool returns true if S is any of the strings listed in TrueBoolStrs (see page 23034) (or differs from one only by case) and false if it is any of the strings listed in FalseBoolStrs (see page 23025) (or differs from one only by case). If S is not a number and not one of the strings listed in TrueBoolStrs (see page 23034) or FalseBoolStrs (see page 23025), StrToBool raises an EConvertError (see page 22724) exception.

Note: If you do not assign a value to TrueBoolStrs (see page 23034), it is treated as if it contains the single string 'True'. Similarly, if you do not assign a value to FalseBoolStrs (see page 23025), it is treated as if it contains the single string 'False';

Note: The TrueBoolStrs (see page 23034) and FalseBoolStrs (see page 23025) variables are undefined when an application starts. Any use of StrToBool, BoolToStr (see page 22804) or TryStrToBool (see page 22982) will cause these variables to be initialised with the default values above.

See Also

BoolToStr (see page 22804)

TrueBoolStrs (see page 23034)

FalseBoolStrs (see page 23025)

159.3.202 SysUtils.StrToBoolDef Function

Converts a string to a Boolean value, with error default.

Pascal

```
function StrToBoolDef(const S: string; const Default: Boolean): Boolean;
```

C++

```
Boolean StrToBoolDef(const AnsiString S, const Boolean Default);
```

File

SysUtils

Description

StrToBoolDef converts the string specified by S to a Boolean. If S can be converted to a number, StrToBoolDef returns false if that number is 0, true otherwise. If S can't be converted to a number, StrToBoolDef returns true if S is any of the strings listed in TrueBoolStrs (see page 23034) (or differs from one only by case) and false if it is any of the strings listed in FalseBoolStrs (see page 23025) (or differs from one only by case). If S is not a number and not one of the strings listed in TrueBoolStrs (see page 23034) or FalseBoolStrs (see page 23025), StrToBoolDef returns Default.

Note: If you do not assign a value to TrueBoolStrs (see page 23034), it is treated as if it contains the single string 'True'. Similarly, if you do not assign a value to FalseBoolStrs (see page 23025), it is treated as if it contains the single string 'False';

Note: The TrueBoolStrs (see page 23034) and FalseBoolStrs (see page 23025) variables are undefined when an application starts. Any use of StrToBool (see page 22961), BoolToStr (see page 22804) or TryStrToBool (see page 22982) will cause these variables to be initialised with the default values above.

See Also

BoolToStr (see page 22804)

TrueBoolStrs (see page 23034)

FalseBoolStrs (see page 23025)

StrToBool (see page 22961)

159.3.203 SysUtils.StrToCurr Function

Converts a string to a Currency value.

Pascal

```
function StrToCurr(const S: string): Currency; overload;
function StrToCurr(const S: string; const FormatSettings: TFormatSettings): Currency; overload;
```

C++

```
Currency StrToCurr(const AnsiString S);
Currency StrToCurr(const AnsiString S, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Call StrToCurr to convert a string that represents a floating-point value to the corresponding Currency value. The source string, S, must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional 'E' or 'e' followed by a signed integer. Leading and trailing blanks are ignored.

Thousand separators and currency symbols are not allowed in the string. If the string doesn't contain a valid value, StrToCurr raises an EConvertError (see page 22724) exception.

The first form of StrToCurr is not thread-safe, because it uses localization information contained in global variables. The second form of StrToCurr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToCurr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.204 SysUtils.StrToCurrDef Function

Converts a string to a Currency value, with error default.

Pascal

```
function StrToCurrDef(const S: string; const Default: Currency): Currency; overload;
function StrToCurrDef(const S: string; const Default: Currency; const FormatSettings:
TFormatSettings): Currency; overload;
```

C++

```
Currency StrToCurrDef(const AnsiString S, const Currency Default);
Currency StrToCurrDef(const AnsiString S, const Currency Default, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call StrToCurrDef to convert a string that represents a floating-point value to the corresponding Currency value. The source string, S, must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional 'E' or 'e' followed by a signed integer. Leading and trailing blanks are ignored.

Thousand separators and currency symbols are not allowed in the string. If the string doesn't contain a valid value, StrToCurrDef returns Default.

The first form of StrToCurrDef is not thread-safe, because it uses localization information contained in global variables. The second form of StrToCurrDef, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToCurrDef, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.205 SysUtils.StrToDate Function

Converts a string to a TDateTime value.

Pascal

```
function StrToDate(const S: string): TDateTime; overload;
function StrToDate(const S: string; const FormatSettings: TFormatSettings): TDateTime;
overload;
```

C++

```
TDateTime StrToDate(const AnsiString S);
TDateTime StrToDate(const AnsiString S, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Call StrToDate to parse a string that specifies a date. If S does not contain a valid date, StrToDate raises an EConvertError (see page 22724) exception.

S must consist of two or three numbers, separated by the character defined by the DateSeparator (see page 23023) global variable or its TFormatSettings (see page 23001) equivalent. The order for month, day, and year is determined by the ShortDateFormat (see page 23030) global variable or its TFormatSettings (see page 23001) equivalent--possible combinations are m/d/y, d/m/y, and y/m/d.

If S contains only two numbers, it is interpreted as a date (m/d or d/m) in the current year.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 23034). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency and Date (see page 22820)-Time (see page 22976) Formatting Variables" for more information.

The first form of StrToDate is not thread-safe, because it uses localization information contained in global variables. The second form of StrToDate, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToDate, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

C++ Examples:

```
/*
This example uses an edit box and a button on a form. When
the user enters a date in the edit box in the format
associated with the current locale (for example MM/DD/YY
format in the US), the string entered is converted to a
TDateTime value. This value is used to indicate the day of
the week the date represents.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  char days[7][10] = {"Sunday", "Monday", "Tuesday", "Wednesday", "Thursday", "Friday",
"Saturday" };
  TDateTime dtDate = StrToDate(Edit1->Text);
  ShowMessage(Edit1->Text + AnsiString(" is a ") + days[dtDate.DayOfWeek() - 1]);
}
```

Delphi Examples:

```
{
This example uses an edit box and a button on a form. When
the user enters a date in the edit box in the format
associated with the current locale (for example MM/DD/YY
format in the US), the string entered is converted to a
TDateTime value. This value is used to indicate the day of
the week the date represents.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  ADate: TDateTime;
  days: array[1..7] of string;
begin
  days[1] := 'Sunday';
  days[2] := 'Monday';
  days[3] := 'Tuesday';
  days[4] := 'Wednesday';
  days[5] := 'Thursday';
  days[6] := 'Friday';
  days[7] := 'Saturday';
  ADate := StrToDate(Edit1.Text);
  ShowMessage(Edit1.Text + ' is a ' + days[SysUtils.DayOfWeek(ADate)]);
end;
```

159.3.206 SysUtils.StrToDateDef Function

Converts a string to a TDateTime value, with error default.

Pascal

```
function StrToDateDef(const S: string; const Default: TDateTime): TDateTime; overload;
function StrToDateDef(const S: string; const Default: TDateTime; const FormatSettings:
TFormatSettings): TDateTime; overload;
```

C++

```
TDateTime StrToDateDef(const AnsiString S, const TDateTime Default);
TDateTime StrToDateDef(const AnsiString S, const TDateTime Default, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call StrToDateDef to parse a string that specifies a date. If S does not contain a valid date, StrToDateDef returns Default.

S must consist of two or three numbers, separated by the character defined by the DateSeparator (see page 23023) global variable or its TFormatSettings (see page 23001) equivalent. The order for month, day, and year is determined by the ShortDateFormat (see page 23030) global variable or its TFormatSettings (see page 23001) equivalent--possible combinations are m/d/y, d/m/y, and y/m/d.

If S contains only two numbers, it is interpreted as a date (m/d or d/m) in the current year.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 23034). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency and Date (see page 22820)-Time (see page 22976) Formatting Variables" for more information.

The first form of StrToDateDef is not thread-safe, because it uses localization information contained in global variables. The second form of StrToDateDef, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToDateDef, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.207 SysUtils.StrToDateTime Function

Converts a string to a TDateTime value.

Pascal

```
function StrToDateTime(const S: string): TDateTime; overload;
function StrToDateTime(const S: string; const FormatSettings: TFormatSettings): TDateTime;
overload;
```

C++

```
TDateTime StrToDateTime(const AnsiString S);
TDateTime StrToDateTime(const AnsiString S, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Call StrToDateTime to parse a string that specifies a date and time value. If S does not contain a valid date, StrToDateTime raises an EConvertError (see page 22724) exception.

The S parameter must use the current locale's date/time format. In the US, this is commonly MM/DD/YY HH:MM:SS format. Specifying AM or PM as part of the time is optional, as are the seconds. Use 24-hour time (7:45 PM is entered as 19:45, for example) if AM or PM is not specified.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 23034). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency and Date (see page 22820)-Time (see page 22976) Formatting Variables" for more information.

The first form of StrToDateTime is not thread-safe, because it uses localization information contained in global variables. The second form of StrToDateTime, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToDateTime, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.208 SysUtils.StrToDateTimeDef Function

Converts a string to a TDateTime value with error default.

Pascal

```
function StrToDateTimeDef(const S: string; const Default: TDateTime): TDateTime; overload;
function StrToDateTimeDef(const S: string; const Default: TDateTime; const FormatSettings:
TFormatSettings): TDateTime; overload;
```

C++

```
TDateTime StrToDateTimeDef(const AnsiString S, const TDateTime Default);
TDateTime StrToDateTimeDef(const AnsiString S, const TDateTime Default, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call StrToDateTimeDef to parse a string that specifies a date and time value. If S does not contain a valid date, StrToDateTimeDef returns Default.

The S parameter must use the current locale's date/time format. In the US, this is commonly MM/DD/YY HH:MM:SS format. Specifying AM or PM as part of the time is optional, as are the seconds. Use 24-hour time (7:45 PM is entered as 19:45, for example) if AM or PM is not specified.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 23034). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency and Date (see page 22820)-Time (see page 22976) Formatting Variables" for more information.

The first form of StrToDateTimeDef is not thread-safe, because it uses localization information contained in global variables. The second form of StrToDateTimeDef, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToDateTimeDef, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

StrToDateTime (see page 22965)

159.3.209 SysUtils.StrToFloat Function

Converts a given string to a floating-point value.

Pascal

```
function StrToFloat(const S: string): Extended; overload;
function StrToFloat(const S: string; const FormatSettings: TFormatSettings): Extended;
overload;
```

C++

```
Extended StrToFloat(const AnsiString S);
Extended StrToFloat(const AnsiString S, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Use StrToFloat to convert a string, S, to a floating-point value. S must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional mantissa. The mantissa consists of 'E' or 'e' followed by an optional sign (+ or -) and a whole number. Leading and trailing blanks are ignored.

The DecimalSeparator (see page 23023) global variable or its TFormatSettings (see page 23001) equivalent defines the character that is used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If S doesn't contain a valid value, StrToFloat raises an EConvertError (see page 22724) exception.

The first form of StrToFloat is not thread-safe, because it uses localization information contained in global variables. The second form of StrToFloat, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToFloat, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

C++ Examples:

```
/*
The following example uses two buttons, a string grid, and
text edit on a form. When the conversion button is clicked,
the values across the top of the string grid are converted
using the formats along the left side.  Select a cell and
use the Alter Cell button and text edit to change the
values converted and the conversion formats.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int x = 1; x < StringGrid1->ColCount; x++)
  {
    for (int y = 1; y < StringGrid1->RowCount; y++)
    {
      StringGrid1->Cells[x][y] = FormatFloat(
      StringGrid1->Cells[0][y], StrToFloat(StringGrid1->Cells[x][0]));
    }
  }
```

```
}

int currCellCol, currCellRow;

void __fastcall TForm1::StringGrid1MouseUp(TObject *Sender, TMouseButton Button,
      TShiftState Shift, int X, int Y)
{
  StringGrid1->MouseToCell(X, Y, currCellCol, currCellRow);
}

// Alter Cell
void __fastcall TForm1::Button2Click(TObject *Sender)
{
  StringGrid1->Cells[currCellCol][currCellRow] = Edit1->Text;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  StringGrid1->Cells[1][0] = "1234";
  StringGrid1->Cells[2][0] = "-1234";
  StringGrid1->Cells[3][0] = "0.5";
  StringGrid1->Cells[4][0] = "0";
  StringGrid1->Cells[0][1] = "";
  StringGrid1->Cells[0][2] = "0";
  StringGrid1->Cells[0][3] = "0.00";
  StringGrid1->Cells[0][4] = "#.##";
  StringGrid1->Cells[0][5] = "#,##0.00";
  StringGrid1->Cells[0][6] = "#,##0.00;(#,##0.00)";
  StringGrid1->Cells[0][7] = "#,##0.00;;Zero";
  StringGrid1->Cells[0][8] = "0.000E+00";
  StringGrid1->Cells[0][9] = "#.###E-0";
}
```

Delphi Examples:

```
{
The following example uses two buttons, a string grid, and
text edit on a form. When the conversion button is clicked,
the values across the top of the string grid are converted
using the formats along the left side.  Select a cell and
use the Alter Cell button and text edit to change the
values converted and the conversion formats.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  X, Y, I: Integer;
begin
  for X := 1 to StringGrid1.ColCount - 1 do
  begin
    for Y := 0 to StringGrid1.RowCount - 1 do
    begin
      StringGrid1.Cells[X,Y] := SysUtils.FormatFloat(
        StringGrid1.Cells[0,Y], StrToFloat(StringGrid1.Cells[X,0]));
    end;
  end;

end;

var currCellCol, currCellRow: Integer;

// Alter Cell
procedure TForm1.Button2Click(Sender: TObject);
begin
  StringGrid1.Cells[currCellCol,currCellRow] := Edit1.Text;
end;

procedure TForm1.StringGrid1MouseUp(Sender: TObject; Button: TMouseButton;
```

```
  Shift: TShiftState; X, Y: Integer);
begin
  StringGrid1.MouseToCell(X, Y, &currCellCol, &currCellRow);
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  StringGrid1.Cells[1,0] := '1234';
  StringGrid1.Cells[2,0] := '-1234';
  StringGrid1.Cells[3,0] := '0.5';
  StringGrid1.Cells[4,0] := '0';
  StringGrid1.Cells[0,1] := '';
  StringGrid1.Cells[0,2] := '0';
  StringGrid1.Cells[0,3] := '0.00';
  StringGrid1.Cells[0,4] := '#.##';
  StringGrid1.Cells[0,5] := '#,##0.00';
  StringGrid1.Cells[0,6] := '#,##0.00;(#,##0.00)';
  StringGrid1.Cells[0,7] := '#,##0.00;;Zero';
  StringGrid1.Cells[0,8] := '0.000E+00';
  StringGrid1.Cells[0,9] := '#.###E-0';
end;
```

159.3.210 SysUtils.StrToFloatDef Function

Converts a given string to a floating-point value with error default.

Pascal

```
function StrToFloatDef(const S: string; const Default: Extended): Extended; overload;
function StrToFloatDef(const S: string; const Default: Extended; const FormatSettings:
TFormatSettings): Extended; overload;
```

C++

```
Extended StrToFloatDef(const AnsiString S, const Extended Default);
Extended StrToFloatDef(const AnsiString S, const Extended Default, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Use StrToFloatDef to convert a string, S, to a floating-point value. S must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional mantissa. The mantissa consists of 'E' or 'e' followed by an optional sign (+ or -) and a whole number. Leading and trailing blanks are ignored.

The DecimalSeparator (see page 23023) global variable or its TFormatSettings (see page 23001) equivalent defines the character that must be used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If S doesn't contain a valid value, StrToFloatDef returns Default.

The first form of StrToFloatDef is not thread-safe, because it uses localization information contained in global variables. The second form of StrToFloatDef, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToFloatDef, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.211 SysUtils.StrToInt Function

Converts a string that represents an integer (decimal or hex notation) to a number.

Pascal

```
function StrToInt(const S: string): Integer;
```

C++

```
int StrToInt(const AnsiString S);
```

File

SysUtils

Description

StrToInt converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a number. If S does not represent a valid number, StrToInt raises an EConvertError (see page 22724) exception.

See Also

IntToHex (see page 22920)

IntToStr (see page 22921)

StrToIntDef (see page 22971)

TryStrToInt (see page 22986)

159.3.212 SysUtils.StrToInt64 Function

Converts a string that represents an integer (decimal or hex notation) to a number.

Pascal

```
function StrToInt64(const S: string): Int64;
```

C++

```
Int64 StrToInt64(const AnsiString S);
```

File

SysUtils

Description

StrToInt64 converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a number. If S does not represent a valid number, StrToInt64 raises an EConvertError (see page 22724) exception.

See Also

IntToHex (see page 22920)

IntToStr (see page 22921)

StrToIntDef (see page 22971)

StrToInt64Def (see page 22971)

StrToInt (see page 22970)

TryStrToInt (see page 22986)

159.3.213 SysUtils.StrToInt64Def Function

Converts a string that represents an integer (decimal or hex notation) to a number.

Pascal

```
function StrToInt64Def(const S: string; const Default: Int64): Int64;
```

C++

```
Int64 StrToInt64Def(const AnsiString S, const Int64 Default);
```

File

SysUtils

Description

StrToInt64Def converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a number. If S does not represent a valid number, StrToInt64Def returns the number passed in Default.

See Also

IntToStr (see page 22921)

StrToInt (see page 22970)

StrToInt64 (see page 22970)

StrToInt (see page 22970)

TryStrToInt64 (see page 22986)

159.3.214 SysUtils.StrToIntDef Function

Converts a string that represents an integer (decimal or hex notation) to a number with error default.

Pascal

```
function StrToIntDef(const S: string; Default: Integer): Integer;
```

C++

```
int StrToIntDef(const AnsiString S, int Default);
```

File

SysUtils

Description

StrToIntDef converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a number. If S does not represent a valid number, StrToIntDef returns Default.

See Also

IntToHex (see page 22920)

IntToStr (see page 22921)

StrToInt (see page 22970)

TryStrToInt (see page 22986)

159.3.215 SysUtils.StrToTime Function

Converts a string to a TDateTime value.

Pascal

```
function StrToTime(const S: string): TDateTime; overload;
function StrToTime(const S: string; const FormatSettings: TFormatSettings): TDateTime;
overload;
```

C++

```
TDateTime StrToTime(const AnsiString S);
TDateTime StrToTime(const AnsiString S, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Call StrToTime to parse a string that specifies a time value. If S does not contain a valid time, StrToTime raises an EConvertError (see page 22724) exception.

The S parameter must consist of two or three numbers, separated by the character defined by the TimeSeparator (see page 23033) global variable or its TFormatSettings (see page 23001) equivalent, optionally followed by an AM or PM indicator. The numbers represent hour, minute, and (optionally) second, in that order. If the time is followed by AM or PM, it is assumed to be in 12-hour clock format. If no AM or PM indicator is included, the time is assumed to be in 24-hour clock format.

The first form of StrToTime is not thread-safe, because it uses localization information contained in global variables. The second form of StrToTime, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToTime, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.216 SysUtils.StrToTimeDef Function

Converts a string to a TDateTime value with error default.

Pascal

```
function StrToTimeDef(const S: string; const Default: TDateTime): TDateTime; overload;
function StrToTimeDef(const S: string; const Default: TDateTime; const FormatSettings:
TFormatSettings): TDateTime; overload;
```

C++

```
TDateTime StrToTimeDef(const AnsiString S, const TDateTime Default);
TDateTime StrToTimeDef(const AnsiString S, const TDateTime Default, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call StrToTimeDef to parse a string that specifies a time value. If S does not contain a valid time, StrToTimeDef returns Default.

The S parameter must consist of two or three numbers, separated by the character defined by the TimeSeparator (see page 23033) global variable or its TFormatSettings (see page 23001) equivalent, optionally followed by an AM or PM indicator. The numbers represent hour, minute, and (optionally) second, in that order. If the time is followed by AM or PM, it is assumed to be in 12-hour clock format. If no AM or PM indicator is included, the time is assumed to be in 24-hour clock format.

The first form of StrToTimeDef is not thread-safe, because it uses localization information contained in global variables. The second form of StrToTimeDef, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of StrToTimeDef, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.217 SysUtils.StrUpper Function

Returns a string in upper case.

Pascal

```
function StrUpper(Str: PChar): PChar;
```

C++

```
const char * StrUpper(const char * Str);
```

File

SysUtils

Description

StrUpper converts Str to uppercase and returns Str.

Note: If the source string contains international characters, use AnsiStrUpper (see page 22800) instead. If the source string is an AnsiString (long string), use UpperCase (see page 22988) (or AnsiUpperCase (see page 22800)) instead.

See Also

AnsiUpperCase (see page 22800)

UpperCase (see page 22988)

StrLower (see page 22956)

159.3.218 SysUtils.Supports Function

Indicates whether a given object or interface supports a specified interface.

Pascal

```
function Supports(const Instance: IInterface; const IID: TGUID; out Intf): Boolean; overload;
function Supports(const Instance: TObject; const IID: TGUID; out Intf): Boolean; overload;
function Supports(const Instance: IInterface; const IID: TGUID): Boolean; overload;
function Supports(const Instance: TObject; const IID: TGUID): Boolean; overload;
function Supports(const AClass: TClass; const IID: TGUID): Boolean; overload;
```

C++

```
Boolean Supports(const IInterface Instance, const TGUID IID,  Intf);
Boolean Supports(const TObject * Instance, const TGUID IID,  Intf);
Boolean Supports(const IInterface Instance, const TGUID IID);
Boolean Supports(const TObject * Instance, const TGUID IID);
Boolean Supports(const TClass AClass, const TGUID IID);
```

File

SysUtils

Description

Call Supports to determine whether the object or interface specified by Instance, or the class specified by AClass, supports the interface identified by the IID parameter. If Instance supports the interface, Supports returns the interface as the Intf parameter and returns true. If AClass supports the interface, Supports does not return an interface, but still returns true. If the interface specified by IID is not supported, Supports returns false.

On the Win32 platform, to determine whether the interface specified by IID is supported, Supports calls the QueryInterface method of the supplied interface (or the interface of the supplied object). However, unlike calling QueryInterface directly, Supports lets you pass a nil (Delphi) or NULL (C++) value as the instance.

On the .NET platform, Supports uses the typecasting facilities of the .NET framework.

See Also

TComponent (see page 2762)

159.3.219 SysUtils.SysErrorMessage Function

Converts OS error codes into strings.

Pascal

```
function SysErrorMessage(ErrorCode: Integer): string;
```

C++

```
AnsiString SysErrorMessage(int ErrorCode);
```

File

SysUtils

Description

SysErrorMessage returns an error message string that corresponds to the specified OS error code.

See Also

RaiseLastOSError (see page 22932)

EWin32Error (see page 22749)

159.3.220 SysUtils.SystemTimeToDateTime Function

Converts a system time value into a TDateTime value.

Pascal

```
function SystemTimeToDateTime(const SystemTime: TSystemTime): TDateTime;
```

C++

```
TDateTime SystemTimeToDateTime(const TSystemTime SystemTime);
```

File

SysUtils

Description

Call SystemTimeToDateTime to convert a value from Windows 32's TSystemTime (Delphi) or _SYSTEMTIME (C++) API format to a TDateTime value. SystemTimeToDateTime is available on Windows only.

See Also

DateTimeToSystemTime (see page 22825)

159.3.221 SysUtils.TextToFloat Function

Converts a null-terminated string to a floating-point value.

Pascal

```
function TextToFloat(Buffer: PChar; var Value; ValueType: TFloatValue): Boolean; overload;
function TextToFloat(Buffer: PChar; var Value; ValueType: TFloatValue; const FormatSettings:
TFormatSettings): Boolean; overload;
```

C++

```
Boolean TextToFloat(const char * Buffer,  Value, TFloatValue ValueType);
Boolean TextToFloat(const char * Buffer,  Value, TFloatValue ValueType, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Use TextToFloat to convert a null-terminated string, Buffer, to a floating-point value. The string must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional mantissa. The mantissa consists of 'E' or 'e' followed by an optional sign (+ or -) and a whole number. Leading and trailing blanks are ignored.

The converted value is assigned to the Value parameter, which must be of type Extended or Currency, as indicated by the ValueType parameter.

TextToFloat returns true if the conversion is successful, or false if the Buffer does not contain a valid floating-point value.

The first form of TextToFloat is not thread-safe, because it uses localization information contained in global variables. The second form of TextToFloat, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TextToFloat, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.222 SysUtils.Time Function

Returns the current time.

Pascal

```
function Time: TDateTime;
```

C++

```
TDateTime Time();
```

File

SysUtils

Description

Time and GetTime (see page 22916) return the current time as a TDateTime value. The two functions are completely equivalent.

Note: Time clashes with an Xlib function of the same name. Use GetTime (see page 22916) in Linux and cross-platform code.

See Also

Date (see page 22820)

DecodeTime (see page 22830)

Now (see page 22930)

TimeToStr (see page 22977)

159.3.223 SysUtils.TimeStampToDateTime Function

Converts a TTimeStamp (see page 23009) value into the corresponding TDateTime value.

Pascal

```
function TimeStampToDateTime(const TimeStamp: TTimeStamp): TDateTime;
```

C++

```
TDateTime TimeStampToDateTime(const TTimeStamp TimeStamp);
```

File

SysUtils

Description

Call TimeStampToDateTime to convert a TTimeStamp (see page 23009) value into a TDateTime value. TTimeStamp (see page 23009) values represent time as separate date and time values, where the date is the number of calendar days since the start of the current calendar (that is, January 1, 0001 would have a value of 1), and time is the number of milliseconds since midnight. TDateTime values represent time as the number of days (including fractional days) that have elapsed since 12:00 am on December 30, 1899.

See Also

DateTimeToTimeStamp (see page 22825)

159.3.224 SysUtils.TimeStampToMSecs Function

Converts a TTimeStamp (see page 23009) value into an absolute number of milliseconds.

Pascal

```
function TimeStampToMSecs(const TimeStamp: TTimeStamp): Comp;
```

C++

```
Comp TimeStampToMSecs(const TTimeStamp TimeStamp);
```

File

SysUtils

Description

Call TimeStampToMSecs to convert a TTimeStamp (see page 23009) value, into the total number of milliseconds that comprise the Date (see page 22820) field plus the number of milliseconds given in the Time (see page 22976) field.

See Also

MSecsToTimeStamp (see page 22929)

TimeStampToDateTime (see page 22976)

159.3.225 SysUtils.TimeToStr Function

Returns a string that represents a TDateTime value.

Pascal

```
function TimeToStr(const DateTime: TDateTime): string; overload;
function TimeToStr(const DateTime: TDateTime; const FormatSettings: TFormatSettings): string;
overload;
```

C++

```
AnsiString TimeToStr(const TDateTime DateTime);
AnsiString TimeToStr(const TDateTime DateTime, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

TimeToStr converts the Time (see page 22976) parameter, a TDateTime value, to a string. The conversion uses the format specified by the LongTimeFormat (see page 23028) global variable or its TFormatSettings (see page 23001) equivalent. Change the format of the string by changing the values of some of the date and time variables.

The first form of TimeToStr is not thread-safe, because it uses localization information contained in global variables. The second form of TimeToStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TimeToStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

C++ Examples:

```
/*
```

```
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TDateTime dt;
  try
  {
    dt = EncodeTime((Word)StrToInt(Edit1->Text), (Word)StrToInt(Edit2->Text),
(Word)StrToInt(Edit3->Text), (Word)StrToInt(Edit4->Text));
    Label1->Caption = TimeToStr(dt);
  }
  catch(...)
  {
    ShowMessage("Invalid hour, minute, second, or millisecond.");
  }
}
```

Delphi Examples:

```
{
This example uses three edit controls, a label, and a button
on a form. When the button is clicked, the day, month, and
year specified in the edit controls is stored in a TDateTime
object. Then the TDateTime object is converted to an
AnsiString that is displayed in the label.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  MyDate: TDateTime;
begin
  MyDate := SysUtils.EncodeTime(StrToInt(Edit1.Text), StrToInt(Edit2.Text),
StrToInt(Edit3.Text), StrToInt(Edit4.Text));
  Label1.Caption := TimeToStr(MyDate);
end;
```

DateTimeToStr (see page 22822)

DateToStr (see page 22825)

StrToDateTime (see page 22965)

Time (see page 22976)

GetLocaleFormatSettings (see page 22913)

159.3.226 SysUtils.Trim Function

Trims leading and trailing spaces and control characters from a string.

Pascal

```
function Trim(const S: string): string; overload;
function Trim(const S: WideString): WideString; overload;
```

C++

```
AnsiString Trim(const AnsiString S);
BSTR Trim(const BSTR S);
```

File

SysUtils

Description

Trim removes leading and trailing spaces and control characters from the given string S.

See Also

TrimLeft (see page 22979)

TrimRight (see page 22979)

159.3.227 SysUtils.TrimLeft Function

Trims leading spaces and control characters from a string.

Pascal

```
function TrimLeft(const S: string): string; overload;
function TrimLeft(const S: WideString): WideString; overload;
```

C++

```
AnsiString TrimLeft(const AnsiString S);
BSTR TrimLeft(const BSTR S);
```

File

SysUtils

Description

TrimLeft returns a copy of the string S with leading spaces and control characters removed.

See Also

Trim (see page 22978)

TrimRight (see page 22979)

159.3.228 SysUtils.TrimRight Function

Trims trailing spaces and control characters from a string.

Pascal

```
function TrimRight(const S: string): string; overload;
function TrimRight(const S: WideString): WideString; overload;
```

C++

```
AnsiString TrimRight(const AnsiString S);
BSTR TrimRight(const BSTR S);
```

File

SysUtils

Description

TrimRight returns a copy of the string S with trailing spaces and control characters removed.

See Also

TrimLeft (see page 22979)

Trim (see page 22978)

159.3.229 SysUtils.TryEncodeDate Function

Creates a TDateTime value that represents a specified Year, Month, and Day.

Pascal

```
function TryEncodeDate(Year: Word; Month: Word; Day: Word; out Date: TDateTime): Boolean;
```

C++

```
Boolean TryEncodeDate(Word Year, Word Month, Word Day, TDateTime Date);
```

File

SysUtils

Description

TryEncodeDate generates a TDateTime value from the values specified as the Year, Month, and Day parameters.

The year must be between 1 and 9999.

Valid Month values are 1 through 12.

Valid Day values are 1 through 28, 29, 30, or 31, depending on the Month value. For example, the possible Day values for month 2 (February) are 1 through 28 or 1 through 29, depending on whether or not the Year value specifies a leap year.

The Date (see page 22820) parameter returns the generated value if TryEncodeDate returns true.

If the specified values are not within range, TryEncodeDate returns false.

See Also

DateToStr (see page 22825)

DecodeDate (see page 22828)

TryEncodeTime (see page 22980)

TryEncodeDateTime (see page 6697)

EncodeDate (see page 22836)

159.3.230 SysUtils.TryEncodeTime Function

Creates a TDateTime value for a specified Hour, Min, Sec, and MSec.

Pascal

```
function TryEncodeTime(Hour: Word; Min: Word; Sec: Word; MSec: Word; out Time: TDateTime):
Boolean;
```

C++

```
Boolean TryEncodeTime(Word Hour, Word Min, Word Sec, Word MSec, TDateTime Time);
```

File

SysUtils

Description

EncodeTime (see page 22837) encodes the given hour, minute, second, and millisecond into a TDateTime value.

Valid Hour values are 0 through 24. If Hour is 24, Min, Sec, and MSec must all be 0, and the resulting TDateTime value represents midnight (12:00:00:000 AM) of the following day.

Valid Min and Sec values are 0 through 59.

Valid MSec values are 0 through 999.

The Time (see page 22976) paremter returns the generated TDateTime value of the specifies values are in range. This value is a number between 0 and 1 (inclusive) that indicates the fractional part of a day given by the specified time or (if 1.0) midnight on the following day. The value 0 corresponds to midnight, 0.5 corresponds to noon, 0.75 corresponds to 6:00 pm, and so on.

See Also

DecodeTime (see page 22830)

TryEncodeDate (see page 22980)

TryEncodeDateTime (see page 6697)

EncodeTime (see page 22837)

159.3.231 SysUtils.TryFloatToCurr Function

Converts a floating-point value to a Currency value.

Pascal

```
function TryFloatToCurr(const Value: Extended; out AResult: Currency): Boolean;
```

C++

```
Boolean TryFloatToCurr(const Extended Value, Currency AResult);
```

File

SysUtils

Description

TryFloatToCurr converts the specified floating-point value into a Currency value.

Value is the floating-point value to convert.

AResult returns the equivalent Currency value, if possible.

If TryFloatToCurr is successful, it returns true. If Value is not within the valid range for a Currency value, TryFloatToCurr returns false.

See Also

FloatToCurr (see page 22889)

159.3.232 SysUtils.TryFloatToDateTime Function

Converts a floating-point value to a TDateTime value.

Pascal

```
function TryFloatToDateTime(const Value: Extended; out AResult: TDateTime): Boolean;
```

C++

```
Boolean TryFloatToDateTime(const Extended Value, TDateTime AResult);
```

File

SysUtils

Description

TryFloatToDateTime converts a floating-point value into the corresponding TDateTime value.

Value is the floating-point value to convert.

AResult returns the corresponding TDateTime value if possible.

TryFloatToDateTime returns true if the conversion was successful, false otherwise.

See Also

MinDateTime (see page 23052)

FloatToDateTime (see page 22889)

159.3.233 SysUtils.TryStrToBool Function

Converts a string to a Boolean value, with a Boolean success code.

Pascal

```
function TryStrToBool(const S: string; out Value: Boolean): Boolean;
```

C++

```
Boolean TryStrToBool(const AnsiString S, Boolean Value);
```

File

SysUtils

Description

TryStrToBool converts the string specified by S to a Boolean and sets Value to the result. If S can be converted to a number, TryStrToBool sets Value to false if that number is 0, true otherwise. If S can't be converted to a number, TryStrToBool returns true if S is any of the strings listed in TrueBoolStrs (see page 23034) (or differs from one only by case) and false if it is any of the strings listed in FalseBoolStrs (see page 23025) (or differs from one only by case). If S is not a number and not one of the strings listed in TrueBoolStrs (see page 23034) or FalseBoolStrs (see page 23025), TryStrToBool returns false to indicate that the conversion failed. If the conversion is successful, TryStrToBool returns true.

Note: If you do not assign a value to TrueBoolStrs (see page 23034), it is treated as if it contains the single string 'True'. Similarly, if you do not assign a value to FalseBoolStrs (see page 23025), it is treated as if it contains the single string 'False';

Note: The TrueBoolStrs (see page 23034) and FalseBoolStrs (see page 23025) variables are undefined when an application starts. Any use of StrToBool (see page 22961), BoolToStr (see page 22804) or TryStrToBool will cause these variables to be initialised with the default values above.

See Also

BoolToStr (see page 22804)

TrueBoolStrs (see page 23034)

FalseBoolStrs (see page 23025)

StrToBool (see page 22961)

159.3.234 SysUtils.TryStrToCurr Function

Converts a string to a Currency value, with a Boolean success code.

Pascal

```
function TryStrToCurr(const S: string; out Value: Currency): Boolean; overload;
function TryStrToCurr(const S: string; out Value: Currency; const FormatSettings:
TFormatSettings): Boolean; overload;
```

C++

```
Boolean TryStrToCurr(const AnsiString S, Currency Value);
Boolean TryStrToCurr(const AnsiString S, Currency Value, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Call TryStrToCurr to convert a string that represents a floating-point value to the corresponding Currency value. The source string, S, must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional 'E' or 'e' followed by a signed integer. Leading and trailing blanks are ignored.

The DecimalSeparator (see page 23023) global variable or its TFormatSettings (see page 23001) equivalent defines the character that is used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If the string doesn't contain a valid value, TryStrToCurr returns Default.

The first form of TryStrToCurr is not thread-safe, because it uses localization information contained in global variables. The second form of TryStrToCurr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TryStrToCurr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.235 SysUtils.TryStrToDate Function

Converts a string to a TDateTime value, with a Boolean success code.

Pascal

```
function TryStrToDate(const S: string; out Value: TDateTime): Boolean; overload;
function TryStrToDate(const S: string; out Value: TDateTime; const FormatSettings:
TFormatSettings): Boolean; overload;
```

C++

```
Boolean TryStrToDate(const AnsiString S, TDateTime Value);
Boolean TryStrToDate(const AnsiString S, TDateTime Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call TryStrToDate to parse a string that specifies a date. If S does not contain a valid date, TryStrToDate returns false.

S must consist of two or three numbers, separated by the character defined by the DateSeparator (see page 23023) global variable or its TFormatSettings (see page 23001) equivalent. The order for month, day, and year is determined by the ShortDateFormat (see page 23030) global variable or its TFormatSettings (see page 23001) equivalent--possible combinations are m/d/y, d/m/y, and y/m/d.

If S contains only two numbers, it is interpreted as a date (m/d or d/m) in the current year.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 23034). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency and Date (see page 22820)-Time (see page 22976) Formatting Variables" for more information.

The first form of TryStrToDate is not thread-safe, because it uses localization information contained in global variables. The second form of TryStrToDate, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TryStrToDate, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.236 SysUtils.TryStrToDateTime Function

Converts a string to a TDateTime value with a Boolean success code.

Pascal

```
function TryStrToDateTime(const S: string; out Value: TDateTime): Boolean; overload;
function TryStrToDateTime(const S: string; out Value: TDateTime; const FormatSettings:
TFormatSettings): Boolean; overload;
```

C++

```
Boolean TryStrToDateTime(const AnsiString S, TDateTime Value);
Boolean TryStrToDateTime(const AnsiString S, TDateTime Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call TryStrToDateTime to parse a string that specifies a date and time value. If S does not contain a valid date, TryStrToDateTime returns false.

The S parameter must use the current locale's date/time format. In the US, this is commonly MM/DD/YY HH:MM:SS format. Specifying AM or PM as part of the time is optional, as are the seconds. Use 24-hour time (7:45 PM is entered as 19:45, for example) if AM or PM is not specified.

Year values between 0 and 99 are converted using the TwoDigitYearCenturyWindow (see page 23034). This value is stored either in a global variable (first form) or as a field in the FormatSettings parameter (second form) See "Currency and Date (see

page 22820)-Time (see page 22976) Formatting Variables" for more information.

The first form of TryStrToDateTime is not thread-safe, because it uses localization information contained in global variables. The second form of TryStrToDateTime, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TryStrToDateTime, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.237 SysUtils.TryStrToFloat Function

Converts a given string to a floating-point value with a boolean success code.

Pascal

```
function TryStrToFloat(const S: string; out Value: Extended): Boolean; overload;
function TryStrToFloat(const S: string; out Value: Extended; const FormatSettings:
TFormatSettings): Boolean; overload;
function TryStrToFloat(const S: string; out Value: Double): Boolean; overload;
function TryStrToFloat(const S: string; out Value: Double; const FormatSettings:
TFormatSettings): Boolean; overload;
function TryStrToFloat(const S: string; out Value: Single): Boolean; overload;
function TryStrToFloat(const S: string; out Value: Single; const FormatSettings:
TFormatSettings): Boolean; overload;
```

C++

```
Boolean TryStrToFloat(const AnsiString S, Extended Value);
Boolean TryStrToFloat(const AnsiString S, Extended Value, const TFormatSettings
FormatSettings);
Boolean TryStrToFloat(const AnsiString S, Double Value);
Boolean TryStrToFloat(const AnsiString S, Double Value, const TFormatSettings FormatSettings);
Boolean TryStrToFloat(const AnsiString S, Single Value);
Boolean TryStrToFloat(const AnsiString S, Single Value, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

Use TryStrToFloat to convert a astring, S, to a floating-point value. S must consist of an optional sign (+ or -), a string of digits with an optional decimal point, and an optional mantissa. The mantissa consists of 'E' or 'e' followed by an optional sign (+ or -) and a whole number. Leading and trailing blanks are ignored.

The DecimalSeparator (see page 23023) global variable defines the character that must be used as a decimal point. Thousand separators and currency symbols are not allowed in the string. If S doesn't contain a valid value, TryStrToFloat returns Default.

TryStrToFloat places the result in Value, and returns true if the conversion was successful, false otherwise.

The first three forms of TryStrToFloat are not thread-safe, because they use localization information contained in global variables. The second three forms of TryStrToFloat, which are thread-safe, refer to localization information contained in the FormatSettings parameter. Before calling the thread-safe forms of TryStrToFloat, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.238 SysUtils.TryStrToInt Function

Converts a string that represents an integer (decimal or hex notation) to a number with Boolean success code.

Pascal

```
function TryStrToInt(const S: string; out Value: Integer): Boolean;
```

C++

```
Boolean TryStrToInt(const AnsiString S, int Value);
```

File

SysUtils

Description

TryStrToInt converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a number, which is assigned to Value. If S does not represent a valid number, TryStrToInt returns false; otherwise TryStrToInt returns true.

To accept decimal but not hexadecimal values in the input string, you may use code like this:

```
function TryDecimalStrToInt( const S: string; out Value: Integer): Boolean;
begin
   result := ( pos( '$', S ) = 0 ) and TryStrToInt( S, Value );
end;
```

See Also

IntToHex (see page 22920)

IntToStr (see page 22921)

StrToInt (see page 22970)

StrToIntDef (see page 22971)

159.3.239 SysUtils.TryStrToInt64 Function

Converts a string that represents an integer (decimal or hex notation) to a number.

Pascal

```
function TryStrToInt64(const S: string; out Value: Int64): Boolean;
```

C++

```
Boolean TryStrToInt64(const AnsiString S, Int64 Value);
```

File

SysUtils

Description

TryStrToInt64 converts the string S, which represents an integer-type number in either decimal or hexadecimal notation, into a number, which is assigned to Value. If S does not represent a valid number, TryStrToInt64 returns false; otherwise TryStrToInt64 returns true.

To accept decimal but not hexadecimal values in the input string, you may use code like this:

```
function TryDecimalStrToInt( const S: string; out Value: Integer): Boolean;
begin
   result := ( pos( '$', S ) = 0 ) and TryStrToInt( S, Value );
end;
```

See Also

IntToStr (see page 22921)

StrToInt (see page 22970)

StrToInt64 (see page 22970)

StrToInt (see page 22970)

159.3.240 SysUtils.TryStrToTime Function

Converts a string to a TDateTime value with an error default.

Pascal

```
function TryStrToTime(const S: string; out Value: TDateTime): Boolean; overload;
function TryStrToTime(const S: string; out Value: TDateTime; const FormatSettings:
TFormatSettings): Boolean; overload;
```

C++

```
Boolean TryStrToTime(const AnsiString S, TDateTime Value);
Boolean TryStrToTime(const AnsiString S, TDateTime Value, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

Call TryStrToTime to parse a string that specifies a time value. If S does not contain a valid time, TryStrToTime returns false.

The S parameter must consist of two or three numbers, separated by the character defined by the TimeSeparator (see page 23033) global variable or its TFormatSettings (see page 23001) equivalent, optionally followed by an AM or PM indicator. The numbers represent hour, minute, and (optionally) second, in that order. If the time is followed by AM or PM, it is assumed to be in 12-hour clock format. If no AM or PM indicator is included, the time is assumed to be in 24-hour clock format.

The first form of TryStrToTime is not thread-safe, because it uses localization information contained in global variables. The second form of TryStrToTime, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of TryStrToTime, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.241 SysUtils.UnloadPackage Function

Unloads a package.

Pascal

```
procedure UnloadPackage(Module: HMODULE);
```

C++

```
UnloadPackage(HMODULE Module);
```

File

SysUtils

Description

Call UnloadPackage to unload a package that was loaded using the LoadPackage (see page 22927) function. UnloadPackage performs any finalization of units contained in the package and then unloads the package BPL.

See Also

LoadPackage (see page 22927)

159.3.242 SysUtils.UpperCase Function

Returns a copy of a string in uppercase.

Pascal

```
function UpperCase(const S: string): string; overload;
function UpperCase(const S: string; LocaleOptions: TLocaleOptions): string; overload;
```

C++

```
AnsiString UpperCase(const AnsiString S);
AnsiString UpperCase(const AnsiString S, TLocaleOptions LocaleOptions);
```

File

SysUtils

Description

UpperCase returns a copy of the string S, with the same text but with all 7-bit ASCII characters between 'a' and 'z' converted to uppercase. To convert 8-bit international characters, use AnsiUpperCase (see page 22800) instead.

C++ Examples:

```
/*
This example uses a list box and a button on a form. Use the
Items property editor in the Object Inspector to enter a
list of strings in the list box. When the application runs
and the button is clicked, the strings in the list box
become uppercase.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  for (int I = 0; I < ListBox1->Items->Count; I++)
    ListBox1->Items->Strings[I] = UpperCase(ListBox1->Items->Strings[I]);
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");
}
```

Delphi Examples:

```
{
This example uses a list box and a button on a form. Use the
Items property editor in the Object Inspector to enter a
```

```
  list of strings in the list box. When the application runs
  and the button is clicked, the strings in the list box
  become uppercase.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    I: Integer;
  begin
    for I := 0 to ListBox1.Items.Count -1 do
      ListBox1.Items[I] := SysUtils.UpperCase(ListBox1.Items[I]);
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ListBox1.Items.Add('Not');
    Listbox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;
```

See Also

AnsiUpperCase (see page 22800)

LowerCase (see page 22928)

159.3.243 SysUtils.WideCompareStr Function

Compares Unicode strings based on the current locale with case sensitivity.

Pascal

```
function WideCompareStr(const S1: WideString; const S2: WideString): Integer;
```

C++

```
int WideCompareStr(const BSTR S1, const BSTR S2);
```

File

SysUtils

Description

WideCompareStr compares S1 to S2, with case sensitivity. The compare operation is controlled by the current locale. The return value is:

Condition	Return Value
S1 > S2	> 0
S1 < S2	< 0
S1 = S2	= 0

Note: Most locales consider lowercase characters to be less than the corresponding uppercase characters. This is in contrast to ASCII order, in which lowercase characters are greater than uppercase characters. with S1 set to 'a' and S2 set to 'A', WideCompareStr returns a value lsess than zero, while CompareStr (see page 22813) returns a value greater than zero.

See Also

WideCompareText (see page 22990)

WideSameStr (see page 22992)

159.3.244 SysUtils.WideCompareText Function

Compares Unicode strings based on the current locale without case sensitivity.

Pascal

```
function WideCompareText(const S1: WideString; const S2: WideString): Integer;
```

C++

```
int WideCompareText(const BSTR S1, const BSTR S2);
```

File

SysUtils

Description

WideCompareText compares S1 to S2, without case sensitivity. The compare operation is controlled by the current locale. WideCompareText returns a value less than 0 if S1 < S2, a value greater than 0 if S1 > S2, and returns 0 if S1 = S2.

See Also

WideCompareStr (see page 22989)

WideSameText (see page 22993)

159.3.245 SysUtils.WideFmtStr Function

Assembles a formatted Unicode string using a format string and an array of arguments.

Pascal

```
procedure WideFmtStr(var Result: WideString; const Format: WideString; const Args: array of
const); overload;
procedure WideFmtStr(var Result: WideString; const Format: WideString; const Args: array of
const; const FormatSettings: TFormatSettings); overload;
```

C++

```
WideFmtStr(BSTR Result, const BSTR Format, const array of const Args);
WideFmtStr(BSTR Result, const BSTR Format, const array of const Args, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

This function formats the series of arguments in the open array Args into a Unicode string. Formatting is controlled by the format string Format (see page 22897); the results are returned in the parameter Result.

For information on the format strings, see Format (see page 22897) Strings.

The first form of WideFmtStr is not thread-safe, because it uses localization information contained in global variables. The second form of WideFmtStr, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of WideFmtStr, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

See Also

GetLocaleFormatSettings (see page 22913)

159.3.246 SysUtils.WideFormat Function

Returns a formatted Unicode string assembled from a format string and an array of arguments.

Pascal

```
function WideFormat(const Format: WideString; const Args: array of const): WideString;
overload;
function WideFormat(const Format: WideString; const Args: array of const; const
FormatSettings: TFormatSettings): WideString; overload;
```

C++

```
BSTR WideFormat(const BSTR Format, const array of const Args);
BSTR WideFormat(const BSTR Format, const array of const Args, const TFormatSettings
FormatSettings);
```

File

SysUtils

Description

This function formats the series of arguments in the open array Args. Formatting is controlled by the format string Format (see page 22897); the results are returned in the function result as a Unicode string.

For information on the format strings, see Format (see page 22897) Strings.

The first form of WideFormat is not thread-safe, because it uses localization information contained in global variables. The second form of WideFormat, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of WideFormat, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

See Also

GetLocaleFormatSettings (see page 22913)

159.3.247 SysUtils.WideFormatBuf Function

Formats the arguments from an array, placing the result in a buffer.

Pascal

```
function WideFormatBuf(var Buffer; BufLen: Cardinal; const Format; FmtLen: Cardinal; const
Args: array of const): Cardinal; overload;
function WideFormatBuf(var Buffer; BufLen: Cardinal; const Format; FmtLen: Cardinal; const
Args: array of const; const FormatSettings: TFormatSettings): Cardinal; overload;
```

C++

```
unsigned WideFormatBuf( Buffer, unsigned BufLen, const  Format, unsigned FmtLen, const array
of const Args);
unsigned WideFormatBuf( Buffer, unsigned BufLen, const  Format, unsigned FmtLen, const array
of const Args, const TFormatSettings FormatSettings);
```

File

SysUtils

Description

This function formats the series of arguments in the open array Args. Formatting is controlled by the Unicode format string Format (see page 22897) (whose length is given by FmtLen); the results are returned in Buffer (whose length is given by BufLen). The function returns the number of Unicode characters in the formatted string.

Note: Both buffers contain wide (Unicode) characters. BufLen and FmtLen must specify the number of Unicode characters in their respective buffers, not the number of bytes.

For information on the format strings, see Format (see page 22897) Strings.

The first form of WideFormatBuf is not thread-safe, because it uses localization information contained in global variables. The second form of WideFormatBuf, which is thread-safe, refers to localization information contained in the FormatSettings parameter. Before calling the thread-safe form of WideFormatBuf, you must populate FormatSettings with localization information. To populate FormatSettings with a set of default locale values, call GetLocaleFormatSettings (see page 22913).

159.3.248 SysUtils.WideLowerCase Function

Returns Unicode string converted to lower case.

Pascal

```
function WideLowerCase(const S: WideString): WideString;
```

C++

```
BSTR WideLowerCase(const BSTR S);
```

File

SysUtils

Description

WideLowerCase returns S converted to lower case. The conversion uses the current locale.

See Also

WideUpperCase (see page 22993)

LowerCase (see page 22928)

159.3.249 SysUtils.WideSameStr Function

Compares Unicode strings based on the current locale with case sensitivity.

Pascal

```
function WideSameStr(const S1: WideString; const S2: WideString): Boolean;
```

C++

```
Boolean WideSameStr(const BSTR S1, const BSTR S2);
```

File

SysUtils

Description

WideSameStr compares S1 to S2, with case sensitivity. The compare operation is controlled by the current locale. The return value is true if the two strings have the same value, Ffalse otherwise.

See Also

WideSameText (see page 22993)

WideCompareStr (see page 22989)

159.3.250 SysUtils.WideSameText Function

Compares Unicode strings based on the current locale without case sensitivity.

Pascal

```
function WideSameText(const S1: WideString; const S2: WideString): Boolean;
```

C++

```
Boolean WideSameText(const BSTR S1, const BSTR S2);
```

File

SysUtils

Description

WideSameText compares S1 to S2, without case sensitivity. The compare operation is controlled by the current locale. The return value is true if the two strings have the same value, false otherwise.

See Also

WideSameStr (see page 22992)

WideCompareText (see page 22990)

159.3.251 SysUtils.WideUpperCase Function

Returns Unicode string converted to upper case.

Pascal

```
function WideUpperCase(const S: WideString): WideString;
```

C++

```
BSTR WideUpperCase(const BSTR S);
```

File

SysUtils

Description

WideUpperCase returns S converted to upper case. The conversion uses the current locale.

See Also

WideLowerCase (see page 22992)

UpperCase (see page 22988)

159.3.252 SysUtils.Win32Check Function

Checks the return value of a Windows API call and raises an appropriate exception when it indicates failure.

Pascal

```
function Win32Check(RetVal: BOOL): BOOL; platform;
```

C++

```
BOOL Win32Check(BOOL RetVal);
```

File

SysUtils

Description

Call Win32Check with the return value of a Windows API call that returns a Boolean to indicate success or failure. If the Windows API returns false (indicating failure), Win32Check calls RaiseLastOSError (see page 22932) to raise an exception. If the Windows function returns true, Win32Check returns true.

Win32Check is available on Windows only.

See Also

RaiseLastOSError (see page 22932)

159.3.253 SysUtils.WrapText Function

Splits a string into multiple lines as its length approaches a specified size.

Pascal

```
function WrapText(const Line: string; const BreakStr: string; const BreakChars: TSysCharSet;
MaxCol: Integer): string; overload;
function WrapText(const Line: string; MaxCol: Integer = 45): string; overload;
```

C++

```
AnsiString WrapText(const AnsiString Line, const AnsiString BreakStr, const TSysCharSet
BreakChars, int MaxCol);
AnsiString WrapText(const AnsiString Line, int MaxCol = 45);
```

File

SysUtils

Description

WrapText scans a string for occurrences of any of the characters specified by nBreakChars and inserts a line-break, specified by BreakStr, at the last occurrence of a character in nBreakChars before MaxCol. Line is the text WrapText scans. MaxCol is the maximum line length.

If the BreakStr and nBreakChars parameters are omitted, WrapText searches for space, hyphen, or tab characters on which to

break the line and inserts a carriage return/line feed pair (Windows) or a linefeed (Linux) at the break points.

WrapText does not insert a break into an embedded quoted string (both single quotes and double quotes are supported).

For example, the following call wraps the text into two lines at the last space character:

```
WrapText('The rain in Spain falls mainly on the plain.', #13#10, ['.',' ',#9,'-'], 42);
```

TSysCharSet (see page 23019) bchars

```
bchars << '.' << '-' << ' ';
WrapText("The rain in Spain falls mainly on the plain.", "\r\n", bchars, 42);
```

The result:

```
The rain in Spain falls mainly on the
plain.
```

159.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TFilenameCaseMatch (see page 22998)	TFilenameCaseMatch indicates how close a match was found to a specified file name.
	TFloatFormat (see page 22999)	TFloatFormat is an enumerated list of formatting codes for float functions.
	TFloatValue (see page 23001)	This is record SysUtils.TFloatValue.
	TLocaleOptions (see page 23003)	TLocaleOptions defines a choice of dependent and independent locale options.
	TMbcsByteType (see page 23004)	TMbcsByteType represents the use of a single byte in a string that uses a multi-byte character set (MBCS).
	TNameType (see page 23005)	This is record SysUtils.TNameType.

Records

	Name	Description
	Int64Rec (see page 22996)	Int64Rec declares a utility record to provide access to the bytes of an Int64 value.
	LongRec (see page 22997)	LongRec declares a utility record to provide access to the bytes of a LongWord value.
	TExceptionRecord (see page 22997)	TExceptionRecord holds information about an exception in an application.
	TFloatRec (see page 23000)	TFloatRec declares a utility record that provides access to the attributes of a floating point number.
	TFormatSettings (see page 23001)	TFormatSettings defines a thread-safe string formatting context.
	TLangRec (see page 23002)	TLangRec declares a record used to describe a Windows locale.
	TSearchRec (see page 23005)	TSearchRec defines file information searched for by FindFirst (see page 22884) or FindNext (see page 22887).
	TSysLocale (see page 23008)	TSysLocale represents locale information.
	TThreadInfo (see page 23009)	This is record SysUtils.TThreadInfo.
	TTimeStamp (see page 23009)	TTimeStamp represents time and date values.
	WordRec (see page 23010)	WordRec declares a utility record to store high and low order bytes of a variable.

159.4.1 SysUtils.Int64Rec Record

Int64Rec declares a utility record to provide access to the bytes of an Int64 value.

Pascal

```
Int64Rec = packed record
  case Integer of
    0: (Hi: Cardinal;
        Lo: Cardinal;);
    1: (Cardinals: array [0..1] of Cardinal);
        Words: array [0..3] of Word);
        Bytes: array [0..7] of Byte););
end;
```

C++

```
struct Int64Rec {
  unsigned Hi;
  unsigned Lo;
  array [0..1] of Cardinal) Cardinals;
  array [0..3] of Word) Words;
```

```
  array [0..7] of Byte) Bytes;
};
```

File

SysUtils

Description

The Int64Rec type declares a utility record that stores 8 contiguous (packed) bytes of data. Int64Rec is used primarily for typecasting, where Int64 data needs to be dissected.

The 8 bytes may be accessed individually via the `Bytes` array, or as an array of 4 `Words`, or an array of 2 `Cardinals`. And finally, the value may be accessed via the `Hi` and `Lo` order Cardinals.

159.4.2 SysUtils.LongRec Record

LongRec declares a utility record to provide access to the bytes of a LongWord value.

Pascal

```
LongRec = packed record
  case Integer of
    0: (Hi: Word;
        Lo: Word;);
    1: (Words: array [0..1] of Word);
        Bytes: array [0..3] of Byte););
end;
```

C++

```
struct LongRec {
  Word Hi;
  Word Lo;
  array [0..1] of Word) Words;
  array [0..3] of Byte) Bytes;
};
```

File

SysUtils

Description

The LongRec type declares a utility record that stores 4 contiguous (packed) bytes of data. LongRec is used primarily for typecasting, where LongWord data needs to be dissected.

The 4 bytes may be accessed individually via the `Bytes` array, or as an array of 2 `Words`, or the value may be accessed via the `Hi` and `Lo` order Words.

159.4.3 SysUtils.TExceptionRecord Record

TExceptionRecord holds information about an exception in an application.

Pascal

```
TExceptionRecord = record
  ExceptionCode: Cardinal;
  ExceptionFlags: Cardinal;
  ExceptionRecord: PExceptionRecord;
```

```
    ExceptionAddress: Pointer;
    NumberParameters: Cardinal;
    ExceptionInformation: array[0..14] of Cardinal;
  end;
```

C++

```
  struct TExceptionRecord {
    unsigned ExceptionCode;
    unsigned ExceptionFlags;
    PExceptionRecord ExceptionRecord;
    void * ExceptionAddress;
    unsigned NumberParameters;
    array[0..14] of Cardinal ExceptionInformation;
  };
```

File

SysUtils

Description

TExceptionRecord holds information about an exception in an application. It is furnished by the Delphi exception handling process.

The record comprises the following elements :

Element	Meaning
`ExceptionCode`	The exception code, such as EXCEPTION_INT_OVERFLOW.
`ExceptionFlags`	Comprises one flag : EXCEPTION_NONCONTINUABLE_EXCEPTION. If 0, then the exception is allowed to continue.
`ExceptionRecord`	Pointer to subsequent exception records, if any.
`ExceptionAddress`	Address where the exception occured.
`NumberParameters`	Number of elements in the `ExceptionInformation` array.
`ExceptionInformation`	An array of numbers that describe the exception.

159.4.4 SysUtils.TFilenameCaseMatch Enumeration

TFilenameCaseMatch indicates how close a match was found to a specified file name.

Pascal

```
  TFilenameCaseMatch = (
    mkNone,
    mkExactMatch,
    mkSingleMatch,
    mkAmbiguous
  );
```

C++

```
  enum TFilenameCaseMatch {
    mkNone,
    mkExactMatch,
    mkSingleMatch,
    mkAmbiguous
  };
```

File

SysUtils

Description

These are the possible values of the TFilenameCaseMatch type:

Value	Meaning
mkNone	No actual file matches the file name.
mkExactMatch	A single file matches the file name.
mkSingleMatch	No file matches the file name, but a single match can be found by ignoring differences in case.
mkAmbiguous	No file matches the file name, but two or more matches can be found by ignoring differences in case.

159.4.5 SysUtils.TFloatFormat Enumeration

TFloatFormat is an enumerated list of formatting codes for float functions.

Pascal

```
TFloatFormat = (
  ffGeneral,
  ffExponent,
  ffFixed,
  ffNumber,
  ffCurrency
);
```

C++

```
enum TFloatFormat {
  ffGeneral,
  ffExponent,
  ffFixed,
  ffNumber,
  ffCurrency
};
```

File

SysUtils

Description

TFloatFormat defines an enumerated list of formatting codes for the float functions.

Format (see page 22897)	Defines
ffGeneral	General number format. The value is converted to the shortest possible decimal string using scientific format. Trailing zeros are removed from the resulting string.
ffExponent	Scientific format. The value is converted to a string of the form "-d.ddd...E+dddd". The resulting string starts with a minus sign if the number is negative, and one digit always precedes the decimal point. The total number of digits before the exponent in the resulting string (including the one before the decimal point) is given by the Precision parameter. The "E" exponent character in the resulting string is always followed by a plus or minus sign and up to four digits. The Digits parameter specifies the minimum number of digits in the exponent (between 0 and 4).

ffFixed	Fixed point format. The value is converted to a string of the form "-ddd.ddd...". The resulting string starts with a minus sign if the number is negative, and at least one digit always precedes the decimal point. The number of digits after the decimal point is given by the Digits parameter--it must be between 0 and 18. If the number of digits to the left of the decimal point is greater than the specified precision, the resulting value will use scientific format. The resulting values is padded with zeros when the Digits parameter is higher than the number of digits dictated by precision. For example, given ffFixed with Precision set to 5 and digits set to 3, fomatting 345.6789 gives the string '345.680', padding with zeros after the precision is met.
ffNumber	Number format. The value is converted to a string of the form "-d,ddd,ddd.ddd...". The ffNumber format corresponds to the ffFixed format, except that the resulting string contains thousandth separators. The resulting values is padded with zeros when the Digits parameter is higher than the number of digits dictated by precision. For example, given ffNumber with Precision set to 5 and digits set to 3, fomatting 345.6789 gives the string '345.680', padding with zeros after the precision is met.
ffCurrency	Currency format. The value is converted to a string that represents a currency amount. The conversion is controlled by the CurrencyString (see page 23023), CurrencyFormat (see page 23022), NegCurrFormat (see page 23029), ThousandSeparator (see page 23032), and DecimalSeparator (see page 23023) global variables, all of which are initialized from the Currency Format (see page 22897) in the International section of the Windows Control Panel. The number of digits after the decimal point is given by the Digits parameter--it must be between 0 and 18. The resulting values is padded with zeros when the Digits parameter is higher than the number of digits dictated by precision. For example, given ffCurrency with Precision set to 5 and digits set to 3, fomatting 345.6789 gives the string '345.680', padding with zeros after the precision is met.

159.4.6 SysUtils.TFloatRec Record

TFloatRec declares a utility record that provides access to the attributes of a floating point number.

Pascal

```
TFloatRec = packed record
  Exponent: Smallint;
  Negative: Boolean;
  Digits: array[0..20] of Char;
end;
```

C++

```
struct TFloatRec {
  Smallint Exponent;
  Boolean Negative;
  array[0..20] of Char Digits;
};
```

File

SysUtils

Description

The TFloatRec type declares a record that holds the attributes of a floating point number. The record makes the attributes accessible for easy formatting or specialised numerical processing.

`Exponent` holds the floating point number exponent value.

`Negative` is set true if the floating point number has a negative value.

`Digits` is a 21 element array of numeric characters representing the floating point number mantissa value : its significant digits.

TFloatRec is used by the FloatToDecimal (see page 22890) function to hold the results of the conversion of a floating point value to its decimal representation.

See Also

FloatToDecimal (see page 22890)

159.4.7 SysUtils.TFloatValue Enumeration

Pascal

```
TFloatValue = (
  fvExtended,
  fvCurrency
);
```

C++

```
enum TFloatValue {
  fvExtended,
  fvCurrency
};
```

File

SysUtils

Description

This is record SysUtils.TFloatValue.

159.4.8 SysUtils.TFormatSettings Record

TFormatSettings defines a thread-safe string formatting context.

Pascal

```
TFormatSettings = record
  CurrencyFormat: Byte;
  NegCurrFormat: Byte;
  ThousandSeparator: Char;
  DecimalSeparator: Char;
  CurrencyDecimals: Byte;
  DateSeparator: Char;
  TimeSeparator: Char;
  ListSeparator: Char;
  CurrencyString: string;
  ShortDateFormat: string;
  LongDateFormat: string;
```

```
    TimeAMString: string;
    TimePMString: string;
    ShortTimeFormat: string;
    LongTimeFormat: string;
    ShortMonthNames: array[1..12] of string;
    LongMonthNames: array[1..12] of string;
    ShortDayNames: array[1..7] of string;
    LongDayNames: array[1..7] of string;
    TwoDigitYearCenturyWindow: Word;
  end;
```

C++

```
  struct TFormatSettings {
    Byte CurrencyFormat;
    Byte NegCurrFormat;
    Char ThousandSeparator;
    Char DecimalSeparator;
    Byte CurrencyDecimals;
    Char DateSeparator;
    Char TimeSeparator;
    Char ListSeparator;
    AnsiString CurrencyString;
    AnsiString ShortDateFormat;
    AnsiString LongDateFormat;
    AnsiString TimeAMString;
    AnsiString TimePMString;
    AnsiString ShortTimeFormat;
    AnsiString LongTimeFormat;
    array[1..12] of string ShortMonthNames;
    array[1..12] of string LongMonthNames;
    array[1..7] of string ShortDayNames;
    array[1..7] of string LongDayNames;
    Word TwoDigitYearCenturyWindow;
  };
```

File

SysUtils

Description

TFormatSettings defines a data structure containing locale information used by string formatting routine. Each member of TFormatSettings is equivalent to the global variable with the same name. A variable of type TFormatSettings defines a thread-safe context that formatting functions can use in place of the default global context, which is not thread-safe.

To create and use the thread-safe environment defined by TFormatSettings, follow these steps:

Define a variable of type TFormatSettings

Call GetLocaleFormatSettings (see page 22913) to populate the TFormatSettings variable with locale information.

Pass the TFormatSettings variable as the last parameter of the string formatting routine.

Each routine that accepts a TFormatSettings parameter is thread-safe, and is an overload of an equivalent function that refers to the global formatting variables.

159.4.9 SysUtils.TLangRec Record

TLangRec declares a record used to describe a Windows locale.

Pascal

```
TLangRec = packed record
  FName: string;
  FLCID: LCID;
  FExt: string;
end;
```

C++

```
struct TLangRec {
  AnsiString FName;
  LCID FLCID;
  AnsiString FExt;
};
```

File

SysUtils

Description

The TLangRec type declares a record that holds the attributes of a Windows language. The record is principally used internally by TLanguages (see page 22762).

`FName` holds the Windows locale name.

`FLCID` holds the local id for the Windows locale.

`FExt` holds the recommended filename extension for the Windows locale.

See Also

TLanguages (see page 22762)

159.4.10 SysUtils.TLocaleOptions Enumeration

TLocaleOptions defines a choice of dependent and independent locale options.

Pascal

```
TLocaleOptions = (
  loInvariantLocale,
  loUserLocale
);
```

C++

```
enum TLocaleOptions {
  loInvariantLocale,
  loUserLocale
};
```

File

SysUtils

Description

The TLocaleOptions type is an enumeration of two choices for dealing with the operating locale of an application. This Microsoft Windows specific type is used in a number of string handling routines, where the locale language may have a bearing on the routine.

Format (see page 22897)	Defines
loInvariantLocale	Use this option where a consistent inter-application operation is desired, inedependent of the actual locale.
loUserLocale	Use this option where the user locale is taken into account.

UpperCase (see page 22988)

159.4.11 SysUtils.TMbcsByteType Enumeration

TMbcsByteType represents the use of a single byte in a string that uses a multi-byte character set (MBCS).

Pascal

```
TMbcsByteType = (
  mbSingleByte,
  mbLeadByte,
  mbTrailByte
);
```

C++

```
enum TMbcsByteType {
  mbSingleByte,
  mbLeadByte,
  mbTrailByte
};
```

File

SysUtils

Description

TMbcsByteType represents the possible return values of the ByteType (see page 22807) and StrByteType (see page 22943) functions. Possible values are as follows:

Values	Meaning
mbSingleByte	The char is used to represent an entire character in the string. The value of Char can not be included in the LeadBytes (see page 23026) set.
mbLeadByte	The char is used to represent the first byte of a multi-byte character. The value of Char must be included in the LeadBytes (see page 23026) set.
mbTrailByte	The char is used to represent one of the trailing bytes in a multi-byte character. There are no a priori restrictions on the value of char.

159.4.12 SysUtils.TNameType Enumeration

Pascal

```
TNameType = (
  ntContainsUnit,
  ntRequiresPackage,
  ntDcpBpiName
);
```

C++

```
enum TNameType {
  ntContainsUnit,
  ntRequiresPackage,
  ntDcpBpiName
};
```

File

SysUtils

Description

This is record SysUtils.TNameType.

159.4.13 SysUtils.TSearchRec Record

TSearchRec defines file information searched for by FindFirst (see page 22884) or FindNext (see page 22887).

Pascal

```
TSearchRec = record
  Time: Integer;
  Size: Int64;
  Attr: Integer;
  Name: TFileName;
  ExcludeAttr: Integer;
  FindHandle: THandle platform;
  FindData: TWin32FindData platform;
end;
```

C++

```
struct TSearchRec {
  int Time;
  Int64 Size;
  int Attr;
  TFileName Name;
  int ExcludeAttr;
  THandle platform FindHandle;
  TWin32FindData platform FindData;
```

```
};
```

File

SysUtils

Description

The TSearchRec type defines file information searched for by a FindFirst (see page 22884) or FindNext (see page 22887) function call. If a file is found, the fields of the TSearchRec type parameter are modified to specify the found file.

Attr represents the file attributes of the file. Test Attr against the following attribute constants or values to determine if a file attribute matches the file's properties.

Note: On Windows, attribute constants map directly to DOS file attributes.

Note: On Linux, attribute constants map to sets of file characteristics; use the Mode field to access the specific permission mode.

Constant	Value	Description	Linux Meaning
faReadOnly (see page 23044)	1	Read-only files	Current user does not have write access.
faHidden (see page 23043)	2	Hidden files	File name begins with ".".
faSysFile (see page 23045)	4	System (see page 22079) files	File is socket, symbolic link, device file, or FIFO.
faVolumeID (see page 23045)	8	Volume ID files	Not used.
faDirectory (see page 23042)	16	Directory files	Directory.
faArchive (see page 23042)	32	Archive files	Not used.
faSymLink (see page 23044)	64	Symbolic link	File is a symbolic link.
faAnyFile (see page 23041)	71	Any file	Any file.

The faReadOnly (see page 23044) constant has the same name as the enumerated value that is defined by the TFieldAttribute type. If both the SysUtils (see page 22709) and the Db units are used in your source files, you must disambiguate by specifying the unit to qualify the use of faReadOnly (see page 23044). That is, write SysUtils.faReadOnly (see page 23044) (Delphi) or SysUtils::faReadOnly (see page 23044) (C++).

To test for an attribute, combine the value of the Attr field with the attribute constant with the and operator. If the file has that attribute, the result will be greater than 0. For example, if the found file is a hidden file, the following expression will evaluate to true:

(SearchRec.Attr and faHidden (see page 23043)) <> 0.

(SearchRec.Attr & faHidden (see page 23043)) != 0.

Time contains the time stamp of the file. It can be converted to a TDateTime value using FileDateToDateTime (see page 22858).

Size contains the size of the file in bytes.

Name contains the base file name, including extension.

FindHandle is an internal handle used to track find state.

FindData (Windows only) contains additional information such as the file creation time, last access time, and both the long and short file names.

Mode (Linux only) is the file's permission mask.

C++ Examples:

```
/*
The following example uses an edit control, a button, a
string grid, and seven check boxes. The check boxes
correspond to the seven possible file attributes. When the
button is clicked, the path specified in the edit control is
searched for files matching the checked file attributes. The
names and sizes of the matching files are inserted into the
string grid.  The Path constant parameter is the directory
and file name mask, including wildcard characters. For
example, '.\test\*.*' specifies all files in the current
directory).
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TSearchRec sr;
  int iAttributes = 0;
  StringGrid1->RowCount = 1;
  iAttributes |= faReadOnly * CheckBox1->Checked;
  iAttributes |= faHidden * CheckBox2->Checked;
  iAttributes |= faSysFile * CheckBox3->Checked;
  iAttributes |= faVolumeID * CheckBox4->Checked;
  iAttributes |= faDirectory * CheckBox5->Checked;
  iAttributes |= faArchive * CheckBox6->Checked;
  iAttributes |= faAnyFile * CheckBox7->Checked;
  StringGrid1->RowCount = 0;
  if (FindFirst(Edit1->Text, iAttributes, sr) == 0)
  {
    do
    {
      if ((sr.Attr & iAttributes) == sr.Attr)
      {
        StringGrid1->RowCount = StringGrid1->RowCount + 1;
        StringGrid1->Cells[1][StringGrid1->RowCount-1] = sr.Name;
        StringGrid1->Cells[2][StringGrid1->RowCount-1] = IntToStr(sr.Size);
      }
    } while (FindNext(sr) == 0);
    FindClose(sr);
  }
}
```

Delphi Examples:

```
{
The following example uses an edit control, a button, a
string grid, and seven check boxes. The check boxes
correspond to the seven possible file attributes. When the
button is clicked, the path specified in the edit control is
searched for files matching the checked file attributes. The
names and sizes of the matching files are inserted into the
string grid.  The Path constant parameter is the directory
and file name mask, including wildcard characters. For
example, '.\test\*.*' specifies all files in the current
directory).
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sr: TSearchRec;
  FileAttrs: Integer;
```

```
begin
  StringGrid1.RowCount := 1;
  if CheckBox1.Checked then
    FileAttrs := faReadOnly
  else
    FileAttrs := 0;
  if CheckBox2.Checked then
    FileAttrs := FileAttrs + faHidden;
  if CheckBox3.Checked then
    FileAttrs := FileAttrs + faSysFile;
  if CheckBox4.Checked then
    FileAttrs := FileAttrs + faVolumeID;
  if CheckBox5.Checked then
    FileAttrs := FileAttrs + faDirectory;
  if CheckBox6.Checked then
    FileAttrs := FileAttrs + faArchive;
  if CheckBox7.Checked then
    FileAttrs := FileAttrs + faAnyFile;
  with StringGrid1 do
  begin
    RowCount := 0;
    if SysUtils.FindFirst(Edit1.Text, FileAttrs, sr) = 0 then
    begin
      repeat
        if (sr.Attr and FileAttrs) = sr.Attr then
        begin
        RowCount := RowCount + 1;
        Cells[1,RowCount-1] := sr.Name;
        Cells[2,RowCount-1] := IntToStr(sr.Size);
        end;
      until FindNext(sr) <> 0;
      FindClose(sr);
    end;
  end;
end;
```

159.4.14 SysUtils.TSysLocale Record

TSysLocale represents locale information.

Pascal

```
TSysLocale = packed record
  DefaultLCID: Integer;
  PriLangID: Integer;
  SubLangID: Integer;
  FarEast: Boolean;
  MiddleEast: Boolean;
end;
```

C++

```
struct TSysLocale {
  int DefaultLCID;
  int PriLangID;
  int SubLangID;
  Boolean FarEast;
  Boolean MiddleEast;
};
```

File

SysUtils

Description

The TSysLocale type represents a locale. The locale determines how dates and times are formatted, how items are alphabetically sorted, and how strings are compared.

The **DefaultLCID** field represents the locale identifier. This is a 32-bit value that specifies a default sort order and a default language identifier.

The **PirLangID** field specifies the primary type of the language identifier. This is one of the constants that identify a language group, such as **LANG_ENGLISH** or **LANG_FRENCH**.

The **SubLangID** field specifies the subtype of the language identifier. This is one of the constants that identify a language subgroup, such as **SUBLANG_ENGLISH_US** or **SUBLANG_FRENCH_CANADIAN**.

FarEast is true or nonzero if User32.dll supports DBCS; false or zero otherwise. In other words, **FarEast** is true or nonzero if the double-byte character-set (DBCS) version of User.exe is installed; false or zero otherwise.

MiddleEast is true if the system is enabled for Hebrew and Arabic languages; false otherwise.

159.4.15 SysUtils.TThreadInfo Record

Pascal

```
TThreadInfo = record
  Next: PThreadInfo;
  ThreadID: Cardinal;
  Active: Integer;
  RecursionCount: Cardinal;
end;
```

C++

```
struct TThreadInfo {
  PThreadInfo Next;
  unsigned ThreadID;
  int Active;
  unsigned RecursionCount;
};
```

File

SysUtils

Description

This is record SysUtils.TThreadInfo.

159.4.16 SysUtils.TTimeStamp Record

TTimeStamp represents time and date values.

Pascal

```
TTimeStamp = record
  Time: Integer;
  Date: Integer;
end;
```

C++

```
struct TTimeStamp {
  int Time;
  int Date;
};
```

File

SysUtils

Description

Use TTimeStamp to represent date and time values when a great deal of accuracy is required for the time portion. When the time values do not need to be precise to the millisecond, use the more compact TDateTime representation. If additional precision is needed, use TSQLTimeStamp (but do NOT assign it to a Variant).

The Time field indicates the number of milliseconds that have elapsed since midnight.

The Date field indicates the number of calendar days since the start of the calendar (the number of days since 1/1/0001 plus one).

159.4.17 SysUtils.WordRec Record

WordRec declares a utility record to store high and low order bytes of a variable.

Pascal

```
WordRec = packed record
  case Integer of
    0: (Hi: Byte;
        Lo: Byte;);
    1: (Bytes: array [0..1] of Byte););
end;
```

C++

```
struct WordRec {
  Byte Hi;
  Byte Lo;
  array [0..1] of Byte) Bytes;
};
```

File

SysUtils

Description

The WordRec type declares a utility record that stores the high and low order bytes of the specified variable as type Byte. WordRec is used primarily for typecasting.

159.5 Types

The following table lists types in this documentation.

Types

Name	Description
ExceptClass (see page 23012)	ExceptClass declares an Exception (see page 22750) class.
PByteArray (see page 23013)	PByteArray declares a pointer to an array of Bytes.
PDayTable (see page 23013)	PDayTable is a pointer to a TDayTable (see page 23015) type.
PExceptionRecord (see page 23014)	PExceptionRecord is a pointer to a TExceptionRecord (see page 22997) type.
PThreadInfo (see page 23014)	This is type SysUtils.PThreadInfo.
PWordArray (see page 23014)	PWordArray is a pointer to a TWordArray (see page 23020) type.
TByteArray (see page 23015)	TByteArray declares an array of Bytes.
TBytes (see page 23015)	TBytes declares an array of Bytes.
TDayTable (see page 23015)	TDayTable is used to hold the number of days of each month of a year.
TFileName (see page 23016)	TFileName is a string that represents a file name.
TIntegerSet (see page 23016)	TIntegerSet is used to treat an integer as a set of bits.
TMREWSync (see page 23017)	TMREWSync is a short name equivalent to TMultiReadExclusiveWriteSynchronizer (see page 22766).
TPackageInfoProc (see page 23017)	TPackageInfoProc is a call-back procedure invoked by GetPackageInfo (see page 22915).
TProcedure (see page 23018)	TProcedure declares a procedure.
TReplaceFlags (see page 23018)	TReplaceFlags indicates how to perform a search-and-replace operation
TSysCharSet (see page 23019)	TSysCharSet is a set containing special characters that can be used to parse a string. The elements of the set vary, depending on the type of parsing performed.
TTerminateProc (see page 23019)	TValidatePackageProc (see page 23019) is a call-back function invoked by LoadPackage (see page 22927).
TValidatePackageProc (see page 23019)	This is type SysUtils.TValidatePackageProc.
TWordArray (see page 23020)	TWordArray declares an array of Words.

159.5.1 SysUtils.ExceptClass Type

ExceptClass declares an Exception (see page 22750) class.

Pascal

```
ExceptClass = class of Exception;
```

C++

```
Exception ExceptClass;
```

File

SysUtils

Description

The ExceptClass type declares an Exception (see page 22750) class. This class encapsulates the fundamental properties and methods for all exceptions. Use Exception (see page 22750) as the base class for creating custom exceptions.

See Also

Exception (see page 22750)

159.5.2 SysUtils.PByteArray Type

PByteArray declares a pointer to an array of Bytes.

Pascal

```
PByteArray = ^TByteArray;
```

C++

```
^TByteArray PByteArray;
```

File

SysUtils

Description

The PByteArray type declares a pointer to a TByteArray (see page 23015) : a static array of Bytes. The array size is 32,768 (2**15) elements.

Note: Static arrays are declared with an immutable size.

See Also

TByteArray (see page 23015)

159.5.3 SysUtils.PDayTable Type

PDayTable is a pointer to a TDayTable (see page 23015) type.

Pascal

```
PDayTable = ^TDayTable;
```

C++

```
^TDayTable PDayTable;
```

File

SysUtils

Description

The TDayTable (see page 23015) type points to a TDayTable (see page 23015) variable. TDayTable (see page 23015) declares a static array of 12 Words. It is principally used by the MonthDays (see page 23054) constant to hold the number of days in a month for normal and leap years.

Note: Static arrays are declared with an immutable size.

See Also

TDayTable (see page 23015)

159.5.4 SysUtils.PExceptionRecord Type

PExceptionRecord is a pointer to a TExceptionRecord (see page 22997) type.

Pascal

```
PExceptionRecord = ^TExceptionRecord;
```

C++

```
^TExceptionRecord PExceptionRecord;
```

File

SysUtils

Description

The PExceptionRecord type points to a TExceptionRecord (see page 22997) variable. TExceptionRecord (see page 22997) holds information about an exception in an application.

See Also

TExceptionRecord (see page 22997)

159.5.5 SysUtils.PThreadInfo Type

Pascal

```
PThreadInfo = ^TThreadInfo;
```

C++

```
^TThreadInfo PThreadInfo;
```

File

SysUtils

Description

This is type SysUtils.PThreadInfo.

159.5.6 SysUtils.PWordArray Type

PWordArray is a pointer to a TWordArray (see page 23020) type.

Pascal

```
PWordArray = ^TWordArray;
```

C++

```
^TWordArray PWordArray;
```

File

SysUtils

Description

The PWordArray type points to a TWordArray (see page 23020) variable. The TWordArray (see page 23020) type declares a static array of Words. The array size is 16,384 (2**14) elements.

See Also

TWordArray (see page 23020)

159.5.7 SysUtils.TByteArray Type

TByteArray declares an array of Bytes.

Pascal

```
TByteArray = array[0..32767] of Byte;
```

C++

```
array[0..32767] of Byte TByteArray;
```

File

SysUtils

Description

The TByteArray type declares a static array of Bytes. The array size is 32,768 (2**15) elements.

Note: Static arrays are declared with an immutable size.

159.5.8 SysUtils.TBytes Type

TBytes declares an array of Bytes.

Pascal

```
TBytes = array of Byte;
```

C++

```
array of Byte TBytes;
```

File

SysUtils

Description

The TBytes type declares a dynamic array of Bytes.

Note: Dynamic arrays have no intrinsic size. SetLength is used to allocate storage for the defined array size desired. Dynamic arrays are always integer-indexed, starting at 0.

159.5.9 SysUtils.TDayTable Type

TDayTable is used to hold the number of days of each month of a year.

Pascal

```
TDayTable = array[1..12] of Word;
```

C++

```
array[1..12] of Word TDayTable;
```

File

SysUtils

Description

The TDayTable type declares a static array of 12 Words. It is principally used by the MonthDays (see page 23054) constant to hold the number of days in a month for normal and leap years.

Note: Static arrays are declared with an immutable size.

See Also

MonthDays (see page 23054)

159.5.10 SysUtils.TFileName Type

TFileName is a string that represents a file name.

Pascal

```
TFileName = type string;
```

C++

```
type string TFileName;
```

File

SysUtils

Description

Use TFileName to represent strings that are only used for file names.

159.5.11 SysUtils.TIntegerSet Type

TIntegerSet is used to treat an integer as a set of bits.

Pascal

```
TIntegerSet = set of 0..SizeOf(Integer) * 8 - 1;
```

C++

```
0..SizeOf(Integer) * 8 - 1 TIntegerSet;
```

File

SysUtils

Description

Type TIntegerSet = set of 0 .. Integer-bit-size-1;

Assuming that an integer is 4 bytes (=32 bits), the set will 0 .. 31. TIntegerSet is typically used to treat an integer as a set of bits. To do so, an integer variable value is assigned to a TIntegerSet variable using TIntegerSet casting.

159.5.12 SysUtils.TMREWSync Type

TMREWSync is a short name equivalent to TMultiReadExclusiveWriteSynchronizer (see page 22766).

Pascal

```
TMREWSync = TMultiReadExclusiveWriteSynchronizer;
```

C++

```
TMultiReadExclusiveWriteSynchronizer TMREWSync;
```

File

SysUtils

Description

The TMREWSync type is used instead of TMultiReadExclusiveWriteSynchronizer (see page 22766).

Note: TMultiReadExclusiveWriteSynchronizer (see page 22766) is a class that minimizes thread serialization to gain read access to a resource shared among threads while still providing complete exclusivity to callers needing write access to the shared resource.

159.5.13 SysUtils.TPackageInfoProc Type

TPackageInfoProc is a call-back procedure invoked by GetPackageInfo (see page 22915).

Pascal

```
TPackageInfoProc = procedure (const Name: string; NameType: TNameType; Flags: Byte; Param:
Pointer);
```

C++

```
(const Name: string; NameType: TNameType; Flags: Byte; Param: Pointer) ( TPackageInfoProc)();
```

File

SysUtils

Description

The TPackageInfoProc type declares the procedure that is invoked by GetPackageInfo (see page 22915) to retrieve package information. It is called for every unit in the package, and every package required by that package.

The following table lists the information provided in these call back invocations of your TPackageInfoProc variable.

Parameter name	Parameter value
Name	Unit or required package name
NameType	Indicates if this call is for a contained unit, required package or DcpBpiName.
Flags	
Param	

See Also

GetPackageInfo (see page 22915)

NameType

159.5.14 SysUtils.TProcedure Type

TProcedure declares a procedure.

Pascal

```
TProcedure = procedure;
```

C++

```
( TProcedure)();
```

File

SysUtils

Description

Use the TProcedure type as a generic Procedure pointer.

159.5.15 SysUtils.TReplaceFlags Type

TReplaceFlags indicates how to perform a search-and-replace operation

Pascal

```
TReplaceFlags = set of (rfReplaceAll, rfIgnoreCase);
```

C++

```
(rfReplaceAll, rfIgnoreCase) TReplaceFlags;
```

File

SysUtils

Description

TReplaceFlags is a set of flags that govern how to locate and replace a substring within a string. This set can contain the following values:

Value	Meaning
rfReplaceAll	Replace all occurrences. If this flag is not present, only the first occurrence of the target substring is replaced.
rfIgnoreCase	Match occurrences of the substring case-insensitively. If this flag is not present, only case-sensitive matches are considered.

See Also

StringReplace

159.5.16 SysUtils.TSysCharSet Type

TSysCharSet is a set containing special characters that can be used to parse a string. The elements of the set vary, depending on the type of parsing performed.

Pascal

```
TSysCharSet = set of Char;
```

C++

```
Char TSysCharSet;
```

File

SysUtils

Description

type TSysCharSet = set of Char;

typedef Set<char, 0, 255> TSysCharSet;

TSysCharSet is a set containing special characters that can be used to parse a string. The elements of the set vary, depending on the type of parsing performed.

159.5.17 SysUtils.TTerminateProc Type

TValidatePackageProc (see page 23019) is a call-back function invoked by LoadPackage (see page 22927).

Pascal

```
TTerminateProc = function : Boolean;
```

C++

```
: Boolean ( TTerminateProc)();
```

File

SysUtils

Description

TValidatePackageProc (see page 23019) is optionally invoked by LoadPackage (see page 22927) when a package is loaded. The package is not loaded if TValidatePackageProc (see page 23019) determines that it is not valid and hence returns false.

See Also

LoadPackage (see page 22927)

159.5.18 SysUtils.TValidatePackageProc Type

Pascal

```
TValidatePackageProc = function (Module: HMODULE): Boolean;
```

C++

```
(Module: HMODULE): Boolean ( TValidatePackageProc)();
```

File

SysUtils

Description

This is type SysUtils.TValidatePackageProc.

159.5.19 SysUtils.TWordArray Type

TWordArray declares an array of Words.

Pascal

```
TWordArray = array[0..16383] of Word;
```

C++

```
array[0..16383] of Word TWordArray;
```

File

SysUtils

Description

The TWordArray type declares a static array of Words. The array size is 16,384 (2**14) elements.

Note: Static arrays are declared with an immutable size.

159.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
CurrencyDecimals (see page 23022)	CurrencyDecimals is the number of digits to the right of the decimal point in a currency amount.
CurrencyFormat (see page 23022)	CurrencyFormat defines the currency symbol placement and separation used in floating-point–to–decimal conversions. Possible values are: 0 = $1 \| 1 = 1$ | 2 = $ 1 | 3 = 1 $
CurrencyString (see page 23023)	CurrencyString defines the currency symbol (or characters) used in floating-point to decimal conversions.
DateSeparator (see page 23023)	DateSeparator is the character used to separate the year, month, and day parts of a date value.
DecimalSeparator (see page 23023)	DecimalSeparator is the character used to separate the integer part from the fractional part of a number. This variable must have a value other than #0.
EmptyStr (see page 23024)	An empty string constant.
EmptyWideStr (see page 23024)	An empty string version of the WideString constant.
EraNames (see page 23024)	Defines the names of calendar eras for East Asian locales.
EraYearOffsets (see page 23025)	Controls (see page 5711) the DateTimeToStr (see page 22822) function (for East Asian locales).
FalseBoolStrs (see page 23025)	Lists strings that can represent the boolean value false.
GetDiskFreeSpaceEx (see page 23026)	This is variable SysUtils.GetDiskFreeSpaceEx.
HexDisplayPrefix (see page 23026)	HexDisplayPrefix contains the prefix to display on hexadecimal values - `$` for Pascal (Delphi) syntax, `0x` for C++ syntax.
LeadBytes (see page 23026)	Lists all values that can be the first byte of a double byte character on the local system.
ListSeparator (see page 23027)	The character used to separate items in a list.
LongDateFormat (see page 23027)	LongDateFormat is the format string used to convert a date value to a long string suitable for display but not for editing.
LongDayNames (see page 23027)	LongDayNames is the array of strings containing long day names. The dddd format specifier in a format string passed to FormatDateTime (see page 22902) causes a long day name to be substituted.
LongMonthNames (see page 23028)	LongMonthNames is the array of strings containing long month names. The mmmm format specifier in a format string passed to FormatDateTime (see page 22902) causes a long month name to be substituted.
LongTimeFormat (see page 23028)	LongTimeFormat is the format string used to convert a time value to a string with hours, minutes, and seconds.
NegCurrFormat (see page 23029)	NegCurrFormat defines the currency format used in floating-point to decimal conversions of negative numbers.
NullStr (see page 23029)	A pointer to an empty string.
NullWideStr (see page 23030)	A pointer to an empty wide string.
ShortDateFormat (see page 23030)	ShortDateFormat is the format string used to convert a date value to a short string suitable for editing.
ShortDayNames (see page 23031)	ShortDayNames is the array of strings containing short day names. The ddd format specifier in a format string passed to FormatDateTime (see page 22902) causes a short day name to be substituted.
ShortMonthNames (see page 23031)	ShortMonthNames is the array of strings containing short month names. The mmm format specifier in a format string passed to FormatDateTime (see page 22902) causes a short month name to be substituted.
ShortTimeFormat (see page 23031)	ShortTimeFormat is the format string used to convert a time value to a short string with only hours and minutes.
SysLocale (see page 23032)	SysLocale holds locale information.
ThousandSeparator (see page 23032)	ThousandSeparator is the character used to separate thousands in numbers with more than three digits to the left of the decimal separator.
TimeAMString (see page 23033)	TimeAMString is the suffix string used for time values between 00:00 and 11:59 in 12-hour clock format.

TimePMString (see page 23033)	TimePMString is the suffix string used for time values between 12:00 and 23:59 in 12-hour clock format.
TimeSeparator (see page 23033)	TimeSeparator is the character used to separate the hour, minute, and second parts of a time value.
TrueBoolStrs (see page 23034)	Lists strings that can represent the boolean value false.
TwoDigitYearCenturyWindow (see page 23034)	Determines what century is added to two-digit years when string dates are converted to numeric dates.
Win32BuildNumber (see page 23035)	Specifies which the build level of the Windows Operating System (see page 22079) operating.
Win32CSDVersion (see page 23035)	Specifies the Win32 latest installed service pack.
Win32MajorVersion (see page 23036)	Specifies which major Windows Operating System (see page 22079) version is operating.
Win32MinorVersion (see page 23036)	Specifies which minor Windows Operating System (see page 22079) version is operating.
Win32Platform (see page 23037)	Specifies the Windows Operating System (see page 22079) platform identifier.

159.6.1 SysUtils.CurrencyDecimals Variable

CurrencyDecimals is the number of digits to the right of the decimal point in a currency amount.

Pascal

```
CurrencyDecimals: Byte;
```

C++

```
Byte CurrencyDecimals;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_ICURRDIGITS.

159.6.2 SysUtils.CurrencyFormat Variable

CurrencyFormat defines the currency symbol placement and separation used in floating-point–to–decimal conversions. Possible values are: 0 = $1 | 1 = 1$ | 2 = $ 1 | 3 = 1 $

Pascal

```
CurrencyFormat: Byte;
```

C++

```
Byte CurrencyFormat;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_ICURRENCY.

159.6.3 SysUtils.CurrencyString Variable

CurrencyString defines the currency symbol (or characters) used in floating-point to decimal conversions.

Pascal

```
CurrencyString: string;
```

C++

```
AnsiString CurrencyString;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_SCURRENCY.

159.6.4 SysUtils.DateSeparator Variable

DateSeparator is the character used to separate the year, month, and day parts of a date value.

Pascal

```
DateSeparator: Char;
```

C++

```
Char DateSeparator;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_SDATE.

159.6.5 SysUtils.DecimalSeparator Variable

DecimalSeparator is the character used to separate the integer part from the fractional part of a number. This variable must have a value other than #0.

Pascal

```
DecimalSeparator: Char;
```

C++

```
Char DecimalSeparator;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_SDECIMAL.

159.6.6 SysUtils.EmptyStr Variable

An empty string constant.

Pascal

```
EmptyStr: string = '';
```

C++

```
AnsiString EmptyStr = '';
```

File

SysUtils

Description

Included for backward compatibility only.

159.6.7 SysUtils.EmptyWideStr Variable

An empty string version of the WideString constant.

Pascal

```
EmptyWideStr: WideString = '';
```

C++

```
BSTR EmptyWideStr = '';
```

File

SysUtils

Description

Included for backward compatibility only.

159.6.8 SysUtils.EraNames Variable

Defines the names of calendar eras for East Asian locales.

Pascal

```
EraNames: array [1..MaxEraCount] of string;
```

C++

```
array [1..MaxEraCount] of string EraNames;
```

File

SysUtils

Description

EraNames defines an array of 7 era names for Japanese and Taiwanese locales. It is principally used for date formatting.

See Also

FormatDateTime (see page 22902)

DateTimeToString (see page 22823)

159.6.9 SysUtils.EraYearOffsets Variable

Controls (see page 5711) the DateTimeToStr (see page 22822) function (for East Asian locales).

Pascal

```
EraYearOffsets: array [1..MaxEraCount] of Integer;
```

C++

```
array [1..MaxEraCount] of Integer EraYearOffsets;
```

File

SysUtils

159.6.10 SysUtils.FalseBoolStrs Variable

Lists strings that can represent the boolean value false.

Pascal

```
FalseBoolStrs: array of String;
```

C++

```
array of String FalseBoolStrs;
```

File

SysUtils

Description

FalseBoolStrs is an array of strings that are used in conversions between Boolean values and strings.

When using the BoolToStr (see page 22804) function, false values are converted to the first string in the list.

When using the StrToBool (see page 22961) function, any string found in the list, regardless of case, is converted to false. If no string match is found, TrueBoolStrs (see page 23034) is checked, true being returned if a match is found. No matches result in the EConvertError (see page 22724) exception being thrown.

See Also

StrToBool (see page 22961)

TryStrToBool (see page 22982)

TrueBoolStrs (see page 23034)

BoolToStr (see page 22804)

159.6.11 SysUtils.GetDiskFreeSpaceEx Variable

Pascal

```
GetDiskFreeSpaceEx: function (Directory: PChar; var FreeAvailable, TotalSpace: TLargeInteger;
TotalFree: PLargeInteger): Bool stdcall = nil;
```

C++

```
function (Directory: PChar; var FreeAvailable, TotalSpace: TLargeInteger; TotalFree:
PLargeInteger): Bool stdcall GetDiskFreeSpaceEx = nil;
```

File

SysUtils

Description

This is variable SysUtils.GetDiskFreeSpaceEx.

159.6.12 SysUtils.HexDisplayPrefix Variable

HexDisplayPrefix contains the prefix to display on hexadecimal values - `$` for Pascal (Delphi) syntax, `0x` for C++ syntax.

Pascal

```
HexDisplayPrefix: string = '$';
```

C++

```
AnsiString HexDisplayPrefix = '$';
```

File

SysUtils

Description

This is for display only - this does not affect the string-to-integer conversion routines.

159.6.13 SysUtils.LeadBytes Variable

Lists all values that can be the first byte of a double byte character on the local system.

Pascal

```
LeadBytes: set of Char = [];
```

C++

```
set of Char LeadBytes = [];
```

File

SysUtils

Description

Use LeadBytes to test whether a value can represent the lead byte in a double byte character. If an individual value is in the

LeadBytes set, it is not necessarily used as the lead byte of a double byte character. It may also appear as the second byte of a double byte character. To determine whether the character is used as a lead byte, use the global ByteType (see page 22807) or StrByteType (see page 22943) function.

Note: LeadBytes is always empty when running on a system with a locale that does not use a multi byte character system (MBCS).

See Also

ByteType (see page 22807)

StrByteType (see page 22943)

159.6.14 SysUtils.ListSeparator Variable

The character used to separate items in a list.

Pascal

```
ListSeparator: Char;
```

C++

```
Char ListSeparator;
```

File

SysUtils

Description

On Windows, the default value is fetched from LOCALE_SLIST.

159.6.15 SysUtils.LongDateFormat Variable

LongDateFormat is the format string used to convert a date value to a long string suitable for display but not for editing.

Pascal

```
LongDateFormat: string;
```

C++

```
AnsiString LongDateFormat;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_SLONGDATE.

159.6.16 SysUtils.LongDayNames Variable

LongDayNames is the array of strings containing long day names. The dddd format specifier in a format string passed to FormatDateTime (see page 22902) causes a long day name to be substituted.

Pascal

```
LongDayNames: array[1..7] of string;
```

C++

```
array[1..7] of string LongDayNames;
```

File

SysUtils

Description

On Windows, the default values are fetched from the LOCALE_SDAYNAME system locale entries.

159.6.17 SysUtils.LongMonthNames Variable

LongMonthNames is the array of strings containing long month names. The mmmm format specifier in a format string passed to FormatDateTime (see page 22902) causes a long month name to be substituted.

Pascal

```
LongMonthNames: array[1..12] of string;
```

C++

```
array[1..12] of string LongMonthNames;
```

File

SysUtils

Description

On Windows, the default values are fetched from the LOCALE_SMONTHNAME system locale entries.

159.6.18 SysUtils.LongTimeFormat Variable

LongTimeFormat is the format string used to convert a time value to a string with hours, minutes, and seconds.

Pascal

```
LongTimeFormat: string;
```

C++

```
AnsiString LongTimeFormat;
```

File

SysUtils

Description

On Windows, the default value is computed from LOCALE_ITIME and LOCALE_ITLZERO.

159.6.19 SysUtils.NegCurrFormat Variable

NegCurrFormat defines the currency format used in floating-point to decimal conversions of negative numbers.

Pascal

```
NegCurrFormat: Byte;
```

C++

```
Byte NegCurrFormat;
```

File

SysUtils

Description

Possible values are:

Value	Format (see page 22897)
0	($1)
1	-$1
2	$-1
3	$1-
4	(1$)
5	-1$
6	1-$
7	1$-
8	-1 $
9	-$ 1
10	1 $-
11	$ 1-
12	$ -1
13	1- $
14	($ 1)
15	(1 $)

On Windows, the initial value is fetched from LOCALE_INEGCURR.

159.6.20 SysUtils.NullStr Variable

A pointer to an empty string.

Pascal

```
NullStr: PString = @EmptyStr;
```

C++

```
PString NullStr = @EmptyStr;
```

File

SysUtils

Description

NullStr defines a pointer to the empty string EmptyStr (see page 23024).

See Also

EmptyStr (see page 23024)

NullWideStr (see page 23030)

PString (see page 22603)

159.6.21 SysUtils.NullWideStr Variable

A pointer to an empty wide string.

Pascal

```
NullWideStr: PWideString = @EmptyWideStr;
```

C++

```
PWideString NullWideStr = @EmptyWideStr;
```

File

SysUtils

Description

NullWideStr defines a pointer to the empty wide string EmptyWideStr (see page 23024).

See Also

EmptyWideStr (see page 23024)

NullStr (see page 23029)

PWideString (see page 22608)

159.6.22 SysUtils.ShortDateFormat Variable

ShortDateFormat is the format string used to convert a date value to a short string suitable for editing.

Pascal

```
ShortDateFormat: string;
```

C++

```
AnsiString ShortDateFormat;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_SSHORTDATE.

159.6.23 SysUtils.ShortDayNames Variable

ShortDayNames is the array of strings containing short day names. The ddd format specifier in a format string passed to FormatDateTime (see page 22902) causes a short day name to be substituted.

Pascal

```
ShortDayNames: array[1..7] of string;
```

C++

```
array[1..7] of string ShortDayNames;
```

File

SysUtils

Description

On Windows, the default values are fetched from the LOCALE_SABBREVDAYNAME system locale entries.

159.6.24 SysUtils.ShortMonthNames Variable

ShortMonthNames is the array of strings containing short month names. The mmm format specifier in a format string passed to FormatDateTime (see page 22902) causes a short month name to be substituted.

Pascal

```
ShortMonthNames: array[1..12] of string;
```

C++

```
array[1..12] of string ShortMonthNames;
```

File

SysUtils

Description

On Windows, the default values are fetched from the LOCALE_SABBREVMONTHNAME system locale entries.

159.6.25 SysUtils.ShortTimeFormat Variable

ShortTimeFormat is the format string used to convert a time value to a short string with only hours and minutes.

Pascal

```
ShortTimeFormat: string;
```

C++

```
AnsiString ShortTimeFormat;
```

File

SysUtils

Description

On Windows, the default value is computed from LOCALE_ITIME and LOCALE_ITLZERO.

159.6.26 SysUtils.SysLocale Variable

SysLocale holds locale information.

Pascal

```
SysLocale: TSysLocale;
```

C++

```
TSysLocale SysLocale;
```

File

SysUtils

Description

The SysLocale holds the attributes of the current locale. The locale determines how dates and times are formatted, how items are alphabetically sorted, and how strings are compared.

The **DefaultLCID** field represents the locale identifier. This is a 32-bit value that specifies a default sort order and a default language identifier.

The **PirLangID** field specifies the primary type of the language identifier. This is one of the constants that identify a language group, such as **LANG_ENGLISH** or **LANG_FRENCH**.

The **SubLangID** field specifies the subtype of the language identifier. This is one of the constants that identify a language subgroup, such as **SUBLANG_ENGLISH_US** or **SUBLANG_FRENCH_CANADIAN**.

FarEast is true or nonzero if User32.dll supports DBCS; false or zero otherwise. In other words, **FarEast** is true or nonzero if the double-byte character-set (DBCS) version of User.exe is installed; false or zero otherwise.

MiddleEast is true if the system is enabled for Hebrew and Arabic languages; false otherwise.

See Also

GetTSysLocale

Languages (see page 22926)

159.6.27 SysUtils.ThousandSeparator Variable

ThousandSeparator is the character used to separate thousands in numbers with more than three digits to the left of the decimal separator.

Pascal

```
ThousandSeparator: Char;
```

C++

```
Char ThousandSeparator;
```

File

SysUtils

Description

A value of #0 indicates that no thousand separator character should be output, even if the format string specifies it.

On Windows, the initial value is fetched from LOCALE_STHOUSAND.

159.6.28 SysUtils.TimeAMString Variable

TimeAMString is the suffix string used for time values between 00:00 and 11:59 in 12-hour clock format.

Pascal

```
TimeAMString: string;
```

C++

```
AnsiString TimeAMString;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_S1159.

159.6.29 SysUtils.TimePMString Variable

TimePMString is the suffix string used for time values between 12:00 and 23:59 in 12-hour clock format.

Pascal

```
TimePMString: string;
```

C++

```
AnsiString TimePMString;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_S2359.

159.6.30 SysUtils.TimeSeparator Variable

TimeSeparator is the character used to separate the hour, minute, and second parts of a time value.

Pascal

```
TimeSeparator: Char;
```

C++

```
Char TimeSeparator;
```

File

SysUtils

Description

On Windows, the initial value is fetched from LOCALE_STIME.

159.6.31 SysUtils.TrueBoolStrs Variable

Lists strings that can represent the boolean value false.

Pascal

```
TrueBoolStrs: array of String;
```

C++

```
array of String TrueBoolStrs;
```

File

SysUtils

Description

TrueBoolStrs is an array of strings that are used in conversions between Boolean values and strings.

When using the BoolToStr (see page 22804) function, false values are converted to the first string in the list.

When using the StrToBool (see page 22961) function, any string found in the list, regardless of case, is converted to true. If no string match is found, FalseBoolStrs (see page 23025) is checked, false being returned if a match is found. No matches result in the EConvertError (see page 22724) exception being thrown.

See Also

StrToBool (see page 22961)

TryStrToBool (see page 22982)

FalseBoolStrs (see page 23025)

BoolToStr (see page 22804)

159.6.32 SysUtils.TwoDigitYearCenturyWindow Variable

Determines what century is added to two-digit years when string dates are converted to numeric dates.

Pascal

```
TwoDigitYearCenturyWindow: Word = 50;
```

C++

```
Word TwoDigitYearCenturyWindow = 50;
```

File

SysUtils

Description

The value of TwoDigitYearCenturyWindow, if it is nonzero, is subtracted from the current year to calculate the floating "pivot" prior to which two-digit years are interpreted as falling in the next century. The default value is 50. The table below shows some examples.

159.6.33 SysUtils.Win32BuildNumber Variable

Specifies which the build level of the Windows Operating System (see page 22079) operating.

Pascal

```
Win32BuildNumber: Integer = 0;
```

C++

```
int Win32BuildNumber = 0;
```

File

SysUtils

Description

Win32BuildNumber specifies the build number of the Operating System (see page 22079). The unique identifier for a Windows Operating System (see page 22079) is Win32MajorVersion.Win32MinorVersion.Win32BuildNumber

Note: Win32BuildNumber is available on Windows only.

See Also

Win32CSDVersion (see page 23035)

Win32MinorVersion (see page 23036)

Win32MajorVersion (see page 23036)

Win32Platform (see page 23037)

159.6.34 SysUtils.Win32CSDVersion Variable

Specifies the Win32 latest installed service pack.

Pascal

```
Win32CSDVersion: string = '';
```

C++

```
AnsiString Win32CSDVersion = '';
```

File

SysUtils

Description

Win32CSDVersion specifies the name of the most recent service pack.

Note: Win32CSDVersion is available on Windows only.

See Also

Win32BuildNumber (see page 23035)

Win32MajorVersion (see page 23036)

Win32MinorVersion (see page 23036)

Win32Platform (see page 23037)

159.6.35 SysUtils.Win32MajorVersion Variable

Specifies which major Windows Operating System (see page 22079) version is operating.

Pascal

```
Win32MajorVersion: Integer = 0;
```

C++

```
int Win32MajorVersion = 0;
```

File

SysUtils

Description

Win32MajorVersion specifies the Major version of the Operating System (see page 22079). The unique identifier for a Windows Operating System (see page 22079) is Win32MajorVersion.Win32MinorVersion.Win32BuildNumber (see page 23035)

Note: Win32MajorVersion is available on Windows only.

See Also

Win32BuildNumber (see page 23035)

Win32CSDVersion (see page 23035)

Win32MinorVersion (see page 23036)

Win32Platform (see page 23037)

159.6.36 SysUtils.Win32MinorVersion Variable

Specifies which minor Windows Operating System (see page 22079) version is operating.

Pascal

```
Win32MinorVersion: Integer = 0;
```

C++

```
int Win32MinorVersion = 0;
```

File

SysUtils

Description

Win32MinorVersion specifies the Minor version of the Operating System (see page 22079). The unique identifier for a Windows Operating System (see page 22079) is Win32MajorVersion.Win32MinorVersion.Win32BuildNumber (see page 23035)

Note: Win32MinorVersion is available on Windows only.

See Also

Win32BuildNumber (see page 23035)

Win32CSDVersion (see page 23035)

Win32MajorVersion (see page 23036)

Win32Platform (see page 23037)

159.6.37 SysUtils.Win32Platform Variable

Specifies the Windows Operating System (see page 22079) platform identifier.

Pascal

```
Win32Platform: Integer = 0;
```

C++

```
int Win32Platform = 0;
```

File

SysUtils

Description

Win32Platform is used to identify the type of Win32 platform the system is running. This will be one of the following values:

Value	Meaning
VER_PLATFORM_WIN32s = 0	System (see page 22079) is Win32s.
VER_PLATFORM_WIN32_WINDOWS = 1	System (see page 22079) is Windows 95.
VER_PLATFORM_WIN32_NT = 2	System (see page 22079) is Windows NT. This includes Windows XP and Vista.

Note: Win32Platform is available on Windows only.

See Also

Win32BuildNumber (see page 23035)

Win32CSDVersion (see page 23035)

Win32MajorVersion (see page 23036)

Win32MinorVersion (see page 23036)

159.7 Constants

The following table lists constants in this documentation.

Constants

Name	Description
DateDelta (see page 23039)	Specifies the difference between TDateTime and TTimeStamp (see page 23009) starting values.
DefaultFalseBoolStr (see page 23039)	Specifies the default string representation of the boolean false value.
DefaultTrueBoolStr (see page 23040)	Specifies the default string representation of the boolean true value.
DriveDelim (see page 23041)	Specifies the character used to separate the Windows drive from the path in a file name.
faAnyFile (see page 23041)	Specifies any file type.
faArchive (see page 23042)	Specifies only Windows archived file types.
faDirectory (see page 23042)	Specifies only directory 'file' types.
faHidden (see page 23043)	Specifies only hidden file types.
faReadOnly (see page 23044)	Specifies only read only file types.
faSymLink (see page 23044)	Specifies only symbolic link file types.
faSysFile (see page 23045)	Specifies only system file types.
faVolumeID (see page 23045)	Specifies Volume ID file types.
fmOpenRead (see page 23046)	Specifies a file should be opened for reading only.
fmOpenReadWrite (see page 23047)	Specifies a file should be opened for reading and writing.
fmOpenWrite (see page 23047)	Specifies a file should be opened for writing only.
fmShareCompat (see page 23048)	This is constant SysUtils.fmShareCompat.
fmShareDenyNone (see page 23048)	This is constant SysUtils.fmShareDenyNone.
fmShareDenyRead (see page 23049)	This is constant SysUtils.fmShareDenyRead.
fmShareDenyWrite (see page 23049)	This is constant SysUtils.fmShareDenyWrite.
fmShareExclusive (see page 23049)	This is constant SysUtils.fmShareExclusive.
HoursPerDay (see page 23050)	Specifies the number of hours in a day.
MaxCurrency (see page 23050)	Defines the largest value supported for Currency data types.
MaxDateTime (see page 23051)	Specifies the highest supported TDateTime value.
MaxEraCount (see page 23051)	This is constant SysUtils.MaxEraCount.
MinCurrency (see page 23051)	Defines the largest negative value supported for Currency data types.
MinDateTime (see page 23052)	Specifies the earliest supported TDateTime value.
MinsPerDay (see page 23052)	Specifies the number of minutes in a day.
MinsPerHour (see page 23053)	Specifies the number of minutes in an hour.
MonthDays (see page 23054)	An array specifying how many days are in a month.
MSecsPerDay (see page 23054)	Specifies the number of milliseconds in a day.
MSecsPerSec (see page 23055)	Specifies the number of milliseconds in a second.
PathDelim (see page 23055)	Specifies a path delimiter character.
PathSep (see page 23055)	Specifies the character used to separate a sequence of file or directory names.
pfBCB4Produced (see page 23056)	Indicates that a package was produced by via C++.
pfConsumerBCB (see page 23056)	Indicates that C++ can be a consumer of a package.
pfConsumerCompat (see page 23057)	This is constant SysUtils.pfConsumerCompat.
pfConsumerDelphi (see page 23057)	Indicates that Delphi can be a consumer of a package.
pfConsumerMask (see page 23058)	Indicates the comsumer of a package.
pfDelphi4Produced (see page 23058)	Indicates that a package was produced by Delphi 4 or later.
pfDesignOnly (see page 23059)	Indicates that a package was compiled with {$DESIGNONLY ON}.
pfExeModule (see page 23059)	Indicates that a module is an executable.
pfIgnoreDupUnits (see page 23060)	Indicates that a package was compiled with {$DUPLICATEENABLE ON}.
pfLibraryModule (see page 23060)	Indicates that a module is a library.

pfModuleTypeMask (see page 23060)	Indicates that a package is a module.
pfNeverBuild (see page 23061)	Indicates that a package was compiled with the -z flag.
pfPackageModule (see page 23061)	Indicates that a module is a package.
pfProducerMask (see page 23062)	Indicates the producer of a package.
pfProducerUndefined (see page 23062)	Indicates that a package was produced by an unknown developmemt environment.
pfRunOnly (see page 23063)	Indicates that a package was compiled with {$RUNONLY ON}.
pfV3Produced (see page 23063)	Indicates that a package was produced by Delphi 3 or later.
SecsPerDay (see page 23064)	Specifies the number of seconds in a day.
SecsPerMin (see page 23064)	Specifies the number of seconds in a minute.
SwitchChars (see page 23065)	Specifies the prefix character(s) for program command line arguments.
ufImplicitUnit (see page 23065)	Indicates that a unit was implicitly imported into a package.
ufMainUnit (see page 23066)	Indicates that a unit is the main one in a project.
ufOrgWeakUnit (see page 23066)	This is constant SysUtils.ufOrgWeakUnit.
ufPackageUnit (see page 23067)	Indicates that a unit is a package.
ufWeakPackageUnit (see page 23067)	This is constant SysUtils.ufWeakPackageUnit.
ufWeakUnit (see page 23068)	Indicates that a unit is a weak unit.
UnixDateDelta (see page 23068)	Specifies the difference between TDateTime and Lunix date/time origins.

159.7.1 SysUtils.DateDelta Constant

Specifies the difference between TDateTime and TTimeStamp (see page 23009) starting values.

Pascal

```
DateDelta = 693594;
```

C++

```
DateDelta = 693594;
```

File

SysUtils

Description

DateDelta is the number of days (693594) between January 1, 0001 (starting TTimeStamp (see page 23009) value), and December 31, 1899 (starting TDateTime value). This value is useful for converting date-time values between TTimeStamp (see page 23009) and TDateTime.

See Also

TDateTime (see page 22612)

TTimeStamp (see page 23009)

UnixDateDelta (see page 23068)

159.7.2 SysUtils.DefaultFalseBoolStr Constant

Specifies the default string representation of the boolean false value.

Pascal

```
DefaultFalseBoolStr = 'False';
```

C++

```
DefaultFalseBoolStr = 'False';
```

File

SysUtils

Description

DefaultFalseBoolStr is 'False'. It is used internally by the StrToBool (see page 22961) and BoolToStr (see page 22804) routines. They assign DefaultFalseBoolStr to the 1st element of the FalseBoolStrs (see page 23025) array, used by these routines as a default string representation of the boolean false value.

See Also

DefaultTrueBoolStr (see page 23040)

StrToBool (see page 22961)

FalseBoolStrs (see page 23025)

TrueBoolStrs (see page 23034)

BoolToStr (see page 22804)

159.7.3 SysUtils.DefaultTrueBoolStr Constant

Specifies the default string representation of the boolean true value.

Pascal

```
DefaultTrueBoolStr = 'True';
```

C++

```
DefaultTrueBoolStr = 'True';
```

File

SysUtils

Description

DefaultTrueBoolStr is 'True'. It is used internally by the StrToBool (see page 22961) and BoolToStr (see page 22804) routines. They assign DefaultTrueBoolStr to the 1st element of the TrueBoolStrs (see page 23034) array, used by these routines as a default string representation of the boolean true value.

See Also

DefaultFalseBoolStr (see page 23039)

StrToBool (see page 22961)

FalseBoolStrs (see page 23025)

TrueBoolStrs (see page 23034)

BoolToStr (see page 22804)

159.7.4 SysUtils.DriveDelim Constant

Specifies the character used to separate the Windows drive from the path in a file name.

Pascal

```
DriveDelim = ':';
```

C++

```
DriveDelim = ':';
```

File

SysUtils

Description

DriveDelim is the ':' character that follows the drive character ('A', 'B' and so on) in a full filename on a Windows Operating System (see page 22079). The value is a null character for Linux Operating Systems since they do not support drive designations.

See Also

PathDelim (see page 23055)

PathSep (see page 23055)

159.7.5 SysUtils.faAnyFile Constant

Specifies any file type.

Pascal

```
faAnyFile = $0000003F;
```

C++

```
faAnyFile = 0x0000003F;
```

File

SysUtils

Description

faAnyFile is principally used by FindFirst (see page 22884) to indicate that files of any type encountered sould be returned. Namely, all files.

See Also

faArchive (see page 23042)

faDirectory (see page 23042)

faHidden (see page 23043)

faReadOnly (see page 23044)

faSymLink (see page 23044)

faSysFile (see page 23045)

FindFirst (see page 22884)

TSearchRec (see page 23005)

159.7.6 SysUtils.faArchive Constant

Specifies only Windows archived file types.

Pascal

```
faArchive = $00000020 platform;
```

C++

```
faArchive = 0x00000020 platform;
```

File

SysUtils

Description

faArchive is principally used by FindFirst (see page 22884) to indicate that only archived files sould be returned. It is Windows specific : Linux does not support archiving.

See Also

faAnyFile (see page 23041)

faDirectory (see page 23042)

faHidden (see page 23043)

faReadOnly (see page 23044)

faSymLink (see page 23044)

faSysFile (see page 23045)

FindFirst (see page 22884)

TSearchRec (see page 23005)

159.7.7 SysUtils.faDirectory Constant

Specifies only directory 'file' types.

Pascal

```
faDirectory = $00000010;
```

C++

```
faDirectory = 0x00000010;
```

File

SysUtils

Description

faDirectory is principally used by FindFirst (see page 22884) to indicate that only directories sould be returned. Whilst FindFirst

(see page 22884) is generally used to search for files, it can also return directories within the search directory.

See Also

faAnyFile (see page 23041)

faArchive (see page 23042)

faHidden (see page 23043)

faReadOnly (see page 23044)

faSymLink (see page 23044)

faSysFile (see page 23045)

FindFirst (see page 22884)

TSearchRec (see page 23005)

159.7.8 SysUtils.faHidden Constant

Specifies only hidden file types.

Pascal

```
faHidden = $00000002 platform;
```

C++

```
faHidden = 0x00000002 platform;
```

File

SysUtils

Description

faHidden is principally used by FindFirst (see page 22884) to indicate that only hidden files sould be returned. On Linux systems, hidden files are those that start with a "." character.

See Also

faAnyFile (see page 23041)

faArchibe

faDirectory (see page 23042)

faReadOnly (see page 23044)

faSymLink (see page 23044)

faSysFile (see page 23045)

FindFirst (see page 22884)

TSearchRec (see page 23005)

159.7.9 SysUtils.faReadOnly Constant

Specifies only read only file types.

Pascal

```
faReadOnly = $00000001 platform;
```

C++

```
faReadOnly = 0x00000001 platform;
```

File

SysUtils

Description

faReadOnly is principally used by FindFirst (see page 22884) to indicate that only read only files sould be returned. On Linux systems, read only is not necessarily a system wide attribute - access rights are user and group dependent. Read only here means that the current application does read but not write to a file.

See Also

faAnyFile (see page 23041)

faArchibe

faDirectory (see page 23042)

faHidden (see page 23043)

faSymLink (see page 23044)

faSysFile (see page 23045)

FindFirst (see page 22884)

TSearchRec (see page 23005)

159.7.10 SysUtils.faSymLink Constant

Specifies only symbolic link file types.

Pascal

```
faSymLink = $00000040 platform;
```

C++

```
faSymLink = 0x00000040 platform;
```

File

SysUtils

Description

faSymLink is principally used by FindFirst (see page 22884) to indicate that only symbolic link files sould be returned. Symbolic links are a feature of Linux systems, with no Windows counterpart.

See Also

faAnyFile (see page 23041)

faArchibe

faDirectory (see page 23042)

faHidden (see page 23043)

faReadOnly (see page 23044)

faSysFile (see page 23045)

FindFirst (see page 22884)

TSearchRec (see page 23005)

159.7.11 SysUtils.faSysFile Constant

Specifies only system file types.

Pascal

```
faSysFile = $00000004 platform;
```

C++

```
faSysFile = 0x00000004 platform;
```

File

SysUtils

Description

faSysFile is principally used by FindFirst (see page 22884) to indicate that only system files sould be returned. On Linux systems, a system file is one that is treated as a socket, symbolic link, device file, or FIFO.

See Also

faAnyFile (see page 23041)

faArchibe

faDirectory (see page 23042)

faHidden (see page 23043)

faReadOnly (see page 23044)

faSymLink (see page 23044)

FindFirst (see page 22884)

TSearchRec (see page 23005)

159.7.12 SysUtils.faVolumeID Constant

Specifies Volume ID file types.

Pascal

```
faVolumeID = $00000008 platform deprecated;
```

C++

```
faVolumeID = 0x00000008 platform deprecated;
```

File

SysUtils

Description

faVolumeID is deprecated.

159.7.13 SysUtils.fmOpenRead Constant

Specifies a file should be opened for reading only.

Pascal

```
fmOpenRead = $0000;
```

C++

```
fmOpenRead = 0x0000;
```

File

SysUtils

Description

fmOpenRead is one of the values you can assign to FileMode. It is also one of the attributes assignable in the Create. The TFileStream is used to read and write files. When you assign the value fmOpenRead, subsequent calls to Reset open files for reading only.

Note: You must use this value when you plan to read a read only file - using fmOpenReadWrite (see page 23047) will cause the open to fail because it will attempt and fail to get write access.

See Also

fmOpenReadWrite (see page 23047)

fmOpenWrite (see page 23047)

faShareCompat

faShareDenyNone

faShareDenyRead

faShareDenyWrite

faShareExclusive

Reset (see page 22511)

FileMode (see page 22644)

Create (see page 2843)

159.7.14 SysUtils.fmOpenReadWrite Constant

Specifies a file should be opened for reading and writing.

Pascal

```
fmOpenReadWrite = $0002;
```

C++

```
fmOpenReadWrite = 0x0002;
```

File

SysUtils

Description

fmOpenReadWrite is one of the values you can assign to FileMode. It is also one of the attributes assignable in the Create. The TFileStream is used to read and write files. When you assign the value fmOpenReadWrite, subsequent calls to Reset open files for reading and writing.

Note: Do not assign this value when you plan to read a read only file - the open will fail because write access will be attempted but be denied.

See Also

fmOpenRead (see page 23046)

fmOpenWrite (see page 23047)

faShareCompat

faShareDenyNone

faShareDenyRead

faShareDenyWrite

faShareExclusive

Reset (see page 22511)

FileMode (see page 22644)

Create (see page 2843)

159.7.15 SysUtils.fmOpenWrite Constant

Specifies a file should be opened for writing only.

Pascal

```
fmOpenWrite = $0001;
```

C++

```
fmOpenWrite = 0x0001;
```

File

SysUtils

Description

fmOpenWrite is one of the values you can assign to FileMode. It is also one of the attributes assignable in the Create. The TFileStream is used to read and write files. When you assign the value fmOpenWrite, subsequent calls to Reset open files for writing only.

See Also

fmOpenRead (see page 23046)

fmOpenReadWrite (see page 23047)

faShareCompat

faShareDenyNone

faShareDenyRead

faShareDenyWrite

faShareExclusive

Reset (see page 22511)

FileMode (see page 22644)

Create (see page 2843)

159.7.16 SysUtils.fmShareCompat Constant

Pascal

```
fmShareCompat = $0000 platform;
```

C++

```
fmShareCompat = 0x0000 platform;
```

File

SysUtils

Description

This is constant SysUtils.fmShareCompat.

159.7.17 SysUtils.fmShareDenyNone Constant

Pascal

```
fmShareDenyNone = $0040;
```

C++

```
fmShareDenyNone = 0x0040;
```

File

SysUtils

Description

This is constant SysUtils.fmShareDenyNone.

159.7.18 SysUtils.fmShareDenyRead Constant

Pascal

```
fmShareDenyRead = $0030 platform;
```

C++

```
fmShareDenyRead = 0x0030 platform;
```

File

SysUtils

Description

This is constant SysUtils.fmShareDenyRead.

159.7.19 SysUtils.fmShareDenyWrite Constant

Pascal

```
fmShareDenyWrite = $0020;
```

C++

```
fmShareDenyWrite = 0x0020;
```

File

SysUtils

Description

This is constant SysUtils.fmShareDenyWrite.

159.7.20 SysUtils.fmShareExclusive Constant

Pascal

```
fmShareExclusive = $0010;
```

C++

```
fmShareExclusive = 0x0010;
```

File

SysUtils

Description

This is constant SysUtils.fmShareExclusive.

159.7.21 SysUtils.HoursPerDay Constant

Specifies the number of hours in a day.

Pascal

```
HoursPerDay = 24;
```

C++

```
HoursPerDay = 24;
```

File

SysUtils

Description

HoursPerDay is the number of hours (24) in a day. Using this constant rather than hard coding 24 makes for more readable code.

See Also

DateDelta (see page 23039)

MinsPerDay (see page 23052)

MinsPerHour (see page 23053)

MSecsPerDay (see page 23054)

MSecsPerSec (see page 23055)

SecsPerDay (see page 23064)

SecsPerMin (see page 23064)

159.7.22 SysUtils.MaxCurrency Constant

Defines the largest value supported for Currency data types.

Pascal

```
MaxCurrency: Currency = 922337203685477.5807;
```

C++

```
Currency MaxCurrency = 922337203685477.5807;
```

File

SysUtils

Description

MaxCurrency is the largest value that can be held by a Currency data variable on the Windows Opersting System (see page 22079).

Note: Linux supports a value 1.0 less than this maximum (922337203685476.5807).

See Also

MinCurrency (see page 23051)

159.7.23 SysUtils.MaxDateTime Constant

Specifies the highest supported TDateTime value.

Pascal

```
MaxDateTime: TDateTime = 2958465.99999;
```

C++

```
TDateTime MaxDateTime = 2958465.99999;
```

File

SysUtils

Description

MaxDateTime is the most future date : 12/31/9999 23:59:59.999 that the TDateTime type supports. The actual shown value of 2958465.99999 reflects the fact that TDateTime is actually a floating point number, rather than a structured type. The mantissa holds the number of days relative to 12/30/1899 00:00:00.000, the exponent holds a fraction of a day.

See Also

TDateTime (see page 22612)

MinDateTime (see page 23052)

159.7.24 SysUtils.MaxEraCount Constant

Pascal

```
MaxEraCount = 7;
```

C++

```
MaxEraCount = 7;
```

File

SysUtils

Description

This is constant SysUtils.MaxEraCount.

159.7.25 SysUtils.MinCurrency Constant

Defines the largest negative value supported for Currency data types.

Pascal

```
MinCurrency: Currency = -922337203685477.5807;
```

C++

```
Currency MinCurrency = -922337203685477.5807;
```

File

SysUtils

Description

MinCurrency is the largest negative value that can be held by a Currency data variable on the Windows Opersting System (see page 22079).

Note: Linux supports a value 1.0 less negative than this minimum (-922337203685476.5807).

See Also

MaxCurrency (see page 23050)

159.7.26 SysUtils.MinDateTime Constant

Specifies the earliest supported TDateTime value.

Pascal

```
MinDateTime: TDateTime = -657434.0;
```

C++

```
TDateTime MinDateTime = -657434.0;
```

File

SysUtils

Description

MinDateTime is the most historic date : 01/01/0100 00:00:00.000 that the TDateTime type supports. The actual shown value of -657434.0 reflects the fact that TDateTime is actually a floating point number, rather than a structured type. The mantissa holds the number of days relative to 12/30/1899 00:00:00.000, the exponent holds a fraction of a day.

Note: The fractional part of a TDateTime is always treated in a positive sense. It always means the elapsed part of a day - if the TDateTime value is negative, this refers only to a negative offset of the integral day value from 12/30/1899.

See Also

TDateTime (see page 22612)

MaxDateTime (see page 23051)

159.7.27 SysUtils.MinsPerDay Constant

Specifies the number of minutes in a day.

Pascal

```
MinsPerDay = HoursPerDay * MinsPerHour;
```

C++

```
MinsPerDay = HoursPerDay * MinsPerHour;
```

File

SysUtils

Description

MinsPerDay is the number of minutes (1440) in a day. It is the product of HoursPerDay (see page 23050) and MinsPerHour (see page 23053).

Using this constant rather than hard coding 1440 makes for more readable code.

See Also

DateDelta (see page 23039)

HoursPerDay (see page 23050)

MinsPerHour (see page 23053)

MSecsPerDay (see page 23054)

MSecsPerSec (see page 23055)

SecsPerDay (see page 23064)

SecsPerMinute

159.7.28 SysUtils.MinsPerHour Constant

Specifies the number of minutes in an hour.

Pascal

```
MinsPerHour = 60;
```

C++

```
MinsPerHour = 60;
```

File

SysUtils

Description

MinsPerHour is the number of minutes (60) in an hour. Using this constant rather than hard coding 60 makes for more readable code.

See Also

DateDelta (see page 23039)

HoursPerDay (see page 23050)

MinsPerHour

MSecsPerDay (see page 23054)

MSecsPerSec (see page 23055)

SecsPerDay (see page 23064)

SecsPerMin (see page 23064)

159.7.29 SysUtils.MonthDays Constant

An array specifying how many days are in a month.

Pascal

```
MonthDays: array [Boolean] of TDayTable = ((31, 28, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31),
(31, 29, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31));
```

C++

```
array [Boolean] of TDayTable MonthDays = ((31, 28, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31),
(31, 29, 31, 30, 31, 30, 31, 31, 30, 31, 30, 31));
```

File

SysUtils

Description

The MonthDays array can be used to quickly find the number of days in a month:

```
MonthDays[IsLeapYear(Y), M]
```

159.7.30 SysUtils.MSecsPerDay Constant

Specifies the number of milliseconds in a day.

Pascal

```
MSecsPerDay = SecsPerDay * MSecsPerSec;
```

C++

```
MSecsPerDay = SecsPerDay * MSecsPerSec;
```

File

SysUtils

Description

MSecsPerDay is the number of milliseconds (86,400,000) in a day. It is the product of SecsPerDay (see page 23064) and MSecsPerSec (see page 23055).

Using this constant rather than hard coding 86400000 makes for more readable code.

See Also

DateDelta (see page 23039)

HoursPerDay (see page 23050)

MinsPerDay (see page 23052)

MinsPerHour (see page 23053)

MSecsPerSec (see page 23055)

SecsPerDay (see page 23064)

SecsPerMin (see page 23064)

159.7.31 SysUtils.MSecsPerSec Constant

Specifies the number of milliseconds in a second.

Pascal

```
MSecsPerSec = 1000;
```

C++

```
MSecsPerSec = 1000;
```

File

SysUtils

Description

MSecsPerSec is the number of milliseconds (1000) in a second.

Using this constant rather than hard coding 1000 makes for more readable code.

See Also

DateDelta (see page 23039)

HoursPerDay (see page 23050)

MinsPerDay (see page 23052)

MinsPerHour (see page 23053)

MSecsPerDay (see page 23054)

SecsPerMin (see page 23064)

SecsPerDay (see page 23064)

159.7.32 SysUtils.PathDelim Constant

Specifies a path delimiter character.

Pascal

```
PathDelim = '\';
```

C++

```
PathDelim = '\';
```

File

SysUtils

159.7.33 SysUtils.PathSep Constant

Specifies the character used to separate a sequence of file or directory names.

Pascal

```
PathSep = ';';
```

C++

```
PathSep = ';';
```

File

SysUtils

Description

PathSep is the ';' character for Windows, or ':' for Linux that is used to separate filenames in a sequence of file or directory names. FileSearch (see page 22872), for example, expects PathSep to be used to separate the values in the string of directory names.

See Also

DriveDelim (see page 23041)

PathSep

FileSearch (see page 22872)

159.7.34 SysUtils.pfBCB4Produced Constant

Indicates that a package was produced by via C++.

Pascal

```
pfBCB4Produced = $08000000;
```

C++

```
pfBCB4Produced = 0x08000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfBCB4Produced is one of these flag values, indicating that a package was produced by C++. BCB stands for Borland (see page 1761) C++ Builder.

See Also

GetPackageInfo (see page 22915)

159.7.35 SysUtils.pfConsumerBCB Constant

Indicates that C++ can be a consumer of a package.

Pascal

```
pfConsumerBCB = $00200000;
```

C++

```
pfConsumerBCB = 0x00200000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfConsumerBCB is one of these flag values, indicating that C++ is a legitimate consumer, or user, of a package. The C++ consumer is the Borland (see page 1761) C++ Builder compiler, linking in the package.

A package will be marked with the pfConsumerBCB when the -JL flag has been set during compilation. This ensures that the extra support files (.lib, .bpi, .hpp)required by a C++ consumer are generated and included in the package.

See Also

GetPackageInfo (see page 22915)

159.7.36 SysUtils.pfConsumerCompat Constant

Pascal

```
pfConsumerCompat = $00000000;
```

C++

```
pfConsumerCompat = 0x00000000;
```

File

SysUtils

Description

This is constant SysUtils.pfConsumerCompat.

159.7.37 SysUtils.pfConsumerDelphi Constant

Indicates that Delphi can be a consumer of a package.

Pascal

```
pfConsumerDelphi = $00100000;
```

C++

```
pfConsumerDelphi = 0x00100000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfConsumerDelphi is one of these flag values, indicating that Delphi is a legitimate consumer, or user, of a package. The Delphi consumer is the Delphi compiler, linking in the package.

See Also

GetPackageInfo (see page 22915)

159.7.38 SysUtils.pfConsumerMask Constant

Indicates the comsumer of a package.

Pascal

```
pfConsumerMask = $00F00000;
```

C++

```
pfConsumerMask = 0x00F00000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfConsumerMask is a mask that you can use to detect the consumers can use a package. This mask covers these flags : pfConsumerBCB (see page 23056), pfConsumerCompat (see page 23057) and pfConsumerDelphi (see page 23057) flags.

Note: pfConsumerMask is not itself a returned flag - it is simply a mask.

See Also

GetPackageInfo (see page 22915)

pfConsumerBCB (see page 23056)

pfConsumerCompat (see page 23057)

pfConsumerDelphi (see page 23057)

159.7.39 SysUtils.pfDelphi4Produced Constant

Indicates that a package was produced by Delphi 4 or later.

Pascal

```
pfDelphi4Produced = $0C000000;
```

C++

```
pfDelphi4Produced = 0x0C000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfDelphi4Produced is one of these flag values, indicating that the a package was produced by Delphi 4 or later. Packages were

introduced in Delphi 3.

See Also

GetPackageInfo (see page 22915)

159.7.40 SysUtils.pfDesignOnly Constant

Indicates that a package was compiled with {$DESIGNONLY ON}.

Pascal

```
pfDesignOnly = $00000002;
```

C++

```
pfDesignOnly = 0x00000002;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfDesignOnly is one of these flag values, indicating that the package was compiled with the $DESIGNONLY compiler directive set ON. This means that the for package is intended for installation in the IDE.

See Also

GetPackageInfo (see page 22915)

159.7.41 SysUtils.pfExeModule Constant

Indicates that a module is an executable.

Pascal

```
pfExeModule = $00000000;
```

C++

```
pfExeModule = 0x00000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfExeModule is one of these flag values, indicating that the module is an executable.

See Also

GetPackageInfo (see page 22915)

159.7.42 SysUtils.pfIgnoreDupUnits Constant

Indicates that a package was compiled with {$DUPLICATEENABLE ON}.

Pascal

```
pfIgnoreDupUnits = $00000008;
```

C++

```
pfIgnoreDupUnits = 0x00000008;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfIgnoreDupUnits is one of these flag values, indicating that the package was compiled with the $DUPLICATEENABLE compiler directive set ON.

See Also

GetPackageInfo (see page 22915)

159.7.43 SysUtils.pfLibraryModule Constant

Indicates that a module is a library.

Pascal

```
pfLibraryModule = $80000000;
```

C++

```
pfLibraryModule = 0x80000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfLibraryModule is one of these flag values, indicating that the module is a library (.dll file extension).

See Also

GetPackageInfo (see page 22915)

159.7.44 SysUtils.pfModuleTypeMask Constant

Indicates that a package is a module.

Pascal

```
pfModuleTypeMask = $C0000000;
```

C++

```
pfModuleTypeMask = 0xC0000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfModuleTypeMask is a mask that you can use to detect whether the package is a module. This mask is the binary AND of the pfExeModule (see page 23059), pfPackageModule (see page 23061) and pfLibraryModule (see page 23060) flags.

Note: pfModuleTypeMask is not itself a returned flag - it is simply a mask.

See Also

GetPackageInfo (see page 22915)

159.7.45 SysUtils.pfNeverBuild Constant

Indicates that a package was compiled with the -z flag.

Pascal

```
pfNeverBuild = $00000001;
```

C++

```
pfNeverBuild = 0x00000001;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfNeverBuild is one of these flag values, indicating that the package was compiled with the -z flag.

See Also

GetPackageInfo (see page 22915)

159.7.46 SysUtils.pfPackageModule Constant

Indicates that a module is a package.

Pascal

```
pfPackageModule = $40000000;
```

C++

```
pfPackageModule = 0x40000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfPackageModule is one of these flag values, indicating that the module is a package (.bpl file extension).

See Also

GetPackageInfo (see page 22915)

159.7.47 SysUtils.pfProducerMask Constant

Indicates the producer of a package.

Pascal

```
pfProducerMask = $0C000000;
```

C++

```
pfProducerMask = 0x0C000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfProducerMask is a mask that you can use to detect the producer of a package. This mask is the binary AND of the pfBCB4Produced (see page 23056), pfDelphi4Produced (see page 23058), pfProducerUndefined (see page 23062) and pfV3Produced (see page 23063) flags.

Note: pfProducerMask is not itself a returned flag - it is simply a mask.

See Also

GetPackageInfo (see page 22915)

pfBCB4Produced (see page 23056)

pfDelphi4Produced (see page 23058)

pfProducerUndefined (see page 23062)

pfV3Produced (see page 23063)

159.7.48 SysUtils.pfProducerUndefined Constant

Indicates that a package was produced by an unknown developmemt environment.

Pascal

```
pfProducerUndefined = $04000000;
```

C++

```
pfProducerUndefined = 0x04000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfProducerUndefined is one of these flag values, indicating that the producer of a package was undefined.

See Also

GetPackageInfo (see page 22915)

159.7.49 SysUtils.pfRunOnly Constant

Indicates that a package was compiled with {$RUNONLY ON}.

Pascal

```
pfRunOnly = $00000004;
```

C++

```
pfRunOnly = 0x00000004;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfRunOnly is one of these flag values, indicating that the package was compiled with the $RUNONLY compiler directive set ON. The {$RUNONLY ON} directive causes the package where it occurs to be compiled as runtime only. Packages compiled with {$RUNONLY ON} cannot be installed as design-time packages in the IDE.

See Also

GetPackageInfo (see page 22915)

159.7.50 SysUtils.pfV3Produced Constant

Indicates that a package was produced by Delphi 3 or later.

Pascal

```
pfV3Produced = $00000000;
```

C++

```
pfV3Produced = 0x00000000;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about a package. It returns a set of flags.

pfV3Produced is one of these flag values, indicating that the a package was produced by Delphi 3 or later. Packages were introduced in Delphi 3.

See Also

GetPackageInfo (see page 22915)

159.7.51 SysUtils.SecsPerDay Constant

Specifies the number of seconds in a day.

Pascal

```
SecsPerDay = MinsPerDay * SecsPerMin;
```

C++

```
SecsPerDay = MinsPerDay * SecsPerMin;
```

File

SysUtils

Description

SecsPerDay is the number of seconds (86,400) in a day. It is the product of MinsPerDay (see page 23052) and SecsPerMin (see page 23064).

Using this constant rather than hard coding 86400 makes for more readable code.

See Also

DateDelta (see page 23039)

HoursPerDay (see page 23050)

MinsPerDay (see page 23052)

MinsPerHour (see page 23053)

MSecsPerDay (see page 23054)

MSecsPerSec (see page 23055)

SecsPerMin (see page 23064)

159.7.52 SysUtils.SecsPerMin Constant

Specifies the number of seconds in a minute.

Pascal

```
SecsPerMin = 60;
```

C++

```
SecsPerMin = 60;
```

File

SysUtils

Description

SecsPerMin is the number of seconds (60) in a minute.

Using this constant rather than hard coding 60 makes for more readable code.

See Also

DateDelta (see page 23039)

HoursPerDay (see page 23050)

MinsPerDay (see page 23052)

MinsPerHour (see page 23053)

MSecsPerDay (see page 23054)

MSecsPerSec (see page 23055)

SecsPerDay (see page 23064)

159.7.53 SysUtils.SwitchChars Constant

Specifies the prefix character(s) for program command line arguments.

Pascal

```
SwitchChars = ['/','-'];
```

C++

```
SwitchChars = ['/','-'];
```

File

SysUtils

Description

When a program is started, an optional 'command line' string may be supplied. Such a string may specify program operational arguments, or 'switches', prefixed by a separator character. SwitchChars defines these separator characters as either '-' or '/' on a Windows system, and as '-' on Linux systems.

See Also

FindCmdLineSwitch (see page 22884)

159.7.54 SysUtils.ufImplicitUnit Constant

Indicates that a unit was implicitly imported into a package.

Pascal

```
ufImplicitUnit = $10;
```

C++

```
ufImplicitUnit = 0x10;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about the units within a package. TPackageInfoProc (see page 23017) is one of the parameters to that function : it is a callback procedure that is invoked for each unit in the package. It passes a set of flags associated with each unit.

If the ufImplicitUnit is set, then the unit was implicitly imported into a package. This means that the unit is not used in another package required by this package, but is used by one of the units this package contains.

See Also

GetPackageInfo (see page 22915)

TPackageInfoProc (see page 23017)

159.7.55 SysUtils.ufMainUnit Constant

Indicates that a unit is the main one in a project.

Pascal

```
ufMainUnit = $01;
```

C++

```
ufMainUnit = 0x01;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about the units within a package. TPackageInfoProc (see page 23017) is one of the parameters to that function : it is a callback procedure that is invoked for each unit in the package. It passes a set of flags associated with each unit.

If the ufMainUnit is set, then the unit is a Main unit.

See Also

GetPackageInfo (see page 22915)

TPackageInfoProc (see page 23017)

159.7.56 SysUtils.ufOrgWeakUnit Constant

Pascal

```
ufOrgWeakUnit = $08;
```

C++

```
ufOrgWeakUnit = 0x08;
```

File

SysUtils

Description

This is constant SysUtils.ufOrgWeakUnit.

159.7.57 SysUtils.ufPackageUnit Constant

Indicates that a unit is a package.

Pascal

```
ufPackageUnit = $02;
```

C++

```
ufPackageUnit = 0x02;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about the units within a package. TPackageInfoProc (see page 23017) is one of the parameters to that function : it is a callback procedure that is invoked for each unit in the package. It passes a set of flags associated with each unit.

If the ufPackageUnit is set, then the unit is a package unit.

See Also

GetPackageInfo (see page 22915)

TPackageInfoProc (see page 23017)

159.7.58 SysUtils.ufWeakPackageUnit Constant

Pascal

```
ufWeakPackageUnit = ufPackageUnit or ufWeakUnit;
```

C++

```
ufWeakPackageUnit = ufPackageUnit or ufWeakUnit;
```

File

SysUtils

Description

This is constant SysUtils.ufWeakPackageUnit.

159.7.59 SysUtils.ufWeakUnit Constant

Indicates that a unit is a weak unit.

Pascal

```
ufWeakUnit = $04;
```

C++

```
ufWeakUnit = 0x04;
```

File

SysUtils

Description

The GetPackageInfo (see page 22915) function returns information about the units within a package. TPackageInfoProc (see page 23017) is one of the parameters to that function : it is a callback procedure that is invoked for each unit in the package. It passes a set of flags associated with each unit.

If the ufWeakUnit is set, then the unit was compiled with the $WEAKPACKAGEUNIT compiler directive set.

See Also

GetPackageInfo (see page 22915)

TPackageInfoProc (see page 23017)

159.7.60 SysUtils.UnixDateDelta Constant

Specifies the difference between TDateTime and Lunix date/time origins.

Pascal

```
UnixDateDelta = 25569;
```

C++

```
UnixDateDelta = 25569;
```

File

SysUtils

Description

UnixDateDelta is the number of days (25569) between December 30, 1899 (starting TDateTime value), and Jamuary 1, 1970 (starting value for Linux date time values). This value is useful for converting date-time values between TDateTime and Linux file date time values.

See Also

TDateTime (see page 22612)

TTimeStamp (see page 23009)

DateDelta (see page 23039)

160 TabNotBk Namespace

This is namespace TabNotBk.

Topics

Name	Description
Classes (see page 23070)	The following table lists classes in this documentation.
Types (see page 23131)	The following table lists types in this documentation.
Constants (see page 23132)	The following table lists constants in this documentation.

Classes

	Name	Description
	TTabbedNotebook (see page 23070)	TTabbedNotebook contains multiple pages, each with its own set of controls.
	TTabPage (see page 23112)	TTabPage implements an individual tab page of a tabbed notebook control.

Constants

Name	Description
CM_TABFONTCHANGED (see page 23132)	This is constant TabNotBk.CM_TABFONTCHANGED.

Types

Name	Description
TPageChangeEvent (see page 23131)	TPageChangeEvent is the type for event handlers that respond when the current page changes in a TTabbedNotebook (see page 23070) control.

160.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TTabbedNotebook (see page 23070)	TTabbedNotebook contains multiple pages, each with its own set of controls.
	TTabPage (see page 23112)	TTabPage implements an individual tab page of a tabbed notebook control.

160.1.1 TTabbedNotebook Class

TTabbedNotebook contains multiple pages, each with its own set of controls.

Class Hierarchy

Pascal

```
TTabbedNotebook = class(TCustomTabControl);
```

C++

```
class TTabbedNotebook : public TCustomTabControl;
```

File

TabNotBk

Description

TTabbedNotebook is provided for backwards compatibility. New applications should use TPageControl instead.

160.1.1.1 TTabbedNotebook Members

The following tables list the members exposed by TTabbedNotebook.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnChanging (see page 3955)	Occurs immediately before a new tab is selected.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.

	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnDrawTab (see page 3956)	Occurs when a tab is about to be drawn.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnGetImageIndex (see page 3956)	Occurs when a tab is about to display its associated image.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 3933)	Calculates the control's display area given a rectangle.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.

	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AlignControls (see page 23082)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanChange (see page 3933)	Change (see page 3934) permission event dispatcher.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	CanShowTab (see page 3934)	Selection permission event dispatcher.
	Change (see page 23083)	Pending tab change event dispatcher.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 23083)	Respond to user click.
	CMTabFontChanged (see page 23084)	This is CMTabFontChanged, a member of class TTabbedNotebook.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 23084)	Creates underlying screen object.
	CreateParams (see page 23084)	Sets up the window-creation parameters for the tab control.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 3935)	Creates the window for a tab control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.

	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
V	DrawTab (see page 3935)	Tab drawing event dispatcher.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
V	GetChildOwner (see page 23085)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
V	GetChildren (see page 23085)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetImageIndex (see page 3936)	Generates an OnGetImageIndex (see page 3956) event
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.

	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 23086)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 23086)	Form load event dispatcher.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 3937)	Event dispatcher for creation and destruction of child objects.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 23087)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.

	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetPageIndex (see page 23087)	This is SetPageIndex, a member of class TTabbedNotebook.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetTabIndex (see page 3938)	This is SetTabIndex, a member of class TCustomTabControl.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 23088)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateTabImages (see page 3939)	Updates the tab images.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
R	DisplayRect (see page 3941)	Specifies the bounding rectangle of a tab control client area.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	HotTrack (see page 3941)	Determines whether labels on the tab under the mouse are automatically highlighted.
	Images (see page 3941)	Specifies the images drawn in tabs.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	MultiLine (see page 3942)	Determines whether the tabs can appear on more than one row.
	MultiSelect (see page 3943)	Specifies whether multiple tabs can be selected.
	OwnerDraw (see page 3944)	Specifies whether the tab control handles its own painting.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	RaggedRight (see page 3944)	Specifies whether rows of tabs stretch to fill the width of the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	ScrollOpposite (see page 3944)	Determines how the rows of tabs are scrolled in a multi-line tab control.
	Style (see page 3945)	Specifies the style of the tab control.
	TabHeight (see page 3945)	Specifies the height, in pixels, of the tabs in the tab control.
	TabIndex (see page 3946)	Identifies the selected tab on a tab control.
	TabPosition (see page 3948)	Determines whether tabs appear at the top or bottom.
	Tabs (see page 3948)	Contains the list of text strings that label the tabs of the tab control.
	TabWidth (see page 3950)	Specifies the horizontal size, in pixels, of the tabs in the tab control.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 23081)	Constructs a tabbed notebook component.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 23082)	Destroys a tabbed notebook component.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetHitTestInfoAt (see page 3936)	Returns information about the location of a point relative to the client area of the tab control.
	GetIndexForPage (see page 23085)	Returns the PageIndex (see page 23095) value of the specified page.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	IndexOfTabAt (see page 3936)	Indicates the index of the tab at a specified point.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.

	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	RowCount (see page 3938)	Sets TabIndex (see page 3946) property.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollTabs (see page 3938)	Scrolls the tabs that are visible when the tab control is not multi-line.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	TabFontChanged (see page 23088)	Invalidates the tabs when the TabFont (see page 23103) property changes.
	TabRect (see page 3939)	Returns the bounding rectangle for a specified tab.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 3940)	Gives access to the tab control's canvas.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.

R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
R	TopFont (see page 23104)	Returns the current value of font used on the tabs of the tabbed notebook.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnChange (see page 23106)	Occurs when the page of a tabbed notebook changes.
	OnClick (see page 23107)	Occurs when a tab of a tabbed notebook is selected.
	OnContextPopup (see page 23107)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnEnter (see page 23108)	Occurs when a control receives the input focus.
	OnExit (see page 23110)	Occurs when the input focus shifts away from one control to another.

Published Properties

	Name	Description
	ActivePage (see page 23089)	Determines which page displays in the tabbed notebook control.
	Align (see page 23089)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.

	Anchors (see page 23093)	Specifies how the control is anchored to its parent.
	Constraints (see page 23093)	Specifies the size constraints for the control.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Enabled (see page 23094)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 23094)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	PageIndex (see page 23095)	Determines which page displays in the tabbed notebook component.
	Pages (see page 23096)	Contains the strings that identify the individual pages of the tabbed notebook control.
	ParentShowHint (see page 23096)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 23097)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 23101)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabFont (see page 23103)	Determines the font used on the tabs of the tabbed notebook control.
	TabOrder (see page 23103)	Indicates the position of the control in its parent's tab order.
	TabsPerRow (see page 23104)	This is TabsPerRow, a member of class TTabbedNotebook.
	TabStop (see page 23104)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 23105)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

160.1.1.2 TTabbedNotebook.Create Constructor

Constructs a tabbed notebook component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TTabbedNotebook(TComponent * AOwner);
```

Description

Call Create TTabbedNotebook (see page 23070) indirectly, using the new keyword, to instantiate a tabbed notebook at runtime. Tabbed notebooks added to forms at design time are created automatically.

The AOwner parameter assigns a value to the notebook's Owner property.

See Also

Owner (see page 2807)

160.1.1.3 TTabbedNotebook.Destroy Destructor

Destroys a tabbed notebook component.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TTabbedNotebook();
```

Description

Do not call Destroy directly in an application, Instead, use Free method, which checks that the notebook is not nil before calling Destroy.

See Also

Free (see page 22300)

160.1.1.4 TTabbedNotebook Methods

The methods of the TTabbedNotebook class are listed here.

Protected Methods

	Name	Description
	AlignControls (see page 23082)	Aligns any controls for which the control is the parent within a specified area of the control.
	Change (see page 23083)	Pending tab change event dispatcher.
	Click (see page 23083)	Respond to user click.
	CMTabFontChanged (see page 23084)	This is CMTabFontChanged, a member of class TTabbedNotebook.
	CreateHandle (see page 23084)	Creates underlying screen object.
	CreateParams (see page 23084)	Sets up the window-creation parameters for the tab control.
	GetChildOwner (see page 23085)	Returns the owner of a child component being read from a stream.
	GetChildren (see page 23085)	Calls a specified method for each child of the control.
	KeyDown (see page 23086)	Respond to key press events.
	Loaded (see page 23086)	Form load event dispatcher.
	ReadState (see page 23087)	Prepares the control for having its properties assigned values from a stream.
	SetPageIndex (see page 23087)	This is SetPageIndex, a member of class TTabbedNotebook.
	ShowControl (see page 23088)	Ensures that a specified child control is visible.

Public Methods

	Name	Description
	GetIndexForPage (see page 23085)	Returns the PageIndex (see page 23095) value of the specified page.
	TabFontChanged (see page 23088)	Invalidates the tabs when the TabFont (see page 23103) property changes.

160.1.1.4.1 TTabbedNotebook.AlignControls Method

Aligns any controls for which the control is the parent within a specified area of the control.

Pascal

```
procedure AlignControls(AControl: TControl; var Rect: TRect); override;
```

C++

```
virtual __fastcall AlignControls(TControl * AControl, TRect Rect);
```

Description

Use AlignControls to align all controls within an area of a form, panel, group box, scroll box, or any container control. Specify the area in which to align the controls as the value of the Rect parameter.

AlignControls uses the Align property value for each child control to determine how to align it. The AControl parameter can be nil (Delphi) or NULL (C++). If you specify a control in AControl, that control takes precedence in alignment over other, similarly-aligned controls.

See Also

Align (see page 5798)

160.1.1.4.2 TTabbedNotebook.Change Method

Pending tab change event dispatcher.

Pascal

```
procedure Change; override;
```

C++

```
virtual __fastcall Change();
```

Description

Change is called automatically when the selected tab changes. Override Change to specify additional processing before the OnChange event handler executes, or to block the OnChange event.

See Also

OnChange (see page 3952)

160.1.1.4.3 TTabbedNotebook.Click Method

Respond to user click.

Pascal

```
procedure Click; override;
```

C++

```
virtual __fastcall Click();
```

Description

Click is called automatically when the user left-clicks the control. Component or application code can call Click to simulate a user mouse click. This is often done in menu actions and hotkey handlers.

As implemented in TControl, Click queries whether the OnClick event handler exists and is different from the OnExecute handler for the control's Action. If this is true, the OnClick event handler is called. If this is false, and the Action OnExecute event handler exists, the Action's Execute method is called. Override Click to provide additional behavior.

See Also

Action (see page 5797)

OnExecute (see page 2716)

Execute (see page 2712)

DblClick (see page 5747)

OnClick (see page 5851)

160.1.1.4.4 TTabbedNotebook.CMTabFontChanged Method

Pascal

```
procedure CMTabFontChanged(var Message: TMessage); message CM_TABFONTCHANGED;
```

C++

```
__fastcall CMTabFontChanged(TMessage Message);
```

Description

This is CMTabFontChanged, a member of class TTabbedNotebook.

160.1.1.4.5 TTabbedNotebook.CreateHandle Method

Creates underlying screen object.

Pascal

```
procedure CreateHandle; override;
```

C++

```
virtual __fastcall CreateHandle();
```

Description

CreateHandle creates the Microsoft Windows screen object that underlies the control. if it does not already exist. The new window handle becomes the value of the Handle property.

CreateHandle creates or locates the parent control's window before it creates a window for the control itself.

Note: If the Parent property is nil (Delphi) or NULL (C++), CreateHandle raises an exception.

See Also

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

Handle (see page 6207)

Parent (see page 5832)

160.1.1.4.6 TTabbedNotebook.CreateParams Method

Sets up the window-creation parameters for the tab control.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

Tab controls call CreateParams internally when the window for the tab control must be generated. CreateParams overrides the inherited method to specify a tab control window with the current property settings.

See Also

CreateWnd (see page 3935)

160.1.1.4.7 TTabbedNotebook.GetChildOwner Method

Returns the owner of a child component being read from a stream.

Pascal

```
function GetChildOwner: TComponent; override;
```

C++

```
virtual __fastcall TComponent * GetChildOwner();
```

Description

GetChildOwner is used internally by the component streaming system. It is rarely necessary to call it directly.

In TComponent, GetChildOwner always returns nil (Delphi) or NULL (C++), indicating that the owner is the root component currently being read (usually a form or data module). The Owner of a component is responsible for destroying it.

See Also

Create (see page 2766)

Owner (see page 2807)

160.1.1.4.8 TTabbedNotebook.GetChildren Method

Calls a specified method for each child of the control.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

GetChildren is called by the streaming system that loads and saves components. Applications seldom need to call this routine.

GetChildren executes the callback specified by the Proc parameter for every child control listed by the Controls property that lists the Root parameter as its Owner.

Override GetChildren to limit or augment which child controls are saved with the control. When overriding GetChildren, call the procedure passed as the Proc parameter for every child control that should be saved. The Root parameter indicates the component (usually a form) that owns the control.

See Also

Controls (see page 6197)

Owner (see page 2807)

160.1.1.4.9 TTabbedNotebook.GetIndexForPage Method

Returns the PageIndex (see page 23095) value of the specified page.

Pascal

```
function GetIndexForPage(const PageName: string): Integer;
```

C++

```
__fastcall int GetIndexForPage(const AnsiString PageName);
```

Description

The PageIndex (see page 23095) property value is determined by the page's position in the Pages (see page 23096) property array. Specify the name of the page as the value of the PageName parameter. The name you specify must be one of the strings in the Pages (see page 23096) property.

See Also

PageIndex (see page 23095)

Pages (see page 23096)

160.1.1.4.10 TTabbedNotebook.KeyDown Method

Respond to key press events.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

When a windowed control receives a key-down message (WM_KEYDOWN) from Windows, its message handler calls the DoKeyDown method. If DoKeyDown determines that the control should, in fact, process the character, it calls KeyDown, passing the key code and shift-key state in the Key and Shift parameters, respectively.

KeyDown calls any event handler attached to the OnKeyDown event. Override KeyDown to provide other responses in addition to the event-handler call.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use WinAPI virtual key codes to determine the key pressed. For more information, search for virtual key codes in the Win32 Developer's Reference (WIN32.HLP).

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

Either KeyDown or the OnKeyDown event handler it calls can suppress further processing of a key by setting the Key parameter to zero.

See Also

KeyUp (see page 6164)

OnKeyDown (see page 6225)

DoKeyDown (see page 6145)

DoKeyPress (see page 6146)

DoKeyUp (see page 6146)

160.1.1.4.11 TTabbedNotebook.Loaded Method

Form load event dispatcher.

Pascal

```
procedure Loaded; override;
```

C++

```
virtual __fastcall Loaded();
```

Description

The protected Loaded method is called automatically when the form that contains the tab control is loaded into memory. It provides an opportunity for the tab control to perform any initializations after the control and all other components in the form are loaded into memory, but before the first paint operation.

In TCustomTabControl, Loaded ensures that the layout of the tabs accommodate the images specified by the Images property.

See Also

Images (see page 3941)

160.1.1.4.12 TTabbedNotebook.ReadState Method

Prepares the control for having its properties assigned values from a stream.

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

Override ReadState to change the preparations the control makes as it readies itself to have its property values assigned from a stream. For example, a control might destroy temporary internal data structures or objects before new instances are loaded from the stream. Be sure to include a call to the inherited method when overriding ReadState.

As implemented in TWinControl, ReadState disables control alignment until all the child controls have been read from the stream, calls the inherited ReadState method, and re-enables the alignment of all the controls. The method then builds the tab order list of controls and synchronizes its visibility with that of its parent control.

160.1.1.4.13 TTabbedNotebook.SetPageIndex Method

Pascal

```
procedure SetPageIndex(Value: Integer);
```

C++

```
__fastcall SetPageIndex(int Value);
```

Description

This is SetPageIndex, a member of class TTabbedNotebook.

160.1.1.4.14 TTabbedNotebook.ShowControl Method

Ensures that a specified child control is visible.

Pascal

```
procedure ShowControl(AControl: TControl); override;
```

C++

```
virtual __fastcall ShowControl(TControl * AControl);
```

Description

Call ShowControl to display a child control. Specify the control you want to ensure will be visible as the value of the AControl parameter.

As implemented in TWinControl, ShowControl simply calls the ShowControl method of the control's parent. Derived objects override ShowControl to perform whatever actions are necessary to allow the indicated child object to be visible. Possible actions include scrolling the particular child object into view, or changing to the appropriate notebook page.

Show (see page 5788)

Parent (see page 5832)

160.1.1.4.15 TTabbedNotebook.TabFontChanged Method

Invalidates the tabs when the TabFont (see page 23103) property changes.

Pascal

```
procedure TabFontChanged(Sender: TObject);
```

C++

```
__fastcall TabFontChanged(TObject * Sender);
```

Description

TabFontChanged is called automatically when the TabFont (see page 23103) property changes. It invalidates the notebook so that the tabs are repainted in the new font.

See Also

TabFont (see page 23103)

Invalidate (see page 6161)

160.1.1.5 TTabbedNotebook Properties

The properties of the TTabbedNotebook class are listed here.

Public Properties

	Name	Description
R	TopFont (see page 23104)	Returns the current value of font used on the tabs of the tabbed notebook.

Published Properties

	Name	Description
	ActivePage (see page 23089)	Determines which page displays in the tabbed notebook control.

	Align (see page 23089)	Determines how the control aligns within its container (parent control).
	Anchors (see page 23093)	Specifies how the control is anchored to its parent.
	Constraints (see page 23093)	Specifies the size constraints for the control.
	Enabled (see page 23094)	Controls whether the control responds to mouse, keyboard, and timer events.
	Font (see page 23094)	Controls the attributes of text written on or in the control.
	PageIndex (see page 23095)	Determines which page displays in the tabbed notebook component.
	Pages (see page 23096)	Contains the strings that identify the individual pages of the tabbed notebook control.
	ParentShowHint (see page 23096)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 23097)	Identifies the pop-up menu associated with the control.
	ShowHint (see page 23101)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	TabFont (see page 23103)	Determines the font used on the tabs of the tabbed notebook control.
	TabOrder (see page 23103)	Indicates the position of the control in its parent's tab order.
	TabsPerRow (see page 23104)	This is TabsPerRow, a member of class TTabbedNotebook.
	TabStop (see page 23104)	Determines if the user can tab to a control.
	Visible (see page 23105)	Determines whether the component appears onscreen.

160.1.1.5.1 TTabbedNotebook.ActivePage Property

Determines which page displays in the tabbed notebook control.

Pascal

```
property ActivePage: string;
```

C++

```
__property AnsiString ActivePage;
```

Description

The value of ActivePage must be one of the strings contained in the Pages (see page 23096) property.

Note: To indicate the page that appears in the tabbed notebook by index rather than text, use the PageIndex (see page 23095) property instead.

See Also

PageIndex (see page 23095)

Pages (see page 23096)

160.1.1.5.2 TTabbedNotebook.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always

equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
```

```
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
```

```
    { make sure the splitter is to the right of the directory list box! }
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane – a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

  var
    I: Integer;

    ProgressBar := TProgressBar.Create(Self);
    with ProgressBar do
    begin
      Parent := Self;
      Align := alBottom;
    end;
  end;
  {
  This example dynamically creates a Page Control, then a
  series of Tab Sheets on the Page Control.
  }
  var
    PageControl1: TPageControl;
    pts: array[0..3] of TTabSheet;
  const
    TabTitles: array[0..3] of ShortString = ('Customer', 'Orders', 'Items', 'Parts' );

  procedure TForm1.FormCreate(Sender: TObject);
  const
    colorpalette: Array[0..11] of TColor = (
      clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia, clTeal,
      clNavy, clMaroon, clLime, clOlive, clPurple);
  var
    i: Integer;
  begin
    PageControl1 := TPageControl.Create(Self);
    PageControl1.Parent := Self;
    PageControl1.Align := alClient;
    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i]:= TTabSheet.Create(PageControl1);
      with pts[i] do
      begin
        PageControl := PageControl1;
        Name := 'ts' + TabTitles[i];
        Caption := TabTitles[i];
        Brush.Color := colorPalette[i];
     end;
    end;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
```

```
    i: Integer;
  begin
    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i].Free;
    end;
    PageControl1.Free;
  end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

160.1.1.5.3 TTabbedNotebook.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

160.1.1.5.4 TTabbedNotebook.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

160.1.1.5.5 TTabbedNotebook.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

160.1.1.5.6 TTabbedNotebook.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name,

Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

DesktopFont (see page 5818)

ParentFont (see page 5834)

Displaying and Editing Text in a Memo Control

160.1.1.5.7 TTabbedNotebook.PageIndex Property

Determines which page displays in the tabbed notebook component.

Pascal

```
property PageIndex: Integer;
```

C++

```
__property int PageIndex;
```

Description

Changing the PageIndex value changes the page in the control.

Each string in the Pages (see page 23096) property is automatically assigned a PageIndex value when the page is created. The first page receives a value of 0, the second has a value of 1, and so on. If you delete a string from the Pages (see page 23096) property, the PageIndex values are reassigned so that the values always begin with 0 and continue to increase without any gaps between values.

See Also

ActivePage (see page 23089)

Pages (see page 23096)

160.1.1.5.8 TTabbedNotebook.Pages Property

Contains the strings that identify the individual pages of the tabbed notebook control.

Pascal

```
property Pages: TStrings;
```

C++

```
__property TStrings Pages;
```

Description

Tabbed notebook controls create a separate page for each string in the Pages property. For example, if Pages contains three strings, First, Second, and Third, the control has three separate pages. Each string in Pages corresponds to a TTabPage (see page 23112) object whose Caption property is the same as the string.

You can change the active page in a tabbed notebook control with either the ActivePage (see page 23089) or PageIndex (see page 23095) property.

See Also

ActivePage (see page 23089)

PageIndex (see page 23095)

160.1.1.5.9 TTabbedNotebook.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

160.1.1.5.10 TTabbedNotebook.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
```

```
    else
      MessageBeep(0);
  }

  void __fastcall TForm1::Cut1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;
    if (pComponent)
    {
      if (pComponent->ClassNameIs("TEdit"))
        ((TEdit *)pComponent)->CutToClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }

  void __fastcall TForm1::Paste1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;
    if (pComponent)
    {
      if (pComponent->ClassNameIs("TEdit"))
        ((TEdit *)pComponent)->PasteFromClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }
  /*
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  */
  void __fastcall TForm1::AddButtonClick(TObject *Sender)
  {
      const int num_items = 4;
      for (int index = 0; index < num_items; ++index)
      {
          TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
          PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
          NewItem->Caption = "Menu Item " + IntToStr(index);
          NewItem->Tag = index;
          NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
          TNotifyEvent();
      }
  }

  void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
  {
      TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
      if (ClickedItem)
      {
          switch (ClickedItem->Tag)
          {
              case 0:
              {
                  ShowMessage("first item clicked");
```

```
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
```

```
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin

160.1.1.5.11 TTabbedNotebook.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
```

```
      Hint := 'Select an item';
      ShowHint := True;
    end;
    Application.ShowHint := True;
  end;
  {
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  }
```

Displaying Fly-over Help

160.1.1.5.12 TTabbedNotebook.TabFont Property

Determines the font used on the tabs of the tabbed notebook control.

Pascal

```
property TabFont: TFont;
```

C++

```
__property TFont TabFont;
```

Description

Use TabFont to specify the font characteristics used to display the label on the tabs of the notebook.

Note: The text on the selected tab is boldfaced if the selected font for the TabFont property is not also boldfaced.

See Also

TopFont (see page 23104)

160.1.1.5.13 TTabbedNotebook.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the

control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

160.1.1.5.14 TTabbedNotebook.TabsPerRow Property

Pascal

```
property TabsPerRow: Integer;
```

C++

```
__property int TabsPerRow;
```

Description

This is TabsPerRow, a member of class TTabbedNotebook.

160.1.1.5.15 TTabbedNotebook.TabStop Property

Determines if the user can tab to a control.

Pascal

```
property TabStop: Boolean;
```

C++

```
__property Boolean TabStop;
```

Description

Use the TabStop to allow or disallow access to the control using the Tab key.

If TabStop is true, the control is in the tab order. If TabStop is false, the control is not in the tab order and the user can't press the Tab key to move to the control.

Note: TabStop is not meaningful for a form unless the form assigns another form to be its parent.

See Also

TabOrder (see page 6211)

160.1.1.5.16 TTabbedNotebook.TopFont Property

Returns the current value of font used on the tabs of the tabbed notebook.

Pascal

```
property TopFont: TFont;
```

C++

```
__property TFont TopFont;
```

Description

TopFont is a read-only property that reports the TabFont (see page 23103) value.

See Also

TabFont (see page 23103)

160.1.1.5.17 TTabbedNotebook.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

160.1.1.6 TTabbedNotebook Events

The events of the TTabbedNotebook class are listed here.

Published Events

	Name	Description
	OnChange (see page 23106)	Occurs when the page of a tabbed notebook changes.
	OnClick (see page 23107)	Occurs when a tab of a tabbed notebook is selected.
	OnContextPopup (see page 23107)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnEnter (see page 23108)	Occurs when a control receives the input focus.
	OnExit (see page 23110)	Occurs when the input focus shifts away from one control to another.

160.1.1.6.1 TTabbedNotebook.OnChange Event

Occurs when the page of a tabbed notebook changes.

Pascal

```
property OnChange: TPageChangeEvent;
```

C++

```
__property TPageChangeEvent OnChange;
```

Description

Write an OnPage event handler to respond to a page change in a tabbed notebook.

See Also

OnClick (see page 23107)

160.1.1.6.2 TTabbedNotebook.OnClick Event

Occurs when a tab of a tabbed notebook is selected.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Write an OnClick event handler to respond when the user selects a tab in the tabbed notebook. Immediately after the OnClick event occurs, the OnChange (see page 23106) event occurs.

See Also

OnChange (see page 23106)

160.1.1.6.3 TTabbedNotebook.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the

default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

See Also

TPopupMenu (see page 16169)

PopupMenu (see page 5835)

AutoPopup (see page 16178)

160.1.1.6.4 TTabbedNotebook.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
```

```
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
```

```
      with myActiveControl as TEdit do
         Font.Assign(TFontDialog(Sender).Font)
    else if myActiveControl is TRichEdit then
      with myActiveControl as TRichEdit do
        SelAttributes.Assign(TFontDialog(Sender).Font)
    else
      Beep;
  end;
  {
  This example uses an edit box and a memo control on a form.
  When either the edit box or the memo is the active control,
  it is colored yellow. When the active control becomes
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }

160.1.1.6.5 TTabbedNotebook.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
```

```
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

160.1.2 TTabPage Class

TTabPage implements an individual tab page of a tabbed notebook control.

Class Hierarchy

Pascal

```
TTabPage = class(TWinControl);
```

C++

```
class TTabPage : public TWinControl;
```

File

TabNotBk

Description

Each instance of this class holds the controls to be displayed when it is the active page of a tabbed notebook. TTabPage objects are associated with the strings in the corresponding tabbed notebook's Pages property by setting their Caption (see page 23124) property.

See Also

TTabbedNotebook (see page 23070)

TTabbedNotebook (see page 23070)

160.1.2.1 TTabPage Members

The following tables list the members exposed by TTabPage.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.

	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.

	ActionChange (see page 5737)	Responds when the action associated with the control changes.
	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.

	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.

	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 23123)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.

	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.

	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.

	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 23122)	Creates an instance of TWinControl.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.

	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.

V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.

	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Caption (see page 23124)	Specifies a text string that identifies the control to the user.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Enabled (see page 23126)	Controls whether the control responds to mouse, keyboard, and timer events.
	Height (see page 23127)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	TabOrder (see page 23128)	Indicates the position of the control in its parent's tab order.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 23129)	Determines whether the component appears onscreen.
	Width (see page 23130)	Specifies the horizontal size of the control or form in pixels.

160.1.2.2 TTabPage.Create Constructor

Creates an instance of TWinControl.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TTabPage(TComponent * AOwner);
```

Description

Call Create to construct and initialize a new control and insert the newly-constructed control into its owner, as specified by the AOwner parameter. Create inserts the control in the owner by calling the owner's InsertComponent method.

Most controls override Create to initialize their unique properties. Objects that override the Create method must always call the inherited Create method first, and then proceed with the component-specific initialization. Specify the override directive when overriding the Create method.

If a component's Create method allocates resources or memory, override the Destroy method to free those resources.

160.1.2.3 TTabPage Methods

The methods of the TTabPage class are listed here.

Protected Methods

	Name	Description
	ReadState (see page 23123)	Prepares the control for having its properties assigned values from a stream.

160.1.2.3.1 TTabPage.ReadState Method

Prepares the control for having its properties assigned values from a stream.

Pascal

```
procedure ReadState(Reader: TReader); override;
```

C++

```
virtual __fastcall ReadState(TReader Reader);
```

Description

Override ReadState to change the preparations the control makes as it readies itself to have its property values assigned from a stream. For example, a control might destroy temporary internal data structures or objects before new instances are loaded from the stream. Be sure to include a call to the inherited method when overriding ReadState.

As implemented in TWinControl, ReadState disables control alignment until all the child controls have been read from the stream, calls the inherited ReadState method, and re-enables the alignment of all the controls. The method then builds the tab order list of controls and synchronizes its visibility with that of its parent control.

See Also

Parent (see page 5832)

ReadState (see page 5778)

160.1.2.4 TTabPage Properties

The properties of the TTabPage class are listed here.

Published Properties

	Name	Description
	Caption (see page 23124)	Specifies a text string that identifies the control to the user.
	Enabled (see page 23126)	Controls whether the control responds to mouse, keyboard, and timer events.
	Height (see page 23127)	Specifies the vertical size of the control in pixels.
	TabOrder (see page 23128)	Indicates the position of the control in its parent's tab order.
	Visible (see page 23129)	Determines whether the component appears onscreen.
	Width (see page 23130)	Specifies the horizontal size of the control or form in pixels.

160.1.2.4.1 TTabPage.Caption Property

Specifies a text string that identifies the control to the user.

Pascal

```
property Caption: TCaption;
```

C++

```
__property TCaption Caption;
```

Description

Use Caption to specify the text string that labels the control.

To underline a character in a Caption that labels a component, include an ampersand (&) before the character. This type of character is called an accelerator character. The user can then select the component by pressing Alt while typing the underlined character. To display an ampersand character in the caption, use two ampersands (&&).

Note: Controls that display text use either the Caption property or the Text property to specify the text value. Which property is used depends on the type of control. In general, Caption is used for text that appears as a window title or label, while Text is used for text that appears as the content of a control.

C++ Examples:

```
/*
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  Label1->AutoSize = false;
  Label1->Caption = "This string is too long as the caption of this label";
}
/*
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would make a TTabSheet variable unnecessary since
PageControl1.->ActivePage is already of type TTabSheet.
```

```
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TTabSheet *sheet = PageControl1->ActivePage;
  sheet->Caption = Edit1->Text;
}
/*
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
*/
#include <comctrls.hpp>

void AddButtons(TToolBar *toolBar, TStringList *captions)
{
  for (int i = 0; i < captions->Count; i++)
  {
    TToolButton *button = new TToolButton(toolBar);
    button->Parent = toolBar;
    button->Caption = captions->Strings[i];
    if (button->Caption == "|")
      button->Style = tbsSeparator;
    else
      button->Style = tbsButton;
  }
}

TToolBar *myToolBar;

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  myToolBar = new TToolBar(this);
  myToolBar->Parent = this;
  TStringList *captions = new TStringList();
  captions->Add("New");
  captions->Add("Save");
  captions->Add("|");
  captions->Add("Cut");
  captions->Add("Copy");
  captions->Add("Paste");
  AddButtons(myToolBar, captions);
  delete captions;
  myToolBar->ShowCaptions = True;
  myToolBar->Height = 40;
}

void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int I = myToolBar->ButtonCount - 1; I >= 0; I--)
    delete myToolBar->Buttons[I];
  delete myToolBar;
}
```

Delphi Examples:

```
{
The following code keeps the size of the label control
constant, even though the length of the label's caption
changes. As a result, the caption of the label is probably
too long to display in the label when the user clicks the
button:
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  Label1.AutoSize := False;
  Label1.Caption :=
    'This string is too long as the caption of this label';
end;
```

```
{
This example requires a TPageControl populated by several
TabSheets, a TEdit and a TButton. When the button is
clicked, the caption of the active tab changes to that of
the TEdit.  These lines of code could also be written:
PageControl1.ActivePage.Caption := Edit1.Text;
This would obviate the need for a TTabSheet variable since
PageControl1.->ActivePage is already of type TTabSheet.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  sheet: TTabSheet;
begin
  sheet := PageControl1.ActivePage;
  sheet.Caption := Edit1.Text;
end;
{
This example creates a ToolBar and adds ToolButtons to it.
Include ComCtlrs in the uses clause.
}
procedure AddButtons(ToolBar: TToolBar;
  Const ButtonCaptions: array of String);
var
  I: Integer;
begin
  for I := 0 to High(ButtonCaptions) do
    begin
      with TToolButton.Create(ToolBar) do
      begin
        Parent := ToolBar;
        Caption := ButtonCaptions[I];
        if (ButtonCaptions[I] = '|') then
          Style := tbsSeparator
        else
          Style := tbsButton;
      end;
    end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
  ToolBar1 := TToolBar.Create(Self);
  ToolBar1.Parent := Self;
  AddButtons(ToolBar1, ['New', 'Save', '|', 'Cut', 'Copy', 'Paste']);
  ToolBar1.ShowCaptions := True;
  ToolBar1.Height := 40;
end;

procedure TForm1.FormDestroy(Sender: TObject);
var
  I: Integer;
begin
  for I := ToolBar1.ButtonCount - 1 downto 0 do
    ToolBar1.Buttons[I].Free;
  ToolBar1.Free;
end;
```

160.1.2.4.2 TTabPage.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

160.1.2.4.3 TTabPage.Height Property

Specifies the vertical size of the control in pixels.

Pascal

```
property Height: Integer;
```

C++

```
__property int Height;
```

Description

Use the Height property to read or change the height of the control.

C++ Examples:

```
/*
This example needs only a blank form.  Three Rich Edit
controls are placed vertically on the form, each contain a
line of text, and the second form has HideSelection set to
false.  Try tabbing between the three Rich Edit controls and
observe the effect on the selected text.
*/
#include <ComCtrls.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int I = 0; I <= 2; I++)
  {
    TRichEdit *pRich = new TRichEdit(this);
    pRich->Parent = this;
    pRich->Top = pRich->Height * I;
    pRich->Text = "This text will take the focus.";
    pRich->SelStart = 0;
    pRich->SelLength = pRich->Text.Length();
    if (I == 1)
      pRich->HideSelection = false;
  }
}
```

Delphi Examples:

```
{
HideSelection, Height example
This example needs only a blank form. Three Rich Edit
```

```
  controls are placed vertically on the form, each contain a
  line of text, and the second form has HideSelection set to
  false.  Try tabbing between the three Rich Edit controls and
  observe the effect on the selected text.
  }
  uses ComCtrls;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    I: Integer;
  begin
    for I := 0 to 2 do
      with TRichEdit.Create(Self) do
      begin
        Parent := Self;
        Top := Height * I;
        Text := 'This text will take the focus.';
        SelStart := 0;
        SelLength := Length(Text);
        if (I = 1) then
          HideSelection := False;
      end;
  end;

Using TDBListBox and TDBComboBox

160.1.2.4.4 TTabPage.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

160.1.2.4.5 TTabPage.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
```

```
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

160.1.2.4.6 TTabPage.Width Property

Specifies the horizontal size of the control or form in pixels.

Pascal

```
property Width: Integer;
```

C++

```
__property int Width;
```

Description

Use the Width property to read or change the width of the control.

Note: For tab sheet controls, changing this property at runtime has no effect.

ClientWidth (see page 5811)

Height (see page 5825)

Left (see page 5830)

160.2 Types

The following table lists types in this documentation.

Types

Name	Description
TPageChangeEvent (see page 23131)	TPageChangeEvent is the type for event handlers that respond when the current page changes in a TTabbedNotebook (see page 23070) control.

160.2.1 TabNotBk.TPageChangeEvent Type

TPageChangeEvent is the type for event handlers that respond when the current page changes in a TTabbedNotebook (see page 23070) control.

Pascal

```
TPageChangeEvent = procedure (Sender: TObject; NewTab: Integer; var AllowChange: Boolean) of object;
```

C++

```
(Sender: TObject; NewTab: Integer; var AllowChange: Boolean) ( TPageChangeEvent)();
```

File

TabNotBk

Description

Sender is the TTabbedNotebook (see page 23070) control.

NewTab is the tab that is about to become the selected or current tab.

AllowChange specifies whether the change to a new page is allowed. If the event handler sets AllowChange to false, a new page change doesn't occur.

160.3 Constants

The following table lists constants in this documentation.

Constants

Name	Description
CM_TABFONTCHANGED (see page 23132)	This is constant TabNotBk.CM_TABFONTCHANGED.

160.3.1 TabNotBk.CM_TABFONTCHANGED Constant

Pascal

```
CM_TABFONTCHANGED = CM_BASE + 100;
```

C++

```
CM_TABFONTCHANGED = CM_BASE + 100;
```

File

TabNotBk

Description

This is constant TabNotBk.CM_TABFONTCHANGED.

161 Tabs Namespace

This is namespace Tabs.

Topics

Name	Description
Classes (see page 23134)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 23229)	The following table lists structs, records, enums in this documentation.
Types (see page 23232)	The following table lists types in this documentation.

Classes

	Name	Description
	TScroller (see page 23134)	TScroller is a horizontal scrolling control that provides basic horizontal scrolling capabilities.
	TTabList (see page 23149)	This is class Tabs.TTabList.
	TTabSet (see page 23159)	The TTabSet component presents horizontal tabs users can click to initiate actions.

Structs, Records, Enums

	Name	Description
	TEdgePart (see page 23229)	This is record Tabs.TEdgePart.
	TEdgeType (see page 23229)	This is record Tabs.TEdgeType.
	TScrollBtn (see page 23230)	This is record Tabs.TScrollBtn.
	TScrollOrientation (see page 23230)	This is record Tabs.TScrollOrientation.
	TTabSetTabStyle (see page 23231)	This is record Tabs.TTabSetTabStyle.

Types

Name	Description
TDrawTabEvent (see page 23232)	TDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 23159) control.
TMeasureTabEvent (see page 23232)	TMeasureTabEvent is the type for event handlers that indicate the size of the tabs in an owner-drawn TTabSet (see page 23159) control.
TTabChangeEvent (see page 23233)	TTabChangeEvent is the type for event handlers that respond when the current tab of a TTabSet (see page 23159) control changes.
TTabSetDrawTabEvent (see page 23233)	TTabSetDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 23159) control.
TTabStyle (see page 23234)	TTabStyle indicates whether a TTabSet (see page 23159) control is owner-drawn.

161.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TScroller (see page 23134)	TScroller is a horizontal scrolling control that provides basic horizontal scrolling capabilities.
	TTabList (see page 23149)	This is class Tabs.TTabList.
	TTabSet (see page 23159)	The TTabSet component presents horizontal tabs users can click to initiate actions.

161.1.1 TScroller Class

TScroller is a horizontal scrolling control that provides basic horizontal scrolling capabilities.

Class Hierarchy

Pascal

```
TScroller = class(TCustomControl);
```

C++

```
class TScroller : public TCustomControl;
```

File

Tabs

Description

The TTabSet (see page 23159) object uses TScroller to scroll its visible tabs. TScroller is provided for backward compatibility only. TScroller is similar to an up-down control (TUpDown) with a horizontal orientation, except that it does not work with a companion control.

See Also

TTabSet (see page 23159)

TUpDown (see page 5380)

161.1.1.1 TScroller Members

The following tables list the members exposed by TScroller.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.

	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWnd (see page 6137)	Creates the underlying window.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
V	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
V	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
V	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.

	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).

	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.

	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
V	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
V	SetDragMode (see page 5785)	Sets the drag mode for the control.
V	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
V	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
V	SetName (see page 5785)	Sets the name of the control.
V	SetParent (see page 5786)	Sets the parent of the control.
V	SetParent (see page 6182)	Sets the parent of the control.
V	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
V	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
V	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
R	Canvas (see page 5921)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.

	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 23145)	Creates an instance of TScroller (see page 23134).
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 23145)	Frees the memory associated with the TScroller (see page 23134) object.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.

	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	Paint (see page 23146)	Paints the image of the TScroller (see page 23134) object into its canvas.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.

	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.

	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnClick (see page 23148)	OnClick occurs after the Position (see page 23148) property has been updated in response to the user clicking one of the arrow buttons.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Change (see page 23146)	Specifies the number of units to scroll when the user clicks the arrow buttons.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Max (see page 23147)	Specifies the maximum value the Position (see page 23148) property can take.
	Min (see page 23147)	Specifies the minimum value the Position (see page 23148) property can take.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Position (see page 23148)	Position is the current position in the scroll range.

	ScrollOrientation (see page 23148)	This is ScrollOrientation, a member of class TScroller.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

161.1.1.2 TScroller.Create Constructor

Creates an instance of TScroller (see page 23134).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TScroller(TComponent * AOwner);
```

Description

Call TScroller (see page 23134) to create an instance of TScroller (see page 23134) at runtime. TScroller (see page 23134) allocates the memory for the TScroller (see page 23134) object and initializes

Width to 24 and Height to 13

Min (see page 23147) and Max (see page 23147) to 0

Position (see page 23148) to 0

Change (see page 23146) to 1

The AOwner parameter specifies the component (usually the form) that is responsible for freeing the scroller.

See Also

Change (see page 23146)

Height (see page 5825)

Max (see page 23147)

Min (see page 23147)

Position (see page 23148)

Width (see page 5849)

161.1.1.3 TScroller.Destroy Destructor

Frees the memory associated with the TScroller (see page 23134) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TScroller();
```

Description

Do not call Destroy directly. Instead, use the Free method, which checks whether the TScroller (see page 23134) reference is nil before calling Destroy.

See Also

Create (see page 23145)

Free (see page 22300)

161.1.1.4 TScroller Methods

The methods of the TScroller class are listed here.

Public Methods

	Name	Description
	Paint (see page 23146)	Paints the image of the TScroller (see page 23134) object into its canvas.

161.1.1.4.1 TScroller.Paint Method

Paints the image of the TScroller (see page 23134) object into its canvas.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

Paint is called automatically in response to WM_PAINT messages. Paint paints the arrow buttons, graying them out when Position (see page 23148) cannot be moved in the associated direction.

See Also

Position (see page 23148)

Canvas (see page 5921)

161.1.1.5 TScroller Properties

The properties of the TScroller class are listed here.

Published Properties

	Name	Description
	Change (see page 23146)	Specifies the number of units to scroll when the user clicks the arrow buttons.
	Max (see page 23147)	Specifies the maximum value the Position (see page 23148) property can take.
	Min (see page 23147)	Specifies the minimum value the Position (see page 23148) property can take.
	Position (see page 23148)	Position is the current position in the scroll range.
	ScrollOrientation (see page 23148)	This is ScrollOrientation, a member of class TScroller.

161.1.1.5.1 TScroller.Change Property

Specifies the number of units to scroll when the user clicks the arrow buttons.

Pascal

```
property Change: Integer;
```

C++

```
__property int Change;
```

Description

Set Change to indicate the number of units between Min (see page 23147) and Max (see page 23147) the Position (see page 23148) moves whenever the user clicks on one of the arrow buttons. Change represents the mapping between the units used to specify Min (see page 23147), Max (see page 23147), and Position (see page 23148), and the logical units represented by the scroller.

For example, if the values of Min (see page 23147), Max (see page 23147), and Position (see page 23148) are given in screen pixels, Change would be the number of pixels to scroll whenever the user clicks the scroll arrow.

See Also

Max (see page 23147)

Min (see page 23147)

Position (see page 23148)

161.1.1.5.2 TScroller.Max Property

Specifies the maximum value the Position (see page 23148) property can take.

Pascal

```
property Max: Longint;
```

C++

```
__property Longint Max;
```

Description

Use Max to set the upper limit of the scrolling range. The Max and Min (see page 23147) properties define the range of values over which the scroller can scroll.

See Also

Change (see page 23146)

Min (see page 23147)

Position (see page 23148)

161.1.1.5.3 TScroller.Min Property

Specifies the minimum value the Position (see page 23148) property can take.

Pascal

```
property Min: Longint;
```

C++

```
__property Longint Min;
```

Description

Use Min to set the lower limit of the scrolling range. The Min and Max (see page 23147) properties define the range of values over which the scroller can scroll.

See Also

Change (see page 23146)

Max (see page 23147)

Position (see page 23148)

161.1.1.5.4 TScroller.Position Property

Position is the current position in the scroll range.

Pascal

```
property Position: Longint;
```

C++

```
__property Longint Position;
```

Description

Read Position to determine the current position the scroller represents. Position is a value between Min (see page 23147) and Max (see page 23147). Use an OnClick (see page 23148) event handler to notify the object being scrolled when the Position changes.

See Also

Max (see page 23147)

Min (see page 23147)

OnClick (see page 23148)

161.1.1.5.5 TScroller.ScrollOrientation Property

Pascal

```
property ScrollOrientation: TScrollOrientation;
```

C++

```
__property TScrollOrientation ScrollOrientation;
```

Description

This is ScrollOrientation, a member of class TScroller.

161.1.1.6 TScroller Events

The events of the TScroller class are listed here.

Published Events

	Name	Description
	OnClick (see page 23148)	OnClick occurs after the Position (see page 23148) property has been updated in response to the user clicking one of the arrow buttons.

161.1.1.6.1 TScroller.OnClick Event

OnClick occurs after the Position (see page 23148) property has been updated in response to the user clicking one of the arrow buttons.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Write an OnClick event handler to implement the scrolling action of the object that uses the TScroller (see page 23134) to control scrolling. When the user clicks one of the arrow buttons, the Position (see page 23148) gets updated by Change (see page 23146) (unless the Max (see page 23147) or Min (see page 23147) value is hit), and then an OnClick event occurs.

See Also

Change (see page 23146)

Max (see page 23147)

Min (see page 23147)

Position (see page 23148)

161.1.2 TTabList Class

Class Hierarchy

Pascal

```
TTabList = class(TStringList);
```

C++

```
class TTabList : public TStringList;
```

File

Tabs

Description

This is class Tabs.TTabList.

161.1.2.1 TTabList Members

The following tables list the members exposed by TTabList.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 3013)	This is Changed, a member of class TStringList.
	Changing (see page 3013)	This is Changing, a member of class TStringList.
	CompareStrings (see page 3014)	Compares two strings.
	CompareStrings (see page 3048)	Compares two strings.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.

	DefineProperties (see page 3049)	Reads and writes the Strings (see page 3080) property as if it were published.
	Error (see page 3052)	This is the overview for the Error method overload.
	ExtractName (see page 3053)	Returns the name portion of a string that is a name value pair.
	Get (see page 3017)	Returns a string given its index.
	Get (see page 3053)	Returns a string given its index.
	GetCapacity (see page 3017)	Returns the currently allocated size of the list of strings.
	GetCapacity (see page 3054)	Returns the currently allocated size of the list of strings.
	GetCount (see page 3018)	Returns the number of strings in the list
	GetCount (see page 3054)	Returns the number of strings in the list
	GetObject (see page 3018)	Returns the object associated with the string at a specified index.
	GetObject (see page 3055)	Returns the object associated with the string at a specified index.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTextStr (see page 3056)	Returns the value of the Text (see page 3084) property.
	InsertItem (see page 3020)	This is InsertItem, a member of class TStringList.
	PutObject (see page 3022)	Changes the object associated with the string at a specified index.
	PutObject (see page 3065)	Changes the object associated with the string at a specified index.
	SetCapacity (see page 3022)	Changes the amount of memory allocated to hold strings in the list.
	SetCapacity (see page 3068)	Changes the amount of memory allocated to hold strings in the list.
	SetTextStr (see page 3069)	Sets the Text (see page 3084) property.
	SetUpdateState (see page 3023)	Performs internal adjustments before or after a series of updates.
	SetUpdateState (see page 3069)	Performs internal adjustments before or after a series of updates.

Protected Properties

	Name	Description
	UpdateCount (see page 3085)	Indicates the number of calls to BeginUpdate (see page 3045) that have not been matched by a call to EndUpdate (see page 3050).

Public Events

	Name	Description
	OnChange (see page 3028)	Occurs immediately after the list of strings changes.
	OnChanging (see page 3028)	Occurs immediately before the list of strings changes.

Public Methods

	Name	Description
	Add (see page 23153)	Adds a new string to the list.
	AddObject (see page 3012)	Adds a string to the list, and associates an object with the string.
	AddObject (see page 3036)	Adds a string to the list, and associates an object with the string.
	AddStrings (see page 23155)	Adds a group of strings to the list.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 3041)	Adds a string to the list.
	Assign (see page 2930)	Copies the contents of another, similar object.
	Assign (see page 3043)	Sets the strings in the list, and possibly associated objects, from a source object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginUpdate (see page 3045)	Enables the TStrings (see page 3029) object to track when the list of strings is changing.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 23157)	Deletes all the strings from the list.
	Create (see page 23152)	This is Create, a member of class TTabList.
	CustomSort (see page 3014)	Sorts the strings in the list in a customized order.

	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 23157)	Removes the string specified by the Index parameter.
	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
	Destroy (see page 3009)	Destroys an instance of TStringList (see page 3006).
	Destroy (see page 3032)	Destroys the TPersistent instance and frees its memory.
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndUpdate (see page 3050)	Enables the TStrings (see page 3029) object to keep track of when the list of strings has finished changing.
	Equals (see page 3051)	Compares the list of strings to the list from another TStrings (see page 3029) object and returns true if the two lists match.
	Exchange (see page 3015)	Swaps the position of two strings in the list.
	Exchange (see page 3053)	Swaps the position of two strings in the list.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Find (see page 3016)	Locates the index for a string in a sorted list and indicates whether a string with that value already exists in the list.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 3054)	Returns a TStrings (see page 3029) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetText (see page 3055)	Allocates a text buffer and fills it with the value of the Text (see page 3084) property.
	IndexOf (see page 3019)	Returns the position of a string in the list.
	IndexOf (see page 3056)	Returns the position of a string in the list.
	IndexOfName (see page 3057)	Returns the position of the first name-value pair with the specified name.
	IndexOfObject (see page 3059)	Returns the index of the first string in the list associated with a given object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Insert (see page 23158)	Inserts a string to the list at the position specified by Index.
	InsertObject (see page 3020)	Inserts a string into the list at the specified position, and associates it with an object.
	InsertObject (see page 3060)	Inserts a string into the list at the specified position, and associates it with an object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	LoadFromFile (see page 3061)	Fills the list with the lines of text in a specified file.
	LoadFromStream (see page 3062)	Fills the list with lines of text read from a stream.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	Move (see page 3063)	Changes the position of a string in the list.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Put (see page 23158)	Changes the value of the string with a specified index.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SaveToFile (see page 3065)	Saves the strings in the list to the specified file.
	SaveToStream (see page 3067)	Writes the value of the Text (see page 3084) property to a stream object.
	SetText (see page 3068)	Sets the Text (see page 3084) property.
	Sort (see page 3023)	Sorts the strings in the list in ascending order.

Public Properties

	Name	Description
	Capacity (see page 3070)	Indicates the number of strings the TStrings (see page 3029) object can hold.

	CaseSensitive (see page 3025)	Controls (see page 5711) whether strings are located, sorted, and identified as duplicates in a case-sensitive or case-insensitive manner.
	CommaText (see page 3070)	Lists the strings in the TStrings (see page 3029) object in system data format (SDF).
R	Count (see page 3071)	Introduces an abstract property to represent the number of strings in the list.
	DelimitedText (see page 3074)	Represents all the strings in the TStrings (see page 3029) object as a single delimited string.
	Delimiter (see page 3074)	Specifies the delimiter used by the DelimitedText (see page 3074) property.
	Duplicates (see page 3025)	Specifies whether duplicate strings can be added to sorted lists.
	LineBreak (see page 3075)	Defines the line break character(s).
R	Names (see page 3075)	Indicates the name part of strings that are name-value pairs.
	NameValueSeparator (see page 3077)	Indicates the character used to separate names from values.
	Objects (see page 3077)	Represents a set of objects that are associated one with each of the strings in the Strings (see page 3080) property.
	QuoteChar (see page 3080)	Specifies the quote character used by the DelimitedText (see page 3074) property.
	Sorted (see page 3026)	Specifies whether the strings in the list should be automatically sorted.
	StrictDelimiter (see page 3080)	Determines how the Delimiter (see page 3074) property is used.
	Strings (see page 3080)	References the strings in the list by their positions.
	StringsAdapter (see page 3084)	Implements an IStringsAdapter (see page 3208) interface for the TStrings (see page 3029) object.
	Text (see page 3084)	Lists the strings in the TStrings (see page 3029) object as a single string with the individual strings delimited by carriage returns and line feeds.
	ValueFromIndex (see page 3085)	Represents the value part of a string with a given index, on strings that are name-value pairs.
	Values (see page 3086)	Represents the value part of a string associated with a given name, on strings that are name-value pairs.

161.1.2.2 TTabList.Create Constructor

Pascal

```
constructor Create(const ATabSet: TTabSet);
```

C++

```
__fastcall TTabList(const TTabSet ATabSet);
```

Description

This is Create, a member of class TTabList.

161.1.2.3 TTabList Methods

The methods of the TTabList class are listed here.

Public Methods

	Name	Description
V	Add (see page 23153)	Adds a new string to the list.
V	AddStrings (see page 23155)	Adds a group of strings to the list.
V	Clear (see page 23157)	Deletes all the strings from the list.
V	Delete (see page 23157)	Removes the string specified by the Index parameter.
V	Insert (see page 23158)	Inserts a string to the list at the position specified by Index.
V	Put (see page 23158)	Changes the value of the string with a specified index.

161.1.2.3.1 TTabList.Add Method

Adds a new string to the list.

Pascal

```
function Add(const S: string): Integer; override;
```

C++

```
virtual __fastcall int Add(const AnsiString S);
```

Description

Call Add to add the string S to the list. If the list is sorted, S is added to the appropriate position in the sort order. If the list is not sorted, S is added to the end of the list. Add returns the position of the item in the list, where the first item in the list has a value of 0.

Note: For sorted lists, Add will raise an EListError exception if the string S already appears in the list and Duplicates is set to dupError. If Duplicates is set to dupIgnore, trying to add a duplicate string causes Add to return the index of the existing entry.

C++ Examples:

```
/*
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  int Index;
  TStringList* MyList = new TStringList();
  try
  {
    MyList->Add("Animals");
    MyList->Add("Flowers");
    MyList->Add("Ocean");
    MyList->Sort(); // Find will only work on sorted lists
    if (MyList->Find("Flowers", Index))
    {
      ListBox1->Items->AddStrings(MyList);
      Label1->Caption = "Flowers has an index value of " + AnsiString(Index);
    }
  }
  __finally
  {
    delete MyList;
  }
}
/*
This example creates a stringlist, adds elements to it and
assigns the strings to items of a combo box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TStrings *StringList = new TStringList();
  try
  {
    StringList->Add("This example uses A string List. ");
```

```
    StringList->Add("It is the easiest way to add strings");
    StringList->Add("to a combobox's list of strings. ");
    StringList->Add("Always remember TStrings is abstract,");
    StringList->Add("So create a TStringList instead.");
    ComboBox1->Width = 210;
    ComboBox1->Items->Assign(StringList);
    ComboBox1->ItemIndex = 0;
  }
  __finally
  {
    delete StringList;
  }
}
```

Delphi Examples:

```
{
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  MyList: TStringList;
  Index: Integer;
begin
  MyList := TStringList.Create;
  try
    MyList.Add('Animals');
    MyList.Add('Flowers');
    MyList.Add('Cars');
    MyList.Sort;   { Find will only work on sorted lists! }
    if MyList.Find('Flowers', Index) then
    begin
      ListBox1.Items.AddStrings(MyList);
      Label1.Caption := 'Flowers has an index value of ' + IntToStr(Index);
    end;
  finally
    MyList.Free;
  end;
end;
{
This example creates a stringlist, adds elements to it and
assigns the strings to items of a combo box.
}
procedure TForm1.Button1Click(Sender: TObject);
var
  StringList: TStringList;
begin
  StringList := TStringList.Create;
  try
    with StringList do begin
      Add('This example uses A string List.');
      Add('It is the easiest way to add strings');
      Add('to a combobox''s list of strings.');
      Add('Always remember TStrings.Create method');
      Add('is abstract; So use TStringList.Create');
      Add('method instead.');
    end;
    with ComboBox1 do begin
      Width := 210;
      Items.Assign(StringList);
      ItemIndex := 0;
```

```
    end;
  finally
    StringList.free;
  end;
end;
```

See Also

AddStrings (see page 3039)

Append (see page 3041)

Delete (see page 3015)

Duplicates (see page 3025)

Insert (see page 3019)

Sorted (see page 3026)

161.1.2.3.2 TTabList.AddStrings Method

Adds a group of strings to the list.

Pascal

```
procedure AddStrings(Strings: TStrings); override;
```

C++

```
virtual __fastcall AddStrings(TStrings Strings);
```

Description

Call AddStrings to add the strings from another TStrings object to the list. If both the source and destination TStrings objects support objects associated with their strings, references to the associated objects will be added as well.

C++ Examples:

```
/*
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  int Index;
  TStringList* MyList = new TStringList();
  try
  {
    MyList->Add("Animals");
    MyList->Add("Flowers");
    MyList->Add("Ocean");
    MyList->Sort(); // Find will only work on sorted lists
    if (MyList->Find("Flowers", Index))
    {
      ListBox1->Items->AddStrings(MyList);
      Label1->Caption = "Flowers has an index value of " + AnsiString(Index);
    }
  }
  __finally
  {
    delete MyList;
```

```
  }
}
/*
This example uses a list box on a form. When the application
runs, a string list object is created and three strings are
added to it. The strings are sorted and added to the list
box, where they appear in their sorted order:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TStringList *list = new TStringList();
  list->Add("Plants");
  list->Add("Animals");
  list->Add("Minerals");
  list->Sorted = true;
  ListBox1->Items->AddStrings(list);
  delete list;
}
```

Delphi Examples:

```
{
This example uses a list box and a label on a form. When the
application runs, a string list object is created and three
strings are added to it. The Find method searches the
strings to look for a match with the string 'Flowers'. If
the string is found, all the strings in the string list are
added to the list box, and the index value of the 'Flowers'
string appears in the caption of the label control.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  MyList: TStringList;
  Index: Integer;
begin
  MyList := TStringList.Create;
  try
    MyList.Add('Animals');
    MyList.Add('Flowers');
    MyList.Add('Cars');
    MyList.Sort;   { Find will only work on sorted lists! }
    if MyList.Find('Flowers', Index) then
    begin
      ListBox1.Items.AddStrings(MyList);
      Label1.Caption := 'Flowers has an index value of ' + IntToStr(Index);
    end;
  finally
    MyList.Free;
  end;
end;
{
This example uses a list box on a form. When the application
runs, a string list object is created and three strings are
added to it. The strings are sorted and added to the list
box, where they appear in their sorted order:
}
procedure TForm1.FormCreate(Sender: TObject);
var
  MyList: TStringList;
begin
  MyList := TStringList.Create;
  MyList.Add('Plants');
  MyList.Add('Animals');
  MyList.Add('Minerals');
  MyList.Sorted := True;
  ListBox1.Items.AddStrings(MyList);
  MyList.Free;
```

```
end;
```

AddObject (see page 3036)

Assign (see page 3043)

Count (see page 3071)

Objects (see page 3077)

161.1.2.3.3 TTabList.Clear Method

Deletes all the strings from the list.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Call clear to empty the list of strings. All references to associated objects are also removed. However, the objects themselves are not freed.

See Also

Delete (see page 3015)

Objects

Strings

161.1.2.3.4 TTabList.Delete Method

Removes the string specified by the Index parameter.

Pascal

```
procedure Delete(Index: Integer); override;
```

C++

```
virtual __fastcall Delete(int Index);
```

Description

Call Delete to remove a single string from the list. If an object is associated with the string, the reference to the object is removed as well. Index gives the position of the string, where 0 is the first string, 1 is the second string, and so on.

See Also

Add (see page 3010)

AddObject (see page 3012)

Clear (see page 3013)

IndexOf (see page 3019)

InsertObject (see page 3060)

Objects

Strings

161.1.2.3.5 TTabList.Insert Method

Inserts a string to the list at the position specified by Index.

Pascal

```
procedure Insert(Index: Integer; const S: string); override;
```

C++

```
virtual __fastcall Insert(int Index, const AnsiString S);
```

Description

Call Insert to add the string S to the list at the position specified by Index. If Index is 0, the string is inserted at the beginning of the list. If Index is 1, the string is put in the second position of the list, and so on.

If the string has an associated object, use the InsertObject method instead.

Note: If the list is sorted, calling Insert or InsertObject will raise an EListError exception. Use Add or AddObject with sorted lists.

See Also

Add (see page 3010)

AddObject (see page 3012)

EListError (see page 2701)

InsertObject (see page 3020)

Sorted (see page 3026)

Strings

161.1.2.3.6 TTabList.Put Method

Changes the value of the string with a specified index.

Pascal

```
procedure Put(Index: Integer; const S: string); override;
```

C++

```
virtual __fastcall Put(int Index, const AnsiString S);
```

Description

Put is the protected write implementation of the Strings property.

Put changes the value of the string with the index specified by Index to S. Put does not change the object at the specified position. That is, any object associated with the previous string becomes associated with the new string.

Strings (see page 3080)

Objects (see page 3077)

161.1.3 TTabSet Class

The TTabSet component presents horizontal tabs users can click to initiate actions.

Class Hierarchy

Pascal

```
TTabSet = class(TCustomControl);
```

C++

```
class TTabSet : public TCustomControl;
```

File

Tabs

Description

Tab set controls are commonly used to display tabbed pages within a dialog box. TTabSet is provided for backward compatibility. Use TTabControl component in 32-bit Windows applications.

You create a set of tabs for the tab set control when you specify a list of strings as the value of the Tabs (see page 23201) property. One tab is created for each string.

To determine which tab is currently selected or to use code to select a tab, use the TabIndex (see page 23200) property. To find out which tab is the first visible tab in the tab set control or to make a tab the first visible tab, use the FirstIndex (see page 23189) property.

161.1.3.1 TTabSet Members

The following tables list the members exposed by TTabSet.

Protected Events

	Name	Description
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.

	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanChange (see page 23171)	This is CanChange, a member of class TTabSet.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	CMHintShow (see page 23171)	This is CMHintShow, a member of class TTabSet.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.

	CreateParams (see page 23172)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	DrawTab (see page 23172)	This is DrawTab, a member of class TTabSet.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.

	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
V	GetChildren (see page 23172)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetImageIndex (see page 23173)	This is GetImageIndex, a member of class TTabSet.
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
V	MeasureTab (see page 23174)	This is MeasureTab, a member of class TTabSet.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
V	MouseDown (see page 23175)	OnMouseDown event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	Notification (see page 23176)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 23176)	Renders the image of a custom control.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.

	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetTabIndex (see page 23177)	This is SetTabIndex, a member of class TTabSet.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.

	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
R	Scroller (see page 23196)	This is Scroller, a member of class TTabSet.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 23170)	Constructs a tab set control.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 23170)	Frees the memory associated with the TTabSet (see page 23159) object.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ItemAtPos (see page 23173)	Returns the index of the tab indicated by the coordinates of a point on the control.
	ItemRect (see page 23173)	Returns the rectangle that surrounds the item specified in the Item parameter.
	ItemWidth (see page 23174)	Returns the width, in pixels, of a specified tab in the set.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MinClientRect (see page 23174)	This is the overview for the MinClientRect method overload.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.

	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SelectNext (see page 23177)	Selects the next tab in a tab set control, scrolling if necessary to bring the selected tab into view.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	Canvas (see page 23183)	Specifies the TCanvas object that presents a drawing surface for the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.

R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
	FirstIndex (see page 23189)	Specifies the tab that appears in the leftmost visible position in the tab set control.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 23204)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 23204)	Occurs when an object with custom alignment is aligned.
	OnChange (see page 23205)	Occurs just before a new tab is selected.
	OnClick (see page 23205)	Occurs when the user clicks the control.
	OnDragDrop (see page 23207)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 23210)	Occurs when the user drags an object over a control.
	OnDrawTab (see page 23212)	Occurs when a tab in an owner-drawn tab set control needs to redisplay.
	OnEndDock (see page 23213)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 23213)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 23214)	Occurs when a control receives the input focus.
	OnExit (see page 23216)	Occurs when the input focus shifts away from one control to another.

	OnGetImageIndex (see page 23218)	This is OnGetImageIndex, a member of class TTabSet.
	OnMeasureTab (see page 23218)	Occurs when an application needs to redisplay a tab in an owner-draw tab set.
	OnMouseActivate (see page 23219)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 23220)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 23222)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 23222)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 23222)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 23225)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 23227)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 23228)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Published Properties

	Name	Description
	Align (see page 23178)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 23182)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 23182)	Determines if scroll buttons automatically appear in a tab set control if there isn't room in the control to display all the tabs.
	BackgroundColor (see page 23183)	Determines the background color of the tab set control.
	Constraints (see page 23185)	Specifies the size constraints for the control.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DitherBackground (see page 23186)	Determines whether the background color set with the BackgroundColor (see page 23183) property is dithered.
	DragCursor (see page 23186)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 23186)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 23187)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 23188)	Controls whether the control responds to mouse, keyboard, and timer events.
	EndMargin (see page 23189)	Determines how far, in pixels, the rightmost tab appears from the right edge of the tab set control.
	Font (see page 23190)	Controls the attributes of text written on or in the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Images (see page 23191)	This is Images, a member of class TTabSet.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	ParentBackground (see page 23191)	Determines whether control uses parent's theme background.
	ParentShowHint (see page 23191)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 23192)	Identifies the pop-up menu associated with the control.
	SelectedColor (see page 23197)	Determines the color of the selected tab in the tab set control.
	ShowHint (see page 23197)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	ShrinkToFit (see page 23198)	This is ShrinkToFit, a member of class TTabSet.
	SoftTop (see page 23199)	Specifies whether a line appears at the edge of the tab set, setting off the non-current tabs.

	StartMargin (see page 23199)	Determines how far, in pixels, the first tab appears from the left edge of the tab set control.
	Style (see page 23199)	Determines whether the tab set is owner-drawn.
	TabHeight (see page 23200)	Determines the height of the tabs in an owner-drawn tab set control.
	TabIndex (see page 23200)	Determines which tab of a tab set control is currently selected.
	TabPosition (see page 23201)	This is TabPosition, a member of class TTabSet.
	Tabs (see page 23201)	Contains the list of text strings that appear on the tabs.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	UnselectedColor (see page 23201)	Determines the color of the tabs that aren't currently selected in the tab set control.
	Visible (see page 23201)	Determines whether the component appears onscreen.
R	VisibleTabs (see page 23203)	Contains the number of tabs currently visible in the tab set control.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

161.1.3.2 TTabSet.Create Constructor

Constructs a tab set control.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TTabSet(TComponent * AOwner);
```

Description

Create sets the initial values of the control, including creating a TTabList (see page 23149) object that holds the list of tabs for the control. The AOwner parameter specifies the component (usually a form) that is responsible for freeing the tab set.

See Also

Destroy (see page 23170)

161.1.3.3 TTabSet.Destroy Destructor

Frees the memory associated with the TTabSet (see page 23159) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TTabSet();
```

Description

Do not call Destroy directly. Instead, use the Free method, which checks that the tab set is not nil before calling Destroy. Destroy frees the TTabList (see page 23149) object that holds the list of tabs.

See Also

Create (see page 23170)

Free (see page 22300)

161.1.3.4 TTabSet Methods

The methods of the TTabSet class are listed here.

Protected Methods

	Name	Description
	CanChange (see page 23171)	This is CanChange, a member of class TTabSet.
	CMHintShow (see page 23171)	This is CMHintShow, a member of class TTabSet.
V	CreateParams (see page 23172)	Initializes a window-creation parameter data structure.
V	DrawTab (see page 23172)	This is DrawTab, a member of class TTabSet.
V	GetChildren (see page 23172)	Calls a specified method for each child of the control.
V	GetImageIndex (see page 23173)	This is GetImageIndex, a member of class TTabSet.
V	MeasureTab (see page 23174)	This is MeasureTab, a member of class TTabSet.
V	MouseDown (see page 23175)	OnMouseDown event dispatcher.
V	Notification (see page 23176)	Responds to notifications that components are being created or destroyed.
V	Paint (see page 23176)	Renders the image of a custom control.
V	SetTabIndex (see page 23177)	This is SetTabIndex, a member of class TTabSet.

Public Methods

	Name	Description
	ItemAtPos (see page 23173)	Returns the index of the tab indicated by the coordinates of a point on the control.
	ItemRect (see page 23173)	Returns the rectangle that surrounds the item specified in the Item parameter.
	ItemWidth (see page 23174)	Returns the width, in pixels, of a specified tab in the set.
	MinClientRect (see page 23174)	This is the overview for the MinClientRect method overload.
	SelectNext (see page 23177)	Selects the next tab in a tab set control, scrolling if necessary to bring the selected tab into view.

161.1.3.4.1 TTabSet.CanChange Method

Pascal

```
function CanChange(NewIndex: Integer): Boolean;
```

C++

```
__fastcall Boolean CanChange(int NewIndex);
```

Description

This is CanChange, a member of class TTabSet.

161.1.3.4.2 TTabSet.CMHintShow Method

Pascal

```
procedure CMHintShow(var Message: TCMHintShow); message CM_HINTSHOW;
```

C++

```
__fastcall CMHintShow(TCMHintShow Message);
```

Description

This is CMHintShow, a member of class TTabSet.

161.1.3.4.3 TTabSet.CreateParams Method

Initializes a window-creation parameter data structure.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

The CreateWnd method calls CreateParams to initialize the parameters it passes to CreateWindowHandle. Override CreateParams to customize the way a control creates its Windows representation. When overriding CreateParams, always call the inherited method first to set the default values, then make any desired adjustments.

CreateParams fills in the parameter that is passed as the value of the Params parameter. This data structure holds information needed when telling Windows to create a window handle. The fields of a TCreateParams record become the parameters to a call to the CreateWindowEx API function.

TWinControl implements CreateParams by setting all the fields of Params to generic base values. A number of the standard controls override CreateParams to change one or more of the default values in Params.

See Also

CreateWindowHandle (see page 6137)

CreateWnd (see page 6137)

AddBiDiModeExStyle (see page 6128)

161.1.3.4.4 TTabSet.DrawTab Method

Pascal

```
procedure DrawTab(TabCanvas: TCanvas; R: TRect; Index: Integer; Selected: Boolean); virtual;
```

C++

```
virtual __fastcall DrawTab(TCanvas TabCanvas, TRect R, int Index, Boolean Selected);
```

Description

This is DrawTab, a member of class TTabSet.

161.1.3.4.5 TTabSet.GetChildren Method

Calls a specified method for each child of the control.

Pascal

```
procedure GetChildren(Proc: TGetChildProc; Root: TComponent); override;
```

C++

```
virtual __fastcall GetChildren(TGetChildProc Proc, TComponent * Root);
```

Description

GetChildren is called by the streaming system that loads and saves components. Applications seldom need to call this routine.

GetChildren executes the callback specified by the Proc parameter for every child control listed by the Controls property that lists the Root parameter as its Owner.

Override GetChildren to limit or augment which child controls are saved with the control. When overriding GetChildren, call the procedure passed as the Proc parameter for every child control that should be saved. The Root parameter indicates the component (usually a form) that owns the control.

See Also

Controls (see page 6197)

Owner (see page 2807)

161.1.3.4.6 TTabSet.GetImageIndex Method

Pascal

```
function GetImageIndex(TabIndex: Integer): Integer; virtual;
```

C++

```
virtual __fastcall int GetImageIndex(int TabIndex);
```

Description

This is GetImageIndex, a member of class TTabSet.

161.1.3.4.7 TTabSet.ItemAtPos Method

Returns the index of the tab indicated by the coordinates of a point on the control.

Pascal

```
function ItemAtPos(Pos: TPoint; IgnoreTabHeight: Boolean = False): Integer;
```

C++

```
__fastcall int ItemAtPos(TPoint Pos, Boolean IgnoreTabHeight = False);
```

Description

Call ItemAtPos to identify the tab under the point specified by the Pos parameter. Pos is the point in the control in client coordinates. If the returned index is 0, the tab is the first tab in the tab set, if the index is 1, the tab is the second tab, and so on. ItemAtPos returns –1 if there is no tab at the specified point.

See Also

ItemRect (see page 23173)

161.1.3.4.8 TTabSet.ItemRect Method

Returns the rectangle that surrounds the item specified in the Item parameter.

Pascal

```
function ItemRect(Index: Integer): TRect;
```

C++

```
__fastcall TRect ItemRect(int Index);
```

Description

Use ItemRect to obtain the rectangle that surrounds the tab when you are drawing on an owner-draw tab set.

See Also

ItemAtPos (see page 23173)

Style (see page 23199)

OnDrawTab (see page 23212)

OnMeasureTab (see page 23218)

161.1.3.4.9 TTabSet.ItemWidth Method

Returns the width, in pixels, of a specified tab in the set.

Pascal

```
function ItemWidth(Index: Integer): Integer;
```

C++

```
__fastcall int ItemWidth(int Index);
```

Description

Use ItemWidth to obtain the width, in pixels of a specified tab.

Index is the index of the tab, where 0 indicates the first tab, 1 indicates the second tab, and so on.

See Also

ItemAtPos (see page 23173)

ItemRect (see page 23173)

161.1.3.4.10 TTabSet.MeasureTab Method

Pascal

```
procedure MeasureTab(Index: Integer; var TabWidth: Integer); virtual;
```

C++

```
virtual __fastcall MeasureTab(int Index, int TabWidth);
```

Description

This is MeasureTab, a member of class TTabSet.

161.1.3.4.11 MinClientRect Method

This is the overview for the MinClientRect method overload.

Overload List

	Name	Description
	TTabSet.MinClientRect () (see page 23174)	Returns the boundaries that are required to display the tabs in the tab set.
	TTabSet.MinClientRect (Boolean) (see page 23174)	Returns the boundaries that are required to display the tabs in the tab set.
	TTabSet.MinClientRect (Integer, Boolean) (see page 23174)	Returns the boundaries that are required to display the tabs in the tab set.

161.1.3.4.11.1 TTabSet.MinClientRect Method ()

Returns the boundaries that are required to display the tabs in the tab set.

Pascal

```
function MinClientRect: TRect; overload;
function MinClientRect(IncludeScroller: Boolean): TRect; overload;
function MinClientRect(TabCount: Integer; IncludeScroller: Boolean = False): TRect; overload;
```

C++

```
__fastcall TRect MinClientRect();
__fastcall TRect MinClientRect(Boolean IncludeScroller);
__fastcall TRect MinClientRect(int TabCount, Boolean IncludeScroller = False);
```

Description

Use MinClientRect to obtain the minimum size that the tab set's client area must be to display its tabs and (if specified) a scroller for scrolling hidden tabs. MinClientRect calculates the width based on the widths of all the tabs up to a specified count, adding in the values of StartMargin (see page 23199) and EndMargin (see page 23189) and the space that appears between tabs. If requested, it also adds the width of a scroller for the tabs. It calculates the height based on the value of the TabHeight (see page 23200) property.

TabCount specifies the number of tabs to display. MinClientRect uses the widths of these tabs to calculate the width of the client rectangle. If you use a syntax that does not include a TabCount parameter, MinClientRect assumes that all tabs must be visible.

IncludeScroller indicates whether the client rectangle must include space for the scroller control that allows users to scroll the tabs, displaying any tabs that are not included in TabCount. If IncludeScroller is false, or if this parameter is omitted, MinClientRect does not include the width for the scroller in the resulting rectange.

MinClientRect returns the dimensions, in pixels, needed to display the specified number of tabs and, if specified, the scroller. The returned rectangle has an origin of 0,0.

See Also

TabHeight (see page 23200)

ItemWidth (see page 23174)

StartMargin (see page 23199)

EndMargin (see page 23189)

161.1.3.4.12 TTabSet.MouseDown Method

OnMouseDown event dispatcher.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

Override the protected MouseDown method to provide other responses in addition to calling the OnMouseDown event handler when the user presses the mouse button down while the cursor's hotspot is over the control.

The Button parameter determines which mouse button the user pressed. Shift indicates which shift keys (Shift, Ctrl, or Alt) were down when the user pressed the mouse button. X and Y are the pixel coordinates of the mouse pointer within the client area of the control.

A control calls MouseDown in response to any of the Windows mouse-down messages (WM_LBUTTONDOWN, WM_MBUTTONDOWN, WM_RBUTTONDOWN), decoding the message parameters into the shift-key state and position, which

it passes in the Shift, X, and Y parameters, respectively. The value of the Button parameter indicates which mouse button was pressed down: left, right, or middle.

See Also

MouseMove (see page 5773)

MouseUp (see page 5774)

OnMouseDown (see page 5862)

161.1.3.4.13 TTabSet.Notification Method

Responds to notifications that components are being created or destroyed.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Notification allows TControl to update its PopupMenu property when the pop-up menu it refers to is destroyed.

Override the Notification method to respond to notifications that other components are about to be destroyed or have just been created. Use the Notification method to update controls that rely on other objects. Remove references to objects that are going away so that the control does not refer to objects that have been destroyed. For example, data-aware objects override the Notification method to update themselves when their data source is removed. Some objects respond to notifications that other objects of a specific type are being created. For example, the session component sets the Session property of new data-aware controls to itself when the AutoSessionName property is true.

By default, components pass along the notification to their owned components, if any.

See Also

PopupMenu (see page 5835)

Notification (see page 2783)

161.1.3.4.14 TTabSet.Paint Method

Renders the image of a custom control.

Pascal

```
procedure Paint; override;
```

C++

```
virtual __fastcall Paint();
```

Description

The Paint method for TCustomControl does nothing other than provide the interface for a method that responds to WM_PAINT messages. Paint is called by the PaintWindow method, after that method has supplied the Canvas with the handle to a device context. When creating a custom control, always override Paint to draw the image of the control.

Tip: To determine which portions of the control's canvas need to be repainted when Paint is called, use the ClipRect property of the canvas.

See Also

Canvas (see page 5921)

PaintWindow (see page 5920)

GetDeviceContext (see page 6155)

ClipRect (see page 14486)

161.1.3.4.15 TTabSet.SelectNext Method

Selects the next tab in a tab set control, scrolling if necessary to bring the selected tab into view.

Pascal

```
procedure SelectNext(Direction: Boolean);
```

C++

```
__fastcall SelectNext(Boolean Direction);
```

Description

The value of the Direction parameters determines if the tab to the left or right is selected. If Direction is true, the tab to the right is selected. If Direction is false, the tab to the left is selected. When the last tab in either direction is selected, calling SelectNext using the same direction wraps around to the beginning of the tab order. For example, if your application has three tabs, First, Second, and Third, and Third is the current tab, calling SelectNext(true) selects First. Likewise, if First is the current tab, SelectNext(false) selects Third.

When SelectNext is called, the OnClick (see page 23205) event of the tab set occurs, followed by the OnChange (see page 23205) event, just as if the user had clicked on a new tab.

See Also

Tabs (see page 23201)

OnChange (see page 23205)

161.1.3.4.16 TTabSet.SetTabIndex Method

Pascal

```
procedure SetTabIndex(Value: Integer); virtual;
```

C++

```
virtual __fastcall SetTabIndex(int Value);
```

Description

This is SetTabIndex, a member of class TTabSet.

161.1.3.5 TTabSet Properties

The properties of the TTabSet class are listed here.

Protected Properties

	Name	Description
R	Scroller (see page 23196)	This is Scroller, a member of class TTabSet.

Public Properties

	Name	Description
	Canvas (see page 23183)	Specifies the TCanvas object that presents a drawing surface for the control.
	FirstIndex (see page 23189)	Specifies the tab that appears in the leftmost visible position in the tab set control.

Published Properties

	Name	Description
	Align (see page 23178)	Determines how the control aligns within its container (parent control).
	Anchors (see page 23182)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 23182)	Determines if scroll buttons automatically appear in a tab set control if there isn't room in the control to display all the tabs.
	BackgroundColor (see page 23183)	Determines the background color of the tab set control.
	Constraints (see page 23185)	Specifies the size constraints for the control.
	DitherBackground (see page 23186)	Determines whether the background color set with the BackgroundColor (see page 23183) property is dithered.
	DragCursor (see page 23186)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 23186)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 23187)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Enabled (see page 23188)	Controls whether the control responds to mouse, keyboard, and timer events.
	EndMargin (see page 23189)	Determines how far, in pixels, the rightmost tab appears from the right edge of the tab set control.
	Font (see page 23190)	Controls the attributes of text written on or in the control.
	Images (see page 23191)	This is Images, a member of class TTabSet.
	ParentBackground (see page 23191)	Determines whether control uses parent's theme background.
	ParentShowHint (see page 23191)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 23192)	Identifies the pop-up menu associated with the control.
	SelectedColor (see page 23197)	Determines the color of the selected tab in the tab set control.
	ShowHint (see page 23197)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	ShrinkToFit (see page 23198)	This is ShrinkToFit, a member of class TTabSet.
	SoftTop (see page 23199)	Specifies whether a line appears at the edge of the tab set, setting off the non-current tabs.
	StartMargin (see page 23199)	Determines how far, in pixels, the first tab appears from the left edge of the tab set control.
	Style (see page 23199)	Determines whether the tab set is owner-drawn.
	TabHeight (see page 23200)	Determines the height of the tabs in an owner-drawn tab set control.
	TabIndex (see page 23200)	Determines which tab of a tab set control is currently selected.
	TabPosition (see page 23201)	This is TabPosition, a member of class TTabSet.
	Tabs (see page 23201)	Contains the list of text strings that appear on the tabs.
	UnselectedColor (see page 23201)	Determines the color of the tabs that aren't currently selected in the tab set control.
	Visible (see page 23201)	Determines whether the component appears onscreen.
R	VisibleTabs (see page 23203)	Contains the number of tabs currently visible in the tab set control.

161.1.3.5.1 TTabSet.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
```

```
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);

    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
```

```
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
  { make sure the splitter is to the right of the directory list box! }
  Split.Left := Dirs.Left + Dirs.Width + 1;
  Split.Align := Dirs.Align; { give it the same alignment as the directory }
  { each pane must be at least one quarter of the form's width }
  Split.MinSize := Form1.ClientWidth div 4;
  { Finally, create the last pane – a file list box }
  Files := TFileListBox.Create(Form1);
  Files.Parent := Form1;
  Files.Align := alClient;
  Dirs.FileList := Files; { link the file list box to the directory list box }
end;
{
Dynamically create a TProgressBar control and align it to
the bottom of the form.
}

  i: Integer;
begin
  for i := Low(TabTitles) to High(TabTitles) do
  begin
    pts[i].Free;
  end;
  PageControl1.Free;
end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

161.1.3.5.2 TTabSet.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

161.1.3.5.3 TTabSet.AutoScroll Property

Determines if scroll buttons automatically appear in a tab set control if there isn't room in the control to display all the tabs.

Pascal

```
property AutoScroll: Boolean;
```

C++

```
__property Boolean AutoScroll;
```

Description

If AutoScroll is false, the application can still access tabs that aren't visible by using the FirstIndex (see page 23189) or TabIndex (see page 23200) properties at design time or runtime, but the user can't click on the tabs with the mouse at runtime.

See Also

FirstIndex (see page 23189)

TabIndex (see page 23200)

161.1.3.5.4 TTabSet.BackgroundColor Property

Determines the background color of the tab set control.

Pascal

```
property BackgroundColor: TColor;
```

C++

```
__property TColor BackgroundColor;
```

Description

Use BackgroundColor to indicate the color that the tab set control uses to paint the area between the tabs and the border of the control.

See Also

DitherBackground (see page 23186)

SelectedColor (see page 23197)

Color (see page 5812)

161.1.3.5.5 TTabSet.Canvas Property

Specifies the TCanvas object that presents a drawing surface for the control.

Pascal

```
property Canvas: TCanvas;
```

C++

```
__property TCanvas Canvas;
```

Description

Use the properties of the TCanvas object to draw or paint on the surface of the control. Canvas encapsulates a Windows device context, providing all the tools and methods needed for drawing and painting.

Canvas is a protected property that is usually redeclared as public in descendants of TCustomControl.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
```

```
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  ImageList1->Draw(DrawGrid1->Canvas,Rect.Left,Rect.Top,index);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(index) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}
//---------------------------------------------------------------------------
void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
/*
The following code uses ClientRect to find and draw a line
from the top left to the bottom right of the current
control.  Select a TControl in the ListBox list.  This
example assumes that the current object is a descendent of
TControl and has a public Canvas property.
*/
{
  TPoint APoint = Point(X, Y);
  int Index = ListBox1->ItemAtPos(APoint, True);
  TStringGrid *myStringGrid;
  TClass ClassRef = ListBox1->Items->Objects[Index]->ClassType();
  if (String(ClassRef->ClassName()) == "TStringGrid")
  {
    myStringGrid = (TStringGrid *)ListBox1->Items->Objects[Index];
    // make sure we are using the TControls canvas and not the from's!
    myStringGrid->Canvas->MoveTo(myStringGrid->ClientRect.Left, myStringGrid->ClientRect.Top);
    myStringGrid->Canvas->LineTo(myStringGrid->ClientRect.Right,
myStringGrid->ClientRect.Bottom);
    myStringGrid = NULL;
  }
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
```

```
    index := ARow * DrawGrid1.ColCount + ACol;
    DrawGrid1.Canvas.Brush.Color := clWhite;
    DrawGrid1.Canvas.FillRect(Rect);
    if (gdFocused in State) then
    begin
      DrawGrid1.Canvas.DrawFocusRect(Rect);
      Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
    end;
    ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  end;

  procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
    var CanSelect: Boolean);
  begin
    CanSelect:= True;
  end;
  {
  The following code uses ClientRect to find and draw a line
  from the top left to the bottom right of the current
  control.  Select a TControl in the ListBox list.  This
  example assumes that the current object is a descendent of
  TControl and has a public Canvas property.
  }
    if (ListBox1.Items.Objects[Index] is TStringGrid) then
    begin
      myStringGrid:= (ListBox1.Items.Objects[Index] as TStringGrid);
      with myStringGrid.ClientRect do
      begin // make sure we are using the TControl's canvas and not the form's!
        myStringGrid.Canvas.MoveTo(Left, Top);
        myStringGrid.Canvas.LineTo(Right, Bottom);
      end;
    myStringGrid:= nil;
    end;
```

Paint (see page 5920)

161.1.3.5.6 TTabSet.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

161.1.3.5.7 TTabSet.DitherBackground Property

Determines whether the background color set with the BackgroundColor (see page 23183) property is dithered.

Pascal

```
property DitherBackground: Boolean;
```

C++

```
__property Boolean DitherBackground;
```

Description

Dithering means the background is lightened by 50%, which is intended to make the tabs easier to see. If DitherBackground is true, the tab set control background is dithered. If it is false, there is no dithering.

See Also

BackgroundColor (see page 23183)

SelectedColor (see page 23197)

161.1.3.5.8 TTabSet.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

161.1.3.5.9 TTabSet.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

161.1.3.5.10 TTabSet.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
```

```
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

DragKind (see page 5819)

Arranging the Order of Persistent Columns

161.1.3.5.11 TTabSet.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

161.1.3.5.12 TTabSet.EndMargin Property

Determines how far, in pixels, the rightmost tab appears from the right edge of the tab set control.

Pascal

```
property EndMargin: Integer;
```

C++

```
__property int EndMargin;
```

Description

EndMargin determines how far in pixels the rightmost tab appears from the right edge of the tab set control. Together with the StartMargin (see page 23199) property, EndMargin can play a role in determining how many tabs can fit within the tab set control.

If AutoScroll (see page 23182) is true and scroll buttons appear in the tab set control, EndMargin determines how far in pixels the rightmost tab appears from the left edge of the scroll buttons, rather than the edge of the tab set control.

See Also

AutoScroll (see page 23182)

EndMargin

StartMargin (see page 23199)

161.1.3.5.13 TTabSet.FirstIndex Property

Specifies the tab that appears in the leftmost visible position in the tab set control.

Pascal

```
property FirstIndex: Integer;
```

C++

```
__property int FirstIndex;
```

Description

Any tabs with a lower value in the FirstIndex property scroll to the left in the tab set control and don't appear until the user scrolls the tabs.

The default value of FirstIndex is 0 indicating that the tab with an index of 0 is in the leftmost position. For example, if you have three tabs labeled First, Second, and Third with TabIndex (see page 23200) values of 0, 1, and 2, respectively, First appears first, by default, because it has an index value of 0. If you want to shift the tabs so the Second or Third tab appears leftmost in the tab set control, change the FirstIndex value to 1 or 2.

See Also

Tabs (see page 23201)

161.1.3.5.14 TTabSet.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;
```

```
procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

161.1.3.5.15 TTabSet.Images Property

Pascal

```
property Images: TCustomImageList;
```

C++

```
__property TCustomImageList Images;
```

Description

This is Images, a member of class TTabSet.

161.1.3.5.16 TTabSet.ParentBackground Property

Determines whether control uses parent's theme background.

Pascal

```
property ParentBackground: Boolean;
```

C++

```
__property Boolean ParentBackground;
```

Description

If ParentBackground is true, the control uses the parent's theme background to draw its own background. ParentBackground has no effect unless XP themes are enabled.

161.1.3.5.17 TTabSet.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

161.1.3.5.18 TTabSet.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
```

```
  else
    MessageBeep(0);
}

void __fastcall TForm1::Cut1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CutToClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}

void __fastcall TForm1::Paste1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->PasteFromClipboard();
    else
      MessageBeep(0);
  }
  else
    MessageBeep(0);
}
/*
This example demonstrates how to add and delete menu items
to a popup menu at runtime and assign an event handler to
the OnClick event.  Place a TPopupMenu and three buttons on
the form named "AddButton", "EditButton",  and
"DestroyButton" and add OnClick events to all three buttons.
Put the TPopupMenu in the PopupMenu property of the form.
Place the PopupMenuItemsClick procedure in the TForm1 type
declaration so that it can be used as the method call for
the menu item OnClick event.
*/
void __fastcall TForm1::AddButtonClick(TObject *Sender)
{
    const int num_items = 4;
    for (int index = 0; index < num_items; ++index)
    {
        TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
        PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
        NewItem->Caption = "Menu Item " + IntToStr(index);
        NewItem->Tag = index;
        NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
        TNotifyEvent();
    }
}

void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
{
    TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
    if (ClickedItem)
    {
        switch (ClickedItem->Tag)
        {
            case 0:
            {
                ShowMessage("first item clicked");
```

```
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
```

```
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.CutToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CutToClipboard
    else
      Beep;
  end;

  procedure TForm1.Paste1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.PasteFromClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.PasteFromClipboard
    else
      Beep;
  end;
  {
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  }

  type
    TForm1 = class(TForm)
      AddButton: TButton;
      EditButton: TButton;
      DestroyButton: TButton;
      PopupMenu1: TPopupMenu;
      procedure AddButtonClick(Sender: TObject);
      procedure EditButtonClick(Sender: TObject);
      procedure DestroyButtonClick(Sender: TObject);
      procedure FormDestroy(Sender: TObject);
    private
      { Private declarations }
    public
      procedure PopupMenuItemsClick(Sender: TObject);

    end;

  var
    Form1: TForm1;

  implementation

  {$R *.dfm}

  procedure TForm1.AddButtonClick(Sender: TObject);
  var
    index: Integer;
    NewItem: TMenuItem;
  begin
```

```
    for index := 0 to 3 do
    begin
      NewItem :=
        TMenuItem.Create(PopupMenu1); // create the new item
      PopupMenu1.Items.Add(NewItem);// add it to the Popupmenu
      NewItem.Caption := 'Menu Item ' + IntToStr(index);
      NewItem.Tag := index;
      NewItem.OnClick :=
        PopupMenuItemsClick; // assign it an event handler
    end;
  end;

  procedure TForm1.PopupMenuItemsClick(Sender: TObject);
  begin
    with Sender as TMenuItem do
    begin
      case Tag of
        0:  ShowMessage('first item clicked');
        1:  ShowMessage('second item clicked');
        2:  ShowMessage('third item clicked');
        3:  ShowMessage('fourth item clicked');
      end;
    end;
  end;

  {
  To edit or destroy an item, grab its pointer via the Items
  property.
  }
  procedure TForm1.EditButtonClick(Sender: TObject);
  var
    ItemToEdit: TMenuItem;
  begin
    ItemToEdit := PopupMenu.Items[1];
    ItemToEdit.Caption := 'Changed Caption';
  end;

  procedure TForm1.DestroyButtonClick(Sender: TObject);
  var
    ItemToDelete: TMenuItem;
  begin
    ItemToDelete := PopupMenu.Items[2];
    ItemToDelete.Free;
  end;
```

161.1.3.5.19 TTabSet.Scroller Property

Pascal

```
property Scroller: TScroller;
```

C++

```
__property TScroller Scroller;
```

Description

This is Scroller, a member of class TTabSet.

161.1.3.5.20 TTabSet.SelectedColor Property

Determines the color of the selected tab in the tab set control.

Pascal

```
property SelectedColor: TColor;
```

C++

```
__property TColor SelectedColor;
```

Description

SelectedColor determines the color of the selected tab in the tab set control.

See Also

BackgroundColor (see page 23183)

DitherBackground (see page 23186)

Color (see page 5812)

161.1.3.5.21 TTabSet.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
```

```
    for(int i = 1; i <= 10; i++)
    {
      strcpy(string, "Item");
      itoa(i, index, 10);
      strcat(string, index);
      ListBox1->Items->Add(string);
    }
    ListBox1->Hint = "Select an item";
    ListBox1->ShowHint = true;
    Application->ShowHint = true;
  }
  /*
  Note: To see an example that displays the hints of controls
  in some place other than in a Help Hint box, see the OnHint
  example.
  */
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}
```

161.1.3.5.22 TTabSet.ShrinkToFit Property

Pascal

```
property ShrinkToFit: Boolean;
```

C++

```
__property Boolean ShrinkToFit;
```

Description

This is ShrinkToFit, a member of class TTabSet.

161.1.3.5.23 TTabSet.SoftTop Property

Specifies whether a line appears at the edge of the tab set, setting off the non-current tabs.

Pascal

```
property SoftTop: Boolean;
```

C++

```
__property Boolean SoftTop;
```

Description

When SoftTop is false (the default), a line appears at the edge of the non-current tabs. When SoftTop is true, this line is not drawn, softening the border of the tab set.

161.1.3.5.24 TTabSet.StartMargin Property

Determines how far, in pixels, the first tab appears from the left edge of the tab set control.

Pascal

```
property StartMargin: Integer;
```

C++

```
__property int StartMargin;
```

Description

Together with the EndMargin (see page 23189) property, StartMargin determines how many tabs fit in the tab set control.

See Also

EndMargin (see page 23189)

161.1.3.5.25 TTabSet.Style Property

Determines whether the tab set is owner-drawn.

Pascal

```
property Style: TTabStyle;
```

C++

```
__property TTabStyle Style;
```

Description

Owner-draw tabs can display objects other than strings, such as graphical images. Owner-draw tabs require more programming, however, because the application needs information on how to render the image for each tab in the tab set control.

Each time an item is displayed in an owner-drawn tab, two events occur. The first is the OnMeasureTab (see page 23218) event. In the OnMeasureTab (see page 23218) event handler, you write the code that calculates the width of the tab needed to hold the text or graphical image. After the OnMeasureTab (see page 23218) event, the OnDrawTab (see page 23212) event occurs. The code you write for the OnDrawTab (see page 23212) event draws the tab and its contents using the width found with the OnMeasureTab (see page 23218) event and the height specified as the value of the TabHeight (see page 23200) property.

Note: The TTabStyle (see page 23234) type defined in the tabs unit for the Style property differs from the TTabStyle (see page 23234) type defined in the comctrls unit. Do not to use or include the comctrls unit in source files where you are working with the tab control. Doing so can lead to compiler errors because of type mismatches.

See Also

TabHeight (see page 23200)

OnDrawTab (see page 23212)

OnMeasureTab (see page 23218)

161.1.3.5.26 TTabSet.TabHeight Property

Determines the height of the tabs in an owner-drawn tab set control.

Pascal

```
property TabHeight: Integer;
```

C++

```
__property int TabHeight;
```

Description

If the Style (see page 23199) property value is tsStandard, the TabHeight property value is ignored. If the Style (see page 23199) property value is tsOwnerDraw, TabHeight is the height of the tabs.

See Also

Style (see page 23199)

161.1.3.5.27 TTabSet.TabIndex Property

Determines which tab of a tab set control is currently selected.

Pascal

```
property TabIndex: Integer;
```

C++

```
__property int TabIndex;
```

Description

The value of TabIndex can be from –1 to one less than the number of strings in the Tabs (see page 23201) property array (Count – 1). TabIndex is an index to the Tabs (see page 23201) array property: A value of 0 indicates the first tab in the tab set control, 1 is the second tab, and so on. If no tabs are selected, TabIndex has a value of –1.

When a value is assigned to TabIndex, the OnClick (see page 23205) event for the tab set occurs, followed by the OnChange (see page 23205) event, just as if the user had clicked on a new tab.

See Also

Tabs (see page 23201)

OnChange (see page 23205)

OnClick (see page 5851)

161.1.3.5.28 TTabSet.TabPosition Property

Pascal

```
property TabPosition: TTabPosition;
```

C++

```
__property TTabPosition TabPosition;
```

Description

This is TabPosition, a member of class TTabSet.

161.1.3.5.29 TTabSet.Tabs Property

Contains the list of text strings that appear on the tabs.

Pascal

```
property Tabs: TStrings;
```

C++

```
__property TStrings Tabs;
```

Description

For each string in the Tabs property, a new tab is created to display the text string. At design time, you enter the text strings you want to appear on the tabs using the String List editor. Double-click the value column of the Tabs property to display the String List editor. You can also change strings in the Tabs property at runtime.

See Also

VisibleTabs (see page 23203)

161.1.3.5.30 TTabSet.UnselectedColor Property

Determines the color of the tabs that aren't currently selected in the tab set control.

Pascal

```
property UnselectedColor: TColor;
```

C++

```
__property TColor UnselectedColor;
```

Description

UnselectedColor determines the color of the tabs that aren't currently selected in the tab set control.

See Also

BackgroundColor (see page 23183)

SelectedColor (see page 23197)

161.1.3.5.31 TTabSet.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
```

```
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

Enabled (see page 5821)

Hide (see page 5769)

Show (see page 5788)

VisibleChanging (see page 5791)

161.1.3.5.32 TTabSet.VisibleTabs Property

Contains the number of tabs currently visible in the tab set control.

Pascal

```
property VisibleTabs: Integer;
```

C++

```
__property int VisibleTabs;
```

Description

Use VisibleTabs to determine how many tabs are visible in the tab set.

See Also

Tabs (see page 23201)

161.1.3.6 TTabSet Events

The events of the TTabSet class are listed here.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 23204)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 23204)	Occurs when an object with custom alignment is aligned.
	OnChange (see page 23205)	Occurs just before a new tab is selected.
	OnClick (see page 23205)	Occurs when the user clicks the control.
	OnDragDrop (see page 23207)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 23210)	Occurs when the user drags an object over a control.
	OnDrawTab (see page 23212)	Occurs when a tab in an owner-drawn tab set control needs to redisplay.
	OnEndDock (see page 23213)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

	OnEndDrag (see page 23213)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 23214)	Occurs when a control receives the input focus.
	OnExit (see page 23216)	Occurs when the input focus shifts away from one control to another.
	OnGetImageIndex (see page 23218)	This is OnGetImageIndex, a member of class TTabSet.
	OnMeasureTab (see page 23218)	Occurs when an application needs to redisplay a tab in an owner-draw tab set.
	OnMouseActivate (see page 23219)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 23220)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 23222)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 23222)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 23222)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 23225)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnStartDock (see page 23227)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 23228)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

161.1.3.6.1 TTabSet.OnAlignInsertBefore Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignInsertBefore: TAlignInsertBeforeEvent;
```

C++

```
__property TAlignInsertBeforeEvent OnAlignInsertBefore;
```

Description

OnAlignInsertBefore occurs for each pair of child controls with an Align property of **alCustom**.

It can determine the order in which custom-aligned child controls are placed. OnAlignInsertBefore returns true if **C2** should be presented before **C1**, and false otherwise. It holds a TAlignInsertBeforeEvent type.

CustomAlignInsertBefore triggers the OnAlignInsertBefore event. If this event is defined, CustomAlignInsertBefore returns the value returned by OnAlignInsertBefore. Defining this event allows users to define the order of control alignment without overriding CustomAlignInsertBefore.

See Also

CustomAlignInsertBefore (see page 6137)

Align (see page 5798)

TAlignInsertBeforeEvent (see page 6293)

161.1.3.6.2 TTabSet.OnAlignPosition Event

Occurs when an object with custom alignment is aligned.

Pascal

```
property OnAlignPosition: TAlignPositionEvent;
```

C++

```
__property TAlignPositionEvent OnAlignPosition;
```

Description

OnAlignPosition occurs when child controls with an Align property of **alCustom** are aligned.

CustomAlignPosition triggers the OnAlignPosition event. If this event is defined, CustomAlignPosition uses the alignment parameters it obtains from OnAlignPosition. Defining this event allows users to set the alignment parameters without overriding CustomAlignPosition. It holds a TAlignPositionEvent type.

These are the parameters:

Parameter	Meaning
NewLeft | NewTop | NewWidth | NewHeight	Location and size of child control, as determined by container's size and the Anchors TControl_Anchors constraints for the control. OnAlignPosition can modify these values to reposition the control.
AlignRect	The client area in which the control is aligned. OnAlignPosition can modify this value.
AlignInfo	Alignment information in a TAlignInfo.
As implemented in TWinControl, OnAlignPosition does nothing.	

See Also

CustomAlignPosition (see page 6138)

Align (see page 5798)

Anchors (see page 5802)

TAlignInfo (see page 6269)

TAlignPositionEvent (see page 6293)

161.1.3.6.3 TTabSet.OnChange Event

Occurs just before a new tab is selected.

Pascal

```
property OnChange: TTabChangeEvent;
```

C++

```
__property TTabChangeEvent OnChange;
```

Description

OnChange occurs just as the TabIndex (see page 23200) value is about to change. To prevent the TabIndex (see page 23200) value from changing, set AllowChange to false in the OnChange event handler.

161.1.3.6.4 TTabSet.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
```

```
  edit control placed somewhere on the client area of the
  sheet.  Unchecking the checkbox will cause the client area
  (not the tab area) of the Tab Control to become invisible.
  }
  procedure TForm1.CheckBox1Click(Sender: TObject);
  begin
    PageControl1.ActivePage.Visible := CheckBox1.Checked;
  end;

  procedure TForm1.PageControl1Change(Sender: TObject);
  begin
    CheckBox1.Checked := PageControl1.ActivePage.Visible;
  end;

  procedure TForm1.FormCreate(Sender: TObject);
  var
    i: Integer;
  begin
    for i := 0 to 9 do
      with TTabSheet.Create(Self) do
      begin
        PageControl := PageControl1;
        Caption := 'TabSheet' + IntToStr(i);
        with TEdit.Create(Self) do
        begin
          Parent := PageControl1.Pages[i];
          Left := Random(PageControl1.ActivePage.ClientWidth - Width);
          Top := Random(PageControl1.ActivePage.ClientHeight - Height);
        end;
      end;
      PageControl1Change(Sender);
  end;
```

161.1.3.6.5 TTabSet.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
```

```
    Accept := False;
    if (Source is TLabel) and (State = dsDragEnter) then
      (Source as TLabel).EndDrag(False);
  end;
  {
  This code comes from an application that contains a list box
  and three labels, each with a different font and color.  The
  DragMode property for each of the labels is dmAutomatic.
  The user can select a label and drag it to a list box and
  drop it. When the label is dropped, the items in the list
  box assume the color and font of the dropped label.
  }

  procedure TForm1.FormCreate(Sender: TObject);
  begin
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

161.1.3.6.6 TTabSet.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
```

```
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
```

```
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

161.1.3.6.7 TTabSet.OnDrawTab Event

Occurs when a tab in an owner-drawn tab set control needs to redisplay.

Pascal

```
property OnDrawTab: TDrawTabEvent;
```

C++

```
__property TDrawTabEvent OnDrawTab;
```

Description

OnDrawTab occurs when a tab redisplays if the Style (see page 23199) property value is tsOwnerDraw. For example, it happens when the user selects a tab or scrolls the tabs.

You must write the code in the OnDrawTab event handler to draw the tab.

OnDrawTab occurs just after the OnMeasureTab (see page 23218) event, which contains the code to calculate the width of the tab needed. The height of the tab is determined by the value of the TabHeight (see page 23200) property of the tab set control. The code you write in the OnDrawTab event handler, therefore, must use the width determined with the OnMeasureTab (see page 23218) event to draw the tab.

Style (see page 23199)

161.1.3.6.8 TTabSet.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

OnStartDock (see page 5871)

161.1.3.6.9 TTabSet.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
```

```
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

161.1.3.6.10 TTabSet.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
```

```
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
```

```
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

161.1.3.6.11 TTabSet.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
```

```
  inactive, the color of the control returns to the Windows
  system color for a window.  These event handlers could also
  be shared.
  }
  procedure TForm1.Edit1Enter(Sender: TObject);
  begin
    Edit1.Color := clYellow;
  end;

  procedure TForm1.Edit1Exit(Sender: TObject);
  begin
    Edit1.Color := clWindow;
  end;

  procedure TForm1.Memo1Enter(Sender: TObject);
  begin
    Memo1.Color := clYellow;
  end;

  procedure TForm1.Memo1Exit(Sender: TObject);
  begin
    Memo1.Color := clWindow;
  end;
```

161.1.3.6.12 TTabSet.OnGetImageIndex Event

Pascal

```
property OnGetImageIndex: TTabGetImageEvent;
```

C++

```
__property TTabGetImageEvent OnGetImageIndex;
```

Description

This is OnGetImageIndex, a member of class TTabSet.

161.1.3.6.13 TTabSet.OnMeasureTab Event

Occurs when an application needs to redisplay a tab in an owner-draw tab set.

Pascal

```
property OnMeasureTab: TMeasureTabEvent;
```

C++

```
__property TMeasureTabEvent OnMeasureTab;
```

Description

OnMeasureTab occurs only if the Style (see page 23199) property is tsOwnerDraw. In the OnMeasureTab event handler, write the code to calculate the width needed to draw the tab. Your code is responsible for calculating and returning the tab width, depending on what you have drawn in the tab (if the tab is of Style (see page 23199) tsOwnerDraw). After the OnMeasureTab event occurs, the OnDrawTab (see page 23212) event occurs, when the OnDrawTab (see page 23212) event handler draws the tab using the width calculated in OnMeasureTab.

See Also

TabHeight (see page 23200)

OnDrawTab (see page 23212)

161.1.3.6.14 TTabSet.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

161.1.3.6.15 TTabSet.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
```

```
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

161.1.3.6.16 TTabSet.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

161.1.3.6.17 TTabSet.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

161.1.3.6.18 TTabSet.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form’s unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
```

```
      }
      else
      {
        StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
        StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
      }
    }
  }
```

161.1.3.6.19 TTabSet.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a

Responding to a Mouse-up Action

161.1.3.6.20 TTabSet.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

161.1.3.6.21 TTabSet.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

161.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TEdgePart (see page 23229)	This is record Tabs.TEdgePart.
	TEdgeType (see page 23229)	This is record Tabs.TEdgeType.
	TScrollBtn (see page 23230)	This is record Tabs.TScrollBtn.
	TScrollOrientation (see page 23230)	This is record Tabs.TScrollOrientation.
	TTabSetTabStyle (see page 23231)	This is record Tabs.TTabSetTabStyle.

161.2.1 Tabs.TEdgePart Enumeration

Pascal

```
TEdgePart = (
  epSelectedLeft,
  epUnselectedLeft,
  epSelectedRight,
  epUnselectedRight
);
```

C++

```
enum TEdgePart {
  epSelectedLeft,
  epUnselectedLeft,
  epSelectedRight,
  epUnselectedRight
};
```

File

Tabs

Description

This is record Tabs.TEdgePart.

161.2.2 Tabs.TEdgeType Enumeration

Pascal

```
TEdgeType = (
  etNone,
  etFirstIsSel,
  etFirstNotSel,
  etLastIsSel,
  etLastNotSel,
  etNotSelToSel,
  etSelToNotSel,
  etNotSelToNotSel
```

```
);
```

C++

```
enum TEdgeType {
  etNone,
  etFirstIsSel,
  etFirstNotSel,
  etLastIsSel,
  etLastNotSel,
  etNotSelToSel,
  etSelToNotSel,
  etNotSelToNotSel
};
```

File

Tabs

Description

This is record Tabs.TEdgeType.

161.2.3 Tabs.TScrollBtn Enumeration

Pascal

```
TScrollBtn = (
  sbLeft,
  sbRight
);
```

C++

```
enum TScrollBtn {
  sbLeft,
  sbRight
};
```

File

Tabs

Description

This is record Tabs.TScrollBtn.

161.2.4 Tabs.TScrollOrientation Enumeration

Pascal

```
TScrollOrientation = (
  soLeftRight,
  soUpDown
);
```

C++

```
enum TScrollOrientation {
  soLeftRight,
  soUpDown
};
```

File

Tabs

Description

This is record Tabs.TScrollOrientation.

161.2.5 Tabs.TTabSetTabStyle Enumeration

Pascal

```
TTabSetTabStyle = (
  tsStandard,
  tsOwnerDraw,
  tsSoftTabs,
  tsModernTabs,
  tsModernPopout
);
```

C++

```
enum TTabSetTabStyle {
  tsStandard,
  tsOwnerDraw,
  tsSoftTabs,
  tsModernTabs,
  tsModernPopout
};
```

File

Tabs

Description

This is record Tabs.TTabSetTabStyle.

161.3 Types

The following table lists types in this documentation.

Types

Name	Description
TDrawTabEvent (see page 23232)	TDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 23159) control.
TMeasureTabEvent (see page 23232)	TMeasureTabEvent is the type for event handlers that indicate the size of the tabs in an owner-drawn TTabSet (see page 23159) control.
TTabChangeEvent (see page 23233)	TTabChangeEvent is the type for event handlers that respond when the current tab of a TTabSet (see page 23159) control changes.
TTabSetDrawTabEvent (see page 23233)	TTabSetDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 23159) control.
TTabStyle (see page 23234)	TTabStyle indicates whether a TTabSet (see page 23159) control is owner-drawn.

161.3.1 Tabs.TDrawTabEvent Type

TDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 23159) control.

Pascal

```
TDrawTabEvent = TTabSetDrawTabEvent;
```

C++

```
TTabSetDrawTabEvent TDrawTabEvent;
```

File

Tabs

Description

TDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 23159) control.

Note: The TDrawTabEvent type defined in the tabs unit for the OnDrawTab event handler differs from the TDrawTabEvent type defined in the comctrls unit. Do not use the comctrls unit in source files where you are working with the tab control.

161.3.2 Tabs.TMeasureTabEvent Type

TMeasureTabEvent is the type for event handlers that indicate the size of the tabs in an owner-drawn TTabSet (see page 23159) control.

Pascal

```
TMeasureTabEvent = procedure (Sender: TObject; Index: Integer; var TabWidth: Integer) of
object;
```

C++

```
(Sender: TObject; Index: Integer; var TabWidth: Integer) ( TMeasureTabEvent)();
```

File

Tabs

Description

Sender is the TTabSet (see page 23159) control whose tab is about to be drawn.

Index identifies the position of the tab in the tab set control.

TabWidth is the width of the tab.

161.3.3 Tabs.TTabChangeEvent Type

TTabChangeEvent is the type for event handlers that respond when the current tab of a TTabSet (see page 23159) control changes.

Pascal

```
TTabChangeEvent = procedure (Sender: TObject; NewTab: Integer; var AllowChange: Boolean) of
object;
```

C++

```
(Sender: TObject; NewTab: Integer; var AllowChange: Boolean) ( TTabChangeEvent)();
```

File

Tabs

Description

Sender is the TTabSet (see page 23159) control whose tab is about to change.

NewTab is the tab that is about to become the selected tab.

AllowChange determines whether the change is permitted. If the event handler sets AllowChange to false, the user won't be able to select the new tab, in effect disabling it.

161.3.4 Tabs.TTabSetDrawTabEvent Type

TTabSetDrawTabEvent is the type for event handlers that render the tab of an owner-drawn TTabSet (see page 23159) control.

Pascal

```
TTabSetDrawTabEvent = procedure (Sender: TObject; TabCanvas: TCanvas; R: TRect; Index:
Integer; Selected: Boolean) of object;
```

C++

```
(Sender: TObject; TabCanvas: TCanvas; R: TRect; Index: Integer; Selected: Boolean) (
TTabSetDrawTabEvent)();
```

File

Tabs

Description

TabCanvas is the canvas on which the item is drawn.

Index is the position of the tab in the tab set control.

R is the area in the tab where the item is to be drawn.

Selected indicates whether the tab is currently selected.

161.3.5 Tabs.TTabStyle Type

TTabStyle indicates whether a TTabSet (see page 23159) control is owner-drawn.

Pascal

```
TTabStyle = TTabSetTabStyle;
```

C++

```
TTabSetTabStyle TTabStyle;
```

File

Tabs

Description

These are the possible values:

Value	Meaning
tsStandard	Each tab has the standard size and look.

tsOwnerDrawEach tab has the height specified with the TabHeight property and width needed to hold the text or glyph.

162 TConnect Namespace

This is namespace TConnect.

Topics

Name	Description
Classes (see page 23236)	The following table lists classes in this documentation.

Classes

	Name	Description
	TLocalConnection (see page 23236)	TLocalConnection represents the connection between a client dataset or XML broker and a provider that resides in the same application.

162.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TLocalConnection (see page 23236)	TLocalConnection represents the connection between a client dataset or XML broker and a provider that resides in the same application.

162.1.1 TLocalConnection Class

TLocalConnection represents the connection between a client dataset or XML broker and a provider that resides in the same application.

Class Hierarchy

Pascal

```
TLocalConnection = class(TCustomRemoteServer, IAppServer, ISupportErrorInfo);
```

C++

```
class TLocalConnection : public TCustomRemoteServer, public IAppServer, public
ISupportErrorInfo;
```

File

TConnect

Description

Use TLocalConnection to manage the connection between one or more client datasets or XML brokers and the providers that reside in the same application. When working with local providers, it is not necessary to set the RemoteServer property of a client dataset or XML broker to a TLocalConnection component. However, using TLocalConnection lets your application communicate directly with local providers through the AppServer (see page 23250) property. This provides access to methods that would otherwise be unavailable, and makes it easier to scale up to a multi-tiered application at a later time.

TLocalConnection implements the IAppServer interface.

Warning: TLocalConnection only links clients to providers that are instances of TDataSetProvider.

162.1.1.1 TLocalConnection Members

The following tables list the members exposed by TLocalConnection.

Protected Events

	Name	Description
	OnGetUsername (see page 8533)	This is OnGetUsername, a member of class TCustomRemoteServer.

Protected Fields

	Name	Description
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	AS_ApplyUpdates (see page 23242)	Applies updates received from a client dataset using a specified provider.
	AS_DataRequest (see page 23242)	Generates an OnAS_DataRequest event on the specified provider component.
	AS_Execute (see page 23243)	AS_Executes the query or stored procedure bound to a specified provider.
	AS_GetParams (see page 23244)	Fetches current parameter values from the dataset bound to a specified provider.
	AS_GetProviderNames (see page 23245)	Returns a list of all the available providers on a remote data module.
	AS_GetRecords (see page 23245)	Returns a data packet that contains the specified data.
	AS_RowRequest (see page 23246)	Returns information from a specified record of the provider's dataset.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DoConnect (see page 6864)	Provides the interface for a method that opens a connection.
V	DoDisconnect (see page 6864)	Provides the interface for a method that terminates the connection.
V	GetAppServer (see page 8530)	Returns the value of the AppServer (see page 8532) property.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetConnected (see page 23247)	Returns the value of the Connected property.
V	GetDataSet (see page 6865)	Returns a dataset, given its index in the DataSets (see page 6870) property array.

	GetDataSetCount (see page 6865)	Returns the value of the DataSetCount (see page 6869) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetProvider (see page 23247)	This is GetProvider, a member of class TLocalConnection.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InterfaceSupportsErrorInfo (see page 23248)	This is InterfaceSupportsErrorInfo, a member of class TLocalConnection.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 6866)	Initializes the connection component after all objects in the form or data module have been loaded.
	Notification (see page 23248)	Forwards notification messages to all owned components.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	RegisterClient (see page 6866)	Registers an object that uses the connection component.
	RegisterProvider (see page 23249)	This is RegisterProvider, a member of class TLocalConnection.
	SendConnectEvent (see page 6867)	Informs all registered clients that use the connection component when a connection is opened or closed.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAppServer (see page 8531)	Sets the AppServer (see page 8532) property.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetConnected (see page 6867)	Changes the value of the Connected (see page 6868) property.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	UnRegisterClient (see page 6868)	Removes a registered client so that it is no longer associated with the connection component.
	UnRegisterProvider (see page 23250)	This is UnRegisterProvider, a member of class TLocalConnection.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	StreamedConnected (see page 6874)	Indicates whether the Connected (see page 6868) property was true when the connection component was loaded from a stream.

Public Events

	Name	Description
	AfterConnect (see page 6874)	Occurs after a connection is established.
	AfterDisconnect (see page 6875)	Occurs after the connection closes.

	BeforeConnect (see page 6875)	Occurs immediately before establishing a connection.
	BeforeDisconnect (see page 6875)	Occurs immediately before the connection closes.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Close (see page 6863)	Closes the connection.
V	Create (see page 23240)	Creates and initializes a local connection component.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 23241)	Frees an instance of TLocalConnection (see page 23236).
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetIDsOfNames (see page 22395)	This is GetIDsOfNames, a member of class IDispatch.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetProviderNames (see page 23248)	Executes a callback for all provider objects on the application server.
V	GetServer (see page 23248)	Returns the IAppServer interface for communicating with local providers.
V	GetServerList (see page 8531)	Returns a list of application servers (remote data modules) to which the component can connect.
	GetTypeInfo (see page 22395)	This is GetTypeInfo, a member of class IDispatch.
	GetTypeInfoCount (see page 22395)	This is GetTypeInfoCount, a member of class IDispatch.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.

	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invoke (see page 22395)	This is Invoke, a member of class IDispatch.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	Open (see page 6866)	Opens the connection.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	SafeCallException (see page 23249)	Handles exceptions in methods declared using the safecall calling convention.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.

Public Properties

	Name	Description
R	AppServer (see page 23250)	Provides access to the IAppServer interface that handles communication with providers.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Connected (see page 6868)	Determines whether a connection has been established to the remote source of data.
R	DataSetCount (see page 6869)	Indicates the number of datasets associated with the connection component.
R	DataSets (see page 6870)	Lists the datasets currently using this connection component.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
	LoginPrompt (see page 6872)	Specifies whether a login dialog appears immediately before opening a new connection.
	OnLogin (see page 6873)	Occurs when a communication channel opens to the server.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
R	ProviderCount (see page 23250)	Indicates the number of providers in the Providers (see page 23251) property list.
R	Providers (see page 23251)	Lists the local providers with which this local connection component can communicate.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

Published Properties

	Name	Description
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.

162.1.1.2 TLocalConnection.Create Constructor

Creates and initializes a local connection component.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TLocalConnection(TComponent * AOwner);
```

Description

Call Create to instantiate TLocalConnection (see page 23236) at runtime. TLocalConnection (see page 23236) components placed in forms or data modules at design time are created automatically.

The AOwner parameter specifies the component (usually the form or data module) that is responsible for freeing the TLocalConnection (see page 23236) instance.

See Also

Owner (see page 2807)

162.1.1.3 TLocalConnection.Destroy Destructor

Frees an instance of TLocalConnection (see page 23236).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TLocalConnection();
```

Description

Do not call Destroy directly in an application. Instead, call Free, which checks that the TLocalConnection (see page 23236) reference is not nil before calling the destructor.

See Also

Free (see page 22300)

162.1.1.4 TLocalConnection Methods

The methods of the TLocalConnection class are listed here.

Protected Methods

	Name	Description
	AS_ApplyUpdates (see page 23242)	Applies updates received from a client dataset using a specified provider.
	AS_DataRequest (see page 23242)	Generates an OnAS_DataRequest event on the specified provider component.
	AS_Execute (see page 23243)	AS_Executes the query or stored procedure bound to a specified provider.
	AS_GetParams (see page 23244)	Fetches current parameter values from the dataset bound to a specified provider.
	AS_GetProviderNames (see page 23245)	Returns a list of all the available providers on a remote data module.
	AS_GetRecords (see page 23245)	Returns a data packet that contains the specified data.
	AS_RowRequest (see page 23246)	Returns information from a specified record of the provider's dataset.
V	GetConnected (see page 23247)	Returns the value of the Connected property.
V	GetProvider (see page 23247)	This is GetProvider, a member of class TLocalConnection.
	InterfaceSupportsErrorInfo (see page 23248)	This is InterfaceSupportsErrorInfo, a member of class TLocalConnection.
V	Notification (see page 23248)	Forwards notification messages to all owned components.
	RegisterProvider (see page 23249)	This is RegisterProvider, a member of class TLocalConnection.
	UnRegisterProvider (see page 23250)	This is UnRegisterProvider, a member of class TLocalConnection.

Public Methods

	Name	Description
	GetProviderNames (see page 23248)	Executes a callback for all provider objects on the application server.
	GetServer (see page 23248)	Returns the IAppServer interface for communicating with local providers.
	SafeCallException (see page 23249)	Handles exceptions in methods declared using the safecall calling convention.

162.1.1.4.1 TLocalConnection.AS_ApplyUpdates Method

Applies updates received from a client dataset using a specified provider.

Pascal

```
function AS_ApplyUpdates(const ProviderName: WideString; Delta: OleVariant; MaxErrors:
Integer; out ErrorCount: Integer; var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_ApplyUpdates(const BSTR ProviderName, OleVariant Delta, int
MaxErrors, int ErrorCount, OleVariant OwnerData);
```

Description

AS_AS_ApplyUpdates writes client updates to a dataset or database server.

ProviderName specifies the name of the provider component that manages the update operation.

Delta is a Variant containing the updated, inserted, and deleted records to write to the database.

MaxErrors indicates the maximum number of errors to permit before stopping the update operation.

ErrorCount returns the actual number of errors encountered during the update operation.

OwnerData is information supplied by the client application in a BeforeAS_ApplyUpdates event handler and returned to the client application in an AfterAS_ApplyUpdates event handler.

AS_AS_ApplyUpdates (Delphi) or AS_ApplyUpdates_result parameter (C++) returns a Variant that is a data packet containing all records that could not be applied to the database.

See Also

ApplyUpdates (see page 8394)

applyupdates (see page 18459)

BeforeApplyUpdates (see page 18479)

AfterApplyUpdates (see page 18475)

BeforeApplyUpdates (see page 8511)

AfterApplyUpdates (see page 8497)

AS_ApplyUpdates (see page 6590)

as_applyupdates (see page 19892)

Communicating with the Client Dataset

162.1.1.4.2 TLocalConnection.AS_DataRequest Method

Generates an OnAS_DataRequest event on the specified provider component.

Pascal

```
function AS_DataRequest(const ProviderName: WideString; Data: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_DataRequest(const BSTR ProviderName, OleVariant Data);
```

Description

Use AS_AS_DataRequest to invoke an OnAS_DataRequest event handler of the provider named by ProviderName. This method is provided to allow application developers to customize the communication between a client application and a provider component. There is no predefined meaning for the Data parameter or the return value (Delphi) or the AS_DataRequest_result parameter (C++), which is returned to the caller.

See Also

OnDataRequest (see page 18482)

DataRequest (see page 8404)

Communicating with the Client Dataset

162.1.1.4.3 TLocalConnection.AS_Execute Method

AS_Executes the query or stored procedure bound to a specified provider.

Pascal

```
procedure AS_Execute(const ProviderName: WideString; const CommandText: WideString; var
Params: OleVariant; var OwnerData: OleVariant); safecall;
```

C++

```
__fastcall AS_Execute(const BSTR ProviderName, const BSTR CommandText, OleVariant Params,
OleVariant OwnerData);
```

Description

Use AS_AS_Execute to pass an execute command to a remote provider, using a specified set of parameters. AS_AS_Execute calls the AS_Execute method of the specified provider after assigning any parameters. Output parameters that result from executing a query or stored procedure are returned in the Params parameter.

The provider's AS_Execute method generates a BeforeAS_Execute event, passes the command on to its associated dataset, and generates an AfterAS_Execute event. The dataset must represent a query or stored procedure that does not return a cursor.

The ProviderName parameter specifies the name of the provider component associated with the query or stored procedure.

CommandText specifies an optional SQL statement that replaces the SQL of the query, or the name of a stored procedure that replaces the dataset's stored procedure. This parameter is ignored if the provider's Options property does not include poAllowCommandText.

The Params parameter encodes any parameters expected by the query or stored procedure and returns any output parameters. To create a properly encoded value for Params from a TParams object, use the PackageParams routine. To decode Params into a TParams object, use the Unpackparams routine.

The OwnerData parameter contains custom information that appears as an argument to the provider's BeforeAS_Execute and AfterAS_Execute event handlers. This information originates in a client dataset's BeforeAS_Execute event handler. The value returned in OwnerData is passed to the client dataset's AfterAS_Execute event handler.

Execute (see page 18466)

BeforeExecute (see page 8514)

AfterExecute (see page 8504)

Options (see page 18440)

PackageParams (see page 8534)

UnpackParams (see page 8534)

Communicating with the Client Dataset

162.1.1.4.4 TLocalConnection.AS_GetParams Method

Fetches current parameter values from the dataset bound to a specified provider.

Pascal

```
function AS_GetParams(const ProviderName: WideString; var OwnerData: OleVariant): OleVariant;
safecall;
```

C++

```
__fastcall OleVariant AS_GetParams(const BSTR ProviderName, OleVariant OwnerData);
```

Description

Use AS_AS_GetParams to retrieve the current parameter values from the dataset associated with a provider.

The ProviderName parameter specifies the name of the provider component whose dataset has the parameters.

The OwnerData represents custom information that originates in a client dataset's BeforeAS_GetParams event handler and returns information that is passed to the client dataset's AfterAS_GetParams event handler.

AS_GetParams_result (C++) or AS_AS_GetParams (Delphi) returns the parameters, encoded as a Variant array, where each element is a 2-element Variant array containing a parameter name and a parameter value. These parameters can be converted to a TParams object using the UnpackParams procedure. If the dataset has no parameters, or if the provider does not support parameter fetching, AS_GetParams_result (C++) or AS_AS_GetParams (Delphi) returns a Null Variant.

Note: AS_AS_GetParams should not be used to retrieve output parameters from stateless application servers, because parameter values may be changed by other applications. When writing a stateless application server, retrieve parameter values using the AS_Execute method instead.

AS_Execute (see page 16453)

UnpackParams (see page 8534)

Communicating with the Client Dataset

162.1.1.4.5 TLocalConnection.AS_GetProviderNames Method

Returns a list of all the available providers on a remote data module.

Pascal

```
function AS_GetProviderNames: OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetProviderNames();
```

Description

Call AS_AS_GetProviderNames for a list of all providers available from a remote data module. These values indicate the possible values for the ProviderName property of a client dataset that uses the IAppServer interface of an application server. When calling any other IAppServer method, pass one of these names to indicate the provider that is the target of the method call.

AS_AS_GetProviderNames returns the names of the providers in a Variant array. Client datasets are associated with a provider by setting their ProviderName property to one of these names.

See Also

providers (see page 6599)

ProviderName (see page 8492)

Providers (see page 19908)

Communicating with the Client Dataset

162.1.1.4.6 TLocalConnection.AS_GetRecords Method

Returns a data packet that contains the specified data.

Pascal

```
function AS_GetRecords(const ProviderName: WideString; Count: Integer; out RecsOut: Integer;
Options: Integer; const CommandText: WideString; var Params: OleVariant; var OwnerData:
OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_GetRecords(const BSTR ProviderName, int Count, int RecsOut, int
Options, const BSTR CommandText, OleVariant Params, OleVariant OwnerData);
```

Description

Call AS_AS_GetRecords to retrieve a specified number of records. AS_GetRecords returns the requested records, starting with the current record of the provider's dataset. When working with a stateless remote data module, you may need to reposition the cursor or re-execute a query or stored procedure in the provider's BeforeAS_GetRecords event handler.

ProviderName gives the name of the provider component that provides the records.

Count indicates the number or type of records to retrieve. If Count is -1, all records are retrieved. If Count is 0, only metadata is retrieved. If Count is greater than 0, only Count records are retrieved.

RecsOut returns the actual number of records retrieved.

Options indicates what information should be added to the data packet in addition to data. It is a combination of the GetRecordOption constants. For example, the following value requests metadata along with a data packet encoded in XML:

```
MetaDataOption + XMLOption
MetaDataOption || XMLOption
```

CommandText specifies an optional SQL statement that replaces the SQL of a query, or the name of a table or stored procedure that replaces the provider's table or stored procedure. This parameter is ignored if the Options property does not include poAllowCommandText.

Params is a Variant containing any parameters that should be passed to the provider's dataset before it executes to generate the requested data. It returns any output parameters. You can convert between the Variant format for parameters used by this argument and a TParams object using the global PackageParams and UnpackParams routines.

OwnerData contains custom information that is supplied by a client dataset's BeforeAS_GetRecords event handler. This information is passed to the provider's BeforeAS_GetRecords event handler. OwnerData returns information supplied by the provider's AfterAS_GetRecords event handler.

Records are returned as a data packet in a Variantparameter, AS_GetRecords_result (C++).

PackageParams (see page 8534)

UnpackParams (see page 8534)

Communicating with the Client Dataset

162.1.1.4.7 TLocalConnection.AS_RowRequest Method

Returns information from a specified record of the provider's dataset.

Pascal

```
function AS_RowRequest(const ProviderName: WideString; Row: OleVariant; RequestType: Integer;
var OwnerData: OleVariant): OleVariant; safecall;
```

C++

```
__fastcall OleVariant AS_RowRequest(const BSTR ProviderName, OleVariant Row, int RequestType,
OleVariant OwnerData);
```

Description

Client datasets call AS_AS_RowRequest automatically to implement their FetchBlobs, FetchDetails , or RefreshRecord method.

The ProviderName parameter indicates the provider associated with the dataset from which information should be fetched.

The Row parameter is an OleVariant that describes the current record on the client dataset.

The RequestType parameter indicates the type of information required. It is an integer version of the TFetchOptions type. (An integer because the value may be marshaled to a remote application server). To create a value for RequestType, take the corresponding TFetchOptions value, cast it to a Byte, and cast the result to an Integer:

```
Integer(Byte([foBlobs, foDetails]));
(int) (Byte) (TFetchOptions() << foBlobs << foDetails);
```

OwnerData contains custom information that is supplied by a client dataset's BeforeAS_RowRequest event handler. This information is passed to the provider's BeforeAS_RowRequest event handler. OwnerData returns custom information supplied by the provider's AfterAS_RowRequest event handler.

The requested data is returned as a delta packet in AS_RowRequest_result (C++).

RowRequest (see page 18472)

BeforeRowRequest (see page 18482)

AfterRowRequest (see page 18478)

FetchBlobs (see page 8414)

FetchDetails (see page 8414)

RefreshRecord (see page 8442)

Communicating with the Client Dataset

162.1.1.4.8 TLocalConnection.GetConnected Method

Returns the value of the Connected property.

Pascal

```
function GetConnected: Boolean; override;
```

C++

```
virtual __fastcall Boolean GetConnected();
```

Description

GetConnected is the protected read implementation of the Connected property. Descendant classes override this method to return true if a connection is open and false otherwise. As defined in TCustomConnection, GetConnected always returns false.

See Also

Connected (see page 6868)

SetConnected (see page 6867)

162.1.1.4.9 TLocalConnection.GetProvider Method

Pascal

```
function GetProvider(const ProviderName: string): TCustomProvider; virtual;
```

C++

```
virtual __fastcall TCustomProvider GetProvider(const AnsiString ProviderName);
```

Description

This is GetProvider, a member of class TLocalConnection.

162.1.1.4.10 TLocalConnection.GetProviderNames Method

Executes a callback for all provider objects on the application server.

Pascal

```
procedure GetProviderNames(Proc: TGetStrProc); override;
```

C++

```
virtual __fastcall GetProviderNames(TGetStrProc Proc);
```

Description

Call GetProviderNames to execute the procedure specified by the Proc parameter for every provider exposed by the application server. For every provider listed by the remote data module's AS_GetProviderNames method, Proc is called with the name of the provider.

See Also

AS_GetProviderNames (see page 16454)

AppServer (see page 8532)

ProviderName (see page 8492)

162.1.1.4.11 TLocalConnection.GetServer Method

Returns the IAppServer interface for communicating with local providers.

Pascal

```
function GetServer: IAppServer; override;
```

C++

```
virtual __fastcall IAppServer GetServer();
```

Description

GetServer returns the value of the AppServer (see page 23250) property.

See Also

AppServer (see page 23250)

162.1.1.4.12 TLocalConnection.InterfaceSupportsErrorInfo Method

Pascal

```
function InterfaceSupportsErrorInfo(const iid: TIID): HResult; stdcall;
```

C++

```
__fastcall __stdcall HRESULT InterfaceSupportsErrorInfo(const TIID iid);
```

Description

This is InterfaceSupportsErrorInfo, a member of class TLocalConnection.

162.1.1.4.13 TLocalConnection.Notification Method

Forwards notification messages to all owned components.

Pascal

```
procedure Notification(AComponent: TComponent; Operation: TOperation); override;
```

C++

```
virtual __fastcall Notification(TComponent * AComponent, TOperation Operation);
```

Description

Do not call the Notification method in an application. Notification is called automatically when the component specified by AComponent is about to be inserted or removed, as specified by Operation. By default, components pass along the notification to their owned components, if any.

A component can, if needed, act on the notification that a component is being inserted or removed. For example, if a component has object fields or properties that contain references to other components, it can check the notifications of component removals and invalidate those references as needed.

Note: Notification is not called for components that are freed implicitly (because their Owner is freed).

See Also

FreeNotification (see page 2775)

InsertComponent (see page 2780)

RemoveComponent (see page 2785)

Owner (see page 2807)

162.1.1.4.14 TLocalConnection.RegisterProvider Method

Pascal

```
procedure RegisterProvider(Prov: TCustomProvider);
```

C++

```
__fastcall RegisterProvider(TCustomProvider Prov);
```

Description

This is RegisterProvider, a member of class TLocalConnection.

162.1.1.4.15 TLocalConnection.SafeCallException Method

Handles exceptions in methods declared using the safecall calling convention.

Pascal

```
function SafeCallException(ExceptObject: TObject; ExceptAddr: Pointer): HResult; override;
```

C++

```
virtual __fastcall HRESULT SafeCallException(TObject * ExceptObject, void * ExceptAddr);
```

Description

SafeCallException handles exceptions in methods that use the safecall calling convention. Some classes that implement interfaces override this method to handle errors that might occur. TComponent calls the implementation of this method for the interface supported by the component, if it exists. If the component does not support interfaces, this method calls the SafeCallException method inherited from TObject, which returns E_UNEXPECTED. This is a default return value that is appropriate for classes that do not support any interfaces.

See Also

SafeCallException

162.1.1.4.16 TLocalConnection.UnRegisterProvider Method

Pascal

```
procedure UnRegisterProvider(Prov: TCustomProvider);
```

C++

```
__fastcall UnRegisterProvider(TCustomProvider Prov);
```

Description

This is UnRegisterProvider, a member of class TLocalConnection.

162.1.1.5 TLocalConnection Properties

The properties of the TLocalConnection class are listed here.

Public Properties

	Name	Description
R	AppServer (see page 23250)	Provides access to the IAppServer interface that handles communication with providers.
R	ProviderCount (see page 23250)	Indicates the number of providers in the Providers (see page 23251) property list.
R	Providers (see page 23251)	Lists the local providers with which this local connection component can communicate.

162.1.1.5.1 TLocalConnection.AppServer Property

Provides access to the IAppServer interface that handles communication with providers.

Pascal

```
property AppServer: IAppServer;
```

C++

```
__property IAppServer AppServer;
```

Description

Use AppServer to make explicit IAppServer calls to communicate with the local providers. The IAppServer interface lets you call provider methods that are otherwise unavailable because they are protected.

See Also

Providers (see page 23251)

AppServer (see page 8462)

162.1.1.5.2 TLocalConnection.ProviderCount Property

Indicates the number of providers in the Providers (see page 23251) property list.

Pascal

```
property ProviderCount: integer;
```

C++

```
__property int ProviderCount;
```

Description

Read ProviderCount to determine the number of local providers. This is the number of entries in the Providers (see page 23251) property list.

See Also

Providers (see page 23251)

162.1.1.5.3 TLocalConnection.Providers Property

Lists the local providers with which this local connection component can communicate.

Pascal

```
property Providers [const ProviderName: string]: TCustomProvider;
```

C++

```
__property TCustomProvider Providers[AnsiString const ProviderName];
```

Description

Providers provides access to the local providers that are available through the IAppServer interface. Providers only lists the providers whose Exported property is set to true.

ProviderName is the name of a provider. If you specify a name of a provider that is not listed, TLocalConnection (see page 23236) raises an exception.

See Also

ProviderCount (see page 23250)

AppServer (see page 23250)

Exported (see page 18474)

163 ToolWin Namespace

This is namespace ToolWin.

Topics

Name	Description
Classes (see page 23254)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 23289)	The following table lists structs, records, enums in this documentation.
Types (see page 23292)	The following table lists types in this documentation.

Classes

	Name	Description
	TToolDockForm (see page 23254)	TToolDockForm is a default floating dock site class for tool buttons.
	TToolDockObject (see page 23271)	Handles drag-and-dock operations for toolbar controls.
	TToolWindow (see page 23274)	TToolWindow is the ancestor for windowed controls that require a custom client area and edge borders.

Structs, Records, Enums

	Name	Description
	TEdgeBorder (see page 23289)	TEdgeBorders (see page 23292) is the type of the EdgeBorders property.
	TEdgeStyle (see page 23290)	TEdgeStyle describes the appearance of an edge border.
	TSizingOrientation (see page 23290)	TSizingOrientation specifies the dimension along which a control's size is adjusted when docked.

Types

Name	Description
TEdgeBorders (see page 23292)	This is type ToolWin.TEdgeBorders.

163.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TToolDockForm (see page 23254)	TToolDockForm is a default floating dock site class for tool buttons.
	TToolDockObject (see page 23271)	Handles drag-and-dock operations for toolbar controls.
	TToolWindow (see page 23274)	TToolWindow is the ancestor for windowed controls that require a custom client area and edge borders.

163.1.1 TToolDockForm Class

TToolDockForm is a default floating dock site class for tool buttons.

Class Hierarchy

Pascal

```
TToolDockForm = class(TCustomDockForm);
```

C++

```
class TToolDockForm : public TCustomDockForm;
```

File

ToolWin

Description

Assign TToolDockForm to the FloatingDockSiteClass property of tool buttons to get appropriate docking behavior.

163.1.1.1 TToolDockForm Members

The following tables list the members exposed by TToolDockForm.

Protected Events

	Name	Description
	OnActivate (see page 13943)	Occurs when the form becomes active.
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnCanResize (see page 13947)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnClick (see page 13947)	Occurs when the user clicks the control.
	OnClose (see page 13949)	Occurs when the form closes.

	OnCloseQuery (see page 13950)	Occurs when close is attempted.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnCreate (see page 13951)	Occurs when the form is created.
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDblClick (see page 13953)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDeactivate (see page 13953)	Occurs when the form loses focus.
	OnDestroy (see page 13953)	Occurs when the form is destroyed.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragDrop (see page 13954)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnDragOver (see page 13957)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnHelp (see page 13959)	Occurs when the form receives a request for help.
	OnHide (see page 13960)	Occurs when the form is hidden (that is, when its Visible (see page 13940) property is set to false).
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyDown (see page 13962)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyPress (see page 13964)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnKeyUp (see page 13966)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseActivate (see page 13967)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseDown (see page 13968)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseMove (see page 13971)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseUp (see page 13973)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnPaint (see page 13975)	Occurs when the form is redrawn.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnResize (see page 13976)	Occurs immediately after the control is resized.
	OnShortCut (see page 13977)	Occurs when the user presses a key (before the OnKeyDown (see page 13962) event).

	OnShow (see page 13977)	Occurs when the form is shown (that is, when its Visible (see page 13940) property is set to true).
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FFormState (see page 13863)	This is FFormState, a member of class TCustomForm.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	Activate (see page 13865)	Activation event dispatcher.
	ActiveChanged (see page 13865)	Active (see page 13896) state event dispatcher.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
V	AdjustClientRect (see page 14324)	Adjusts the ClientRect property to exclude the scroll bars.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
V	AlignControls (see page 13866)	Aligns all child controls of the form that fall within a specified rectangle.
V	AlignControls (see page 14325)	Aligns the controls in the scrolling windowed control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
V	AutoScrollEnabled (see page 14325)	Indicates whether automatic scrolling is enabled.
V	AutoScrollInView (see page 14325)	Scrolls a control into the visible area of the scrolling windowed control.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
V	BeginAutoDrag (see page 13867)	Responds when the user starts dragging the form if DragMode is dmAutomatic.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.

	CanResize (see page 23269)	Specifies whether the control can resize itself.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	ChangeScale (see page 13867)	Repositions and resizes the form by the ratio M/D, adjusting its client area and font size as needed.
	ChangeScale (see page 14326)	Resizes the scrolling windowed control by a specific ratio.
	Click (see page 5743)	Respond to user click.
	CloseModal (see page 13868)	This is CloseModal, a member of class TCustomForm.
	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
	CreateHandle (see page 6135)	Creates underlying screen object.
	CreateParams (see page 23269)	Initializes the window-creation parameter record when the form window is created.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWindowHandle (see page 13869)	Creates a form window given a set of window-creation parameters.
	CreateWnd (see page 6137)	Creates the underlying window.
	CreateWnd (see page 13869)	Creates the form window.
	CreateWnd (see page 14327)	Creates a Windows control corresponding to the TScrollingWinControl (see page 14312) object.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	Deactivate (see page 13870)	Generates an OnDeactivate (see page 13953) event.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DefineProperties (see page 13871)	Designates methods for storing a form's unpublished data on a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyHandle (see page 13871)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWindowHandle (see page 13872)	Destroys the window created in the CreateWindowHandle (see page 13869) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 23269)	Performs actions when a control is docked to the form.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoClose (see page 13873)	Form closing event dispatcher.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoCreate (see page 13873)	Form creation event dispatcher.
	DoDestroy (see page 13873)	Form destruction event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDock (see page 13874)	Docking event dispatcher.

	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
V	DoFlipChildren (see page 14327)	Flips the control's children.
	DoHide (see page 13874)	Form hide event dispatcher.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
V	DoRemoveDockClient (see page 13844)	Performs actions when a control is undocked from the dock form.
	DoShow (see page 13875)	Form show event dispatcher.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
V	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
V	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetBorderIconStyles (see page 13875)	This is GetBorderIconStyles, a member of class TCustomForm.
	GetBorderStyles (see page 13876)	This is GetBorderStyles, a member of class TCustomForm.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetChildren (see page 13876)	Returns the "child" components of the form; that is, those components that return the form from their GetParentComponent method.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetClientRect (see page 13876)	Returns the value of the ClientRect property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloating (see page 13877)	Returns the value of the Floating property.

	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetOwnerWindow (see page 13878)	This is GetOwnerWindow, a member of class TCustomForm.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetSiteInfo (see page 13844)	Returns docking information for the dock form.
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HandleCreateException (see page 13878)	Handles exceptions that are raised by the OnCreate (see page 13951) event handler.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	Loaded (see page 13845)	Specifies actions to perform when the dock form is loaded.
	Loaded (see page 13880)	Performs fix-ups when the form is first loaded into memory.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
	Notification (see page 2783)	Forwards notification messages to all owned components.
	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	Notification (see page 13882)	Responds to notifications that objects are about to be inserted or removed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	Paint (see page 13882)	Generates an OnPaint (see page 13975) event.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaintWindow (see page 13882)	Renders the image of the form.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteChanged (see page 13883)	Responds to changes in the system's palette by realizing the control's palette as returned from GetPalette.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.

	QueryInterface (see page 13884)	Returns a reference to a specified interface if that interface is supported by the form.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	ReadState (see page 13884)	Reads the form's published properties, stored data, and owned components from a reader object.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	RequestAlign (see page 13885)	Instructs the form's parent (if any) to reposition the form, enforcing its Align property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	Resizing (see page 13885)	Makes any required adjustments when the form changes size.
	Resizing (see page 14328)	This is Resizing, a member of class TScrollingWinControl.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetChildOrder (see page 13886)	Changes the order in which Child appears when GetChildren (see page 13876) is called.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParent (see page 13887)	Sets the Parent property.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentBiDiMode (see page 13887)	Sets the ParentBiDiMode property.
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.

V	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
V	ShowControl (see page 6183)	Ensures that a specified child control is visible.
V	UpdateActions (see page 13891)	Updates all actions associated with the form.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
V	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
V	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	UpdateWindowState (see page 13892)	Updates the WindowState (see page 13942) property to reflect the current state of the form.
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
V	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
V	ValidateRename (see page 13892)	Determines if a form can rename one of its owned components.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
V	VisibleChanging (see page 13893)	Responds just before the form changes the value of its Visible (see page 13940) property.
	WMNCCreate (see page 23270)	This is WMNCCreate, a member of class TToolDockForm.
	WMNCHitTest (see page 23270)	This is WMNCHitTest, a member of class TToolDockForm.
	WMNCLButtonDown (see page 23270)	This is WMNCLButtonDown, a member of class TToolDockForm.
	WMSize (see page 23270)	This is WMSize, a member of class TToolDockForm.
	WMSysCommand (see page 23271)	This is WMSysCommand, a member of class TToolDockForm.
V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WndProc (see page 13893)	Provides specific message responses for the form.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
R	ActiveMDIChild (see page 13897)	Specifies the MDI child that has focus.
	AlphaBlend (see page 13898)	Specifies whether the form is translucent.
	AlphaBlendValue (see page 13898)	Specifies the degree of translucency on a translucent form.
	AutoScroll (see page 13899)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoScroll (see page 14329)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderIcons (see page 13899)	Specifies which icons appear on the title bar of the form.
	BorderWidth (see page 6195)	Specifies the width of the control's border.

	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
R	ClientHandle (see page 13904)	Provides access to the handle of the form's internal MDI client window.
W	ClientHeight (see page 13905)	Specifies the height (in pixels) of the form's client area.
W	ClientWidth (see page 13905)	Specifies the width (in pixels) of the form's client area.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Ctl3D (see page 13909)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultMonitor (see page 13909)	Specifies the monitor on which the form appears.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	FormStyle (see page 13912)	Determines the form's style.
	Height (see page 13915)	Specifies the vertical size of the control in pixels.
	HorzScrollBar (see page 13916)	Represents the horizontal scroll bar for the scrolling windowed control.
	Icon (see page 13917)	Specifies the icon that appears when the form is minimized.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
R	MDIChildCount (see page 13921)	Specifies the number of open MDI child forms.
R	MDIChildren (see page 13922)	Provides indexed access to all MDI child forms.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ObjectMenuItem (see page 13926)	Represents an OLE object menu item that reacts to selections of OLE objects.
	OldCreateOrder (see page 13926)	Specifies when OnCreate (see page 13951) and OnDestroy (see page 13953) events occur.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentFont (see page 13927)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.
	PixelsPerInch (see page 13928)	Represents the proportion of the font on the system on which the form was designed.
R	PopupChildren (see page 13928)	This is PopupChildren, a member of class TCustomForm.
	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	PopupMenu (see page 13928)	Identifies the pop-up menu associated with the control.
	Position (see page 13933)	Represents the size and placement of the form.
	PrintScale (see page 13934)	Represents the proportions of a printed form.
	Scaled (see page 13935)	Specifies whether the form is sized according to the value of the PixelsPerInch (see page 13928) property.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	TileMode (see page 13936)	Represents how MDI child forms are arranged when the Tile method is called.
	TransparentColor (see page 13938)	Specifies whether a color on the form appears transparent.
	TransparentColorValue (see page 13939)	Indicates the color on the form that appears transparent when TransparentColor (see page 13938) is true.
	VertScrollBar (see page 13939)	Represents the vertical scroll bar for the scrolling windowed control.
W	Visible (see page 13940)	Indicates whether the form is visible.

	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	Width (see page 13941)	Specifies the horizontal size of the control or form in pixels.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowMenu (see page 13941)	Specifies the Window menu for an MDI parent form.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 13866)	Construction event dispatcher.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 13866)	Destruction event dispatcher.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	Close (see page 13867)	Closes the form.
V	CloseQuery (see page 13868)	Close (see page 13867) attempt event dispatcher.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 23268)	Creates an instance of TToolDockForm (see page 23254).
V	CreateNew (see page 13862)	Creates and initializes a new form.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 13870)	Provides message handling for all messages that the form does not fully process.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DefocusControl (see page 13871)	Removes focus from a control on the form.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 13862)	Removes the form from memory.
V	Destroy (see page 14323)	Removes the TScrollingWinControl (see page 14312) object from memory.
V	Destroy (see page 22287)	Disposes of an object instance.

	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	DisableAutoRange (see page 14327)	Disables automatic scrolling.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
V	Dock (see page 13872)	Handles automatic docking of the form into other windows.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EnableAutoRange (see page 14328)	Reenables automatic scrolling.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	FocusControl (see page 13875)	Sets focus to a control on the form.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetFormImage (see page 13877)	Returns a bitmap of the form.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	Hide (see page 13879)	Hides the form.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.

	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	IsShortCut (see page 13880)	Processes shortcut keys when the form has focus.
	MakeFullyVisible (see page 13881)	Ensures that the form is fully visible on a specified monitor.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	MouseWheelHandler (see page 13881)	Directs mouse wheel messages to the appropriate control.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	Print (see page 13883)	Prints the form.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	RecreateAsPopup (see page 13884)	This is RecreateAsPopup, a member of class TCustomForm.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	Release (see page 13885)	Destroys the form and frees its associated memory.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	ScrollInView (see page 14328)	Scrolls a control into the visible area of the scrolling windowed control.
	SendCancelMode (see page 13886)	Cancels modes on the form.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
	SetDesignVisible (see page 6178)	Makes a control visible at design time.
	SetFocus (see page 6179)	Gives the input focus to the control.

V	SetFocus (see page 13886)	Sets focus to the form.
V	SetFocusedControl (see page 13887)	Sets focus to a control on the form.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
	Show (see page 13888)	Shows the form.
V	ShowModal (see page 13890)	Shows a form as a modal dialog.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UpdateGlassFrame (see page 13892)	This is UpdateGlassFrame, a member of class TCustomForm.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.
V	WantChildKey (see page 13893)	Indicates whether the form processes keyboard input for a control it owns.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Action (see page 13895)	Designates the action associated with the control.
R	Active (see page 13896)	Specifies whether the form has focus.
	ActiveControl (see page 13896)	Specifies the control that has focus on the form.
	ActiveOleControl (see page 13897)	Specifies the OLE control on the form that reacts to changes in focus.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	AutoScroll (see page 13845)	Indicates whether scroll bars appear automatically on the scrolling windowed control if it is not large enough to display all of its controls.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 13846)	Specifies the appearance and behavior of the form border.
	BorderStyle (see page 13900)	Specifies the appearance and behavior of the form border.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
R	Canvas (see page 13900)	Provides access to the drawing area of the form.
	Caption (see page 13902)	Specifies a text string that identifies the control to the user.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
	Color (see page 13908)	Specifies the background color of the control.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.

	Designer (see page 13910)	Specifies the designer interface for the form.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	DropTarget (see page 13910)	Specifies whether the form is the target of a drag-and-drop operation.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	Font (see page 13910)	Controls the attributes of text written on or in the control.
R	FormState (see page 13911)	Indicates transitional state information about the form.
	FormStyle (see page 13846)	Determines the form's style.
	GlassFrame (see page 13914)	This is GlassFrame, a member of class TCustomForm.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HelpFile (see page 13916)	Specifies the name of the file the form uses to display Help.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	KeyPreview (see page 13918)	Specifies whether the form should receive keyboard events before the active control.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
	Menu (see page 13923)	Specifies the form's main menu.
	ModalResult (see page 13924)	Represents the return value of a form that is used as a modal dialog.
R	Monitor (see page 13926)	Provides access to the monitor on which the form appears.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
	OleFormObject (see page 13927)	Specifies the IOleForm (see page 14340) interface for an in-place OLE object contained in the form.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	PopupMode (see page 13933)	This is PopupMode, a member of class TCustomForm.
	PopupParent (see page 13933)	Sets an order for stacked forms that users cannot change.
	ScreenSnap (see page 13935)	Specifies whether form snaps to edge of screen.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	SnapBuffer (see page 13936)	Specifies distance for screen snap.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.
	WindowState (see page 13942)	Represents how the form appears on the screen.

Published Events

	Name	Description
	OnAlignInsertBefore (see page 14332)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 14332)	Occurs when an object with custom alignment is aligned.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	HorzScrollBar (see page 14329)	Represents the horizontal scroll bar for the scrolling windowed control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Left (see page 13920)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	PixelsPerInch (see page 13848)	Represents the proportion of the font on the system on which the form was designed.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Top (see page 13937)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	VertScrollBar (see page 14330)	Represents the vertical scroll bar for the scrolling windowed control.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

163.1.1.2 TToolDockForm.Create Constructor

Creates an instance of TToolDockForm (see page 23254).

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TToolDockForm(TComponent * AOwner);
```

Description

AOwner is the dock form's owner, which is responsible for freeing the tool dock form.

The constructor initializes the BorderWidth property to 1.

See Also

BorderWidth (see page 6195)

Owner (see page 2807)

163.1.1.3 TToolDockForm Methods

The methods of the TToolDockForm class are listed here.

Protected Methods

	Name	Description
	CanResize (see page 23269)	Specifies whether the control can resize itself.
	CreateParams (see page 23269)	Initializes the window-creation parameter record when the form window is created.
	DoAddDockClient (see page 23269)	Performs actions when a control is docked to the form.
	WMNCCreate (see page 23270)	This is WMNCCreate, a member of class TToolDockForm.
	WMNCHitTest (see page 23270)	This is WMNCHitTest, a member of class TToolDockForm.
	WMNCLButtonDown (see page 23270)	This is WMNCLButtonDown, a member of class TToolDockForm.
	WMSize (see page 23270)	This is WMSize, a member of class TToolDockForm.
	WMSysCommand (see page 23271)	This is WMSysCommand, a member of class TToolDockForm.

163.1.1.3.1 TToolDockForm.CanResize Method

Specifies whether the control can resize itself.

Pascal

```
function CanResize(var NewWidth: Integer; var NewHeight: Integer): Boolean; override;
```

C++

```
virtual __fastcall Boolean CanResize(int NewWidth, int NewHeight);
```

Description

CanResize is called automatically when an attempt is made to resize the control, after any autosizing has occurred. The NewWidth and NewHeight parameters specify the attempted new values for the control's height and width. CanResize optionally adjusts the values of NewWidth and NewHeight, and returns true if the control can be resized to the returned values. CanResize returns false if the control can't be resized.

163.1.1.3.2 TToolDockForm.CreateParams Method

Initializes the window-creation parameter record when the form window is created.

Pascal

```
procedure CreateParams(var Params: TCreateParams); override;
```

C++

```
virtual __fastcall CreateParams(TCreateParams Params);
```

Description

CreateParams calls the inherited CreateParams method, and then adds WS_POPUP to the Style property.

163.1.1.3.3 TToolDockForm.DoAddDockClient Method

Performs actions when a control is docked to the form.

Pascal

```
procedure DoAddDockClient(Client: TControl; const ARect: TRect); override;
```

C++

```
virtual __fastcall DoAddDockClient(TControl * Client, const TRect ARect);
```

Description

DoAddDockClient sets the client's Align property to alNone and its BoundsRect property to ClientRect. Then DoAddDockClient calls the inherited DoAddDockClient method and sets the form's AutoSize property to true.

163.1.1.3.4 TToolDockForm.WMNCCreate Method

Pascal

```
procedure WMNCCreate(var Message: TWMNCCreate); message WM_NCCREATE;
```

C++

```
__fastcall WMNCCreate(TWMNCCreate Message);
```

Description

This is WMNCCreate, a member of class TToolDockForm.

163.1.1.3.5 TToolDockForm.WMNCHitTest Method

Pascal

```
procedure WMNCHitTest(var Message: TWMNCHitTest); message WM_NCHITTEST;
```

C++

```
__fastcall WMNCHitTest(TWMNCHitTest Message);
```

Description

This is WMNCHitTest, a member of class TToolDockForm.

163.1.1.3.6 TToolDockForm.WMNCLButtonDown Method

Pascal

```
procedure WMNCLButtonDown(var Message: TWMNCLButtonDown); message WM_NCLBUTTONDOWN;
```

C++

```
__fastcall WMNCLButtonDown(TWMNCLButtonDown Message);
```

Description

This is WMNCLButtonDown, a member of class TToolDockForm.

163.1.1.3.7 TToolDockForm.WMSize Method

Pascal

```
procedure WMSize(var Message: TWMSize); message WM_SIZE;
```

C++

```
__fastcall WMSize(TWMSize Message);
```

Description

This is WMSize, a member of class TToolDockForm.

163.1.1.3.8 TToolDockForm.WMSysCommand Method

Pascal

```
procedure WMSysCommand(var Message: TWMSysCommand); message WM_SYSCOMMAND;
```

C++

```
__fastcall WMSysCommand(TWMSysCommand Message);
```

Description

This is WMSysCommand, a member of class TToolDockForm.

163.1.2 TToolDockObject Class

Handles drag-and-dock operations for toolbar controls.

Class Hierarchy

Pascal

```
TToolDockObject = class(TDragDockObject);
```

C++

```
class TToolDockObject : public TDragDockObject;
```

File

ToolWin

Description

Use TToolDockObject to handle drag-and-dock operations for toolbar controls that are docked to a TControlBar object.

Note: TToolDockObject is designed for tool bars that are docked to TControlBar. It may not work as expected when the application is docking a tool bar to a form or panel.

See Also

TToolBar (see page 4994)

TControlBar (see page 12316)

163.1.2.1 TToolDockObject Members

The following tables list the members exposed by TToolDockObject.

Protected Methods

	Name	Description
	AdjustDockRect (see page 23273)	This is AdjustDockRect, a member of class TToolDockObject.
	DrawDragDockImage (see page 23274)	Called when the dock image for a toolbar control is drawn.
	EndDrag (see page 5723)	Generates an OnEndDrag event for the control that is being dragged.
	EndDrag (see page 6013)	Called when a control is released from dragging.
	EraseDragDockImage (see page 23274)	Called when the dock image for a toolbar control is erased.
	Finished (see page 5723)	Finished ends a drag and drop operation.

	Finished (see page 6035)	Responds when the mouse is released indicating the drag operation is complete.
	GetDragCursor (see page 6014)	Returns the cursor used during dragging.
	GetDragCursor (see page 6035)	Indicates which cursor should be displayed in response to mouse moves.
	GetDragImages (see page 6035)	Returns an image list containing the image to be displayed while dragging.
	GetEraseWhenMoving (see page 6014)	This is GetEraseWhenMoving, a member of class TDragDockObject.
	GetFrameWidth (see page 6014)	Returns the value of the FrameWidth (see page 6018) property.
	MainWndProc (see page 6037)	This is MainWndProc, a member of class TDragObject.
	WndProc (see page 6038)	This is WndProc, a member of class TDragObject.

Public Methods

	Name	Description
	AfterConstruction (see page 6033)	Responds after the last constructor has executed.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 5722)	Copies the properties of another drag control object.
	Assign (see page 6012)	Enables assignments of TDragDockObject (see page 6009) objects.
	Assign (see page 6034)	Copies the properties of another drag control object.
	BeforeDestruction (see page 6034)	Responds before the first destructor executes.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 23273)	Creates and initializes an instance of TDragDockObject.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 6012)	Destroys an instance of TDragDockObject (see page 6009).
	Destroy (see page 22287)	Disposes of an object instance.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetName (see page 6036)	Returns a string that identifies the drag operation.
	HideDragImage (see page 6036)	Provides the interface for a method that hides the current drag image.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	Instance (see page 6037)	Returns the instance (module) handle of the EXE or DLL that created the drag object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ShowDragImage (see page 6037)	Provides the interface for a method that hides the current drag image.

Public Properties

	Name	Description
	AlwaysShowDragImages (see page 6038)	This is AlwaysShowDragImages, a member of class TDragObject.
	Brush (see page 6015)	Specifies the brush used to draw the dock image.
	Cancelling (see page 6038)	Specifies whether the drag operation is being canceled.
	Control (see page 5724)	Indicates the control that is being dragged.
	DockRect (see page 6015)	Specifies the rectangle on which the control is docked if released.
	DragHandle (see page 6039)	Specifies the window handle of the dragged object.
	DragPos (see page 6039)	Specifies the position of the dragged object.
	DragTarget (see page 6039)	Specifies the dragged object's target.
	DragTargetPos (see page 6040)	Specifies the position of the drag object relative to the drag target.
R	DropAlign (see page 6017)	Specifies how the control will be aligned when docked.
R	DropOnControl (see page 6017)	Specifies the control on which the dragged control will be docked if released.
R	Dropped (see page 6040)	Drag ended with drop.
	EraseDockRect (see page 6017)	This is EraseDockRect, a member of class TDragDockObject.
R	EraseWhenMoving (see page 6018)	This is EraseWhenMoving, a member of class TDragDockObject.
	Floating (see page 6018)	Specifies whether the control is floating.
R	FrameWidth (see page 6018)	Specifies the border width, in pixels, of the frame drawn around the drag image.
R	MouseDeltaX (see page 6040)	Specifies the x-coordinate of the mouse position relative to the position of the dragged object's target.
R	MouseDeltaY (see page 6041)	Specifies the y-coordinate of the mouse position relative to the position of the dragged object's target.
	RightClickCancels (see page 6041)	This is RightClickCancels, a member of class TDragObject.

163.1.2.2 TToolDockObject.Create Constructor

Creates and initializes an instance of TDragDockObject.

Pascal

```
constructor Create(AControl: TControl); override;
```

C++

```
virtual __fastcall TToolDockObject(TControl * AControl);
```

Description

Create calls the inherited constructor and allocates memory for the Brush property.

163.1.2.3 TToolDockObject Methods

The methods of the TToolDockObject class are listed here.

Protected Methods

	Name	Description
V	AdjustDockRect (see page 23273)	This is AdjustDockRect, a member of class TToolDockObject.
V	DrawDragDockImage (see page 23274)	Called when the dock image for a toolbar control is drawn.
V	EraseDragDockImage (see page 23274)	Called when the dock image for a toolbar control is erased.

163.1.2.3.1 TToolDockObject.AdjustDockRect Method

Pascal

```
procedure AdjustDockRect(ARect: TRect); override;
```

C++

```
virtual __fastcall AdjustDockRect(TRect ARect);
```

Description

This is AdjustDockRect, a member of class TToolDockObject.

163.1.2.3.2 TToolDockObject.DrawDragDockImage Method

Called when the dock image for a toolbar control is drawn.

Pascal

```
procedure DrawDragDockImage; override;
```

C++

```
virtual __fastcall DrawDragDockImage();
```

Description

DrawDragDockImage draws a control that is moved in a toolbar.

163.1.2.3.3 TToolDockObject.EraseDragDockImage Method

Called when the dock image for a toolbar control is erased.

Pascal

```
procedure EraseDragDockImage; override;
```

C++

```
virtual __fastcall EraseDragDockImage();
```

Description

EraseDragDockImage erases a control that is moved in a toolbar.

163.1.3 TToolWindow Class

TToolWindow is the ancestor for windowed controls that require a custom client area and edge borders.

Class Hierarchy

Pascal

```
TToolWindow = class(TWinControl);
```

C++

```
class TToolWindow : public TWinControl;
```

File

ToolWin

Description

TToolWindow is the ancestor of the TCoolBar and TToolBar components, which facilitate the arrangement of buttons and other visual controls.

See Also

TCoolBar (see page 3603)

TToolBar (see page 4994)

163.1.3.1 TToolWindow Members

The following tables list the members exposed by TToolWindow.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.
	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnClick (see page 5851)	Occurs when the user clicks the control.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnContextPopup (see page 5854)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 5854)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnDragDrop (see page 5855)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 5857)	Occurs when the user drags an object over a control.
	OnEndDock (see page 5859)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 5860)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 6219)	Occurs when a control receives the input focus.
	OnExit (see page 6221)	Occurs when the input focus shifts away from one control to another.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnKeyDown (see page 6225)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 6227)	Occurs when a key is pressed.
	OnKeyUp (see page 6228)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 5861)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 5862)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 5864)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 5864)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 5865)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 5867)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnMouseWheelDown (see page 5869)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 5870)	Occurs when the mouse wheel is rotated upward.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnStartDock (see page 5871)	Occurs when the user begins to drag a control with a DragKind (see page 5819) of dkDock.
	OnStartDrag (see page 5871)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
V	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
V	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
V	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
V	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
V	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
V	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
V	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	Click (see page 5743)	Respond to user click.
	CMBorderChanged (see page 23285)	This is CMBorderChanged, a member of class TToolWindow.
	CMCtl3DChanged (see page 23286)	This is CMCtl3DChanged, a member of class TToolWindow.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateHandle (see page 6135)	Creates underlying screen object.

	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
	CreateWnd (see page 6137)	Creates the underlying window.
	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.
	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 6144)	Respond to losing input focus
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.

	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
V	GetChildren (see page 6153)	Calls a specified method for each child of the control.
V	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
V	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
V	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
V	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.
V	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
V	GetDeviceContext (see page 5760)	Returns a device context for the control.
V	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
V	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
V	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
V	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
V	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
V	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 6163)	Respond to key press events.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyUp (see page 6164)	Respond to released key.
V	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
V	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.
	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
	MouseDown (see page 5773)	OnMouseDown (see page 5862) event dispatcher.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	NCPaint (see page 23286)	This is NCPaint, a member of class TToolWindow.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.

	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
	Resize (see page 5780)	Respond to control resize.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.
	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.

	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.
	WMNCCalcSize (see page 23286)	This is WMNCCalcSize, a member of class TToolWindow.
	WMNCPaint (see page 23286)	This is WMNCPaint, a member of class TToolWindow.
	WndProc (see page 5791)	Provides specific message responses for the control.
	WndProc (see page 6187)	Provides specific message responses for the control.
	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Color (see page 5812)	Specifies the background color of the control.
	Ctl3D (see page 6198)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
	DragCursor (see page 5818)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 5819)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 5819)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	Font (see page 5823)	Controls (see page 5711) the attributes of text written on or in the control.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	ParentBiDiMode (see page 5833)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	ParentColor (see page 5834)	Determines where a control looks for its color information.
	ParentCtl3D (see page 6209)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 5834)	Determines where a control looks for its font information.
	ParentShowHint (see page 5835)	Determines where a control looks to find out if its Help Hint (see page 5827) should be shown.

	PopupMenu (see page 5835)	Identifies the pop-up menu associated with the control.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Text (see page 5842)	Contains a text string associated with the control.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	Assign (see page 2930)	Copies the contents of another, similar object.
V	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
V	Create (see page 23285)	Creates and initializes a TToolWindow (see page 23274) instance.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
V	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
V	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 2766)	Disposes of the component and its owned components.
V	Destroy (see page 2929)	Destroys the TPersistent (see page 2928) instance and frees its memory.
V	Destroy (see page 5732)	Destroys an instance of TControl (see page 5724).
V	Destroy (see page 6124)	Destroys an instance of TWinControl (see page 6112).
V	Destroy (see page 22287)	Disposes of an object instance.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.

	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
V	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
V	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
V	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	Invalidate (see page 5770)	Completely repaint control.
V	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.

V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.
	Refresh (see page 5779)	Repaints the control on the screen.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
	Align (see page 5798)	Determines how the control aligns within its container (parent control).
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	Anchors (see page 5802)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 5803)	Specifies the bi-directional mode for the control.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.

R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.
R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
	Constraints (see page 5812)	Specifies the size constraints for the control.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	EdgeBorders (see page 23287)	Determines which sides of the control have visible borders.
	EdgeInner (see page 23287)	Determines the border style for the control's inner edge.
	EdgeOuter (see page 23288)	Determines the border style for the control's outer edge.
	Enabled (see page 5821)	Controls (see page 5711) whether the control responds to mouse, keyboard, and timer events.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	ShowHint (see page 5840)	Determines whether the control displays a Help Hint (see page 5827) when the mouse pointer rests momentarily on the control.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabOrder (see page 6211)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.

	Visible (see page 5847)	Determines whether the component appears onscreen.
R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.

Published Properties

	Name	Description
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Tag (see page 2808)	Stores an integer value as part of a component.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

163.1.3.2 TToolWindow.Create Constructor

Creates and initializes a TToolWindow (see page 23274) instance.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TToolWindow(TComponent * AOwner);
```

Description

Create generates a TToolWindow (see page 23274) and initializes its properties.

163.1.3.3 TToolWindow Methods

The methods of the TToolWindow class are listed here.

Protected Methods

	Name	Description
	CMBorderChanged (see page 23285)	This is CMBorderChanged, a member of class TToolWindow.
	CMCtl3DChanged (see page 23286)	This is CMCtl3DChanged, a member of class TToolWindow.
V	NCPaint (see page 23286)	This is NCPaint, a member of class TToolWindow.
	WMNCCalcSize (see page 23286)	This is WMNCCalcSize, a member of class TToolWindow.
	WMNCPaint (see page 23286)	This is WMNCPaint, a member of class TToolWindow.

163.1.3.3.1 TToolWindow.CMBorderChanged Method

Pascal

```
procedure CMBorderChanged(var Message: TMessage); message CM_BORDERCHANGED;
```

C++

```
__fastcall CMBorderChanged(TMessage Message);
```

Description

This is CMBorderChanged, a member of class TToolWindow.

163.1.3.3.2 TToolWindow.CMCtl3DChanged Method

Pascal

```
procedure CMCtl3DChanged(var Message: TMessage); message CM_CTL3DCHANGED;
```

C++

```
__fastcall CMCtl3DChanged(TMessage Message);
```

Description

This is CMCtl3DChanged, a member of class TToolWindow.

163.1.3.3.3 TToolWindow.NCPaint Method

Pascal

```
procedure NCPaint(DC: HDC); virtual;
```

C++

```
virtual __fastcall NCPaint(HDC DC);
```

Description

This is NCPaint, a member of class TToolWindow.

163.1.3.3.4 TToolWindow.WMNCCalcSize Method

Pascal

```
procedure WMNCCalcSize(var Message: TWMNCCalcSize); message WM_NCCALCSIZE;
```

C++

```
__fastcall WMNCCalcSize(TWMNCCalcSize Message);
```

Description

This is WMNCCalcSize, a member of class TToolWindow.

163.1.3.3.5 TToolWindow.WMNCPaint Method

Pascal

```
procedure WMNCPaint(var Message: TMessage); message WM_NCPAINT;
```

C++

```
__fastcall WMNCPaint(TMessage Message);
```

Description

This is WMNCPaint, a member of class TToolWindow.

163.1.3.4 TToolWindow Properties

The properties of the TToolWindow class are listed here.

Public Properties

	Name	Description
	EdgeBorders (see page 23287)	Determines which sides of the control have visible borders.
	EdgeInner (see page 23287)	Determines the border style for the control's inner edge.
	EdgeOuter (see page 23288)	Determines the border style for the control's outer edge.

163.1.3.4.1 TToolWindow.EdgeBorders Property

Determines which sides of the control have visible borders.

Pascal

```
property EdgeBorders: TEdgeBorders;
```

C++

```
__property TEdgeBorders EdgeBorders;
```

Description

Use the EdgeBorders property to add or remove borders. The appearance of the borders can be set with the EdgeInner (see page 23287) and EdgeOuter (see page 23288) properties.

See Also

EdgeInner (see page 23287)

EdgeOuter (see page 23288)

163.1.3.4.2 TToolWindow.EdgeInner Property

Determines the border style for the control's inner edge.

Pascal

```
property EdgeInner: TEdgeStyle;
```

C++

```
__property TEdgeStyle EdgeInner;
```

Description

Use EdgeInner to provide the tool window with a three-dimensional beveled look. A tool window has two borders on each side, an outer border drawn next to the outer edge, and an inner border drawn inside the outer border. EdgeInner specifies the appearance of the inner border. It can be raised (esRaised), lowered (esLowered), or left off altogether (esNone).

Note: The EdgeInner property has an effect only on the sides specified by the EdgeBorders (see page 23287) property.

Use EdgeInner with EdgeOuter (see page 23288) to give the component a three-dimensional look.

See Also

EdgeBorders (see page 23287)

EdgeOuter (see page 23288)

163.1.3.4.3 TToolWindow.EdgeOuter Property

Determines the border style for the control's outer edge.

Pascal

```
property EdgeOuter: TEdgeStyle;
```

C++

```
__property TEdgeStyle EdgeOuter;
```

Description

Use EdgeOuter to provide the tool window with a three-dimensional beveled look. A tool window has two borders on each side, an outer border drawn next to the outer edge, and an inner border drawn inside the outer border. EdgeOuter specifies the appearance of the outer border. It can be raised (esRaised), lowered (esLowered), or left off altogether (esNone).

Note: The EdgeInner (see page 23287) property has an effect only on the sides specified by the EdgeBorders (see page 23287) property.

Use EdgeOuter with EdgeInner (see page 23287) to give the component a three-dimensional look.

See Also

EdgeBorders (see page 23287)

EdgeInner (see page 23287)

163.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TEdgeBorder (see page 23289)	TEdgeBorders (see page 23292) is the type of the EdgeBorders property.
	TEdgeStyle (see page 23290)	TEdgeStyle describes the appearance of an edge border.
	TSizingOrientation (see page 23290)	TSizingOrientation specifies the dimension along which a control's size is adjusted when docked.

163.2.1 ToolWin.TEdgeBorder Enumeration

TEdgeBorders (see page 23292) is the type of the EdgeBorders property.

Pascal

```
TEdgeBorder = (
  ebLeft,
  ebTop,
  ebRight,
  ebBottom
);
```

C++

```
enum TEdgeBorder {
  ebLeft,
  ebTop,
  ebRight,
  ebBottom
};
```

File

ToolWin

Description

TEdgeBorders (see page 23292) is a set of TEdgeBorder values. Each TEdgeBorder value indicates whether a beveled edge appears on a particular side of a control. The following table lists the TEdgeBorder values:

Value	Meaning
ebLeft	The control has a beveled left edge.
ebTop	The control has a beveled top edge.
ebRight	The control has a beveled right edge.
ebBottom	The control has a beveled bottom edge.

In addition to the values in the preceding table, the QGraphics unit defines the ebRect constant to represent all the edges of a control:

const ebRect = [ebLeft, ebTop, ebRight, ebBottom];

#define ebRect (System::Set<TEdgeBorder, ebLeft, ebBottom> () << TEdgeBorder(0) << TEdgeBorder(1) << TEdgeBorder(2)

<< TEdgeBorder(3))

163.2.2 ToolWin.TEdgeStyle Enumeration

TEdgeStyle describes the appearance of an edge border.

Pascal

```
TEdgeStyle = (
  esNone,
  esRaised,
  esLowered
);
```

C++

```
enum TEdgeStyle {
  esNone,
  esRaised,
  esLowered
};
```

File

ToolWin

Description

TEdgeStyle indicates the appearance of a particular border. The following table lists the possible values:

Value	Meaning
esNone	The border is not drawn.
esRaised	The border appears raised.
esLowered	The border appears lowered.

163.2.3 ToolWin.TSizingOrientation Enumeration

TSizingOrientation specifies the dimension along which a control's size is adjusted when docked.

Pascal

```
TSizingOrientation = (
  soNone,
  soHorizontal,
  soVertical
);
```

C++

```
enum TSizingOrientation {
  soNone,
  soHorizontal,
  soVertical
};
```

File

ToolWin

Description

TSizingOrientation can have one of the following values:

Value	Meaning
soNone	The control's size is not readjusted when it is docked.
soHorizontal	The control's width is adjusted when it is docked.
soVertical	The control's height is adjusted when it is docked.

163.3 Types

The following table lists types in this documentation.

Types

Name	Description
TEdgeBorders (see page 23292)	This is type ToolWin.TEdgeBorders.

163.3.1 ToolWin.TEdgeBorders Type

Pascal

```
TEdgeBorders = set of TEdgeBorder;
```

C++

```
TEdgeBorder TEdgeBorders;
```

File

ToolWin

Description

This is type ToolWin.TEdgeBorders.

164 Types Namespace

This is namespace Types.

Topics

Name	Description
Functions (see page 23295)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 23301)	The following table lists structs, records, enums in this documentation.
Types (see page 23304)	The following table lists types in this documentation.
Constants (see page 23316)	The following table lists constants in this documentation.

Constants

Name	Description
EqualsValue (see page 23316)	EqualsValue indicates that both values are equal in a comparison operation.
GreaterThanValue (see page 23316)	GreaterThanValue indicates that one value is greater than an other in a comparison operation.
LessThanValue (see page 23317)	LessThanValue indicates that one value is less than an other in a comparison operation.
RT_RCDATA (see page 23317)	This is constant Types.RT_RCDATA.

Functions

	Name	Description
	Bounds (see page 23295)	Returns the TRect (see page 23302) for a rectangle of given dimensions.
	CenterPoint (see page 23295)	Returns the point in the center of a rectangle.
	EqualRect (see page 23296)	Indicates whether two TRect (see page 23302) values are the same.
	IntersectRect (see page 23296)	Returns the intersection of two rectangles
	IsRectEmpty (see page 23297)	Indicates wither a specified rectangle has a positive width and height.
	OffsetRect (see page 23297)	Changes the origin of a rectangle by a specified amount.
	Point (see page 23298)	Creates a TPoint (see page 23301) structure from a pair of coordinates.
	PtInRect (see page 23298)	Indicates whether a specified point lies inside a specified rectangle.
	Rect (see page 23299)	Creates a TRect (see page 23302) structure from a set of coordinates.
	SmallPoint (see page 23299)	Creates a TSmallPoint (see page 23303) structure from a pair of coordinates.
	SmallPoint (see page 23299)	Creates a TSmallPoint (see page 23303) structure from a pair of coordinates.
	UnionRect (see page 23300)	Returns the union of two rectangles

Structs, Records, Enums

	Name	Description
	tagSIZE (see page 23301)	tagSIZE is a record holding width and height values.
	TPoint (see page 23301)	TPoint type defines a pixel location onscreen.
	TRect (see page 23302)	TRect defines a rectangle.
	TSmallPoint (see page 23303)	TSmallPoint type defines a point with two 16-bit coordinates.

Types

Name	Description
DWORD (see page 23304)	DWORD is equivalent to LongWord.
PByte (see page 23305)	PByte is a pointer to a Byte variable.
PDouble (see page 23305)	PDouble is a pointer to a Double variable.
PInteger (see page 23306)	PInteger is a pointer to a Integer variable.
PLongint (see page 23306)	This is type Types.PLongint.
PPoint (see page 23306)	PPoint is a pointer to a TPoint (see page 23301) variable.
PRect (see page 23307)	PRect is a pointer to a TRect (see page 23302) variable.
PSize (see page 23307)	PSize is a pointer to a TSize (see page 23313) variable.
PSmallInt (see page 23308)	This is type Types.PSmallInt.
PSmallPoint (see page 23308)	This is type Types.PSmallPoint.
SIZE (see page 23308)	This is type Types.SIZE.
tagPOINT (see page 23309)	This is type Types.tagPOINT.
TBooleanDynArray (see page 23309)	TBooleanDynArray defines an array of Boolean elements.
TByteDynArray (see page 23309)	This is type Types.TByteDynArray.
TCardinalDynArray (see page 23310)	TCardinalDynArray defines an array of Cardinal elements.
TDoubleDynArray (see page 23310)	TDoubleDynArray defines an array of Double elements.
TInt64DynArray (see page 23311)	TInt64DynArray defines an array of Int64 elements.
TIntegerDynArray (see page 23311)	This is type Types.TIntegerDynArray.
TLongWordDynArray (see page 23311)	TLongWordDynArray defines an array of LongWord elements.
TShortIntDynArray (see page 23312)	TShortIntDynArray defines an array of ShortInt elements.
TSingleDynArray (see page 23312)	TSingleDynArray defines an array of Single elements.
TSize (see page 23313)	TSize represents a width and height.
TSmallIntDynArray (see page 23313)	TSmallIntDynArray defines an array of SmallInt elements.
TStringDynArray (see page 23313)	TStringDynArray defines an array of String elements.
TValueRelationship (see page 23314)	TValueRelationship defines value comparison possibilities.
TWideStringDynArray (see page 23314)	TWideStringDynArray defines an array of WideString elements.
TWordDynArray (see page 23315)	TWordDynArray defines an array of Word elements.

164.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	Bounds (see page 23295)	Returns the TRect (see page 23302) for a rectangle of given dimensions.
	CenterPoint (see page 23295)	Returns the point in the center of a rectangle.
	EqualRect (see page 23296)	Indicates whether two TRect (see page 23302) values are the same.
	IntersectRect (see page 23296)	Returns the intersection of two rectangles
	IsRectEmpty (see page 23297)	Indicates wither a specified rectangle has a positive width and height.
	OffsetRect (see page 23297)	Changes the origin of a rectangle by a specified amount.
	Point (see page 23298)	Creates a TPoint (see page 23301) structure from a pair of coordinates.
	PtInRect (see page 23298)	Indicates whether a specified point lies inside a specified rectangle.
	Rect (see page 23299)	Creates a TRect (see page 23302) structure from a set of coordinates.
	SmallPoint (see page 23299)	Creates a TSmallPoint (see page 23303) structure from a pair of coordinates.
	SmallPoint (see page 23299)	Creates a TSmallPoint (see page 23303) structure from a pair of coordinates.
	UnionRect (see page 23300)	Returns the union of two rectangles

164.1.1 Types.Bounds Function

Returns the TRect (see page 23302) for a rectangle of given dimensions.

Pascal

```
function Bounds(ALeft: Integer; ATop: Integer; AWidth: Integer; AHeight: Integer): TRect;
```

C++

```
TRect Bounds(int ALeft, int ATop, int AWidth, int AHeight);
```

File

Types

Description

Call Bounds to obtain a TRect (see page 23302) for a rectangle with upper left corner at the point (ALeft, ATop) with width AWidth and height AHeight.

See Also

Rect (see page 23299)

164.1.2 Types.CenterPoint Function

Returns the point in the center of a rectangle.

Pascal

```
function CenterPoint(const Rect: TRect): TPoint;
```

C++

```
TPoint CenterPoint(const TRect Rect);
```

File

Types

Description

Call CenterPoint to obtain the point in the center of a rectangle.

Rect (see page 23299) is the rectangle whose center you want to locate.

See Also

PtInRect (see page 23298)

IsRectEmpty (see page 23297)

UnionRect (see page 23300)

IntersectRect (see page 23296)

164.1.3 Types.EqualRect Function

Indicates whether two TRect (see page 23302) values are the same.

Pascal

```
function EqualRect(const R1: TRect; const R2: TRect): Boolean;
```

C++

```
Boolean EqualRect(const TRect R1, const TRect R2);
```

File

Types

Description

Call EqualRect to compare two TRect (see page 23302) values. EqualRect returns true if R1 and R2 are identical (same position and size), false if they are different.

See Also

Rect (see page 23299)

Bounds (see page 23295)

IntersectRect (see page 23296)

164.1.4 Types.IntersectRect Function

Returns the intersection of two rectangles

Pascal

```
function IntersectRect(out Rect: TRect; const R1: TRect; const R2: TRect): Boolean;
```

C++

```
Boolean IntersectRect(TRect Rect, const TRect R1, const TRect R2);
```

File

Types

Description

Call IntersectRect to obtain the rectangle that is the intersection of R1 and R2. The intersection is returned as the Rect (see page 23299) parameter.

IntersectRect returns true if the two rectangles have a nonempty intersection. If R1 and R2 do not overlap, IntersectRect returns false, and the Rect (see page 23299) parameter is set to a rectangle at position (0,0) with 0 Width and 0 Height.

See Also

PtInRect (see page 23298)

IsRectEmpty (see page 23297)

UnionRect (see page 23300)

164.1.5 Types.IsRectEmpty Function

Indicates wither a specified rectangle has a positive width and height.

Pascal

```
function IsRectEmpty(const Rect: TRect): Boolean;
```

C++

```
Boolean IsRectEmpty(const TRect Rect);
```

File

Types

Description

Call IsRectEmpty to determine whether the rectangle specified by Rect (see page 23299) encloses a positive amount of space.

IsRectEmpty returns true if both the width and height of Rect (see page 23299) are greater than 0. If either the width or height is less than or equal to 0, IsRectEmpty returns false. Note that this means non-normalized rectangles (rectangles with negative height or width) are considered empty.

See Also

PtInRect (see page 23298)

IntersectRect (see page 23296)

164.1.6 Types.OffsetRect Function

Changes the origin of a rectangle by a specified amount.

Pascal

```
function OffsetRect(var Rect: TRect; DX: Integer; DY: Integer): Boolean;
```

C++

```
Boolean OffsetRect(TRect Rect, int DX, int DY);
```

File

Types

Description

Call OffsetRect to move the upper left corner of the rectangle specified by Rect (see page 23299) while maintaining the same width and height. The left of the rectangle moves by DX while the top moves by DY.

OffsetRect returns true if the Rect (see page 23299) parameter is not nil (Delphi) or NULL (C++), false if it can't return a new rectangle because Rect (see page 23299) is nil(Delphi) or NULL (C++).

See Also

Rect (see page 23299)

Bounds (see page 23295)

164.1.7 Types.Point Function

Creates a TPoint (see page 23301) structure from a pair of coordinates.

Pascal

```
function Point(X: Integer; Y: Integer): TPoint;
```

C++

```
TPoint Point(int X, int Y);
```

File

Types

Description

Call Point to create a TPoint (see page 23301) that represents the specified coordinates. Use Point to construct parameters for functions that require a point, rather than setting up local variables for each parameter.

See Also

SmallPoint (see page 23299)

Rect (see page 23299)

164.1.8 Types.PtInRect Function

Indicates whether a specified point lies inside a specified rectangle.

Pascal

```
function PtInRect(const Rect: TRect; const P: TPoint): Boolean;
```

C++

```
Boolean PtInRect(const TRect Rect, const TPoint P);
```

File

Types

Description

PtInRect returns true if the point, P, lies inside the rectangle, Rect (see page 23299), and false if P is not in Rect (see page 23299).

PtInRect does not consider a point inside a rectangle if the rectangle has a negative width or height. A point is considered inside a rectangle if it lies on the left or top edge, but not if it lies on the right or bottom edge.

See Also

IntersectRect (see page 23296)

IsRectEmpty (see page 23297)

CenterPoint (see page 23295)

164.1.9 Types.Rect Function

Creates a TRect (see page 23302) structure from a set of coordinates.

Pascal

```
function Rect(Left: Integer; Top: Integer; Right: Integer; Bottom: Integer): TRect;
```

C++

```
TRect Rect(int Left, int Top, int Right, int Bottom);
```

File

Types

Description

Call Rect to create a TRect (see page 23302) that represents the rectangle with the specified coordinates. Use Rect to construct parameters for functions that require TRect (see page 23302), rather than setting up local variables for each parameter.

See Also

Bounds (see page 23295)

Point (see page 23298)

164.1.10 Types.SmallPoint Function

Creates a TSmallPoint (see page 23303) structure from a pair of coordinates.

Pascal

```
function SmallPoint(X: Integer; Y: Integer): TSmallPoint; overload;
function SmallPoint(XY: LongWord): TSmallPoint; overload;
```

C++

```
TSmallPoint SmallPoint(int X, int Y);
TSmallPoint SmallPoint(LongWord XY);
```

File

Types

Description

Call SmallPoint to create a TSmallPoint (see page 23303) that represents the specified coordinates.

See Also

Point (see page 3244)

164.1.11 Types.UnionRect Function

Returns the union of two rectangles

Pascal

```
function UnionRect(out Rect: TRect; const R1: TRect; const R2: TRect): Boolean;
```

C++

```
Boolean UnionRect(TRect Rect, const TRect R1, const TRect R2);
```

File

Types

Description

Call UnionRect to obtain the smallest rectangle that includes both R1 and R2. The union is returned as the Rect (see page 23299) parameter.

UnionRect returns true if the resulting rectangle is nonempty. If the resulting rectangle as a width or height that is less than or equal to 0, UnionRect returns false.

See Also

IntersectRect (see page 23296)

OffsetRect (see page 23297)

IsRectEmpty (see page 23297)

164.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Records

	Name	Description
	tagSIZE (see page 23301)	tagSIZE is a record holding width and height values.
	TPoint (see page 23301)	TPoint type defines a pixel location onscreen.
	TRect (see page 23302)	TRect defines a rectangle.
	TSmallPoint (see page 23303)	TSmallPoint type defines a point with two 16-bit coordinates.

164.2.1 Types.tagSIZE Record

tagSIZE is a record holding width and height values.

Pascal

```
tagSIZE = packed record
  cx: Longint;
  cy: Longint;
end;
```

C++

```
struct tagSIZE {
  Longint cx;
  Longint cy;
};
```

File

Types

Description

The SIZE (see page 23308) equates to a TSize (see page 23313) type, which in turn equates to a tagSIZE record.

tagSIZE holds the width (cx) and height (cy) of something, typically in pixels. For example, TextExtent returns the width and height, in pixels, of a string rendered in the current font.

See Also

SIZE (see page 23308)

TextExtent (see page 14474)

TSize (see page 23313)

164.2.2 Types.TPoint Record

TPoint type defines a pixel location onscreen.

Pascal

```
TPoint = packed record
  X: Longint;
  Y: Longint;
end;
```

C++

```
struct TPoint {
  Longint X;
  Longint Y;
};
```

File

Types

Description

The TPoint type defines a pixel location onscreen, with the origin in the top left corner. X specifies the horizontal coordinate of the point, Y specifies the vertical coordinate.

C++ Examples:

```
/*
This example draws a polygon in the specified shape, and
fills it with the color teal.
*/
void __fastcall TForm1::PaintBox1Paint(TObject *Sender)
{
  TPoint points[4];
  points[0] = Point(10,10);
  points[1] = Point(30,10);
  points[2] = Point(130,30);
  points[3] = Point(240,120);
  ((TPaintBox *)Sender)->Canvas->Brush->Color = clTeal;
  ((TPaintBox *)Sender)->Canvas->Polygon(points, 3);
}
```

See Also

Point

164.2.3 Types.TRect Record

TRect defines a rectangle.

Pascal

```
TRect = packed record
  case Integer of
    0: (Bottom: Longint;
        Left: Longint;
        Right: Longint;
        Top: Longint;);
    1: (BottomRight: TPoint;
        TopLeft: TPoint;);
end;
```

C++

```
struct TRect {
  Longint Bottom;
  Longint Left;
```

```
    Longint Right;
    Longint Top;
    TPoint BottomRight;
    TPoint TopLeft;
  };
```

File

Types

Description

TRect represents the dimensions of a rectangle. The coordinates are specified as either four separate integers representing the left, top, right, and bottom sides, or as two points representing the locations of the top left and bottom right corners.

Typically, TRect values represent pixel locations, where the origin of the pixel coordinate system is in the top left corner of the screen (screen coordinates) or the top left corner of a control's client area (client coordinates). When a TRect value represents a rectangle on the screen, by convention the top and left edges are considered inside the rectangle and the bottom and right edges are considered outside the rectangle. This convention allows the width of the rectangle to be Right - Left and the height to be Bottom - Top.

164.2.4 Types.TSmallPoint Record

TSmallPoint type defines a point with two 16-bit coordinates.

Pascal

```
  TSmallPoint = packed record
    x: SmallInt;
    y: SmallInt;
  end;
```

C++

```
  struct TSmallPoint {
    SmallInt x;
    SmallInt y;
  };
```

File

Types

Description

The TSmallPoint type defines a point where each coordinate is a 16-bit integer. x specifies the horizontal coordinate of the point, y specifies the vertical coordinate.

164.3 Types

The following table lists types in this documentation.

Types

Name	Description
DWORD (see page 23304)	DWORD is equivalent to LongWord.
PByte (see page 23305)	PByte is a pointer to a Byte variable.
PDouble (see page 23305)	PDouble is a pointer to a Double variable.
PInteger (see page 23306)	PInteger is a pointer to a Integer variable.
PLongint (see page 23306)	This is type Types.PLongint.
PPoint (see page 23306)	PPoint is a pointer to a TPoint (see page 23301) variable.
PRect (see page 23307)	PRect is a pointer to a TRect (see page 23302) variable.
PSize (see page 23307)	PSize is a pointer to a TSize (see page 23313) variable.
PSmallInt (see page 23308)	This is type Types.PSmallInt.
PSmallPoint (see page 23308)	This is type Types.PSmallPoint.
SIZE (see page 23308)	This is type Types.SIZE.
tagPOINT (see page 23309)	This is type Types.tagPOINT.
TBooleanDynArray (see page 23309)	TBooleanDynArray defines an array of Boolean elements.
TByteDynArray (see page 23309)	This is type Types.TByteDynArray.
TCardinalDynArray (see page 23310)	TCardinalDynArray defines an array of Cardinal elements.
TDoubleDynArray (see page 23310)	TDoubleDynArray defines an array of Double elements.
TInt64DynArray (see page 23311)	TInt64DynArray defines an array of Int64 elements.
TIntegerDynArray (see page 23311)	This is type Types.TIntegerDynArray.
TLongWordDynArray (see page 23311)	TLongWordDynArray defines an array of LongWord elements.
TShortIntDynArray (see page 23312)	TShortIntDynArray defines an array of ShortInt elements.
TSingleDynArray (see page 23312)	TSingleDynArray defines an array of Single elements.
TSize (see page 23313)	TSize represents a width and height.
TSmallIntDynArray (see page 23313)	TSmallIntDynArray defines an array of SmallInt elements.
TStringDynArray (see page 23313)	TStringDynArray defines an array of String elements.
TValueRelationship (see page 23314)	TValueRelationship defines value comparison possibilities.
TWideStringDynArray (see page 23314)	TWideStringDynArray defines an array of WideString elements.
TWordDynArray (see page 23315)	TWordDynArray defines an array of Word elements.

164.3.1 Types.DWORD Type

DWORD is equivalent to LongWord.

Pascal

```
DWORD = LongWord;
```

C++

```
LongWord DWORD;
```

File

Types

Description

The DWORD holds positive integers up to a maximum value of 4,294,967,295.

See Also

LongWord

164.3.2 Types.PByte Type

PByte is a pointer to a Byte variable.

Pascal

```
PByte = System.PByte;
```

C++

```
System.PByte PByte;
```

File

Types

Description

Types.PByte is the same as System.PByte (see page 22588).

See Also

Byte

PByte (see page 22588)

164.3.3 Types.PDouble Type

PDouble is a pointer to a Double variable.

Pascal

```
PDouble = System.PDouble;
```

C++

```
System.PDouble PDouble;
```

File

Types

Description

Types.PDouble is the same as System.PDouble (see page 22592).

See Also

Double

PDouble (see page 22592)

164.3.4 Types.PInteger Type

PInteger is a pointer to a Integer variable.

Pascal

```
PInteger = System.PInteger;
```

C++

```
System.PInteger PInteger;
```

File

Types

Description

Types.PInteger is the same as System.PInteger (see page 22594).

See Also

Integer

PInteger (see page 22594)

164.3.5 Types.PLongint Type

Pascal

```
PLongint = System.PLongint;
```

C++

```
System.PLongint PLongint;
```

File

Types

Description

This is type Types.PLongint.

164.3.6 Types.PPoint Type

PPoint is a pointer to a TPoint (see page 23301) variable.

Pascal

```
PPoint = ^TPoint;
```

C++

```
^TPoint PPoint;
```

File

Types

Description

The TPoint (see page 23301) type defines a pixel location onscreen, with the origin in the top left corner.

See Also

TPoint (see page 23301)

164.3.7 Types.PRect Type

PRect is a pointer to a TRect (see page 23302) variable.

Pascal

```
PRect = ^TRect;
```

C++

```
^TRect PRect;
```

File

Types

Description

The TRect (see page 23302) type represents the dimensions of a rectangle.

See Also

TRect (see page 23302)

164.3.8 Types.PSize Type

PSize is a pointer to a TSize (see page 23313) variable.

Pascal

```
PSize = ^TSize;
```

C++

```
^TSize PSize;
```

File

Types

Description

The TSize (see page 23313) type holds the width and height of something, typically in pixels.

See Also

TSize (see page 23313)

164.3.9 Types.PSmallInt Type

Pascal

```
PSmallInt = System.PSmallInt;
```

C++

```
System.PSmallInt PSmallInt;
```

File

Types

Description

This is type Types.PSmallInt.

164.3.10 Types.PSmallPoint Type

Pascal

```
PSmallPoint = ^TSmallPoint;
```

C++

```
^TSmallPoint PSmallPoint;
```

File

Types

Description

This is type Types.PSmallPoint.

164.3.11 Types.SIZE Type

Pascal

```
SIZE = tagSIZE;
```

C++

```
tagSIZE SIZE;
```

File

Types

Description

This is type Types.SIZE.

164.3.12 Types.tagPOINT Type

Pascal

```
tagPOINT = TPoint;
```

C++

```
TPoint tagPOINT;
```

File

Types

Description

This is type Types.tagPOINT.

164.3.13 Types.TBooleanDynArray Type

TBooleanDynArray defines an array of Boolean elements.

Pascal

```
TBooleanDynArray = array of Boolean;
```

C++

```
array of Boolean TBooleanDynArray;
```

File

Types

Description

The TBooleanDynArray defines a dynamic array of Boolean elements.

Use SetLength to allocate storage for such an array.

See Also

TSize (see page 23313)

164.3.14 Types.TByteDynArray Type

Pascal

```
TByteDynArray = array of Byte;
```

C++

```
array of Byte TByteDynArray;
```

File

Types

Description

This is type Types.TByteDynArray.

164.3.15 Types.TCardinalDynArray Type

TCardinalDynArray defines an array of Cardinal elements.

Pascal

```
TCardinalDynArray = array of Cardinal;
```

C++

```
array of Cardinal TCardinalDynArray;
```

File

Types

Description

The TCardinalDynArray defines a dynamic array of Cardinal elements.

Use SetLength to allocate storage for such an array.

See Also

TSize (see page 23313)

164.3.16 Types.TDoubleDynArray Type

TDoubleDynArray defines an array of Double elements.

Pascal

```
TDoubleDynArray = array of Double;
```

C++

```
array of Double TDoubleDynArray;
```

File

Types

Description

The TDoubleDynArray defines a dynamic array of Double elements.

Use SetLength to allocate storage for such an array.

See Also

TSize (see page 23313)

164.3.17 Types.TInt64DynArray Type

TInt64DynArray defines an array of Int64 elements.

Pascal

```
TInt64DynArray = array of Int64;
```

C++

```
array of Int64 TInt64DynArray;
```

File

Types

Description

The TInt64DynArray defines a dynamic array of Int64 elements.

Use SetLength to allocate storage for such an array.

See Also

TSize (see page 23313)

164.3.18 Types.TIntegerDynArray Type

Pascal

```
TIntegerDynArray = array of Integer;
```

C++

```
array of Integer TIntegerDynArray;
```

File

Types

Description

This is type Types.TIntegerDynArray.

164.3.19 Types.TLongWordDynArray Type

TLongWordDynArray defines an array of LongWord elements.

Pascal

```
TLongWordDynArray = array of LongWord;
```

C++

```
array of LongWord TLongWordDynArray;
```

File

Types

Description

The TLongWordDynArray defines a dynamic array of LongWord elements.

Use SetLength to allocate storage for such an array.

See Also

TSize (see page 23313)

164.3.20 Types.TShortIntDynArray Type

TShortIntDynArray defines an array of ShortInt elements.

Pascal

```
TShortIntDynArray = array of ShortInt;
```

C++

```
array of ShortInt TShortIntDynArray;
```

File

Types

Description

The TShortIntDynArray defines a dynamic array of ShortInt elements.

Use SetLength to allocate storage for such an array.

See Also

TSize (see page 23313)

164.3.21 Types.TSingleDynArray Type

TSingleDynArray defines an array of Single elements.

Pascal

```
TSingleDynArray = array of Single;
```

C++

```
array of Single TSingleDynArray;
```

File

Types

Description

The TSingleDynArray defines a dynamic array of Single elements.

Use SetLength to allocate storage for such an array.

See Also

TSize (see page 23313)

164.3.22 Types.TSize Type

TSize represents a width and height.

Pascal

```
TSize = tagSIZE;
```

C++

```
tagSIZE TSize;
```

File

Types

Description

TSize represents the size of something. Typically, the implied units of measurement are pixels.

cx is the width.

cy is the height.

164.3.23 Types.TSmallIntDynArray Type

TSmallIntDynArray defines an array of SmallInt elements.

Pascal

```
TSmallIntDynArray = array of SmallInt;
```

C++

```
array of SmallInt TSmallIntDynArray;
```

File

Types

Description

The TSmallIntDynArray defines a dynamic array of SmallInt elements.

Use SetLength to allocate storage for such an array.

See Also

TSize (see page 23313)

164.3.24 Types.TStringDynArray Type

TStringDynArray defines an array of String elements.

Pascal

```
TStringDynArray = array of string;
```

C++

```
array of string TStringDynArray;
```

File

Types

Description

The TStringDynArray defines a dynamic array of String elements.

Use SetLength to allocate storage for such an array.

See Also

TSize (see page 23313)

164.3.25 Types.TValueRelationship Type

TValueRelationship defines value comparison possibilities.

Pascal

```
TValueRelationship = -1..1;
```

C++

```
-1..1 TValueRelationship;
```

File

Types

Description

Routines such as the CompareValue routine compare two values for equality. They return the result in a TValueRelationship value as follows :

Value	Associated constant	Meaning
-1	LessThanValue (see page 23317)	The first value is less than the second value.
0	EqualsValue (see page 23316)	The two values are equal.
+1	GreaterThanValue (see page 23316)	The first value is greater than the second value.

See Also

LessThanValue (see page 23317)

EqualsValue (see page 23316)

GreaterThanValue (see page 23316)

TValueRelationship

164.3.26 Types.TWideStringDynArray Type

TWideStringDynArray defines an array of WideString elements.

Pascal

```
TWideStringDynArray = array of WideString;
```

C++

```
array of WideString TWideStringDynArray;
```

File

Types

Description

The TWideStringDynArray defines a dynamic array of WideString elements.

Use SetLength to allocate storage for such an array.

See Also

TSize (see page 23313)

164.3.27 Types.TWordDynArray Type

TWordDynArray defines an array of Word elements.

Pascal

```
TWordDynArray = array of Word;
```

C++

```
array of Word TWordDynArray;
```

File

Types

Description

The TWordDynArray defines a dynamic array of Word elements.

Use SetLength to allocate storage for such an array.

See Also

TSize (see page 23313)

164.4 Constants

The following table lists constants in this documentation.

Constants

Name	Description
EqualsValue (see page 23316)	EqualsValue indicates that both values are equal in a comparison operation.
GreaterThanValue (see page 23316)	GreaterThanValue indicates that one value is greater than an other in a comparison operation.
LessThanValue (see page 23317)	LessThanValue indicates that one value is less than an other in a comparison operation.
RT_RCDATA (see page 23317)	This is constant Types.RT_RCDATA.

164.4.1 Types.EqualsValue Constant

EqualsValue indicates that both values are equal in a comparison operation.

Pascal

```
EqualsValue = 0;
```

C++

```
EqualsValue = 0;
```

File

Types

Description

Routines such as the CompareValue routine compare two values for equality. They return the result in a TValueRelationship (see page 23314) value. If the first value is equal to the second, the value is EqualsValue

See Also

CompareValue (see page 15938)

GreaterThanValue

LessThanValue

TValueRelationship

164.4.2 Types.GreaterThanValue Constant

GreaterThanValue indicates that one value is greater than an other in a comparison operation.

Pascal

```
GreaterThanValue = High(TValueRelationship);
```

C++

```
GreaterThanValue = High(TValueRelationship);
```

File

Types

Description

Routines such as the CompareValue routine compare two values for equality. They return the result in a TValueRelationship (see page 23314) value. If the first value is greater than the second, the value is GreaterThanValue

See Also

EqualsValue

CompareValue (see page 15938)

LessThanValue

TValueRelationship

164.4.3 Types.LessThanValue Constant

LessThanValue indicates that one value is less than an other in a comparison operation.

Pascal

```
LessThanValue = Low(TValueRelationship);
```

C++

```
LessThanValue = Low(TValueRelationship);
```

File

Types

Description

Routines such as the CompareValue routine compare two values for equality. They return the result in a TValueRelationship (see page 23314) value. If the first value is less than the second, the value is LessThanValue

See Also

EqualsValue

CompareValue (see page 15938)

GreaterThanValue

TValueRelationship

164.4.4 Types.RT_RCDATA Constant

Pascal

```
RT_RCDATA = PChar(10);
```

C++

```
RT_RCDATA = PChar(10);
```

File

Types

Description

This is constant Types.RT_RCDATA.

165 TypeTrans Namespace

This is namespace TypeTrans.

Topics

Name	Description
Classes (see page 23320)	The following table lists classes in this documentation.
Functions (see page 23324)	The following table lists functions in this documentation.
Variables (see page 23326)	The following table lists variables in this documentation.

Classes

	Name	Description
	ETypeTransException (see page 23320)	ETypeTransException is the exception raised when a conversion between a SOAP type description and an Object Pascal type fails.
	TTypeTranslator (see page 23320)	This is class TypeTrans.TTypeTranslator.

Functions

	Name	Description
	FloatToStrEx (see page 23324)	This is function TypeTrans.FloatToStrEx.
	GetEnumValueEx (see page 23324)	This is function TypeTrans.GetEnumValueEx.
	SetEnumPropEx (see page 23325)	This is function TypeTrans.SetEnumPropEx.
	StrToFloatEx (see page 23325)	This is function TypeTrans.StrToFloatEx.

Variables

Name	Description
TypeTranslator (see page 23326)	This is variable TypeTrans.TypeTranslator.

165.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	ETypeTransException (see page 23320)	ETypeTransException is the exception raised when a conversion between a SOAP type description and an Object Pascal type fails.
	TTypeTranslator (see page 23320)	This is class TypeTrans.TTypeTranslator.

165.1.1 ETypeTransException Class

ETypeTransException is the exception raised when a conversion between a SOAP type description and an Object Pascal type fails.

Class Hierarchy

Pascal

```
ETypeTransException = class(Exception);
```

C++

```
class ETypeTransException : public Exception;
```

File

TypeTrans

Description

ETypeTransException is thrown when an application attempts to convert a type in a SOAP packet to an Object Pascal type and fails for some reason.

See Also

TOPToSoapDomConvert (see page 18137)

165.1.2 TTypeTranslator Class

Class Hierarchy

Pascal

```
TTypeTranslator = class;
```

C++

```
class TTypeTranslator;
```

File

TypeTrans

Description

This is class TypeTrans.TTypeTranslator.

165.1.2.1 TTypeTranslator Members

The following tables list the members exposed by TTypeTranslator.

Public Methods

	Name	Description
	Base64ToVar (see page 23322)	This is the overview for the Base64ToVar method overload.
	CastNativeToSoap (see page 23322)	This is CastNativeToSoap, a member of class TTypeTranslator.
	CastSoapToNative (see page 23323)	This is CastSoapToNative, a member of class TTypeTranslator.
	CastSoapToVariant (see page 23323)	This is the overview for the CastSoapToVariant method overload.
	Create (see page 23321)	This is Create, a member of class TTypeTranslator.
V	Destroy (see page 23321)	This is Destroy, a member of class TTypeTranslator.

165.1.2.2 TTypeTranslator.Create Constructor

Pascal

```
constructor Create;
```

C++

```
__fastcall TTypeTranslator();
```

Description

This is Create, a member of class TTypeTranslator.

165.1.2.3 TTypeTranslator.Destroy Destructor

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TTypeTranslator();
```

Description

This is Destroy, a member of class TTypeTranslator.

165.1.2.4 TTypeTranslator Methods

The methods of the TTypeTranslator class are listed here.

Public Methods

	Name	Description
	Base64ToVar (see page 23322)	This is the overview for the Base64ToVar method overload.

	CastNativeToSoap (see page 23322)	This is CastNativeToSoap, a member of class TTypeTranslator.
	CastSoapToNative (see page 23323)	This is CastSoapToNative, a member of class TTypeTranslator.
	CastSoapToVariant (see page 23323)	This is the overview for the CastSoapToVariant method overload.

165.1.2.4.1 Base64ToVar Method

This is the overview for the Base64ToVar method overload.

Overload List

	Name	Description
	TTypeTranslator.Base64ToVar (Pointer, WideString) (see page 23322)	This is Base64ToVar, a member of class TTypeTranslator.
	TTypeTranslator.Base64ToVar (Variant, WideString) (see page 23322)	This is Base64ToVar, a member of class TTypeTranslator.

165.1.2.4.1.1 TTypeTranslator.Base64ToVar Method (Pointer, WideString)

Pascal

```
procedure Base64ToVar(NatData: Pointer; const SoapData: WideString); overload;
```

C++

```
__fastcall Base64ToVar(void * NatData, const BSTR SoapData);
```

Description

This is Base64ToVar, a member of class TTypeTranslator.

165.1.2.4.1.2 TTypeTranslator.Base64ToVar Method (Variant, WideString)

Pascal

```
procedure Base64ToVar(var V: Variant; const SoapData: WideString); overload;
```

C++

```
__fastcall Base64ToVar(Variant V, const BSTR SoapData);
```

Description

This is Base64ToVar, a member of class TTypeTranslator.

165.1.2.4.2 TTypeTranslator.CastNativeToSoap Method

Pascal

```
procedure CastNativeToSoap(Info: PTypeInfo; var SoapData: WideString; NatData: Pointer; var
IsNull: Boolean);
```

C++

```
__fastcall CastNativeToSoap(PTypeInfo Info, BSTR SoapData, void * NatData, Boolean IsNull);
```

Description

This is CastNativeToSoap, a member of class TTypeTranslator.

165.1.2.4.3 TTypeTranslator.CastSoapToNative Method

Pascal

```
function CastSoapToNative(Info: PTypeInfo; const SoapData: WideString; NatData: Pointer;
IsNull: Boolean): Boolean;
```

C++

```
__fastcall Boolean CastSoapToNative(PTypeInfo Info, const BSTR SoapData, void * NatData,
Boolean IsNull);
```

Description

This is CastSoapToNative, a member of class TTypeTranslator.

165.1.2.4.4 CastSoapToVariant Method

This is the overview for the CastSoapToVariant method overload.

Overload List

	Name	Description
	TTypeTranslator.CastSoapToVariant (PTypeInfo, WideString) (see page 23323)	This is CastSoapToVariant, a member of class TTypeTranslator.
	TTypeTranslator.CastSoapToVariant (PTypeInfo, WideString, Pointer) (see page 23323)	This is CastSoapToVariant, a member of class TTypeTranslator.

165.1.2.4.4.1 TTypeTranslator.CastSoapToVariant Method (PTypeInfo, WideString)

Pascal

```
function CastSoapToVariant(SoapInfo: PTypeInfo; const SoapData: WideString): Variant; overload;
```

C++

```
__fastcall Variant CastSoapToVariant(PTypeInfo SoapInfo, const BSTR SoapData);
```

Description

This is CastSoapToVariant, a member of class TTypeTranslator.

165.1.2.4.4.2 TTypeTranslator.CastSoapToVariant Method (PTypeInfo, WideString, Pointer)

Pascal

```
procedure CastSoapToVariant(SoapInfo: PTypeInfo; const SoapData: WideString; NatData:
Pointer); overload;
```

C++

```
__fastcall CastSoapToVariant(PTypeInfo SoapInfo, const BSTR SoapData, void * NatData);
```

Description

This is CastSoapToVariant, a member of class TTypeTranslator.

165.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	FloatToStrEx (see page 23324)	This is function TypeTrans.FloatToStrEx.
	GetEnumValueEx (see page 23324)	This is function TypeTrans.GetEnumValueEx.
	SetEnumPropEx (see page 23325)	This is function TypeTrans.SetEnumPropEx.
	StrToFloatEx (see page 23325)	This is function TypeTrans.StrToFloatEx.

165.2.1 TypeTrans.FloatToStrEx Function

Pascal

```
function FloatToStrEx(Value: Extended): string;
```

C++

```
AnsiString FloatToStrEx(Extended Value);
```

File

TypeTrans

Description

This is function TypeTrans.FloatToStrEx.

165.2.2 TypeTrans.GetEnumValueEx Function

Pascal

```
function GetEnumValueEx(TypInfo: PTypeInfo; const Name: string): Integer;
```

C++

```
int GetEnumValueEx(PTypeInfo TypInfo, const AnsiString Name);
```

File

TypeTrans

Description

This is function TypeTrans.GetEnumValueEx.

165.2.3 TypeTrans.SetEnumPropEx Function

Pascal

```
procedure SetEnumPropEx(Instance: TObject; PropInfo: PPropInfo; const Value: string);
```

C++

```
SetEnumPropEx(TObject * Instance, PPropInfo PropInfo, const AnsiString Value);
```

File

TypeTrans

Description

This is function TypeTrans.SetEnumPropEx.

165.2.4 TypeTrans.StrToFloatEx Function

Pascal

```
function StrToFloatEx(const S: string): Extended;
```

C++

```
Extended StrToFloatEx(const AnsiString S);
```

File

TypeTrans

Description

This is function TypeTrans.StrToFloatEx.

165.3 Variables

The following table lists variables in this documentation.

Variables

Name	Description
TypeTranslator (see page 23326)	This is variable TypeTrans.TypeTranslator.

165.3.1 TypeTrans.TypeTranslator Variable

Pascal

```
TypeTranslator: TTypeTranslator;
```

C++

```
TTypeTranslator TypeTranslator;
```

File

TypeTrans

Description

This is variable TypeTrans.TypeTranslator.

166 TypInfo Namespace

This is namespace TypInfo.

Topics

Name	Description
Classes (see page 23331)	The following table lists classes in this documentation.
Functions (see page 23338)	The following table lists functions in this documentation.
Structs, Records, Enums (see page 23372)	The following table lists structs, records, enums in this documentation.
Types (see page 23381)	The following table lists types in this documentation.
Variables (see page 23388)	The following table lists variables in this documentation.
Constants (see page 23389)	The following table lists constants in this documentation.

Classes

	Name	Description
	EPropertyConvertError (see page 23331)	EPropertyConvertError is the exception class for type errors when attempting to get or set the value of a property.
	EPropertyError (see page 23331)	EPropertyError is the exception class for unsuccessful attempts to set the value of a property.
	TPublishableVariantType (see page 23332)	TPublishableVariantType is the base class for custom Variant types that surface the published properties of an object that represents the Variant's data.

Constants

Name	Description
tkAny (see page 23389)	This is constant TypInfo.tkAny.
tkMethods (see page 23389)	This is constant TypInfo.tkMethods.
tkProperties (see page 23389)	This is constant TypInfo.tkProperties.

Functions

	Name	Description
	FreeAndNilProperties (see page 23339)	Frees any property values that are objects and sets their value to nil (Delphi) or NULL (C++).
	GetDynArrayProp (see page 23340)	Returns the value of a component property that is a dynamic array type.
	GetDynArrayProp (see page 23340)	Returns the value of a component property that is a dynamic array type.
	GetEnumName (see page 23341)	Returns the name of a Delphi enumerated type constant given its value.
	GetEnumProp (see page 23341)	Returns the value of a component property that is an enumerated type.
	GetEnumProp (see page 23341)	Returns the value of a component property that is an enumerated type.
	GetEnumValue (see page 23342)	Returns the value of an enumerated type constant given its string representation.

	GetFloatProp (see page 23343)	Returns the value of a component property that is a float type.
	GetFloatProp (see page 23343)	Returns the value of a component property that is a float type.
	GetInt64Prop (see page 23343)	Returns the value of a component property that is an Int64 type.
	GetInt64Prop (see page 23343)	Returns the value of a component property that is an Int64 type.
	GetInterfaceProp (see page 23344)	Returns the value of a component property that is an interface type.
	GetInterfaceProp (see page 23344)	Returns the value of a component property that is an interface type.
	GetMethodProp (see page 23345)	Returns the value of a component property that is a method type.
	GetMethodProp (see page 23345)	Returns the value of a component property that is a method type.
	GetObjectProp (see page 23346)	Returns the value of a component property that is an object type.
	GetObjectProp (see page 23346)	Returns the value of a component property that is an object type.
	GetObjectPropClass (see page 23347)	Returns the class type of a component property that is an object type.
	GetObjectPropClass (see page 23347)	Returns the class type of a component property that is an object type.
	GetObjectPropClass (see page 23347)	Returns the class type of a component property that is an object type.
	GetOrdProp (see page 23347)	Returns the value of a component property that is an ordinal type.
	GetOrdProp (see page 23347)	Returns the value of a component property that is an ordinal type.
	GetPropInfo (see page 23348)	Retrieves information about a component's property.
	GetPropInfo (see page 23348)	Retrieves information about a component's property.
	GetPropInfo (see page 23348)	Retrieves information about a component's property.
	GetPropInfo (see page 23348)	Retrieves information about a component's property.
	GetPropInfos (see page 23349)	Retrieves a list of component properties.
	GetPropList (see page 23350)	Retrieves a list of component properties.
	GetPropList (see page 23350)	Retrieves a list of component properties.
	GetPropList (see page 23350)	Retrieves a list of component properties.
	GetPropValue (see page 23351)	Retrieves a component's property value as a variant.
	GetPropValue (see page 23351)	Retrieves a component's property value as a variant.
	GetSetElementName (see page 23351)	This is function TypInfo.GetSetElementName.
	GetSetElementValue (see page 23352)	This is function TypInfo.GetSetElementValue.
	GetSetProp (see page 23352)	Returns the value of a component property that is a set type.
	GetSetProp (see page 23352)	Returns the value of a component property that is a set type.
	GetStrProp (see page 23353)	Returns the value of a component property that is a string type.
	GetStrProp (see page 23353)	Returns the value of a component property that is a string type.
	GetTypeData (see page 23354)	Returns a pointer to information about a type.
	GetVariantProp (see page 23354)	Returns the value of a component property that is a variant type.
	GetVariantProp (see page 23354)	Returns the value of a component property that is a variant type.
	GetWideStrProp (see page 23355)	Returns the value of a component property that is a WideString type.
	GetWideStrProp (see page 23355)	Returns the value of a component property that is a WideString type.
	IsPublishedProp (see page 23356)	Determines if a specified component property is a published property.
	IsPublishedProp (see page 23356)	Determines if a specified component property is a published property.
	IsStoredProp (see page 23356)	Determines if a specified component property has the stored attribute.
	IsStoredProp (see page 23356)	Determines if a specified component property has the stored attribute.
	PropIsType (see page 23357)	Determines if a component property is of a particular data type.
	PropIsType (see page 23357)	Determines if a component property is of a particular data type.
	PropType (see page 23358)	Retrieves a component's property type.
	PropType (see page 23358)	Retrieves a component's property type.
	SetDynArrayProp (see page 23358)	Sets the value of a component property that is a dynamic array type.
	SetDynArrayProp (see page 23358)	Sets the value of a component property that is a dynamic array type.
	SetEnumProp (see page 23359)	Sets the value of a component property that is an enumerated type.
	SetEnumProp (see page 23359)	Sets the value of a component property that is an enumerated type.
	SetFloatProp (see page 23360)	Sets the value of a component property that is a float type.
	SetFloatProp (see page 23360)	Sets the value of a component property that is a float type.
	SetInt64Prop (see page 23361)	Sets the value of a component property that is an Int64 type.
	SetInt64Prop (see page 23361)	Sets the value of a component property that is an Int64 type.
	SetInterfaceProp (see page 23362)	Sets the value of a component property that is an Interface type.
	SetInterfaceProp (see page 23362)	Sets the value of a component property that is an Interface type.

	SetMethodProp (see page 23362)	Sets the value of a component property that is a method type.
	SetMethodProp (see page 23362)	Sets the value of a component property that is a method type.
	SetObjectProp (see page 23363)	Sets the value of a component property that is an object type.
	SetObjectProp (see page 23363)	Sets the value of a component property that is an object type.
	SetOrdProp (see page 23364)	Sets the value of a component property that is an ordinal type.
	SetOrdProp (see page 23364)	Sets the value of a component property that is an ordinal type.
	SetPropValue (see page 23365)	Sets the value of a component property using a variant value.
	SetPropValue (see page 23365)	Sets the value of a component property using a variant value.
	SetSetProp (see page 23366)	Sets the value of a component property that is a set type.
	SetSetProp (see page 23366)	Sets the value of a component property that is a set type.
	SetStrProp (see page 23367)	Sets the value of a component property that is a string type.
	SetStrProp (see page 23367)	Sets the value of a component property that is a string type.
	SetToString (see page 23367)	Returns one or more of the set values of a component's property.
	SetVariantProp (see page 23368)	Sets the value of a component property that is a variant type.
	SetVariantProp (see page 23368)	Sets the value of a component property that is a variant type.
	SetWideStrProp (see page 23369)	Sets the value of a component property that is a WideString type.
	SetWideStrProp (see page 23369)	Sets the value of a component property that is a WideString type.
	SortPropList (see page 23370)	Sorts a list of component properties into alphanumeric sequence.
	StringToSet (see page 23370)	Returns a bit mask of set values for a set type component property.

Structs, Records, Enums

	Name	Description
	TFloatType (see page 23372)	This is record TypInfo.TFloatType.
	TIntfFlag (see page 23373)	This is record TypInfo.TIntfFlag.
	TMethodKind (see page 23373)	Enumerates floating point number types in the TTypeData (see page 23377) record.
	TOrdType (see page 23374)	Enumerates floating point number types in the TTypeData (see page 23377) record.
	TParamFlag (see page 23375)	TParamFlag and TParamFlags (see page 23386) indicates the attributes of a method parameter.
	TPropData (see page 23376)	This is record TypInfo.TPropData.
	TPropInfo (see page 23376)	TPropInfo is a record of component property type information.
	TTypeData (see page 23377)	TTypeData is used internally to represent type information.
	TTypeInfo (see page 23379)	Holds information for a data type as returned by TypeInfo.
	TTypeKind (see page 23379)	These types describe a type that is manipulated in the forms designer.

Types

Name	Description
PPropInfo (see page 23381)	PPropInfo points to a TPropInfo (see page 23376) record that holds component property information.
PPropList (see page 23382)	Defines a pointer to a TPropList (see page 23387) array.
PPTypeInfo (see page 23382)	Holds a pointer to a pointer to information for a data type as returned by TypeInfo.
PTypeData (see page 23383)	PTypeData points to a TTypeData (see page 23377) record that holds component property type information.
PTypeInfo (see page 23383)	Holds a pointer to information for a data type as returned by TypeInfo.
ShortStringBase (see page 23384)	Defines a fixed length string for general use in the TTypeData (see page 23377) record.
TIntfFlags (see page 23384)	Enumerates interface flag types in the TTypeData (see page 23377) record.
TIntfFlagsBase (see page 23385)	Set of interface flag types in the TTypeData (see page 23377) record.
TParamFlags (see page 23386)	This is type TypInfo.TParamFlags.
TParamFlagsBase (see page 23386)	This is type TypInfo.TParamFlagsBase.
TPropInfoProc (see page 23386)	This is type TypInfo.TPropInfoProc.
TPropList (see page 23387)	Defines an array of PPropInfo (see page 23381) values.
TTypeKinds (see page 23387)	Defines a set of TTypeKind (see page 23379) values.

Variables

Name	Description
BooleanIdents (see page 23388)	An array of string representations of true and false.
DotSep (see page 23388)	This is variable TypInfo.DotSep.

166.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EPropertyConvertError (see page 23331)	EPropertyConvertError is the exception class for type errors when attempting to get or set the value of a property.
	EPropertyError (see page 23331)	EPropertyError is the exception class for unsuccessful attempts to set the value of a property.
	TPublishableVariantType (see page 23332)	TPublishableVariantType is the base class for custom Variant types that surface the published properties of an object that represents the Variant's data.

166.1.1 EPropertyConvertError Class

EPropertyConvertError is the exception class for type errors when attempting to get or set the value of a property.

Class Hierarchy

Pascal

```
EPropertyConvertError = class(Exception);
```

C++

```
class EPropertyConvertError : public Exception;
```

File

TypInfo

Description

EPropertyConvertError is raised when an application tries to set a property to a value of the wrong type or to read a property that has invalid type information.

See Also

EPropertyError (see page 23331)

TPropertyEditor (see page 11019)

166.1.2 EPropertyError Class

EPropertyError is the exception class for unsuccessful attempts to set the value of a property.

Class Hierarchy

Pascal

```
EPropertyError = class(Exception);
```

C++

```
class EPropertyError : public Exception;
```

File

TypInfo

Description

EPropertyError is raised by the SetValue (or Edit) methods of property-editor objects when they cannot set a requested property value. This usually occurs because the requested value is out of range or of an invalid data type.

See Also

TPropertyEditor (see page 11019)

TPropertyEditor (see page 11019)

166.1.3 TPublishableVariantType Class

TPublishableVariantType is the base class for custom Variant types that surface the published properties of an object that represents the Variant's data.

Class Hierarchy

Pascal

```
TPublishableVariantType = class(TInvokeableVariantType, IVarInstanceReference);
```

C++

```
class TPublishableVariantType : public TInvokeableVariantType, public IVarInstanceReference;
```

File

TypInfo

Description

TPublishableVariantType is the base class for new data types for Variants (see page 23567) that have properties and methods. TPublishableVariantType descendants do not represent the Variants (see page 23567) themselves. Rather, they act as utility classes that the custom Variants (see page 23567) call on to perform their operations. TPublishableVariantType adds to its ancestor's ability to implement properties and methods on Variants (see page 23567) of the custom type by automatically implementing all published properties of the object it uses to store its data.

Note: To create a Variant type that descends from TPublishableVariantType,

Note: 1. Map the storage of the Variant's data on to the TVarData record.

Note: 2. Write a method that creates instances of your custom Variant. This fills in the Variant's data as defined in step 1.

Note: 3. Declare a class that descends from TPublishableVariantType.

Note: 4. Override the GetInstance (see page 23336) method to return the object that stores the custom Variant's data.

Note: 5. Implement all other required behavior (including type conversion rules) in the new class. This involves overriding the appropriate virtual methods (typically DoFunction, DoProcedure, BinaryOp, UnaryOp, CompareOp or Compare, Cast, CastTo, Clear, Copy, IsClear, LeftPromotion, and RightPromotion).

Note: 6. In the initialization section of the unit that defines your TPublishableVariantType descendant, create an instance of your class. When you instantiate your object, it automatically registers itself with the Variant-handling system so that the new Variant type is enabled.

Note: 7. In the finalization section of the unit that defines your TPublishableVariantType descendant, free the instance of your class. This automatically unregisters the Variant type.

Note: For an example, see the VarCmplx (see page 23513) (Windows) or FMTBcd (see page 13627) (Linux) unit, which implements a custom Variant type for complex (Windows) or binary-coded decimal (Linux) numbers.

Note: Do not create your own custom Variant types in C++. They are only supported in Delphi.

Supporting Properties and Methods in Custom Variants

166.1.3.1 TPublishableVariantType Members

The following tables list the members exposed by TPublishableVariantType.

Protected Methods

	Name	Description
	_AddRef (see page 23586)	Increments the reference count for this interface.
	_Release (see page 23587)	Decrements the reference count for this interface.
V	DispInvoke (see page 23592)	Invokes a method call when the Variant supports such operations.
V	DispInvoke (see page 23610)	Invokes a method call by dispatching it to the appropriate TInvokeableVariantType (see page 23606) method.
V	FixupIdent (see page 23612)	Fixes up dispatch identifier.
A	GetInstance (see page 23336)	Returns the object instance that represents the data from a Variant of the custom type.
V	LeftPromotion (see page 23593)	Indicates whether the left argument to a binary operation should be coerced to a different type.

	OlePromotion (see page 23594)	Indicates the type to which a Variant value must be cast to make it Automation-compatible.
	QueryInterface (see page 23594)	Returns a reference to a specified interface if the object supports that interface.
	RaiseCastError (see page 23595)	Generates a system error that indicates an invalid cast.
	RaiseDispError (see page 23595)	Generates a system error indicating an invalid dispatch attempt.
	RaiseInvalidOp (see page 23596)	Generates a system error indicating an invalid operation.
	RightPromotion (see page 23596)	Indicates whether the right argument to a binary operation should be coerced to a different type.
	SimplisticClear (see page 23597)	Clears a TVarData record by re-initializing it.
	SimplisticCopy (see page 23598)	Performs a simple block copy of one TVarData record to another.
	VarDataCast (see page 23599)	Performs a cast from one Variant type to another.
	VarDataCastTo (see page 23599)	This is the overview for the VarDataCastTo method overload.
	VarDataCastToOleStr (see page 23600)	Performs a cast to a Variant type of varOleStr.
	VarDataClear (see page 23600)	Clears the data from a built-in Variant type.
	VarDataCopy (see page 23601)	Copies the data from one built-in Variant type to another.
	VarDataCopyNoInd (see page 23601)	Copies the data from one built-in Variant type to another.
	VarDataFromOleStr (see page 23602)	Creates a TVarData record to represent a Unicode string.
	VarDataFromStr (see page 23602)	Creates a TVarData record to represent a string.
	VarDataInit (see page 23602)	Initializes a TVarData record.
	VarDataIsArray (see page 23603)	Indicates whether a TVarData record represents the data from a Variant array.
	VarDataIsByRef (see page 23603)	Indicates whether a TVarData record stores its data indirectly.
	VarDataIsEmptyParam (see page 23603)	Indicates whether a TVarData record represents an unassigned optional parameter.
	VarDataIsFloat (see page 23604)	Indicates whether a TVarData record represents a floating-point value.
	VarDataIsNumeric (see page 23604)	Indicates whether a TVarData record represents a numeric value.
	VarDataIsOrdinal (see page 23605)	Indicates whether a TVarData record represents a ordinal value.
	VarDataIsStr (see page 23605)	Indicates whether a TVarData record represents a string (normal or Unicode).
	VarDataToStr (see page 23605)	Returns a string that represents the value from a TVarData record.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BinaryOp (see page 23587)	Implements any binary operations of which the custom Variant type is capable.
	Cast (see page 23588)	Converts the data from another Variant type so that it represents this custom type's data format.
	CastTo (see page 23589)	This is CastTo, a member of class TCustomVariantType.
	CastToOle (see page 23589)	This is CastToOle, a member of class TCustomVariantType.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 23589)	Sets the data for this custom Variant type to a blank or unassigned value.
	Compare (see page 23590)	Implements comparisons that involve the custom Variant type.
	CompareOp (see page 23590)	Implements any comparison operations of which the custom Variant type is capable.
	Copy (see page 23591)	Copies the data from a Variant of this custom type.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	Create (see page 23584)	This is the overview for the Create constructor overload.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 22287)	Disposes of an object instance.

	Destroy (see page 23585)	Frees an instance of TCustomVariantType (see page 23581).
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	DoFunction (see page 23616)	This is DoFunction, a member of class IVarInvokeable.
	DoFunction (see page 23610)	Implements all methods that return values.
	DoProcedure (see page 23616)	This is DoProcedure, a member of class IVarInvokeable.
	DoProcedure (see page 23611)	Implements all methods that do not return values.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetProperty (see page 23336)	Returns the value of a published property on the object that GetInstance (see page 23336) returns, so that it is available in custom Variants (see page 23567).
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsClear (see page 23592)	Indicates whether the data from a custom Variant represents a blank or unassigned value.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	SetProperty (see page 23337)	Sets the value of a published property on the object that GetInstance (see page 23336) returns, so that it is available in custom Variants (see page 23567).
	UnaryOp (see page 23598)	Implements any unary operations of which the custom Variant type is capable.

Public Properties

	Name	Description
	VarType (see page 23606)	Indicates the Variant type code for the custom Variant type.

166.1.3.2 TPublishableVariantType Methods

The methods of the TPublishableVariantType class are listed here.

Protected Methods

	Name	Description
	GetInstance (see page 23336)	Returns the object instance that represents the data from a Variant of the custom type.

Public Methods

	Name	Description
	GetProperty (see page 23336)	Returns the value of a published property on the object that GetInstance (see page 23336) returns, so that it is available in custom Variants (see page 23567).
	SetProperty (see page 23337)	Sets the value of a published property on the object that GetInstance (see page 23336) returns, so that it is available in custom Variants (see page 23567).

166.1.3.2.1 TPublishableVariantType.GetInstance Method

Returns the object instance that represents the data from a Variant of the custom type.

Pascal

```
function GetInstance(const V: TVarData): TObject; virtual; abstract;
```

C++

```
virtual __fastcall TObject * GetInstance(const TVarData V) = 0;
```

Description

Override GetInstance to return the object that represents the data from a Variant of the custom Type. TPublishableVariantType (see page 23332) implements all the published properties of that object so that they are published properties of the Variant.

V is the data from a Variant of the custom type. This data must include a reference to an object that represents the Variant's data, and which GetInstance returns.

GetInstance is abstract or, in C++ terminology, pure virtual in TPublishableVariantType (see page 23332), which means it has no implementation. Descendant classes override this method to enable Variants (see page 23567) to publish the properties from the object that implements their data.

See Also

GetProperty (see page 23336)

SetProperty (see page 23337)

Supporting Properties and Methods in Custom Variants

166.1.3.2.2 TPublishableVariantType.GetProperty Method

Returns the value of a published property on the object that GetInstance (see page 23336) returns, so that it is available in custom Variants (see page 23567).

Pascal

```
function GetProperty(var Dest: TVarData; const V: TVarData; const Name: string): Boolean;
override;
```

C++

```
virtual __fastcall Boolean GetProperty(TVarData Dest, const TVarData V, const AnsiString Name);
```

Description

GetProperty enables an application to read the properties of instances of the publishable Variant type. It implements all the properties that are published by the object that GetInstance (see page 23336) returns.

When the application contains a line such as

```
PropValue := MyVariant.SpecialProperty;
```

(Delphi) or calls the Exec method of the Variant (C++), a call is automatically generated to GetProperty. If SpecialProperty is a published property on the object that implements the Variant's data, GetProperty fills in the Dest parameter with the property value.

Dest is a TVarData record (Delphi) or structure (C++) that receives the property value.

V is the TVarData record or structure from the Variant instance whose property is being read.

Name is the name of the property.

GetProperty returns true if it returns a property value, and raises an exception if it does not implement the specified property.

See Also

DoFunction (see page 23610)

DoProcedure (see page 23611)

GetInstance (see page 23336)

Exec

166.1.3.2.3 TPublishableVariantType.SetProperty Method

Sets the value of a published property on the object that GetInstance (see page 23336) returns, so that it is available in custom Variants (see page 23567).

Pascal

```
function SetProperty(const V: TVarData; const Name: string; const Value: TVarData): Boolean;
override;
```

C++

```
virtual __fastcall Boolean SetProperty(const TVarData V, const AnsiString Name, const TVarData
Value);
```

Description

SetProperty enables an application to set the properties of instances of the publishable Variant type. It implements all the settable properties that are published by the object that GetInstance (see page 23336) returns.

When the application contains a line such as

```
MyVariant.SpecialProperty := NewValue;
```

(Delphi) or calls the Exec method of the Variant (C++), a call is automatically generated to SetProperty. If SpecialProperty is a published settable property on the object that implements the Variant's data, SetProperty sets the property on the object included in V so that the Variant's value is changed accordingly.

V is the TVarData record (Delphi) or structure (C++) from the Variant instance whose property is being set. It includes the object that the GetInstance (see page 23336) method returns.

Name is the name of the property.

Value is a TVarData record or structure that contains the new property value.

GetProperty (see page 23336) returns true if it sets a property value, and raises an exception of Name does not specify a published settable property on the object that GetInstance (see page 23336) returns.

166.2 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	FreeAndNilProperties (see page 23339)	Frees any property values that are objects and sets their value to nil (Delphi) or NULL (C++).
	GetDynArrayProp (see page 23340)	Returns the value of a component property that is a dynamic array type.
	GetDynArrayProp (see page 23340)	Returns the value of a component property that is a dynamic array type.
	GetEnumName (see page 23341)	Returns the name of a Delphi enumerated type constant given its value.
	GetEnumProp (see page 23341)	Returns the value of a component property that is an enumerated type.
	GetEnumProp (see page 23341)	Returns the value of a component property that is an enumerated type.
	GetEnumValue (see page 23342)	Returns the value of an enumerated type constant given its string representation.
	GetFloatProp (see page 23343)	Returns the value of a component property that is a float type.
	GetFloatProp (see page 23343)	Returns the value of a component property that is a float type.
	GetInt64Prop (see page 23343)	Returns the value of a component property that is an Int64 type.
	GetInt64Prop (see page 23343)	Returns the value of a component property that is an Int64 type.
	GetInterfaceProp (see page 23344)	Returns the value of a component property that is an interface type.
	GetInterfaceProp (see page 23344)	Returns the value of a component property that is an interface type.
	GetMethodProp (see page 23345)	Returns the value of a component property that is a method type.
	GetMethodProp (see page 23345)	Returns the value of a component property that is a method type.
	GetObjectProp (see page 23346)	Returns the value of a component property that is an object type.
	GetObjectProp (see page 23346)	Returns the value of a component property that is an object type.
	GetObjectPropClass (see page 23347)	Returns the class type of a component property that is an object type.
	GetObjectPropClass (see page 23347)	Returns the class type of a component property that is an object type.
	GetObjectPropClass (see page 23347)	Returns the class type of a component property that is an object type.
	GetOrdProp (see page 23347)	Returns the value of a component property that is an ordinal type.
	GetOrdProp (see page 23347)	Returns the value of a component property that is an ordinal type.
	GetPropInfo (see page 23348)	Retrieves information about a component's property.
	GetPropInfo (see page 23348)	Retrieves information about a component's property.
	GetPropInfo (see page 23348)	Retrieves information about a component's property.
	GetPropInfo (see page 23348)	Retrieves information about a component's property.
	GetPropInfos (see page 23349)	Retrieves a list of component properties.
	GetPropList (see page 23350)	Retrieves a list of component properties.
	GetPropList (see page 23350)	Retrieves a list of component properties.
	GetPropList (see page 23350)	Retrieves a list of component properties.
	GetPropValue (see page 23351)	Retrieves a component's property value as a variant.
	GetPropValue (see page 23351)	Retrieves a component's property value as a variant.
	GetSetElementName (see page 23351)	This is function TypInfo.GetSetElementName.
	GetSetElementValue (see page 23352)	This is function TypInfo.GetSetElementValue.
	GetSetProp (see page 23352)	Returns the value of a component property that is a set type.
	GetSetProp (see page 23352)	Returns the value of a component property that is a set type.
	GetStrProp (see page 23353)	Returns the value of a component property that is a string type.
	GetStrProp (see page 23353)	Returns the value of a component property that is a string type.
	GetTypeData (see page 23354)	Returns a pointer to information about a type.
	GetVariantProp (see page 23354)	Returns the value of a component property that is a variant type.
	GetVariantProp (see page 23354)	Returns the value of a component property that is a variant type.
	GetWideStrProp (see page 23355)	Returns the value of a component property that is a WideString type.
	GetWideStrProp (see page 23355)	Returns the value of a component property that is a WideString type.
	IsPublishedProp (see page 23356)	Determines if a specified component property is a published property.

	IsPublishedProp (see page 23356)	Determines if a specified component property is a published property.
	IsStoredProp (see page 23356)	Determines if a specified component property has the stored attribute.
	IsStoredProp (see page 23356)	Determines if a specified component property has the stored attribute.
	PropIsType (see page 23357)	Determines if a component property is of a particular data type.
	PropIsType (see page 23357)	Determines if a component property is of a particular data type.
	PropType (see page 23358)	Retrieves a component's property type.
	PropType (see page 23358)	Retrieves a component's property type.
	SetDynArrayProp (see page 23358)	Sets the value of a component property that is a dynamic array type.
	SetDynArrayProp (see page 23358)	Sets the value of a component property that is a dynamic array type.
	SetEnumProp (see page 23359)	Sets the value of a component property that is an enumerated type.
	SetEnumProp (see page 23359)	Sets the value of a component property that is an enumerated type.
	SetFloatProp (see page 23360)	Sets the value of a component property that is a float type.
	SetFloatProp (see page 23360)	Sets the value of a component property that is a float type.
	SetInt64Prop (see page 23361)	Sets the value of a component property that is an Int64 type.
	SetInt64Prop (see page 23361)	Sets the value of a component property that is an Int64 type.
	SetInterfaceProp (see page 23362)	Sets the value of a component property that is an Interface type.
	SetInterfaceProp (see page 23362)	Sets the value of a component property that is an Interface type.
	SetMethodProp (see page 23362)	Sets the value of a component property that is a method type.
	SetMethodProp (see page 23362)	Sets the value of a component property that is a method type.
	SetObjectProp (see page 23363)	Sets the value of a component property that is an object type.
	SetObjectProp (see page 23363)	Sets the value of a component property that is an object type.
	SetOrdProp (see page 23364)	Sets the value of a component property that is an ordinal type.
	SetOrdProp (see page 23364)	Sets the value of a component property that is an ordinal type.
	SetPropValue (see page 23365)	Sets the value of a component property using a variant value.
	SetPropValue (see page 23365)	Sets the value of a component property using a variant value.
	SetSetProp (see page 23366)	Sets the value of a component property that is a set type.
	SetSetProp (see page 23366)	Sets the value of a component property that is a set type.
	SetStrProp (see page 23367)	Sets the value of a component property that is a string type.
	SetStrProp (see page 23367)	Sets the value of a component property that is a string type.
	SetToString (see page 23367)	Returns one or more of the set values of a component's property.
	SetVariantProp (see page 23368)	Sets the value of a component property that is a variant type.
	SetVariantProp (see page 23368)	Sets the value of a component property that is a variant type.
	SetWideStrProp (see page 23369)	Sets the value of a component property that is a WideString type.
	SetWideStrProp (see page 23369)	Sets the value of a component property that is a WideString type.
	SortPropList (see page 23370)	Sorts a list of component properties into alphanumeric sequence.
	StringToSet (see page 23370)	Returns a bit mask of set values for a set type component property.

166.2.1 TypInfo.FreeAndNilProperties Function

Frees any property values that are objects and sets their value to nil (Delphi) or NULL (C++).

Pascal

```
procedure FreeAndNilProperties(AObject: TObject);
```

C++

```
FreeAndNilProperties(TObject * AObject);
```

File

TypInfo

Description

Call FreeAndNilProperties from a destructor to free all internally created objects and set the corresponding property values to nil

(Delphi) or NULL (C++). FreeAndNilProperties searches the properties of AObject, identifying any that are objects. It frees those objects, and sets the corresponding property to nil (Delphi) or NULL (C++).

. By default, all persistent objects (TPersistent and descendants) are compiled with RTTI. Other TObject descendants can be compiled with RTTI by using the $M+ compiler switch in Delphi or the __declspec(delphirtti) directive in C++.

Warning: Calling FreeAndNilProperties frees all object properties, which may lead to unintended results. FreeAndNilProperties can't distinguish between objects that were created by AObject (and typically stored in a class member) from objects that are created independently and which should not be freed with AObject. To avoid unintentionally freeing independently-created objects, set properties that refer to external objects to nil (Delphi) or NULL (C++) before calling FreeAndNilProperties.

FreeAndNil

166.2.2 TypInfo.GetDynArrayProp Function

Returns the value of a component property that is a dynamic array type.

Pascal

```
function GetDynArrayProp(Instance: TObject; const PropName: string): Pointer; overload;
function GetDynArrayProp(Instance: TObject; PropInfo: PPropInfo): Pointer; overload;
```

C++

```
void * GetDynArrayProp(TObject * Instance, const AnsiString PropName);
void * GetDynArrayProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetDynArrayProp utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property where that property is a dynamic array type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a pointer to the array.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.3 TypInfo.GetEnumName Function

Returns the name of a Delphi enumerated type constant given its value.

Pascal

```
function GetEnumName(TypeInfo: PTypeInfo; Value: Integer): string;
```

C++

```
AnsiString GetEnumName(PTypeInfo TypeInfo, int Value);
```

File

TypInfo

Description

Use GetEnumName to convert a Delphi enumerated value into the symbolic name that represents it in code.

TypeInfo is the type information record that describes the enumerated type. You can obtain the type information for a type by calling the TypeInfo function in Delphi or the __delphirtti operator in C++.

Value is the enumerated value, represented as an integer.

GetEnumName returns the string that represents the specified value.

See Also

IntToIdent

TypeInfo

GetEnumValue (see page 23342)

166.2.4 TypInfo.GetEnumProp Function

Returns the value of a component property that is an enumerated type.

Pascal

```
function GetEnumProp(Instance: TObject; const PropName: string): string; overload;
function GetEnumProp(Instance: TObject; PropInfo: PPropInfo): string; overload;
```

C++

```
AnsiString GetEnumProp(TObject * Instance, const AnsiString PropName);
AnsiString GetEnumProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetEnumProp utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property where that property is an enumerated type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a string.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.5 TypInfo.GetEnumValue Function

Returns the value of an enumerated type constant given its string representation.

Pascal

```
function GetEnumValue(TypeInfo: PTypeInfo; const Name: string): Integer;
```

C++

```
int GetEnumValue(PTypeInfo TypeInfo, const AnsiString Name);
```

File

TypInfo

Description

Use GetEnumValue to convert the string that represents an enumerated value into the corresponding integer that is its implemented value.

TypeInfo is the type information record that describes the enumerated type. You can obtain the type information for a type by calling the TypeInfo function in Delphi or using the __delphirtti operator in C++.

Name is the string that is used in code to represent the enumerated value.

GetEnumValue returns the corresponding integer value.

IdentToInt

TypeInfo

GetEnumName (see page 23341)

166.2.6 TypInfo.GetFloatProp Function

Returns the value of a component property that is a float type.

Pascal

```
function GetFloatProp(Instance: TObject; const PropName: string): Extended; overload;
function GetFloatProp(Instance: TObject; PropInfo: PPropInfo): Extended; overload;
```

C++

```
Extended GetFloatProp(TObject * Instance, const AnsiString PropName);
Extended GetFloatProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetFloatProp utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property where that property is a floating point number type. 0.0 is returned if the property is not of this type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a float value.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.7 TypInfo.GetInt64Prop Function

Returns the value of a component property that is an Int64 type.

Pascal

```
function GetInt64Prop(Instance: TObject; const PropName: string): Int64; overload;
function GetInt64Prop(Instance: TObject; PropInfo: PPropInfo): Int64; overload;
```

C++

```
Int64 GetInt64Prop(TObject * Instance, const AnsiString PropName);
Int64 GetInt64Prop(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetInt64Prop utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property where that property is an Int64 type. 0 is returned if the property is not of this type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as an Int64 value.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.8 TypInfo.GetInterfaceProp Function

Returns the value of a component property that is an interface type.

Pascal

```
function GetInterfaceProp(Instance: TObject; const PropName: string): IInterface; overload;
function GetInterfaceProp(Instance: TObject; PropInfo: PPropInfo): IInterface; overload;
```

C++

```
IInterface GetInterfaceProp(TObject * Instance, const AnsiString PropName);
IInterface GetInterfaceProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetInterfaceProp utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property where that property is an interface type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as an interface value.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

See Also

166.2.9 TypInfo.GetMethodProp Function

Returns the value of a component property that is a method type.

Pascal

```
function GetMethodProp(Instance: TObject; const PropName: string): TMethod; overload;
function GetMethodProp(Instance: TObject; PropInfo: PPropInfo): TMethod; overload;
```

C++

```
TMethod GetMethodProp(TObject * Instance, const AnsiString PropName);
TMethod GetMethodProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetMethodProp utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property where that property is a method type : an event routine.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a method value.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is

thrown.

166.2.10 TypInfo.GetObjectProp Function

Returns the value of a component property that is an object type.

Pascal

```
function GetObjectProp(Instance: TObject; const PropName: string; MinClass: TClass = nil):
TObject; overload;
function GetObjectProp(Instance: TObject; PropInfo: PPropInfo; MinClass: TClass = nil):
TObject; overload;
```

C++

```
TObject * GetObjectProp(TObject * Instance, const AnsiString PropName, TClass MinClass = nil);
TObject * GetObjectProp(TObject * Instance, PPropInfo PropInfo, TClass MinClass = nil);
```

File

TypInfo

Description

GetObjectProp utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property where that property is an object type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as an object, or nil if the property is not an object type.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.11 TypInfo.GetObjectPropClass Function

Returns the class type of a component property that is an object type.

Pascal

```
function GetObjectPropClass(Instance: TObject; const PropName: string): TClass; overload;
function GetObjectPropClass(Instance: TObject; PropInfo: PPropInfo): TClass; overload;
function GetObjectPropClass(PropInfo: PPropInfo): TClass; overload;
```

C++

```
TClass GetObjectPropClass(TObject * Instance, const AnsiString PropName);
TClass GetObjectPropClass(TObject * Instance, PPropInfo PropInfo);
TClass GetObjectPropClass(PPropInfo PropInfo);
```

File

TypInfo

Description

GetObjectPropClass utilises Delphi's RTTI (Run Time Type Information) to return the class type of a component's property where that property is an object.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the class type of the property object value is returned.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

See Also

GetPropInfo (see page 23348)

GetPropValue (see page 23351)

PPropInfo (see page 23381)

166.2.12 TypInfo.GetOrdProp Function

Returns the value of a component property that is an ordinal type.

Pascal

```
function GetOrdProp(Instance: TObject; const PropName: string): Longint; overload;
function GetOrdProp(Instance: TObject; PropInfo: PPropInfo): Longint; overload;
```

C++

```
Longint GetOrdProp(TObject * Instance, const AnsiString PropName);
Longint GetOrdProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetOrdProp utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property where that property is an Integer, Char, WideChar, or Class type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as an LongInt value.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

See Also

GetPropInfo (see page 23348)

GetPropValue (see page 23351)

PPropInfo (see page 23381)

SetOrdProp (see page 23364)

166.2.13 TypInfo.GetPropInfo Function

Retrieves information about a component's property.

Pascal

```
function GetPropInfo(Instance: TObject; const PropName: string; AKinds: TTypeKinds = []):
PPropInfo; overload;
function GetPropInfo(AClass: TClass; const PropName: string; AKinds: TTypeKinds = []):
PPropInfo; overload;
function GetPropInfo(TypeInfo: PTypeInfo; const PropName: string): PPropInfo; overload;
function GetPropInfo(TypeInfo: PTypeInfo; const PropName: string; AKinds: TTypeKinds):
PPropInfo; overload;
```

C++

```
PPropInfo GetPropInfo(TObject * Instance, const AnsiString PropName, TTypeKinds AKinds = []);
PPropInfo GetPropInfo(TClass AClass, const AnsiString PropName, TTypeKinds AKinds = []);
PPropInfo GetPropInfo(PTypeInfo TypeInfo, const AnsiString PropName);
PPropInfo GetPropInfo(PTypeInfo TypeInfo, const AnsiString PropName, TTypeKinds AKinds);
```

File

TypInfo

Description

GetPropInfo utilises Delphi's RTTI (Run Time Type Information) to retrieve a pointer to a property information record for a component.

In the first form of this function, **TypeInfo** specifies the component type whose property you want to retrieve. **PropName** specifies the property name as a string. You may optionally specify a **AKinds** set of TTypeKind (see page 23379) property value types that the property must belong to.

The second form of the function is similar to the first, with **AClass** replacing **TypeInfo** as the means of specifying the component type. **AKinds** is now a required value.

The final form of the function is like the second form, with **Instance** specifying a component instance.

In all forms of the function, the returned value is a pointer to a TPropInfo (see page 23376) value. This provides rich data about the property being investigated at run time. This enables more elegant component processing than can be achieved with hard coded component names/properties.

Note: If the specified property does not exist, a nil pointer is returned.

See Also

PTypeInfo (see page 23383)

PPropInfo (see page 23381)

TTypeKinds (see page 23387)

166.2.14 TypInfo.GetPropInfos Function

Retrieves a list of component properties.

Pascal

```
procedure GetPropInfos(TypeInfo: PTypeInfo; PropList: PPropList);
```

C++

```
GetPropInfos(PTypeInfo TypeInfo, PPropList PropList);
```

File

TypInfo

Description

GetPropInfos utilises Delphi's RTTI (Run Time Type Information) to retrieve a list of property information records for a component or component type.

The **TypeInfo** defines the component type and **PropList** defines a variable to receive the list of properties : a pointer to a TPropList (see page 23387) variable

The Delphi inbuilt TypeInfo function may be used to provide the **TypeInfo** value.

Note: If you want the count of properties returned in PropList

, use GetPropList (see page 23350) instead.

See Also

GetPropList (see page 23350)

PTypeInfo (see page 23383)

PPropList (see page 23382)

TPropList (see page 23387)

TTypeKinds (see page 23387)

166.2.15 TypInfo.GetPropList Function

Retrieves a list of component properties.

Pascal

```
function GetPropList(TypeInfo: PTypeInfo; TypeKinds: TTypeKinds; PropList: PPropList;
SortList: Boolean = True): Integer; overload;
function GetPropList(TypeInfo: PTypeInfo; out PropList: PPropList): Integer; overload;
function GetPropList(AObject: TObject; out PropList: PPropList): Integer; overload;
```

C++

```
int GetPropList(PTypeInfo TypeInfo, TTypeKinds TypeKinds, PPropList PropList, Boolean SortList
= True);
int GetPropList(PTypeInfo TypeInfo, PPropList PropList);
int GetPropList(TObject * AObject, PPropList PropList);
```

File

TypInfo

Description

GetPropList utilises Delphi's RTTI (Run Time Type Information) to retrieve a list of property information records for a component or component type.

In one form of this function, **TypeInfo** defines the component type, **PropList** defines a variable to receive the list of properties : a pointer to a TPropList (see page 23387) variable, and **TypeKinds** defines the type of properties that will be returned. Use tkAny (see page 23389) to return all types. The list may optionally be sorted by setting **SortList** true.

The Delphi inbuilt TypeInfo function may be used to provide the **TypeInfo** value.

In the other form of this function, you specify a component instance rather than component type. The **TypeKinds** and **SortList** parameters can no longer be specified.

In both forms of the function, the returned value is the number of properties in **PropList**.

Note: If you do not need the count of properties returned, use GetPropInfos (see page 23349).

166.2.16 TypInfo.GetPropValue Function

Retrieves a component's property value as a variant.

Pascal

```
function GetPropValue(Instance: TObject; const PropName: string; PreferStrings: Boolean =
True): Variant; overload;
function GetPropValue(Instance: TObject; PropInfo: PPropInfo; PreferStrings: Boolean = True):
Variant; overload;
```

C++

```
Variant GetPropValue(TObject * Instance, const AnsiString PropName, Boolean PreferStrings =
True);
Variant GetPropValue(TObject * Instance, PPropInfo PropInfo, Boolean PreferStrings = True);
```

File

TypInfo

Description

GetPropValue utilises Delphi's RTTI (Run Time Type Information) to retrieve a a component property as a variant.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the returned value the property value as a variant.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

See Also

PTypeInfo (see page 23383)

TTypeKinds (see page 23387)

SetPropValue (see page 23365)

166.2.17 TypInfo.GetSetElementName Function

Pascal

```
function GetSetElementName(TypeInfo: PTypeInfo; Value: Integer): string;
```

C++

```
AnsiString GetSetElementName(PTypeInfo TypeInfo, int Value);
```

File

TypInfo

Description

This is function TypInfo.GetSetElementName.

166.2.18 TypInfo.GetSetElementValue Function

Pascal

```
function GetSetElementValue(TypeInfo: PTypeInfo; const Name: string): Integer;
```

C++

```
int GetSetElementValue(PTypeInfo TypeInfo, const AnsiString Name);
```

File

TypInfo

Description

This is function TypInfo.GetSetElementValue.

166.2.19 TypInfo.GetSetProp Function

Returns the value of a component property that is a set type.

Pascal

```
function GetSetProp(Instance: TObject; const PropName: string; Brackets: Boolean = False):
string; overload;
function GetSetProp(Instance: TObject; PropInfo: PPropInfo; Brackets: Boolean = False):
string; overload;
```

C++

```
AnsiString GetSetProp(TObject * Instance, const AnsiString PropName, Boolean Brackets = False);
AnsiString GetSetProp(TObject * Instance, PPropInfo PropInfo, Boolean Brackets = False);
```

File

TypInfo

Description

GetSetProp utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property where that property is a set of values type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the list if set values is returned as a comma separated string. You may optionally set **Brackets** true so as to enclose this within square brackets, as shown in the IDE for the property.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

See Also

GetPropInfo (see page 23348)

GetPropValue (see page 23351)

PPropInfo (see page 23381)

SetSetProp (see page 23366)

166.2.20 TypInfo.GetStrProp Function

Returns the value of a component property that is a string type.

Pascal

```
function GetStrProp(Instance: TObject; const PropName: string): string; overload;
function GetStrProp(Instance: TObject; PropInfo: PPropInfo): string; overload;
```

C++

```
AnsiString GetStrProp(TObject * Instance, const AnsiString PropName);
AnsiString GetStrProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetStrProp utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property where that property is a String, LongString or WideString type. An empty string is returned if the property is not of this type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a string.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

See Also

GetPropInfo (see page 23348)

SetStrProp (see page 23367)

166.2.21 TypInfo.GetTypeData Function

Returns a pointer to information about a type.

Pascal

```
function GetTypeData(TypeInfo: PTypeInfo): PTypeData;
```

C++

```
PTypeData GetTypeData(PTypeInfo TypeInfo);
```

File

TypInfo

Description

GetTypeData utilises Delphi's RTTI (Run Time Type Information) to return a pointer to TTypeData (see page 23377) record.

The TTypeData (see page 23377) record is a variant type, but does not contain the variant as a tag. To identify which variant applies to a particular type, you should retrieve the TTypeKind (see page 23379) value using the TypeInfo routine.

The TTypeData (see page 23377) record holds meta data about a property. For example, the name of the unit a class type is stored in.

See Also

PTypeData (see page 23383)

TTypeData (see page 23377)

TTypeKind (see page 23379)

166.2.22 TypInfo.GetVariantProp Function

Returns the value of a component property that is a variant type.

Pascal

```
function GetVariantProp(Instance: TObject; const PropName: string): Variant; overload;
function GetVariantProp(Instance: TObject; PropInfo: PPropInfo): Variant; overload;
```

C++

```
Variant GetVariantProp(TObject * Instance, const AnsiString PropName);
Variant GetVariantProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetVariantProp utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property that is a variant type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a variant.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown. If the property is not a variant type, an EVariantBadVarTypeError exception is thrown.

See Also

GetPropInfo (see page 23348)

GetPropList (see page 23350)

GetPropValue (see page 23351)

PPropInfo (see page 23381)

SetVariantProp (see page 23368)

166.2.23 TypInfo.GetWideStrProp Function

Returns the value of a component property that is a WideString type.

Pascal

```
function GetWideStrProp(Instance: TObject; const PropName: string): WideString; overload;
function GetWideStrProp(Instance: TObject; PropInfo: PPropInfo): WideString; overload;
```

C++

```
BSTR GetWideStrProp(TObject * Instance, const AnsiString PropName);
BSTR GetWideStrProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

GetWideStrProp utilises Delphi's RTTI (Run Time Type Information) to return the current value of a component's property where that property is a WideString type. A string or LongString type is returned via a call to the GetWideStrProp routine. Otherwise, for other types, an empty string is returned if the property is not of this type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the current value of the property is returned as a WideString.

The intrinsic value of this function is to allow retrieval of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use GetPropValue (see page 23351) to retrieve a property value where the type is unknown - it is returned in a Variant type.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

See Also

GetPropInfo (see page 23348)

GetPropValue (see page 23351)

PPropInfo (see page 23381)

SetWideStrProp (see page 23369)

166.2.24 TypInfo.IsPublishedProp Function

Determines if a specified component property is a published property.

Pascal

```
function IsPublishedProp(Instance: TObject; const PropName: string): Boolean; overload;
function IsPublishedProp(AClass: TClass; const PropName: string): Boolean; overload;
```

C++

```
Boolean IsPublishedProp(TObject * Instance, const AnsiString PropName);
Boolean IsPublishedProp(TClass AClass, const AnsiString PropName);
```

File

TypInfo

Description

IsPublishedProp returns true if the specified property is published. Delphi's RTTI (Run Time Type Information) facility requires that properties are published.

In one form of this function, the component is defined by the **TClass** parameter.

In the other form of this function, an **Instance** of the component is used.

In both forms of the function, **PropName** specifies the property as a string.

See Also

GetPropInfo (see page 23348)

GetPropValue (see page 23351)

166.2.25 TypInfo.IsStoredProp Function

Determines if a specified component property has the stored attribute.

Pascal

```
function IsStoredProp(Instance: TObject; const PropName: string): Boolean; overload;
function IsStoredProp(Instance: TObject; PropInfo: PPropInfo): Boolean; overload;
```

C++

```
Boolean IsStoredProp(TObject * Instance, const AnsiString PropName);
Boolean IsStoredProp(TObject * Instance, PPropInfo PropInfo);
```

File

TypInfo

Description

IsStoredProp returns true if the specified property is saved in the form file. The stored attribute is set true by default : only those that have the keyword stored defined as false do not.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the value of the stored attribute is returned.

See Also

GetPropInfo (see page 23348)

GetPropValue (see page 23351)

PPropInfo (see page 23381)

166.2.26 TypInfo.PropIsType Function

Determines if a component property is of a particular data type.

Pascal

```
function PropIsType(Instance: TObject; const PropName: string; TypeKind: TTypeKind): Boolean;
overload;
function PropIsType(AClass: TClass; const PropName: string; TypeKind: TTypeKind): Boolean;
overload;
```

C++

```
Boolean PropIsType(TObject * Instance, const AnsiString PropName, TTypeKind TypeKind);
Boolean PropIsType(TClass AClass, const AnsiString PropName, TTypeKind TypeKind);
```

File

TypInfo

Description

PropIsType returns true if the property is of the specified data type.

In the first form of this function, **AClass** specifies the component class whose property you want to look at.

The second form of the function a class **Instance** replaces **AClass**.

In both forms of the function, **PropName** specifies the property name as a string. If the property has the **TypeKind** data type, then true is returned. Otherwise false is returned.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

See Also

GetPropInfo (see page 23348)

GetPropValue (see page 23351)

PPropInfo (see page 23381)

TTypeKinds (see page 23387)

166.2.27 TypInfo.PropType Function

Retrieves a component's property type.

Pascal

```
function PropType(Instance: TObject; const PropName: string): TTypeKind; overload;
function PropType(AClass: TClass; const PropName: string): TTypeKind; overload;
```

C++

```
TTypeKind PropType(TObject * Instance, const AnsiString PropName);
TTypeKind PropType(TClass AClass, const AnsiString PropName);
```

File

TypInfo

Description

PropType utilises Delphi's RTTI (Run Time Type Information) to return the type of a component property in a TTypeKind (see page 23379) value.

In the first form of this function, **AClass** specifies the component class whose property you want to retrieve. **PropName** specifies the property name as a string.

The second form of the function is similar to the first, with **Instance** replacing **AClass** as the means of specifying the component.

In both forms of the function, the returned value is a TTypeKind (see page 23379) value.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

See Also

PTypeInfo (see page 23383)

PPropInfo (see page 23381)

TTypeKind (see page 23379)

166.2.28 TypInfo.SetDynArrayProp Function

Sets the value of a component property that is a dynamic array type.

Pascal

```
procedure SetDynArrayProp(Instance: TObject; const PropName: string; const Value: Pointer);
overload;
procedure SetDynArrayProp(Instance: TObject; PropInfo: PPropInfo; const Value: Pointer);
overload;
```

C++

```
SetDynArrayProp(TObject * Instance, const AnsiString PropName, const void * Value);
SetDynArrayProp(TObject * Instance, PPropInfo PropInfo, const void * Value);
```

File

TypInfo

Description

SetDynArrayProp utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that property is a dynamic array type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.29 TypInfo.SetEnumProp Function

Sets the value of a component property that is an enumerated type.

Pascal

```
procedure SetEnumProp(Instance: TObject; const PropName: string; const Value: string);
overload;
procedure SetEnumProp(Instance: TObject; PropInfo: PPropInfo; const Value: string); overload;
```

C++

```
SetEnumProp(TObject * Instance, const AnsiString PropName, const AnsiString Value);
SetEnumProp(TObject * Instance, PPropInfo PropInfo, const AnsiString Value);
```

File

TypInfo

Description

SetEnumProp utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that property is an enumerated type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.30 TypInfo.SetFloatProp Function

Sets the value of a component property that is a float type.

Pascal

```
procedure SetFloatProp(Instance: TObject; const PropName: string; const Value: Extended);
overload;
procedure SetFloatProp(Instance: TObject; PropInfo: PPropInfo; const Value: Extended);
overload;
```

C++

```
SetFloatProp(TObject * Instance, const AnsiString PropName, const Extended Value);
SetFloatProp(TObject * Instance, PPropInfo PropInfo, const Extended Value);
```

File

TypInfo

Description

SetFloatProp utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that property is a floating point number.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.31 TypInfo.SetInt64Prop Function

Sets the value of a component property that is an Int64 type.

Pascal

```
procedure SetInt64Prop(Instance: TObject; const PropName: string; const Value: Int64);
overload;
procedure SetInt64Prop(Instance: TObject; PropInfo: PPropInfo; const Value: Int64); overload;
```

C++

```
SetInt64Prop(TObject * Instance, const AnsiString PropName, const Int64 Value);
SetInt64Prop(TObject * Instance, PPropInfo PropInfo, const Int64 Value);
```

File

TypInfo

Description

SetInt64Prop utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that property is an Int64 number.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.32 TypInfo.SetInterfaceProp Function

Sets the value of a component property that is an Interface type.

Pascal

```
procedure SetInterfaceProp(Instance: TObject; const PropName: string; const Value:
IInterface); overload;
procedure SetInterfaceProp(Instance: TObject; PropInfo: PPropInfo; const Value: IInterface);
overload;
```

C++

```
SetInterfaceProp(TObject * Instance, const AnsiString PropName, const IInterface Value);
SetInterfaceProp(TObject * Instance, PPropInfo PropInfo, const IInterface Value);
```

File

TypInfo

Description

SetInterfaceProp utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that property is an Interface.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.33 TypInfo.SetMethodProp Function

Sets the value of a component property that is a method type.

Pascal

```
procedure SetMethodProp(Instance: TObject; const PropName: string; const Value: TMethod);
overload;
procedure SetMethodProp(Instance: TObject; PropInfo: PPropInfo; const Value: TMethod);
overload;
```

C++

```
SetMethodProp(TObject * Instance, const AnsiString PropName, const TMethod Value);
SetMethodProp(TObject * Instance, PPropInfo PropInfo, const TMethod Value);
```

File

TypInfo

Description

SetMethodProp utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that property is an Event (Method property).

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.34 TypInfo.SetObjectProp Function

Sets the value of a component property that is an object type.

Pascal

```
procedure SetObjectProp(Instance: TObject; const PropName: string; Value: TObject); overload;
procedure SetObjectProp(Instance: TObject; PropInfo: PPropInfo; Value: TObject; ValidateClass:
Boolean = True); overload;
```

C++

```
SetObjectProp(TObject * Instance, const AnsiString PropName, TObject * Value);
SetObjectProp(TObject * Instance, PPropInfo PropInfo, TObject * Value, Boolean ValidateClass =
True);
```

File

TypInfo

Description

SetObjectProp utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that property is an object.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.35 TypInfo.SetOrdProp Function

Sets the value of a component property that is an ordinal type.

Pascal

```
procedure SetOrdProp(Instance: TObject; const PropName: string; Value: Longint); overload;
procedure SetOrdProp(Instance: TObject; PropInfo: PPropInfo; Value: Longint); overload;
```

C++

```
SetOrdProp(TObject * Instance, const AnsiString PropName, Longint Value);
SetOrdProp(TObject * Instance, PPropInfo PropInfo, Longint Value);
```

File

TypInfo

Description

SetOrdProp utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that property is an Integer, Char, WideChar, or Class type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.36 TypInfo.SetPropValue Function

Sets the value of a component property using a variant value.

Pascal

```
procedure SetPropValue(Instance: TObject; const PropName: string; const Value: Variant);
overload;
procedure SetPropValue(Instance: TObject; PropInfo: PPropInfo; const Value: Variant); overload;
```

C++

```
SetPropValue(TObject * Instance, const AnsiString PropName, const Variant Value);
SetPropValue(TObject * Instance, PPropInfo PropInfo, const Variant Value);
```

File

TypInfo

Description

SetPropValue utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property using a variant value.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**. Note that only certain property assignments are possible using variants. It is normally be used when using GetPropValue (see page 23351) from another property.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

SetPropValue

PPropInfo (see page 23381)

166.2.37 TypInfo.SetSetProp Function

Sets the value of a component property that is a set type.

Pascal

```
procedure SetSetProp(Instance: TObject; const PropName: string; const Value: string); overload;
procedure SetSetProp(Instance: TObject; PropInfo: PPropInfo; const Value: string); overload;
```

C++

```
SetSetProp(TObject * Instance, const AnsiString PropName, const AnsiString Value);
SetSetProp(TObject * Instance, PPropInfo PropInfo, const AnsiString Value);
```

File

TypInfo

Description

SetSetProp utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that property is a set type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**. You specify the set of values as a comma separated string. You may optionally enclose these in square brackets. This allows the returned value from one GetSetProp (see page 23352) call to be used as the assignment value in a SetSetProp call.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.38 TypInfo.SetStrProp Function

Sets the value of a component property that is a string type.

Pascal

```
procedure SetStrProp(Instance: TObject; const PropName: string; const Value: string); overload;
procedure SetStrProp(Instance: TObject; PropInfo: PPropInfo; const Value: string); overload;
```

C++

```
SetStrProp(TObject * Instance, const AnsiString PropName, const AnsiString Value);
SetStrProp(TObject * Instance, PPropInfo PropInfo, const AnsiString Value);
```

File

TypInfo

Description

SetStrProp utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that property is a String, LongString or WideString type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

See Also

GetStrProp (see page 23353)

GetPropList (see page 23350)

SetPropValue (see page 23365)

PPropInfo (see page 23381)

166.2.39 TypInfo.SetToString Function

Returns one or more of the set values of a component's property.

Pascal

```
function SetToString(PropInfo: PPropInfo; Value: Integer; Brackets: Boolean = False): string;
```

C++

```
AnsiString SetToString(PPropInfo PropInfo, int Value, Boolean Brackets = False);
```

File

TypInfo

Description

SetToString utilises Delphi's RTTI (Run Time Type Information) to retrieve one or more of the values of a component property that is of the set type.

The property to interrogate is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

Value defines a bit mask that selects the possible values of this property. Each bit corresponds to a set value. The low order bit corresponds to the first set value. A string is returned with the selected set values as a comma separated value string. Note that the current property set values are not taken into account - the set values selected by **Value** are those in the complete set.

You may optionally set **Brackets** true so as to enclose this returned string within square brackets, as shown in the IDE for the property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.40 TypInfo.SetVariantProp Function

Sets the value of a component property that is a variant type.

Pascal

```
procedure SetVariantProp(Instance: TObject; const PropName: string; const Value: Variant);
overload;
procedure SetVariantProp(Instance: TObject; PropInfo: PPropInfo; const Value: Variant);
overload;
```

C++

```
SetVariantProp(TObject * Instance, const AnsiString PropName, const Variant Value);
SetVariantProp(TObject * Instance, PPropInfo PropInfo, const Variant Value);
```

File

TypInfo

Description

SetVariantProp utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that

property is a variant type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name. This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.41 TypInfo.SetWideStrProp Function

Sets the value of a component property that is a WideString type.

Pascal

```
procedure SetWideStrProp(Instance: TObject; const PropName: string; const Value: WideString);
overload;
procedure SetWideStrProp(Instance: TObject; PropInfo: PPropInfo; const Value: WideString);
overload;
```

C++

```
SetWideStrProp(TObject * Instance, const AnsiString PropName, const BSTR Value);
SetWideStrProp(TObject * Instance, PPropInfo PropInfo, const BSTR Value);
```

File

TypInfo

Description

SetWideStrProp utilises Delphi's RTTI (Run Time Type Information) to set the value of a component's property where that property is a WideString type.

In one form of this function, the object **Instance**'s property is defined by a **PropInfo** record. GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record.

In the other form of this function, the name of the property, **PropName**, is explicitly given.

In both forms of the function, the new property value is defined by **Value**.

The intrinsic value of this function is to allow setting of component properties without the need to hard code the property name.

This allows mass visual component processing at run time.

Use SetPropValue (see page 23365) to set a property value where the type is unknown. This would normally be used when using GetPropValue (see page 23351) from another property.

Note: If the specified property does not exist, or is not a published property, an EPropertyError (see page 23331) exception is thrown.

166.2.42 TypInfo.SortPropList Function

Sorts a list of component properties into alphanumeric sequence.

Pascal

```
procedure SortPropList(PropList: PPropList; PropCount: Integer);
```

C++

```
SortPropList(PPropList PropList, int PropCount);
```

File

TypInfo

Description

SortPropList is used to sort a PPropList (see page 23382) that was originally created in natural rather than sorted sequence (by GetPropList (see page 23350)).

PropList defines a pointer to the array of TPropInfo (see page 23376) pointers (normally obtained using GetPropList (see page 23350)). **Count** specifies the number of TPropList (see page 23387)

See Also

GetPropList (see page 23350)

PPropList (see page 23382)

PPropInfo (see page 23381)

TPropInfo (see page 23376)

166.2.43 TypInfo.StringToSet Function

Returns a bit mask of set values for a set type component property.

Pascal

```
function StringToSet(PropInfo: PPropInfo; const Value: string): Integer;
```

C++

```
int StringToSet(PPropInfo PropInfo, const AnsiString Value);
```

File

TypInfo

Description

StringToSet utilises Delphi's RTTI (Run Time Type Information) to return a bit mask of set indices for component's property where that property is a set type.

The property is defined by the **PropInfo** pointer. (GetPropInfo (see page 23348) and GetPropList (see page 23350) can be used to obtain such a record).

Value defines a comma separated string of set values the property may have.

The resulting integer value is a bit mask. The 0 bit relates to the 1st set value for the property. If that property value is included in the **Value** string, it is set to 1, otherwise 0. This continues for bits 1, 2 and so on referring to set positions 2, 3 and so on.

PPropInfo (see page 23381)

TPropInfo (see page 23376)

166.3 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TFloatType (see page 23372)	This is record TypInfo.TFloatType.
	TIntfFlag (see page 23373)	This is record TypInfo.TIntfFlag.
	TMethodKind (see page 23373)	Enumerates floating point number types in the TTypeData (see page 23377) record.
	TOrdType (see page 23374)	Enumerates floating point number types in the TTypeData (see page 23377) record.
	TParamFlag (see page 23375)	TParamFlag and TParamFlags (see page 23386) indicates the attributes of a method parameter.
	TTypeKind (see page 23379)	These types describe a type that is manipulated in the forms designer.

Records

	Name	Description
	TPropData (see page 23376)	This is record TypInfo.TPropData.
	TPropInfo (see page 23376)	TPropInfo is a record of component property type information.
	TTypeData (see page 23377)	TTypeData is used internally to represent type information.
	TTypeInfo (see page 23379)	Holds information for a data type as returned by TypeInfo.

166.3.1 TypInfo.TFloatType Enumeration

Pascal

```
TFloatType = (
  ftSingle,
  ftDouble,
  ftExtended,
  ftComp,
  ftCurr
);
```

C++

```
enum TFloatType {
  ftSingle,
  ftDouble,
  ftExtended,
  ftComp,
  ftCurr
};
```

File

TypInfo

Description

This is record TypInfo.TFloatType.

166.3.2 TypInfo.TIntfFlag Enumeration

Pascal

```
TIntfFlag = (
  ifHasGuid,
  ifDispInterface,
  ifDispatch
);
```

C++

```
enum TIntfFlag {
  ifHasGuid,
  ifDispInterface,
  ifDispatch
};
```

File

TypInfo

Description

This is record TypInfo.TIntfFlag.

166.3.3 TypInfo.TMethodKind Enumeration

Enumerates floating point number types in the TTypeData (see page 23377) record.

Pascal

```
TMethodKind = (
  mkProcedure,
  mkFunction,
  mkConstructor,
  mkDestructor,
  mkClassProcedure,
  mkClassFunction,
  mkClassConstructor,
  mkOperatorOverload,
  mkSafeProcedure,
  mkSafeFunction
);
```

C++

```
enum TMethodKind {
  mkProcedure,
  mkFunction,
  mkConstructor,
  mkDestructor,
  mkClassProcedure,
  mkClassFunction,
  mkClassConstructor,
  mkOperatorOverload,
  mkSafeProcedure,
  mkSafeFunction
};
```

File

TypInfo

Description

The GetTypeData (see page 23354) routine utilises Delphi's RTTI (Run Time Type Information) to return a pointer to TTypeData (see page 23377) record that describes a component property data type.

TTypeData (see page 23377) is a variant record : the layout depends on the property TTypeKind (see page 23379) value. When it is tkMethod, the data is one of the TMethodKind enumerated values.

The TMethodKind value meanings are as follows :

Value	Meaning
mkProcedure	Stand alone procedure.
mkFunction	Stand alone function.
mkDestructor	Destructor.
mkConstructor	Constructor.
mkClassProcedure	Class procedure.
mkClassFunction	Class function.
mkClassConstructor	Class constructor.
mkOperatorOverload	Operator overload.
mkSafeProcedure	Safe procedure.
mkSafeFunction	Safe function.

See Also

GetTypeData (see page 23354)

TTypeData (see page 23377)

TTypeKind (see page 23379)

166.3.4 TypInfo.TOrdType Enumeration

Enumerates floating point number types in the TTypeData (see page 23377) record.

Pascal

```
TOrdType = (
  otSByte,
  otUByte,
  otSWord,
  otUWord,
  otSLong,
  otULong
);
```

C++

```
enum TOrdType {
  otSByte,
  otUByte,
  otSWord,
```

```
    otUWord,
    otSLong,
    otULong
  };
```

File

TypInfo

Description

The GetTypeData (see page 23354) routine utilises Delphi's RTTI (Run Time Type Information) to return a pointer to TTypeData (see page 23377) record that describes a component property data type.

TTypeData (see page 23377) is a variant record : the layout depends on the property TTypeKind (see page 23379) value. When it is tkWChar, the data is one of the TOrdType enumerated values.

The TOrdType value meanings are as follows :

Value	Meaning
otSByte	Signed byte.
otUByte	Unsigned byte
otSWord	Signed Word
otUWord	Unsigned Word
otSLong	Signed Long
otULong	Unsigned Long

See Also

GetTypeData (see page 23354)

TTypeData (see page 23377)

TTypeKind (see page 23379)

166.3.5 TypInfo.TParamFlag Enumeration

TParamFlag and TParamFlags (see page 23386) indicates the attributes of a method parameter.

Pascal

```
  TParamFlag = (
    pfVar,
    pfConst,
    pfArray,
    pfAddress,
    pfReference,
    pfOut
  );
```

C++

```
  enum TParamFlag {
    pfVar,
    pfConst,
    pfArray,
    pfAddress,
    pfReference,
    pfOut
```

```
};
```

File

TypInfo

Description

TParamFlags (see page 23386) indicates the attributes of a parameter on a Delphi language function or procedure. It is a set of TParamFlag values:

Value	Meaning
pfVar	The parameter is input/output. Caller must supply a variable to receive output.
pfConst	The parameter can't be changed by the function or procedure.
pfArray	The parameter represents an open array of values.
pfAddress	The parameter is a memory address (pointer).
pfReference	The parameter is passed by reference.
pfOut	The parameter is output. Caller supplies a variable to receive the output.

166.3.6 TypInfo.TPropData Record

Pascal

```
TPropData = packed record
  PropCount: Word;
  PropList: record;
end;
```

C++

```
struct TPropData {
  Word PropCount;
  record PropList;
};
```

File

TypInfo

Description

This is record TypInfo.TPropData.

166.3.7 TypInfo.TPropInfo Record

TPropInfo is a record of component property type information.

Pascal

```
TPropInfo = packed record
  PropType: PPTypeInfo;
  GetProc: Pointer;
  SetProc: Pointer;
  StoredProc: Pointer;
  Index: Integer;
  Default: Longint;
```

```
    NameIndex: SmallInt;
    Name: ShortString;
  end;
```

C++

```
  struct TPropInfo {
    PPTypeInfo PropType;
    void * GetProc;
    void * SetProc;
    void * StoredProc;
    int Index;
    Longint Default;
    SmallInt NameIndex;
    ShortString Name;
  };
```

File

TypInfo

Description

TPropInfo is principally used to hold the results of a call to GetPropInfo (see page 23348). It provides meta details about a component property as part of Delphi's RTTI (Run Time Type Information) mechanism, giving run time component property processing. This allows for more generalised component handling that avoids excessive hard coded values.

The TPropInfo fields have the foillowing meanings :

Field	Meaning
PropType	Points to a data structure that gives information about the property type.
GetProc	Method pointer for the method that gets the component property value.
SetProc	Method pointer for the method that sets the component property value.
Index	The index of the property. It is used as a parameter to the GetProc and SetProc methods on indexed properties.
Default	The default value of the property.
NameIndex	The offset into the Name field where the property's name starts.
Name	The qualified property name.

See Also

GetPropInfo (see page 23348)

PPropInfo (see page 23381)

166.3.8 TypInfo.TTypeData Record

TTypeData is used internally to represent type information.

Pascal

```
  TTypeData = packed record
    case TTypeKind of
      tkClass: (ClassType: TClass;
                ParentInfo: PPTypeInfo;
                PropCount: SmallInt;
                UnitName: ShortStringBase;);
      tkDynArray: (elSize: Longint;
```

```
                    elType: PPTypeInfo;
                    varType: Integer;
                    elType2: PPTypeInfo;
                    DynUnitName: ShortStringBase;));
      tkEnumeration: (BaseType: PPTypeInfo;
                       NameList: ShortStringBase;
                       EnumUnitName: ShortStringBase;));
      tkFloat: (FloatType: TFloatType;));
      tkInt64: (MaxInt64Value: Int64;
                MinInt64Value: Int64;));
      tkMethod: (MethodKind: TMethodKind;
                 ParamCount: Byte;
                 ParamList: array[0..1023] of Char );
                 tkInterface: ( IntfParent : PPTypeInfo; IntfFlags : TIntfFlagsBase; Guid :
  TGUID; IntfUnit : ShortStringBase;;));
      tkSet: (CompType: PPTypeInfo;));
      tkString: (MaxLength: Byte;));
      tkWChar: (OrdType: TOrdType;
                MinValue: Longint;
                MaxValue: Longint;));
  end;
```

C++

```
  struct TTypeData {
    TOrdType OrdType;
    Longint MinValue;
    Longint MaxValue;
    PPTypeInfo BaseType;
    ShortStringBase NameList;
    ShortStringBase EnumUnitName;
    PPTypeInfo CompType;
    TFloatType FloatType;
    Byte MaxLength;
    TClass ClassType;
    PPTypeInfo ParentInfo;
    SmallInt PropCount;
    ShortStringBase UnitName;
    TMethodKind MethodKind;
    Byte ParamCount;
    array[0..1023] of Char ) ParamList;
    ( IntfParent : PPTypeInfo; IntfFlags : TIntfFlagsBase; Guid : TGUID; IntfUnit :
  ShortStringBase; tkInterface;
    Int64 MaxInt64Value;
    Int64 MinInt64Value;
    Longint elSize;
    PPTypeInfo elType;
    int varType;
    PPTypeInfo elType2;
    ShortStringBase DynUnitName;
  };
```

File

TypInfo

Description

A TTypeData structure represents a category of properties, events, or methods in parameters passed to several routines in the TypInfo (see page 23327) unit.

166.3.9 TypInfo.TTypeInfo Record

Holds information for a data type as returned by TypeInfo.

Pascal

```
TTypeInfo = record
  Kind: TTypeKind;
  Name: ShortString;
end;
```

C++

```
struct TTypeInfo {
  TTypeKind Kind;
  ShortString Name;
};
```

File

TypInfo

Description

The TypeInfo function is part of Delphi's Run Time Type Information (RTTI) mechanism. It provides run time information about a specific data type. TypeInfo returns a PTypeInfo (see page 23383) pointer to a TTypeInfo value.

The TTypeInfo holds the following fields :

Field	Meaning
Kind	The kind of type in RTTI terms. This value is required to select the appropriate variant section in the TTypeData (see page 23377) returned by the GetTypeData (see page 23354).
Name	The name of the data type.

See Also

GetTypeData (see page 23354)

PTypeInfo (see page 23383)

PPTypeInfo (see page 23382)

TTypeKind (see page 23379)

TTypeData (see page 23377)

166.3.10 TypInfo.TTypeKind Enumeration

These types describe a type that is manipulated in the forms designer.

Pascal

```
TTypeKind = (
  tkUnknown,
  tkInteger,
  tkChar,
  tkEnumeration,
  tkFloat,
```

```
    tkString,
    tkSet,
    tkClass,
    tkMethod,
    tkWChar,
    tkLString,
    tkWString,
    tkVariant,
    tkArray,
    tkRecord,
    tkInterface,
    tkInt64,
    tkDynArray
  );
```

C++

```
  enum TTypeKind {
    tkUnknown,
    tkInteger,
    tkChar,
    tkEnumeration,
    tkFloat,
    tkString,
    tkSet,
    tkClass,
    tkMethod,
    tkWChar,
    tkLString,
    tkWString,
    tkVariant,
    tkArray,
    tkRecord,
    tkInterface,
    tkInt64,
    tkDynArray
  };
```

File

TypInfo

Description

TTypeKind is an enumerated type that classifies a type.

TTypeInfo (see page 23379) describes a type by giving its classification and its name.

PTypeInfo (see page 23383) is a pointer to a TTypeInfo (see page 23379) value.

PPTypeInfo (see page 23382) is a pointer to a PTypeInfo (see page 23383) pointer.

166.4 Types

The following table lists types in this documentation.

Types

Name	Description
PPropInfo (see page 23381)	PPropInfo points to a TPropInfo (see page 23376) record that holds component property information.
PPropList (see page 23382)	Defines a pointer to a TPropList (see page 23387) array.
PPTypeInfo (see page 23382)	Holds a pointer to a pointer to information for a data type as returned by TypeInfo.
PTypeData (see page 23383)	PTypeData points to a TTypeData (see page 23377) record that holds component property type information.
PTypeInfo (see page 23383)	Holds a pointer to information for a data type as returned by TypeInfo.
ShortStringBase (see page 23384)	Defines a fixed length string for general use in the TTypeData (see page 23377) record.
TIntfFlags (see page 23384)	Enumerates interface flag types in the TTypeData (see page 23377) record.
TIntfFlagsBase (see page 23385)	Set of interface flag types in the TTypeData (see page 23377) record.
TParamFlags (see page 23386)	This is type TypInfo.TParamFlags.
TParamFlagsBase (see page 23386)	This is type TypInfo.TParamFlagsBase.
TPropInfoProc (see page 23386)	This is type TypInfo.TPropInfoProc.
TPropList (see page 23387)	Defines an array of PPropInfo (see page 23381) values.
TTypeKinds (see page 23387)	Defines a set of TTypeKind (see page 23379) values.

166.4.1 TypInfo.PPropInfo Type

PPropInfo points to a TPropInfo (see page 23376) record that holds component property information.

Pascal

```
PPropInfo = ^TPropInfo;
```

C++

```
^TPropInfo PPropInfo;
```

File

TypInfo

Description

TPropInfo (see page 23376) is principally used to hold the results of a call to GetPropInfo (see page 23348). It provides meta details about a component property as part of Delphi's RTTI (Run Time Type Information) mechanism, giving run time component property processing. This allows for more generalised component handling that avoids excessive hard coded values. PPropInfo is a pointer to a TPropInfo (see page 23376) record.

See Also

GetPropInfo (see page 23348)

TPropInfo (see page 23376)

166.4.2 TypInfo.PPropList Type

Defines a pointer to a TPropList (see page 23387) array.

Pascal

```
PPropList = ^TPropList;
```

C++

```
^TPropList PPropList;
```

File

TypInfo

Description

PPropList defines a pointer to an array of PPropInfo (see page 23381) values. This TPropList (see page 23387) array is principally used to hold the results of a call to GetPropList (see page 23350). This list (array) holds pointers to TPropInfo (see page 23376) records that describe the nature of the properties of the component provided to GetPropList (see page 23350).

See Also

GetPropList (see page 23350)

PPropInfo (see page 23381)

TPropInfo (see page 23376)

TPropList (see page 23387)

166.4.3 TypInfo.PPTypeInfo Type

Holds a pointer to a pointer to information for a data type as returned by TypeInfo.

Pascal

```
PPTypeInfo = ^PTypeInfo;
```

C++

```
^PTypeInfo PPTypeInfo;
```

File

TypInfo

Description

The TypeInfo function is part of Delphi's Run Time Type Information (RTTI) mechanism. It provides run time information about a specific data type. TypeInfo returns a PTypeInfo (see page 23383) pointer to a TTypeInfo (see page 23379) value. PPTypeInfo is a PTypeInfo (see page 23383) pointer.

See Also

GetTypeData (see page 23354)

PTypeInfo (see page 23383)

TTypeInfo (see page 23379)

TTypeKind (see page 23379)

TTypeData (see page 23377)

166.4.4 TypInfo.PTypeData Type

PTypeData points to a TTypeData (see page 23377) record that holds component property type information.

Pascal

```
PTypeData = ^TTypeData;
```

C++

```
^TTypeData PTypeData;
```

File

TypInfo

Description

TTypeData (see page 23377) is principally used to hold the results of a call to GetTypeData (see page 23354). It provides meta details about a component property type as part of Delphi's RTTI (Run Time Type Information) mechanism, giving run time component property processing. This allows for more generalised component handling that avoids excessive hard coded values. PTypeData is a pointer to a TTypeData (see page 23377) record.

See Also

GetTypeData (see page 23354)

TTypeData (see page 23377)

166.4.5 TypInfo.PTypeInfo Type

Holds a pointer to information for a data type as returned by TypeInfo.

Pascal

```
PTypeInfo = ^TTypeInfo;
```

C++

```
^TTypeInfo PTypeInfo;
```

File

TypInfo

Description

The TypeInfo function is part of Delphi's Run Time Type Information (RTTI) mechanism. It provides run time information about a specific data type. TypeInfo returns a PTypeInfo pointer to a TTypeInfo (see page 23379) value.

The TTypeInfo (see page 23379) holds the following fields :

Field	Meaning
Kind	The kind of type in RTTI terms. This value is required to select the appropriate variant section in the TTypeData (see page 23377) returned by the GetTypeData (see page 23354).
Name	The name of the data type.

See Also

GetTypeData (see page 23354)

PPTypeInfo (see page 23382)

TTypeInfo (see page 23379)

TTypeKind (see page 23379)

TTypeData (see page 23377)

166.4.6 TypInfo.ShortStringBase Type

Defines a fixed length string for general use in the TTypeData (see page 23377) record.

Pascal

```
ShortStringBase = string[255];
```

C++

```
string[255] ShortStringBase;
```

File

TypInfo

Description

The GetTypeData (see page 23354) routine utilises Delphi's RTTI (Run Time Type Information) to return a pointer to TTypeData (see page 23377) record that describes a component property data type.

A number of the variant data sections in the TTypeData (see page 23377) record use the ShortStringBase to define a 255 character string to hold Name values such as UnitName for a class data type.

See Also

GetTypeData (see page 23354)

TTypeData (see page 23377)

166.4.7 TypInfo.TIntfFlags Type

Enumerates interface flag types in the TTypeData (see page 23377) record.

Pascal

```
TIntfFlags = set of TIntfFlag;
```

C++

```
TIntfFlag TIntfFlags;
```

File

TypInfo

Description

The GetTypeData (see page 23354) routine utilises Delphi's RTTI (Run Time Type Information) to return a pointer to TTypeData (see page 23377) record that describes a component property data type.

TTypeData (see page 23377) is a variant record : the layout depends on the property TTypeKind (see page 23379) value. When it is tkInterface, the data contains a TIntfFlagsBase (see page 23385) set of TIntfFlags values.

The TIntfFlags value meanings are as follows :

Value	Meaning
ifHasGuid	Interface has a GUID (Globally Unique IDentifier).
ifDispInterface	Is a dispatch interface.
ifDispatch	Can be dispatched.

See Also

GetTypeData (see page 23354)

TIntfFlagsBase (see page 23385)

TTypeData (see page 23377)

TTypeKind (see page 23379)

166.4.8 TypInfo.TIntfFlagsBase Type

Set of interface flag types in the TTypeData (see page 23377) record.

Pascal

```
TIntfFlagsBase = set of TIntfFlag;
```

C++

```
TIntfFlag TIntfFlagsBase;
```

File

TypInfo

Description

The GetTypeData (see page 23354) routine utilises Delphi's RTTI (Run Time Type Information) to return a pointer to TTypeData (see page 23377) record that describes a component property data type.

TTypeData (see page 23377) is a variant record : the layout depends on the property TTypeKind (see page 23379) value. When it is tkInterface, the data contains a TIntfFlagsBase set of TIntfFlag (see page 23373) values.

The TIntfFlag (see page 23373) value meanings are as follows :

Value	Meaning
ifHasGuid	Interface has a GUID (Globally Unique IDentifier).
ifDispInterface	Is a dispatch interface.

ifDispatch	Can be dispatched.

See Also

GetTypeData (see page 23354)

TIntfFlag (see page 23373)

TTypeData (see page 23377)

TTypeKind (see page 23379)

166.4.9 TypInfo.TParamFlags Type

Pascal

```
TParamFlags = set of TParamFlag;
```

C++

```
TParamFlag TParamFlags;
```

File

TypInfo

Description

This is type TypInfo.TParamFlags.

166.4.10 TypInfo.TParamFlagsBase Type

Pascal

```
TParamFlagsBase = set of TParamFlag;
```

C++

```
TParamFlag TParamFlagsBase;
```

File

TypInfo

Description

This is type TypInfo.TParamFlagsBase.

166.4.11 TypInfo.TPropInfoProc Type

Pascal

```
TPropInfoProc = procedure (PropInfo: PPropInfo) of object;
```

C++

```
(PropInfo: PPropInfo) ( TPropInfoProc)();
```

File

TypInfo

Description

This is type TypInfo.TPropInfoProc.

166.4.12 TypInfo.TPropList Type

Defines an array of PPropInfo (see page 23381) values.

Pascal

```
TPropList = array[0..16379] of PPropInfo;
```

C++

```
array[0..16379] of PPropInfo TPropList;
```

File

TypInfo

Description

TPropList is principally used to hold the results of a call to GetPropList (see page 23350). This list (array) holds pointers to TPropInfo (see page 23376) records that describe the nature of the properties of the component provided to GetPropList (see page 23350).

See Also

GetPropList (see page 23350)

TPropInfo (see page 23376)

166.4.13 TypInfo.TTypeKinds Type

Defines a set of TTypeKind (see page 23379) values.

Pascal

```
TTypeKinds = set of TTypeKind;
```

C++

```
TTypeKind TTypeKinds;
```

File

TypInfo

Description

TTypeKinds defines a set of TTypeKind (see page 23379) values. It is used to select which component property types to use in various routines, such as GetPropInfo (see page 23348).

See Also

GetPropInfo (see page 23348)

TTypeKind (see page 23379)

166.5 Variables

The following table lists variables in this documentation.

Variables

Name	Description
BooleanIdents (see page 23388)	An array of string representations of true and false.
DotSep (see page 23388)	This is variable TypInfo.DotSep.

166.5.1 TypInfo.BooleanIdents Variable

An array of string representations of true and false.

Pascal

```
BooleanIdents: array [Boolean] of string = ('False', 'True');
```

C++

```
array [Boolean] of string BooleanIdents = ('False', 'True');
```

File

TypInfo

Description

The GetEnumName (see page 23341) routine is part of Delphi's RTTI (Run Time Type Information). It returns a string representation of an enumerated type value. If that type is true or false, BooleanIdents is used internally.

See Also

GetEnumName (see page 23341)

166.5.2 TypInfo.DotSep Variable

Pascal

```
DotSep: string = '.';
```

C++

```
AnsiString DotSep = '.';
```

File

TypInfo

Description

This is variable TypInfo.DotSep.

166.6 Constants

The following table lists constants in this documentation.

Constants

Name	Description
tkAny (see page 23389)	This is constant TypInfo.tkAny.
tkMethods (see page 23389)	This is constant TypInfo.tkMethods.
tkProperties (see page 23389)	This is constant TypInfo.tkProperties.

166.6.1 TypInfo.tkAny Constant

Pascal

```
tkAny = [Low(TTypeKind)..High(TTypeKind)];
```

C++

```
tkAny = [Low(TTypeKind)..High(TTypeKind)];
```

File

TypInfo

Description

This is constant TypInfo.tkAny.

166.6.2 TypInfo.tkMethods Constant

Pascal

```
tkMethods = [tkMethod];
```

C++

```
tkMethods = [tkMethod];
```

File

TypInfo

Description

This is constant TypInfo.tkMethods.

166.6.3 TypInfo.tkProperties Constant

Pascal

```
tkProperties = tkAny - tkMethods - [tkUnknown];
```

C++

```
tkProperties = tkAny - tkMethods - [tkUnknown];
```

File

TypInfo

Description

This is constant TypInfo.tkProperties.

167 UDDIHelper Namespace

This is namespace UDDIHelper.

Topics

Name	Description
Functions (see page 23392)	The following table lists functions in this documentation.

Functions

	Name	Description
	GetBindingkeyAccessPoint (see page 23392)	Returns the URL for a Web Service as specified in a UDDI browser.

167.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	GetBindingkeyAccessPoint (see page 23392)	Returns the URL for a Web Service as specified in a UDDI browser.

167.1.1 UDDIHelper.GetBindingkeyAccessPoint Function

Returns the URL for a Web Service as specified in a UDDI browser.

Pascal

```
function GetBindingkeyAccessPoint(const Operator: String; const key: String): String;
```

C++

```
AnsiString GetBindingkeyAccessPoint(const AnsiString Operator, const AnsiString key);
```

File

UDDIHelper

Description

Use GetBindingkeyAccessPoint to fetch the URL for calling a Web Service from a specified UDDI registry.

Operator is the URL of the UDDI registry from which to fetch the entry. You can obtain this value for a registered invokable interface by calling the invocation registry's GetUDDIInfo method.

BindingKey is the unique identifier for the TModel that describes the Web Service for which you want the URL.

GetBindingkeyAccessPoint returns the URL for the specified Web Service. This can be used to set the URL property of a THTTPRIO component.

See Also

THTTPRIO

TInvokableClassRegistry

168 ValEdit Namespace

This is namespace ValEdit.

Topics

Name	Description
Classes (see page 23394)	The following table lists classes in this documentation.
Structs, Records, Enums (see page 23509)	The following table lists structs, records, enums in this documentation.
Types (see page 23511)	The following table lists types in this documentation.

Classes

	Name	Description
	TItemProp (see page 23394)	TItemProp configures how users can edit the item values in a value list editor.
	TValueListEditor (see page 23401)	TValueListEditor provides a simple way to edit string lists that contain name/value pairs.
	TValueListStrings (see page 23498)	This is class ValEdit.TValueListStrings.

Structs, Records, Enums

	Name	Description
	TDisplayOption (see page 23509)	TDisplayOption and TDisplayOptions (see page 23511) control the appearance of a value list editor.
	TKeyOption (see page 23510)	TKeyOption and TKeyOptions (see page 23512) indicate the response of a value list editor to certain keystrokes.

Types

Name	Description
TDisplayOptions (see page 23511)	This is type ValEdit.TDisplayOptions.
TGetPickListEvent (see page 23511)	This is type ValEdit.TGetPickListEvent.
TItemProps (see page 23512)	This is type ValEdit.TItemProps.
TKeyOptions (see page 23512)	This is type ValEdit.TKeyOptions.
TOnValidateEvent (see page 23512)	This is type ValEdit.TOnValidateEvent.

168.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	TItemProp (see page 23394)	TItemProp configures how users can edit the item values in a value list editor.
	TValueListEditor (see page 23401)	TValueListEditor provides a simple way to edit string lists that contain name/value pairs.
	TValueListStrings (see page 23498)	This is class ValEdit.TValueListStrings.

168.1.1 TItemProp Class

TItemProp configures how users can edit the item values in a value list editor.

Class Hierarchy

Pascal

```
TItemProp = class(TPersistent);
```

C++

```
class TItemProp : public TPersistent;
```

File

ValEdit

Description

For each item that it allows users to edit, the TValueListEditor (see page 23401) component maintains a TItemProp object. This object's properties govern how users can edit the value in the value list editor.

TItemProp objects are created and owned by the value list editor that uses them to represent properties of item values (such as an edit mask or maximum length) or to supply a fixed pick list of values that users can assign to the item.

See Also

TValueListEditor (see page 23401)

TValueListEditor (see page 23401)

168.1.1.1 TItemProp Members

The following tables list the members exposed by TItemProp.

Protected Methods

	Name	Description
	AssignTo (see page 23396)	Copies the properties of an object to a destination object.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.

	GetOwner (see page 2932)	Returns the owner of an object.
	UpdateEdit (see page 23397)	This is UpdateEdit, a member of class TItemProp.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Create (see page 23395)	Creates an instance of TItemProp (see page 23394).
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 23396)	Destroys the TPersistent instance and frees its memory.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	HasPickList (see page 23397)	Indicates whether the PickList (see page 23400) property provides a static set of values for this item.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.

Published Properties

	Name	Description
	EditMask (see page 23398)	Restricts the value that can be entered for the associated item.
	EditStyle (see page 23398)	Determines whether the cell that contains the associated value has a drop-down arrow or ellipsis button.
	KeyDesc (see page 23399)	Specifies the name of the item, which appears in the names column of the Value list editor.
	MaxLength (see page 23399)	Specifies the maximum number of characters that users can enter for the item's value.
	PickList (see page 23400)	Lists the items that appear in the drop-down pick list for the item.
	ReadOnly (see page 23400)	Indicates whether users can edit the item's value by typing in a new value.

168.1.1.2 TItemProp.Create Constructor

Creates an instance of TItemProp (see page 23394).

Pascal

```
constructor Create(AEditor: TValueListEditor);
```

C++

```
__fastcall TItemProp(TValueListEditor AEditor);
```

Description

Do not call Create directly in an application. TValueListEditor (see page 23401) creates TItemProp (see page 23394) instances as needed when you make assignments to its ItemProps property.

The AEditor parameter is the value list editor that creates the TItemProp (see page 23394) instance to represent the properties of one of its items.

See Also

ItemProps (see page 23445)

168.1.1.3 TItemProp.Destroy Destructor

Destroys the TPersistent instance and frees its memory.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TItemProp();
```

Description

Do not call Destroy directly. Call Free instead. Free checks that the object reference is not nil before calling Destroy.

See Also

Free (see page 22300)

Destroy (see page 22287)

168.1.1.4 TItemProp Methods

The methods of the TItemProp class are listed here.

Protected Methods

	Name	Description
	AssignTo (see page 23396)	Copies the properties of an object to a destination object.
	UpdateEdit (see page 23397)	This is UpdateEdit, a member of class TItemProp.

Public Methods

	Name	Description
	HasPickList (see page 23397)	Indicates whether the PickList (see page 23400) property provides a static set of values for this item.

168.1.1.4.1 TItemProp.AssignTo Method

Copies the properties of an object to a destination object.

Pascal

```
procedure AssignTo(Dest: TPersistent); override;
```

C++

```
virtual __fastcall AssignTo(TPersistent * Dest);
```

Description

Override the AssignTo method to extend the functionality of the Assign method of destination objects so that they handle newly created object classes. When defining a new object class, override the Assign method for every existing object class that should be able to copy its properties to the new class. Override the AssignTo method for every existing class to which the new class can copy.

The Assign method of TPersistent calls AssignTo if the descendant object does not succeed in copying the properties of a source object. The AssignTo method defined by TPersistent raises an EConvertError exception.

For example, given the following code in which A and B are instance variables:

```
A.Assign(B); {Delphi}
A->Assign(B); // C++
```

if A knows how to handle B, then it does so and returns. If A doesn't know how to handle B's type, execution will trickle to the TPersistent version of Assign, which calls:

```
B.AssignTo(A); {Delphi}
B->AssignTo(A); // C++
```

If B knows how to copy to A, the assignment succeeds. Otherwise, TPersistent raises an exception.

See Also

Assign (see page 2930)

EConvertError (see page 22724)

168.1.1.4.2 TItemProp.HasPickList Method

Indicates whether the PickList (see page 23400) property provides a static set of values for this item.

Pascal

```
function HasPickList: Boolean;
```

C++

```
__fastcall Boolean HasPickList();
```

Description

Call PickList (see page 23400) to determine whether this TItemProp (see page 23394) object supplies values using the PickList (see page 23400) property. HasPickList returns true if the PickList (see page 23400) property contains a nonempty list of values.

See Also

PickList (see page 23400)

168.1.1.4.3 TItemProp.UpdateEdit Method

Pascal

```
procedure UpdateEdit;
```

C++

```
__fastcall UpdateEdit();
```

Description

This is UpdateEdit, a member of class TItemProp.

168.1.1.5 TItemProp Properties

The properties of the TItemProp class are listed here.

Published Properties

	Name	Description
	EditMask (see page 23398)	Restricts the value that can be entered for the associated item.
	EditStyle (see page 23398)	Determines whether the cell that contains the associated value has a drop-down arrow or ellipsis button.
	KeyDesc (see page 23399)	Specifies the name of the item, which appears in the names column of the Value list editor.
	MaxLength (see page 23399)	Specifies the maximum number of characters that users can enter for the item's value.
	PickList (see page 23400)	Lists the items that appear in the drop-down pick list for the item.
	ReadOnly (see page 23400)	Indicates whether users can edit the item's value by typing in a new value.

168.1.1.5.1 TItemProp.EditMask Property

Restricts the value that can be entered for the associated item.

Pascal

```
property EditMask: string;
```

C++

```
__property AnsiString EditMask;
```

Description

Use EditMask to restrict the characters a user can enter. If the user attempts to enter a character that is not valid, the character is not accepted. Validation using the EditMask property is performed on a character-by-character basis.

A mask consists of three fields with semicolons separating the fields. The first part of the mask is the mask itself. The second part is the character that determines whether the literal characters of a mask are included as part of the data. The third part of the mask is the character used to represent unentered characters in the mask.

Setting EditMask to an empty string removes the mask.

For more information on using edit masks, see the TEditMask type.

See Also

Values (see page 23457)

OnSetEditText (see page 14936)

168.1.1.5.2 TItemProp.EditStyle Property

Determines whether the cell that contains the associated value has a drop-down arrow or ellipsis button.

Pascal

```
property EditStyle: TEditStyle;
```

C++

```
__property TEditStyle EditStyle;
```

Description

Set EditStyle to specify whether the cell in the value list editor that contains the associated value should allow users to drop down a pick list or to launch a dialog to edit the value.

When EditStyle is esSimple, the value cell is a simple edit box that lets users edit the associated value directly (unless the ReadOnly (see page 23400) property is true).

When EditStyle is esEllipsis, the value cell contains an ellipsis button that users can click to generate an OnEditButtonClick event. Typically, applications use this event to launch a dialog that edits the value.

When EditStyle is esPickList, the value cell contains a drop-down arrow that users can click to display a list of values from which to select. This value must be supplied by the PickList (see page 23400) property or in an OnGetPickList event handler (or supplied by the PickList (see page 23400) property and modified in an OnGetPickList event handler).

See Also

PickList (see page 23400)

OnGetPickList (see page 23477)

OnEditButtonClick (see page 23470)

ReadOnly (see page 23400)

KeyOptions (see page 23445)

DisplayOptions (see page 23438)

168.1.1.5.3 TItemProp.KeyDesc Property

Specifies the name of the item, which appears in the names column of the Value list editor.

Pascal

```
property KeyDesc: string;
```

C++

```
__property AnsiString KeyDesc;
```

Description

Set KeyDesc to specify a name for this item. This name appears in the names column of the Value list editor.

If ItemProp is not set, then the name that appears in the key column of the Value list editor is the corresponding value of the Keys property.

See Also

Keys (see page 23445)

168.1.1.5.4 TItemProp.MaxLength Property

Specifies the maximum number of characters that users can enter for the item's value.

Pascal

```
property MaxLength: Integer;
```

C++

```
__property int MaxLength;
```

Description

Use MaxLength to limit the number of characters that can be typed when assigning a value to the item. A value of 0 indicates that there is no application-defined limit on the length.

Note: Setting MaxLength will not truncate the existing value, it merely prevents the user from adding more text after reaching the limit of MaxLength characters.

Note: Even when MaxLength is 0, there may be limitations imposed by the operating system on the number of characters that may be entered.

See Also

Values (see page 23457)

EditMask (see page 23398)

168.1.1.5.5 TItemProp.PickList Property

Lists the items that appear in the drop-down pick list for the item.

Pascal

```
property PickList: TStrings;
```

C++

```
__property TStrings PickList;
```

Description

Use PickList to supply the values that appear in the drop-down pick list for the associated item. PickList lets you supply a static set of items that appear in the drop-down list for the associated item when EditStyle (see page 23398) is esPickList. These items can be subsequently modified by an OnGetPickList event handler.

Note: PickList is only used when the EditStyle (see page 23398) property is esPickList. If EditStyle (see page 23398) is esPickList, and PickList does list a set of values, you must supply an OnGetPickList event handler to supply the items.

See Also

EditStyle (see page 23398)

OnGetPickList (see page 23477)

DropDownRows (see page 23440)

168.1.1.5.6 TItemProp.ReadOnly Property

Indicates whether users can edit the item's value by typing in a new value.

Pascal

```
property ReadOnly: Boolean;
```

C++

```
__property Boolean ReadOnly;
```

Description

Set ReadOnly to true to prevent users from typing in a new value for the associated item. For example, to force users to select item values only from a pick list, you can set the EditStyle (see page 23398) to esPickList and set ReadOnly to true. Similarly, to force users to enter values only using a property editor, you can set EditStyle (see page 23398) to esEllipsis and set ReadOnly to true.

See Also

EditStyle (see page 23398)

168.1.2 TValueListEditor Class

TValueListEditor provides a simple way to edit string lists that contain name/value pairs.

Class Hierarchy

Pascal

```
TValueListEditor = class(TCustomDrawGrid);
```

C++

```
class TValueListEditor : public TCustomDrawGrid;
```

File

ValEdit

Description

Use TValueListEditor to let users edit string lists that consist of strings with the form Name=Value. By default, the names appear in a column headed "Key", and the values in a column headed "Value", although you can customize these labels. You can control whether users can select, add, or edit the strings in the Key column. For each entry in the Value column, you can let users edit the string, supply a drop-down list from which they can select values, or provide a dialog in which they can edit values.

TStringList (see page 3006)

TStrings (see page 3029)

Value List Editors (VCL Only)

168.1.2.1 TValueListEditor Members

The following tables list the members exposed by TValueListEditor.

Protected Events

	Name	Description
	OnAlignInsertBefore (see page 6213)	Occurs when an object with custom alignment is aligned.

	OnAlignPosition (see page 6214)	Occurs when an object with custom alignment is aligned.
	OnCanResize (see page 5851)	Occurs when an attempt is made to resize the control.
	OnColumnMoved (see page 14794)	Occurs immediately after the position of a column changes.
	OnConstrainedResize (see page 5853)	Adjust resize constraints.
	OnDockDrop (see page 6214)	Occurs when another control is docked to the control.
	OnDockOver (see page 6216)	Occurs when another control is dragged over the control.
	OnGetSiteInfo (see page 6223)	Returns the control's docking information.
	OnMouseWheel (see page 5869)	Occurs when the mouse wheel is rotated.
	OnResize (see page 5870)	Occurs immediately after the control is resized.
	OnUnDock (see page 6230)	Occurs when the application tries to undock a control that is docked to the windowed control.

Protected Fields

	Name	Description
	DesignOptionsBoost (see page 14814)	This is DesignOptionsBoost, a member of class TCustomGrid.
	FAnchorMove (see page 5733)	This is FAnchorMove, a member of class TControl.
	FAnchorOrigin (see page 5734)	This is FAnchorOrigin, a member of class TControl.
	FAnchorRules (see page 5734)	This is FAnchorRules, a member of class TControl.
	FComponentStyle (see page 2767)	This is FComponentStyle, a member of class TComponent.
	FDesignSize (see page 6124)	This is FDesignSize, a member of class TWinControl.
	FDoubleBuffered (see page 6124)	This is FDoubleBuffered, a member of class TWinControl.
	FExplicitHeight (see page 5734)	This is FExplicitHeight, a member of class TControl.
	FExplicitLeft (see page 5734)	This is FExplicitLeft, a member of class TControl.
	FExplicitTop (see page 5734)	This is FExplicitTop, a member of class TControl.
	FExplicitWidth (see page 5735)	This is FExplicitWidth, a member of class TControl.
	FGridState (see page 14814)	This is FGridState, a member of class TCustomGrid.
	FInImeComposition (see page 6125)	This is FInImeComposition, a member of class TWinControl.
	FOriginalParentSize (see page 5735)	This is FOriginalParentSize, a member of class TControl.
	FSaveCellExtents (see page 14814)	This is FSaveCellExtents, a member of class TCustomGrid.
	VirtualView (see page 14814)	This is VirtualView, a member of class TCustomGrid.

Protected Methods

	Name	Description
	_AddRef (see page 2769)	Called when an application uses a component interface.
	_Release (see page 2769)	Called when an application releases a component interface.
	ActionChange (see page 5737)	Responds when the action associated with the control changes.
	ActionChange (see page 6127)	Updates the control to reflect changes in its associated action.
	AddBiDiModeExStyle (see page 6128)	Sets control's window style according to its bi-directional support.
	AdjustClientRect (see page 6128)	Provides the interface that adjusts the ClientRect (see page 5810) property for idiosyncrasies of the window.
	AdjustColWidths (see page 23416)	This is AdjustColWidths, a member of class TValueListEditor.
	AdjustRowCount (see page 23416)	This is AdjustRowCount, a member of class TValueListEditor.
	AdjustSize (see page 5738)	Sets the size of the control as determined by the AutoSize (see page 5803) property.
	AdjustSize (see page 6129)	Adjusts the control's size according to its contents and constraints.
	AdjustSize (see page 14816)	Adds or deletes rows or columns from the grid.
	AlignControls (see page 6129)	Aligns any controls for which the control is the parent within a specified area of the control.
	ArrangeControl (see page 6130)	This is ArrangeControl, a member of class TWinControl.
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	AssignTo (see page 5739)	Overrides the inherited AssignTo function to enable assignments to TAction objects.
	AssignTo (see page 6130)	Copies the properties of the windowed control to another object.
	BeginAutoDrag (see page 5739)	Begin Automatic Drag.
	BeginColumnDrag (see page 14817)	Starts the dragging of a column in the grid.
	BeginRowDrag (see page 14817)	Starts the dragging of a row in the grid.

	BoxRect (see page 14818)	Returns the screen coordinates of a specified set of cells.
	CalcCursorPos (see page 5741)	This is CalcCursorPos, a member of class TControl.
	CalcDrawInfo (see page 14818)	Calculates the pixel locations of the grid boundaries.
	CalcFixedInfo (see page 14818)	Calculates the pixel locations of the fixed cells.
V	CalcSizingState (see page 14819)	Determines the appearance of the mouse cursor during resizing.
V	CanAutoSize (see page 5741)	Indicates whether the control can resize itself automatically to accommodate its contents.
V	CanAutoSize (see page 6131)	Indicates how the control can be resized.
	CanEditAcceptKey (see page 14819)	Indicates whether the Key parameter can be entered into the current cell.
V	CanEditModify (see page 23417)	Indicates whether the current cell in the grid can be edited.
V	CanEditShow (see page 14820)	Indicates whether the inplace edit control can be created to allow editing.
	CanGridAcceptKey (see page 14820)	Indicates whether the grid should respond to a given key combination.
V	CanResize (see page 5742)	OnCanResize (see page 5851) event dispatcher.
V	CanResize (see page 6132)	Indicates how the control can respond to a resize attempt.
	CellRect (see page 14821)	Returns the screen coordinates of a cell in the grid.
	Changed (see page 5742)	Sends a CM_CHANGED (see page 6330) message to the control.
	ChangeGridOrientation (see page 14821)	Prepares the grid's canvas for painting to reflect a right-to-left or left-to-right orientation.
	ChangeName (see page 2770)	Sets the private, internal storage for the Name (see page 2805) property to the string passed in NewName.
	ChangeScale (see page 5743)	Rescaling event dispatcher.
V	ChangeScale (see page 6132)	Resize (see page 5780) and reposition children and self.
	CheckColumnDrag (see page 14821)	CheckColumnDrag validates whether the column currently selected for dragging can be dropped at the current location.
	CheckRowDrag (see page 14822)	CheckRowDrag validates whether the row currently selected for dragging can be dropped at the current location.
	Click (see page 5743)	Respond to user click.
V	ColumnMoved (see page 14781)	Generates an OnColumnMoved (see page 14794) event.
	ColumnMoved (see page 14822)	Provides the interface for a method that responds when the position of a column changes.
V	ColWidthsChanged (see page 23417)	Responds when the column widths change.
V	ConstrainedResize (see page 5746)	Notify control of resize with constraints.
V	ConstrainedResize (see page 6133)	Generates an OnConstrainedResize (see page 5853) event.
	ControlsAligned (see page 6134)	This is ControlsAligned, a member of class TWinControl.
	CreateDockManager (see page 6134)	Creates the dock manager for the control.
V	CreateEditor (see page 23417)	Creates the inplace editor control.
V	CreateHandle (see page 6135)	Creates underlying screen object.
V	CreateParams (see page 6135)	Initializes a window-creation parameter data structure.
V	CreateParams (see page 14823)	Initializes the window-creation parameter record.
	CreateSubClass (see page 6136)	Creates a windowed control derived from an existing Windows window class.
V	CreateWindowHandle (see page 6137)	Creates a Windows control to represent the control.
V	CreateWnd (see page 23418)	Creates the underlying window.
V	CustomAlignInsertBefore (see page 6137)	Returns placement order of custom-aligned child control.
V	CustomAlignPosition (see page 6138)	Returns aligned position of custom-aligned child control.
	DblClick (see page 5747)	OnDblClick (see page 5854) event dispatcher.
	DefaultDockImage (see page 5747)	Handles the painting and erasing of a dock image.
V	DefineProperties (see page 2771)	Designates methods for storing an object's unpublished data on a stream such as a form file.
V	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
V	DefineProperties (see page 5748)	Provides methods to read and write the IsControl (see page 5829) property to a stream such as a form file.
V	DefineProperties (see page 6139)	Provides methods to read and write the IsControl property to a stream such as a form file.
V	DefineProperties (see page 14824)	Adds the ColWidths (see page 14845) and RowHeights (see page 14855) properties to the values saved with the grid.
V	DeleteColumn (see page 14824)	Deletes a specified column from the grid.
	DesignWndProc (see page 5749)	This is DesignWndProc, a member of class TControl.

	DestroyHandle (see page 6140)	Destroys the control's window without destroying the control.
	DestroyWindowHandle (see page 6140)	Destroys the window created in the CreateWindowHandle (see page 6137) method.
	DestroyWnd (see page 6141)	Destroys the control's window.
	DoAddDockClient (see page 6142)	Performs actions when a control is docked to the windowed control.
	DockOver (see page 6143)	Responds when a docking client is dragged over the windowed control.
	DockReplaceDockClient (see page 6143)	This is DockReplaceDockClient, a member of class TWinControl.
	DockTrackNoTarget (see page 5749)	Handles dragging of the control over an invalid docking target.
	DoContextPopup (see page 5750)	OnContextPopup (see page 5854) event dispatcher.
	DoDock (see page 5750)	Docking event dispatcher.
	DoDockOver (see page 6143)	Generates an OnDockOver (see page 6216) event.
	DoEndDock (see page 5750)	OnEndDock (see page 5859) event dispatcher.
	DoEndDrag (see page 5751)	OnEndDrag (see page 5860) event dispatcher.
	DoEnter (see page 6144)	Respond to receiving input focus.
	DoExit (see page 23419)	Hides the inplace editor when selection moves to another control in a form.
	DoFlipChildren (see page 6145)	Flips the control's children.
	DoKeyDown (see page 6145)	Performs some preprocessing before generating an OnKeyDown (see page 6225) event.
	DoKeyPress (see page 6146)	Performs some preprocessing before generating an OnKeyPress (see page 6227) event.
	DoKeyUp (see page 6146)	Performs some preprocessing before generating an OnKeyUp (see page 6228) event.
	DoMouseWheel (see page 5751)	Processes mouse wheel motion.
	DoMouseWheelDown (see page 5752)	OnMouseWheelDown (see page 5869) event dispatcher.
	DoMouseWheelDown (see page 14825)	Performs tasks when the mouse wheel is rotated downward.
	DoMouseWheelUp (see page 5752)	OnMouseWheelUp (see page 5870) event dispatcher.
	DoMouseWheelUp (see page 14826)	Performs tasks when the mouse wheel is rotated upward.
	DoOnValidate (see page 23419)	This is DoOnValidate, a member of class TValueListEditor.
	DoRemoveDockClient (see page 6147)	Responds when a control is undocked from the windowed control.
	DoStartDock (see page 5753)	OnStartDock (see page 5871) event dispatcher.
	DoStartDrag (see page 5753)	OnStartDrag (see page 5871) event dispatcher.
	DoUnDock (see page 6147)	Undocks a control that is currently docked to the windowed control.
	DragCanceled (see page 5754)	Provides the interface for a method that responds to the cancellation of a drag.
	DragOver (see page 5755)	OnDragOver (see page 5857) event dispatcher.
	DrawCell (see page 23419)	Generates an OnDrawCell event.
	DrawDragDockImage (see page 5755)	Draws the dock image for the control.
	EditListGetItems (see page 23420)	This is EditListGetItems, a member of class TValueListEditor.
	EndColumnDrag (see page 14827)	Ends the dragging of a column in the grid.
	EndRowDrag (see page 14827)	Ends the dragging of a row in the grid.
	EraseDragDockImage (see page 5757)	Erases the dock image for the control.
	FindNextControl (see page 6149)	Returns the control's next child in the tab order after the specified control.
	FixupTabList (see page 6149)	Sorts the child controls by their tab order.
	FocusCell (see page 14827)	Changes the current cell to a specified cell.
	GetAction (see page 5758)	This is GetAction, a member of class TControl.
	GetActionLinkClass (see page 5758)	Returns the appropriate action link class that is associated with the control class.
	GetActionLinkClass (see page 6152)	Returns the associated action link class.
	GetCell (see page 23420)	This is GetCell, a member of class TValueListEditor.
	GetChildOwner (see page 2776)	Returns the owner of a child component being read from a stream.
	GetChildParent (see page 2776)	Returns the parent, or if there is no parent, returns the owner of a child component being read from a stream.
	GetChildren (see page 2777)	This is GetChildren, a member of class TComponent.
	GetChildren (see page 6153)	Calls a specified method for each child of the control.
	GetClientOrigin (see page 5758)	Returns the screen coordinates of the top-left corner of the control's client area.
	GetClientOrigin (see page 6153)	Returns the value of the ClientOrigin (see page 5809) property.
	GetClientRect (see page 5759)	Returns a rectangle defining the client area of the control.
	GetClientRect (see page 6154)	Returns the value of the ClientRect (see page 5810) property.

	GetColCount (see page 23421)	This is GetColCount, a member of class TValueListEditor.
	GetControlExtents (see page 6154)	Returns the smallest rectangle in which all the control's children fit.
	GetDeviceContext (see page 5760)	Returns a device context for the control.
	GetDeviceContext (see page 6155)	Provides access to a device context for the control.
	GetDockEdge (see page 5763)	Returns the edge on which another control should be docked when it is dragged over the control.
	GetDragImages (see page 5763)	Returns the control's image list containing the image to be displayed while dragging.
	GetEditLimit (see page 23421)	Provides the interface for a method that limits the number of characters the user can type into cells.
	GetEditMask (see page 23421)	Generates an OnGetEditMask event.
	GetEditStyle (see page 23421)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
	GetEditText (see page 23422)	This is GetEditText, a member of class TValueListEditor.
	GetEnabled (see page 5763)	Returns the value of the Enabled (see page 5821) property.
	GetFloating (see page 5764)	Returns the value of the Floating (see page 5823) property.
	GetFloatingDockSiteClass (see page 5764)	Returns the class used for the control when it is floating.
	GetGridHeight (see page 14829)	Returns the value of the GridHeight (see page 14850) property.
	GetGridWidth (see page 14830)	Returns the value of the GridWidth (see page 14851) property.
	GetIDsOfNames (see page 2777)	Maps a single member and an optional set of argument names to a corresponding set of integer dispatch identifiers (dispIDs).
	GetOwner (see page 2778)	Returns the owner of a component.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetPalette (see page 5765)	Returns the handle to a palette for use by the control.
	GetParentHandle (see page 6157)	Returns the window handle for the window of the control's parent.
	GetPickList (see page 23422)	This is GetPickList, a member of class TValueListEditor.
	GetPopupMenu (see page 5765)	Returns the pop-up menu associated with the control.
	GetRowCount (see page 23422)	This is GetRowCount, a member of class TValueListEditor.
	GetSiteInfo (see page 6158)	Generates an OnGetSiteInfo (see page 6223) event
	GetTopParentHandle (see page 6159)	Returns the window handle of the first window not associated with a VCL control that contains the windowed control.
	GetTypeInfo (see page 2779)	Retrieves the type information for an object.
	GetTypeInfoCount (see page 2779)	Returns the number of type information interfaces that an object provides (either 0 or 1).
	HideEdit (see page 14830)	Hides the inplace editor.
	HideEditor (see page 14830)	Hides the inplace editor when it is not in use.
	InvalidateCell (see page 14831)	Invalidates the region occupied by a cell so that it will be repainted with the next Windows paint message.
	InvalidateCol (see page 14831)	Invalidates the region occupied by a column so that it will be repainted with the next Windows paint message.
	InvalidateDockHostSite (see page 6162)	This is InvalidateDockHostSite, a member of class TWinControl.
	InvalidateEditor (see page 14832)	Causes the inplace editor to repaint itself, moving to a new location if necessary.
	InvalidateGrid (see page 14832)	Tells Windows to repaint the grid after other important Windows messages are handled.
	InvalidateRow (see page 14832)	Invalidates the region occupied by a row so that it will be repainted with the next Windows paint message.
	Invoke (see page 2781)	Provides access to Automation properties and methods when the component wraps an Automation object.
	IsControlActivateMsg (see page 6162)	This is IsControlActivateMsg, a member of class TWinControl.
	IsControlMouseMsg (see page 6162)	Indicates whether a specified mouse message is directed to one of the windowed control's child controls.
	IsEmptyRow (see page 23423)	This is IsEmptyRow, a member of class TValueListEditor.
	IsQualifyingSite (see page 6163)	This is IsQualifyingSite, a member of class TWinControl.
	KeyDown (see page 23423)	Provides special processing when the user presses a key.
	KeyPress (see page 6163)	Respond to keyboard input.
	KeyPress (see page 14833)	Provides special processing when the user presses a key.
	KeyUp (see page 6164)	Respond to released key.
	Loaded (see page 2782)	Initializes the component after the form file has been read into memory.
	Loaded (see page 5771)	Initializes the control after it is loaded from a stream.

	MainWndProc (see page 6165)	Receives Windows messages for the control.
	MouseActivate (see page 5773)	This is MouseActivate, a member of class TControl.
V	MouseDown (see page 23424)	Provides special processing when the user presses a mouse button.
	MouseMove (see page 5773)	Respond to mouse moving over control area..
V	MouseMove (see page 14834)	Provides special processing when the user moves the mouse.
	MouseUp (see page 5774)	OnMouseUp (see page 5867) event dispatcher.
V	MouseUp (see page 14835)	Provides special processing when the user releases the mouse button.
	MoveColRow (see page 14835)	Selects the cell indicated by the ACol and ARow parameters.
	MoveColumn (see page 14836)	Moves a column to a new position.
	MoveRow (see page 14836)	Moves a row to a new position.
V	Notification (see page 2783)	Forwards notification messages to all owned components.
V	Notification (see page 5775)	Responds to notifications that components are being created or destroyed.
V	Notification (see page 6165)	Responds to notifications that components are being created or destroyed.
	NotifyControls (see page 6165)	Sends a message to all the child controls.
V	Paint (see page 5920)	Renders the image of a custom control.
V	Paint (see page 14836)	Draws the image of the grid control on the screen.
	PaintControls (see page 6166)	Paints each of the child controls in a windowed control using the specified device context.
	PaintHandler (see page 6166)	Responds to WM_PAINT messages.
V	PaintWindow (see page 5920)	Renders the image of the control on a specified device context.
V	PaintWindow (see page 6169)	Renders the image of a windowed control.
	PaletteChanged (see page 5775)	Responds to changes in the system's palette by realizing the control's palette.
V	PaletteChanged (see page 6170)	Responds to changes in the system's palette by realizing the control's palette and the palette for each child control.
	PaletteCreated (see page 2783)	Responds when the component is created from the component palette.
	PositionDockRect (see page 5777)	Positions the docking rectangle according to the current drag-and-dock state.
V	QueryInterface (see page 2784)	Returns a reference to a specified interface if the object supports that interface.
V	ReadState (see page 2784)	This is ReadState, a member of class TComponent.
V	ReadState (see page 5778)	Prepares the control for having its properties assigned values read from a stream.
V	ReadState (see page 6171)	Prepares the control for having its properties assigned values from a stream.
	RecreateWnd (see page 6171)	Recreate underlying Windows screen object.
	ReloadDockedControl (see page 6172)	Reloads a docked control.
	RemoveWindowProps (see page 6174)	This is RemoveWindowProps, a member of class TWinControl.
V	RequestAlign (see page 5780)	Instructs the parent of a control to reposition the control, enforcing its Align (see page 5798) property.
	ResetIme (see page 6174)	Restores the input method editor (IME) that was active when the application started.
	ResetImeComposition (see page 6175)	Directs the composition window of the input method editor (IME) to perform a specific action.
V	Resize (see page 23425)	Respond to control resize.
	RowHeightsChanged (see page 14837)	Responds when the row heights change.
V	RowMoved (see page 23425)	Generates an OnRowMoved event.
	ScaleConstraints (see page 5781)	This is ScaleConstraints, a member of class TControl.
	ScaleControls (see page 6176)	Rescale child controls only.
	ScrollData (see page 14838)	Scrolls the visual image of the cells in the grid.
V	SelectCell (see page 23426)	Determines whether a particular cell in the grid can be selected.
	SelectFirst (see page 6177)	Locates first selectable child control.
	SelectNext (see page 6177)	Moves the input focus from the current child control to the next one in the tab order.
	SendCancelMode (see page 5781)	Cancels the modal state of the control.
	SendDockNotification (see page 5782)	Sends a Windows message to the control's host dock site.
	SetAncestor (see page 2787)	This is SetAncestor, a member of class TComponent.
V	SetAutoSize (see page 5783)	This is SetAutoSize, a member of class TControl.
V	SetBiDiMode (see page 5783)	Sets the control's bi-directional mode.
V	SetCell (see page 23426)	This is SetCell, a member of class TValueListEditor.
	SetChildOrder (see page 2788)	This is SetChildOrder, a member of class TComponent.

	SetChildOrder (see page 6178)	Changes the order in which the child component appears in the list of child components returned by the GetChildren (see page 6153) method.
	SetDesigning (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDesignInstance (see page 2788)	Ensures that components inserted at design time have their design-mode flag set.
	SetDragMode (see page 5785)	Sets the drag mode for the control.
	SetEditText (see page 23426)	This is SetEditText, a member of class TValueListEditor.
	SetEnabled (see page 5785)	Sets the value of the Enabled (see page 5821) property.
	SetIme (see page 6181)	Activates an input method editor (IME) using the values specified by the ImeMode (see page 6207) and ImeName (see page 6208) properties.
	SetImeCompositionWindow (see page 6181)	Sets the position and font of the composition window.
	SetInline (see page 2789)	Sets the csInline bit of the component's ComponentState (see page 2804) property
	SetName (see page 2789)	Sets the value of the Name (see page 2805) property.
	SetName (see page 5785)	Sets the name of the control.
	SetParent (see page 5786)	Sets the parent of the control.
	SetParent (see page 6182)	Sets the parent of the control.
	SetParentBackground (see page 6182)	This is SetParentBackground, a member of class TWinControl.
	SetParentBiDiMode (see page 5786)	Specifies whether the control uses its parent's BiDiMode (see page 5803).
	SetParentComponent (see page 2790)	This is SetParentComponent, a member of class TComponent.
	SetParentComponent (see page 5787)	Sets the parent for the control.
	SetStrings (see page 23426)	This is SetStrings, a member of class TValueListEditor.
	SetZOrder (see page 5788)	Repositions the control in its parent's control list, thereby changing position onscreen.
	SetZOrder (see page 6182)	Moves the control to the top or bottom of the parent control's (or screen's) list of TWinControl (see page 6112) controls.
	ShowControl (see page 6183)	Ensures that a specified child control is visible.
	ShowEditor (see page 14839)	Displays the inplace editor when the grid enters edit mode.
	ShowEditorChar (see page 14839)	Displays the inplace editor, with its text set to the specified character.
	SizeChanged (see page 14840)	Responds to changes in the size of the grid.
	Sizing (see page 14840)	Indicates whether the indicated coordinates are on one of the resize hot zones of the graph.
	StringsChanging (see page 23427)	This is StringsChanging, a member of class TValueListEditor.
	TimedScroll (see page 14840)	Extends a move, resize, or selection out of the scrollable region when the user drags the mouse in a direction where the grid is scrolled.
	TitleCaptionsStored (see page 23427)	This is TitleCaptionsStored, a member of class TValueListEditor.
	TopLeftChanged (see page 14784)	Generates an OnTopLeftChanged (see page 14800) event.
	TopLeftChanged (see page 14841)	Updates the position of the inplace editor when the grid scrolls.
	UpdateBounds (see page 6185)	This is UpdateBounds, a member of class TWinControl.
	UpdateBoundsRect (see page 5789)	Changes the Top (see page 5844), Left (see page 5830), Width (see page 5849), and Height (see page 5825) properties of the control, but doesn't update its screen image and bypasses all resize events.
	UpdateControlOriginalParentSize (see page 6186)	This is UpdateControlOriginalParentSize, a member of class TWinControl.
	Updated (see page 2791)	Clears the csUpdating state in the component's ComponentState (see page 2804) property when the component finishes updating.
	UpdateDesigner (see page 14841)	Notifies the designer when rows and columns of the grid are moved or resized.
	UpdateExplicitBounds (see page 5789)	This is UpdateExplicitBounds, a member of class TControl.
	UpdateRecreatingFlag (see page 6186)	This is UpdateRecreatingFlag, a member of class TWinControl.
	UpdateRegistry (see page 2791)	Provides the interface for a method that adds type library and version information to the Registry (see page 18633) on components that implement COM interfaces.
	UpdateUIState (see page 6186)	Updates form User Interface State as needed
	Updating (see page 2791)	Sets the csUpdating state in the component's ComponentState (see page 2804) property.
	ValidateContainer (see page 2792)	Determines whether an object can be inserted into a container.
	ValidateInsert (see page 2792)	Provides the interface for a method that validates an child component before it is inserted.
	ValidateRename (see page 2792)	Ensures that renaming an owned component does not create name conflict.
	VisibleChanging (see page 5791)	Provides the interface for a method that responds to changes in the control's visibility.

V	WndProc (see page 5791)	Provides specific message responses for the control.
V	WndProc (see page 6187)	Provides specific message responses for the control.
V	WriteState (see page 2793)	This is WriteState, a member of class TComponent.

Protected Properties

	Name	Description
	ActionLink (see page 5798)	Contains the action link object associated with the control.
	AutoSize (see page 5803)	Specifies whether the control sizes itself automatically to accommodate its contents.
	BevelEdges (see page 6192)	Specifies which edges of the control are beveled.
	BevelInner (see page 6193)	Specifies the cut of the inner bevel.
	BevelKind (see page 6193)	Specifies the control's bevel style.
	BevelOuter (see page 6194)	Specifies the cut of the outer bevel.
	BevelWidth (see page 6194)	Specifies the width of the inner and outer bevels.
	BorderWidth (see page 6195)	Specifies the width of the control's border.
R	Canvas (see page 5921)	Specifies the TCanvas object that presents a drawing surface for the control.
	Caption (see page 5806)	Specifies a text string that identifies the control to the user.
	Col (see page 14843)	Specifies the index of the column that contains the selected cell.
	ColWidths (see page 14845)	Indicates the width (in pixels) of all the columns in the grid.
	DefWndProc (see page 6199)	Specifies the default window procedure for the windowed control.
	DesktopFont (see page 5818)	Specifies whether the control uses the Windows icon font when writing text.
R	EditList (see page 23441)	This is EditList, a member of class TValueListEditor.
	EditorMode (see page 14848)	Determines whether the current cell can be edited.
	FixedRows (see page 14849)	Specifies the number of rows on the top of the grid that cannot be scrolled.
R	GridHeight (see page 14850)	Specifies the height of the grid in pixels.
R	GridWidth (see page 14851)	Specifies the width of the grid in pixels.
R	HitTest (see page 14851)	Indicates the current position of the mouse cursor.
	ImeMode (see page 6207)	Determines the behavior of the input method editor (IME).
	ImeName (see page 6208)	Specifies the input method editor (IME) to use for converting keyboard input to Asian language characters.
R	InplaceEditor (see page 14852)	Designates the edit control the grid uses to allow users to edit the contents of the selected cell.
	IsControl (see page 5829)	Determines whether a form stores its form-specific properties to a stream.
	LeftCol (see page 14852)	Specifies the index of the first visible scrollable column in the grid.
	MouseCapture (see page 5831)	Indicates whether the control has "captured" mouse events.
	ParentBackground (see page 6209)	Determines whether control uses parent's theme background.
	Row (see page 14854)	Specifies the index of the row that contains the selected cell.
	RowHeights (see page 14855)	Gives the height (in pixels) of all rows in the grid.
	ScalingFlags (see page 5840)	Reflects which attributes of the control have been scaled.
	Selection (see page 14856)	Indicates the boundaries of the current selection.
	TabStops (see page 14858)	Indicates whether the user can tab to specified columns in the grid.
	Text (see page 5842)	Contains a text string associated with the control.
	TopRow (see page 14858)	Specifies the index of the first visible scrollable row in the grid.
	WheelAccumulator (see page 5849)	Accumulates mouse wheel rotations.
	WindowHandle (see page 6212)	Provides access to a window handle for the control.
	WindowText (see page 5850)	Contains the text string of the control.

Public Events

	Name	Description
	WindowProc (see page 5872)	Points to the window procedure that responds to messages sent to the control.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.

	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Assign (see page 2930)	Copies the contents of another, similar object.
	BeforeDestruction (see page 2770)	Performs any necessary actions before the first destructor is called.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginDrag (see page 5740)	Starts the dragging of a control.
	BringToFront (see page 5740)	Puts the control in front of all other controls in its parent control.
	Broadcast (see page 6130)	Sends a message to each of the child controls.
	CanFocus (see page 6131)	Indicates whether a control can receive focus.
	CellRect (see page 14781)	Returns the screen coordinates of a cell in the grid.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	ClientToParent (see page 5744)	Translates client coordinates to parent coordinates.
	ClientToScreen (see page 5744)	Translates a given point from client area coordinates to global screen coordinates.
	ContainsControl (see page 6133)	Indicates whether a specified control exists within the control.
	ControlAtPos (see page 6133)	Returns the child control located at a specified position within the control.
	Create (see page 23415)	Creates and initializes new TValueListEditor (see page 23401) object.
	CreateParented (see page 6123)	Creates and initializes a control as the child of a specified non-VCL container.
	CreateParentedControl (see page 6136)	Creates and initializes a control as the child of a specified non-VCL window.
	DefaultHandler (see page 5748)	Provides message handling for all messages that do not have specific handlers.
	DefaultHandler (see page 6139)	Provides message handling for all messages that the control does not fully process itself.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	DeleteRow (see page 23418)	Deletes a row in the value list editor and a corresponding string from the associated TStrings object.
	Destroy (see page 23415)	Frees the memory associated with the TValueListEditor (see page 23401) object.
	DestroyComponents (see page 2771)	Destroys all owned components.
	Destroying (see page 2772)	Indicates that the component and its owned components are about to be destroyed.
	DisableAlign (see page 6141)	Disables the realignment of child controls.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	Dock (see page 5749)	Used internally to dock the control.
	DockDrop (see page 6142)	Generates an OnDockDrop (see page 6214) event.
	DragDrop (see page 5754)	OnDragDrop (see page 5855) event dispatcher.
	Dragging (see page 5754)	Indicates whether a control is being dragged.
	DrawTextBiDiModeFlags (see page 5756)	Returns the text flags that reflect the current setting of the BiDiMode (see page 5803) property.
	DrawTextBiDiModeFlagsReadingOnly (see page 5756)	Returns the text flag to add that indicates whether the control's text should read from right to left.
	EnableAlign (see page 6148)	Decrements the reference count incremented by the DisableAlign (see page 6141) method, eventually realigning the child controls.
	EndDrag (see page 5757)	Stops a control from being dragged any further.
	ExecuteAction (see page 2772)	This is ExecuteAction, a member of class TComponent.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	FindChildControl (see page 6148)	Returns a child control given its name.
	FindComponent (see page 2772)	Indicates whether a given component is owned by the component.
	FindRow (see page 23420)	Locates the row that corresponds to a specified key name.
	FlipChildren (see page 6150)	Reverses the positions of child controls.
	Focused (see page 6150)	Determines whether the control has input focus.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	FreeNotification (see page 2775)	Ensures that AComponent is notified that the component is going to be destroyed.
	FreeOnRelease (see page 2776)	Frees the interface reference for components that were created from COM classes.
	GetComponent (see page 3197)	Returns a reference to the component associated by the implementing class.
	GetControlsAlignment (see page 5759)	Indicates how text is aligned within the control.
	GetEnumerator (see page 2777)	Returns a TComponent (see page 2762) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2778)	Returns a string used by the Object Inspector.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
	GetParentComponent (see page 2778)	Returns the containing Component.
	GetParentComponent (see page 5765)	Returns the parent of the control.
	GetTabOrderList (see page 6158)	Builds a list of controls in tab order.
	GetTextBuf (see page 5766)	Retrieves the control's text, copies it into a buffer, and returns the number of characters copied.
	GetTextLen (see page 5767)	Returns the length of the control's text.
	HandleAllocated (see page 6159)	Reports whether a screen object handle exists for the control.
	HandleNeeded (see page 6160)	Creates a screen object for the control if it doesn't already exist.
	HasParent (see page 2780)	This is HasParent, a member of class TComponent.
	HasParent (see page 5768)	Indicates whether the control has a parent.
	Hide (see page 5769)	Makes the control invisible.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitiateAction (see page 5769)	Calls the action link's Update (see page 5789) method if the control is associated with an action link.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InsertComponent (see page 2780)	Establishes the component as the owner of a specified component.
	InsertControl (see page 6160)	Inserts a control into the Controls (see page 6197) array property.
	InsertRow (see page 23422)	Inserts a row in the value list editor and a corresponding string into the associated TStrings object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	Invalidate (see page 5770)	Completely repaint control.
	Invalidate (see page 6161)	Schedules a control repaint.
	IsImplementorOf (see page 2782)	Indicates whether the component implements a specified interface.
	IsRightToLeft (see page 5770)	Indicates whether the control should be reversed right to left.
	ManualDock (see page 5771)	Docks the control.
	ManualFloat (see page 5772)	Undocks the control.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	MouseCoord (see page 14834)	Returns the row and column indexes of the cell that contains a point specified in screen coordinates.
	MouseToCell (see page 14783)	Returns the column and row of the cell at the position with screen coordinates (X,Y).
	MouseWheelHandler (see page 5774)	Dispatches messages received from a mouse wheel.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	PaintTo (see page 6167)	This is the overview for the PaintTo method overload.
	ParentToClient (see page 5776)	Translate parent coordinates to client coordinates.
	Perform (see page 5776)	Responds as if the control received a specified Windows message.
	PreProcessMessage (see page 6170)	This is PreProcessMessage, a member of class TWinControl.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
	Realign (see page 6171)	Forces the control to realign children.
	ReferenceInterface (see page 2785)	Establishes or removes internal links that cause this component to be notified when the implementer of a specified interface is destroyed.

	Refresh (see page 23424)	Updates the display to reflect the current value of the Strings (see page 23456) property.
	RemoveComponent (see page 2785)	Removes a specified component specified from the component's Components (see page 2799) list.
	RemoveControl (see page 6172)	Removes a specified control from the Controls (see page 6197) array.
	RemoveFreeNotification (see page 2787)	Disables destruction notification that was enabled by FreeNotification (see page 2775)
V	Repaint (see page 5779)	Forces the control to repaint its image on the screen.
V	Repaint (see page 6174)	Repaints the entire control.
	ReplaceDockedControl (see page 5779)	Docks the control in the place where another control is already docked.
	RestoreCurrentRow (see page 23425)	Undoes all edits to the current row.
V	SafeCallException (see page 2787)	Handles exceptions in methods declared using the safecall calling convention.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	ScaleBy (see page 6175)	Rescale control and its children.
	ScreenToClient (see page 5781)	Converts the screen coordinates of a specified point on the screen to client coordinates.
	ScrollBy (see page 6176)	Scroll control contents.
	SendToBack (see page 5782)	Puts a windowed control behind all other windowed controls, or puts a non-windowed control behind all other non-windowed controls.
V	SetBounds (see page 5783)	Sets the Left (see page 5830), Top (see page 5844), Width (see page 5849), and Height (see page 5825) properties all at once.
V	SetBounds (see page 6178)	Sets the windowed control's boundary properties all at once.
	SetDesignVisible (see page 5784)	Makes a control visible at design time.
V	SetDesignVisible (see page 6178)	Makes a control visible at design time.
V	SetFocus (see page 6179)	Gives the input focus to the control.
	SetSubComponent (see page 2790)	Identifies whether the component is a subcomponent.
	SetTextBuf (see page 5787)	Sets the text of the control.
	Show (see page 5788)	Makes a control visible.
V	Update (see page 5789)	Processes any pending paint messages immediately.
V	Update (see page 6183)	Forces the control to update.
	UpdateAction (see page 2790)	This is UpdateAction, a member of class TComponent.
	UpdateControlState (see page 6186)	Respond to state change.
	UseRightToLeftAlignment (see page 5790)	Specifies whether the control's alignment should be reversed right-to-left.
	UseRightToLeftReading (see page 5790)	Specifies whether the control is using a right-to-left reading order.
	UseRightToLeftScrollBar (see page 5791)	Specifies whether the vertical scroll bar appears on the left side of the control.

Public Properties

	Name	Description
	Action (see page 5797)	Designates the action associated with the control.
R	AlignDisabled (see page 6192)	Indicates child control realignment disabled.
	BoundsRect (see page 5803)	Specifies the bounding rectangle of the control, expressed in the coordinate system of the parent control.
R	Brush (see page 6195)	Determines the color and pattern used for painting the background of the control.
	Canvas (see page 14785)	Specifies the TCanvas object that presents a drawing surface for the control.
	Cells (see page 23433)	Lists the strings for each cell in the editor.
	ClientHeight (see page 5808)	Specifies the height of the control's client area in pixels.
R	ClientOrigin (see page 5809)	Specifies the screen coordinates (in pixels) of the top left corner of a control's client area.
R	ClientRect (see page 5810)	Specifies the size (in pixels) of a control's client area.
	ClientWidth (see page 5811)	Specifies the horizontal size of the control's client area in pixels.
	Col (see page 14787)	Specifies the index of the column that contains the selected cell.
R	ColCount (see page 23434)	Indicates the number of columns in the value list editor.
	ColWidths (see page 14788)	Indicates the width (in pixels) of all the columns in the grid.
R	ComObject (see page 2793)	Specifies the interface reference implemented by the component.
R	ComponentCount (see page 2794)	Indicates the number of components owned by the component.
	ComponentIndex (see page 2799)	Indicates the position of the component in its owner's Components (see page 2799) property array.

R	Components (see page 2799)	Lists all components owned by the component.
R	ComponentState (see page 2804)	Describes the current state of the component, indicating when a component needs to avoid certain actions.
R	ComponentStyle (see page 2805)	Governs the behavior of the component.
R	ControlCount (see page 6195)	Returns the number of child controls.
R	Controls (see page 6197)	Lists all child controls.
	ControlState (see page 5813)	Indicates the current state of a control at runtime.
	ControlStyle (see page 5814)	Determines style characteristics of the control.
	DesignInfo (see page 2805)	Contains information used by the Form designer.
R	DockClientCount (see page 6199)	Specifies the number of controls that are docked on the windowed control.
R	DockClients (see page 6201)	Lists the controls that are docked to the windowed control.
	DockManager (see page 6202)	Specifies the control's docking manager interface.
	DockOrientation (see page 5818)	Specifies how the control is docked relative to other controls docked in the same parent.
	DockSite (see page 6204)	Specifies whether the control can be the target of drag-and-dock operations.
	DoubleBuffered (see page 6205)	Determines whether the control's image is rendered directly to the window or painted to an in-memory bitmap first.
	EditorMode (see page 14789)	Determines whether the current cell can be edited.
R	ExplicitHeight (see page 5821)	Specifies the explicit vertical size of the control in pixels.
R	ExplicitLeft (see page 5822)	Specifies the explicit horizontal pixel coordinate of the left edge of a component relative to its parent.
R	ExplicitTop (see page 5822)	Specifies the explicit vertical pixel coordinate of the top edge of a component relative to its parent.
R	ExplicitWidth (see page 5822)	Specifies the explicit horizontal size of the control in pixels.
R	Floating (see page 5823)	Indicates whether the control is floating.
	FloatingDockSiteClass (see page 5823)	Specifies the class of the temporary control that hosts the control when it is floating.
	GridHeight (see page 14789)	Specifies the height of the grid in pixels.
	GridWidth (see page 14789)	Specifies the width of the grid in pixels.
R	Handle (see page 6207)	Provides access to the underlying Windows screen object for the control.
	HostDockSite (see page 5829)	Specifies the control in which the control is docked.
	ItemProps (see page 23445)	Specifies various constraints on the way users can enter a value for each item in the list.
	Keys (see page 23445)	Lists the strings for each cell in the name (key) column.
	LeftCol (see page 14790)	Specifies the index of the first visible scrollable column in the grid.
	LRDockWidth (see page 5831)	Specifies the width of the control when it is docked horizontally.
R	MouseInClient (see page 6209)	This is MouseInClient, a member of class TWinControl.
R	Owner (see page 2807)	Indicates the component that is responsible for streaming and freeing this component.
	Padding (see page 6209)	Specifies the padding of a control.
	Parent (see page 5832)	Indicates the parent of the control.
	ParentWindow (see page 6210)	Reference to parent's underlying control.
	Row (see page 14790)	Specifies the index of the row that contains the selected cell.
R	RowCount (see page 23453)	Indicates the number of rows in the value list editor.
	RowHeights (see page 14791)	Gives the height (in pixels) of all rows in the grid.
	Selection (see page 14791)	Indicates the boundaries of the current selection.
R	Showing (see page 6210)	Indicates whether the control is showing on the screen.
	TabStop (see page 6211)	Determines if the user can tab to a control.
	TabStops (see page 14793)	Indicates whether the user can tab to specified columns in the grid.
	TBDockHeight (see page 5842)	Specifies the height of the control when it is docked vertically.
	TopRow (see page 14793)	Specifies the index of the first visible scrollable row in the grid.
	UndockHeight (see page 5845)	Specifies the height of the control when it is floating.
	UndockWidth (see page 5846)	Specifies the width of the control when it is floating.
	UseDockManager (see page 6212)	Specifies whether the docking manager is used in drag-and-dock operations.
	Values (see page 23457)	Lists the strings for each value from the value column.
	VCLComObject (see page 2812)	Represents information used internally by components that support COM.
	VisibleColCount (see page 23459)	Indicates the number of scrollable columns visible in the grid.

R	VisibleDockClientCount (see page 6212)	Specifies the number of visible controls that are docked on the windowed control.
	VisibleRowCount (see page 23459)	Indicates the number of scrollable rows visible in the grid.

Published Events

	Name	Description
	OnClick (see page 23461)	Occurs when the user clicks the control.
	OnContextPopup (see page 23463)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 23463)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 23464)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 23466)	Occurs when the user drags an object over a control.
	OnDrawCell (see page 23468)	Occurs when a cell in the grid needs to be drawn.
	OnEditButtonClick (see page 23470)	Occurs when the user click the ellipsis button on a cell in the values column or types Ctrl+Enter while focus is on a value cell with an ellipsis button.
	OnEndDock (see page 23470)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 23471)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 23472)	Occurs when a control receives the input focus.
	OnExit (see page 23474)	Occurs when the input focus shifts away from one control to another.
	OnGetEditMask (see page 23476)	Occurs when the in-place editor requests an edit mask.
	OnGetEditText (see page 23476)	Occurs when the in-place editor requests the value of a cell.
	OnGetPickList (see page 23477)	Supplies a pick list for values associated with a particular key.
	OnKeyDown (see page 23478)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 23480)	Occurs when a key is pressed.
	OnKeyUp (see page 23481)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 23483)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 23484)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 23486)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 23487)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 23487)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 23489)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheelDown (see page 23492)	Occurs when the mouse wheel is rotated downward.
	OnMouseWheelUp (see page 23492)	Occurs when the mouse wheel is rotated upward.
	OnRowMoved (see page 23492)	Occurs immediately after the position of a row changes.
	OnSelectCell (see page 23493)	Occurs before a cell in the grid is selected.
	OnSetEditText (see page 23494)	Occurs when the user edits the value of a cell.
	OnStartDock (see page 23495)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 23495)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnStringsChange (see page 23496)	Occurs immediately after the names or values in the string list change.
	OnStringsChanging (see page 23496)	Occurs immediately before the names or values in the string list change.
	OnTopLeftChanged (see page 23497)	Occurs immediately after the TopRow property or the LeftCol property changes.
	OnValidate (see page 23497)	Occurs when focus shifts away from a cell in the value list editor.

Published Properties

	Name	Description
	Align (see page 23428)	Determines how the control aligns within its container (parent control).
	AlignWithMargins (see page 5802)	Indicates whether a control should be constrained by margins.
	Anchors (see page 23432)	Specifies how the control is anchored to its parent.
	BiDiMode (see page 23432)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 23433)	Determines whether a single line border is drawn around the grid.

	Color (see page 23434)	Specifies the background color of the control.
	Constraints (see page 23435)	Specifies the size constraints for the control.
	Ctl3D (see page 23435)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	Cursor (see page 5815)	Specifies the image used to represent the mouse pointer when it passes into the region covered by the control.
	DefaultColWidth (see page 23436)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 23437)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 23437)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DisplayOptions (see page 23438)	Controls (see page 5711) aspects of the value list editor's appearance.
	DragCursor (see page 23438)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 23438)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 23439)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	DropDownRows (see page 23440)	Limits the length of the drop-down list that appears for values that use a pick list.
	Enabled (see page 23441)	Controls whether the control responds to mouse, keyboard, and timer events.
	FixedColor (see page 23442)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 23442)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	Font (see page 23442)	Controls the attributes of text written on or in the control.
	GridLineWidth (see page 23444)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
	Height (see page 5825)	Specifies the vertical size of the control in pixels.
	HelpContext (see page 5826)	Numeric ID for control's context-sensitive help topic
	HelpKeyword (see page 5826)	Keyword for control's context-sensitive help topic
	HelpType (see page 5827)	Indicates whether the control's context sensitive help topic is identified by context ID or by keyword.
	Hint (see page 5827)	Contains the text string that can appear when the user moves the mouse over the control.
	KeyOptions (see page 23445)	Controls (see page 5711) the way the value list editor responds to user keystrokes.
	Left (see page 5830)	Specifies the horizontal coordinate of the left edge of a component relative to its parent.
	Margins (see page 5831)	Specifies the margins for the control.
	Name (see page 2805)	Specifies the name of the component as referenced in code.
	Options (see page 23446)	Specifies various display and behavioral properties of the grid.
	ParentBiDiMode (see page 23446)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 23447)	Determines where a control looks for its color information.
	ParentCtl3D (see page 23447)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 23448)	Determines where a control looks for its font information.
	ParentShowHint (see page 23448)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 23449)	Identifies the pop-up menu associated with the control.
	ScrollBars (see page 23454)	Specifies whether the grid includes horizontal and vertical scroll bars.
	ShowHint (see page 23454)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Strings (see page 23456)	Provides access to the string list that is being edited.
	TabOrder (see page 23456)	Indicates the position of the control in its parent's tab order.
	TabStop (see page 14857)	Determines if the user can tab to a control.
	Tag (see page 2808)	Stores an integer value as part of a component.
	TitleCaptions (see page 23457)	Specifies the captions that label the columns of the value list editor.
	Top (see page 5844)	Specifies the Y coordinate of the top left corner of a control, relative to its parent or containing control in pixels.
	Visible (see page 23458)	Determines whether the component appears onscreen.
	Width (see page 5849)	Specifies the horizontal size of the control or form in pixels.

168.1.2.2 TValueListEditor.Create Constructor

Creates and initializes new TValueListEditor (see page 23401) object.

Pascal

```
constructor Create(AOwner: TComponent); override;
```

C++

```
virtual __fastcall TValueListEditor(TComponent * AOwner);
```

Description

Call Create to create a value list editor component at runtime. TValueListEditor (see page 23401) components added to forms at design time are created automatically.

The AOwner parameter specifies another component (typically the form) that is responsible for freeing the TValueListEditor (see page 23401) instance.

See Also

Owner (see page 2807)

168.1.2.3 TValueListEditor.Destroy Destructor

Frees the memory associated with the TValueListEditor (see page 23401) object.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TValueListEditor();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the value list editor reference is not nil, and only then calls Destroy.

See Also

Free (see page 22300)

168.1.2.4 TValueListEditor Methods

The methods of the TValueListEditor class are listed here.

Protected Methods

	Name	Description
	AdjustColWidths (see page 23416)	This is AdjustColWidths, a member of class TValueListEditor.
	AdjustRowCount (see page 23416)	This is AdjustRowCount, a member of class TValueListEditor.
	CanEditModify (see page 23417)	Indicates whether the current cell in the grid can be edited.
	ColWidthsChanged (see page 23417)	Responds when the column widths change.
	CreateEditor (see page 23417)	Creates the inplace editor control.
	CreateWnd (see page 23418)	Creates the underlying window.
	DoExit (see page 23419)	Hides the inplace editor when selection moves to another control in a form.
	DoOnValidate (see page 23419)	This is DoOnValidate, a member of class TValueListEditor.

	DrawCell (see page 23419)	Generates an OnDrawCell event.
	EditListGetItems (see page 23420)	This is EditListGetItems, a member of class TValueListEditor.
	GetCell (see page 23420)	This is GetCell, a member of class TValueListEditor.
	GetColCount (see page 23421)	This is GetColCount, a member of class TValueListEditor.
	GetEditLimit (see page 23421)	Provides the interface for a method that limits the number of characters the user can type into cells.
	GetEditMask (see page 23421)	Generates an OnGetEditMask event.
	GetEditStyle (see page 23421)	Indicates whether a specified cell has an ellipsis button or drop-down arrow.
	GetEditText (see page 23422)	This is GetEditText, a member of class TValueListEditor.
	GetPickList (see page 23422)	This is GetPickList, a member of class TValueListEditor.
	GetRowCount (see page 23422)	This is GetRowCount, a member of class TValueListEditor.
	IsEmptyRow (see page 23423)	This is IsEmptyRow, a member of class TValueListEditor.
	KeyDown (see page 23423)	Provides special processing when the user presses a key.
	MouseDown (see page 23424)	Provides special processing when the user presses a mouse button.
	Resize (see page 23425)	Respond to control resize.
	RowMoved (see page 23425)	Generates an OnRowMoved event.
	SelectCell (see page 23426)	Determines whether a particular cell in the grid can be selected.
	SetCell (see page 23426)	This is SetCell, a member of class TValueListEditor.
	SetEditText (see page 23426)	This is SetEditText, a member of class TValueListEditor.
	SetStrings (see page 23426)	This is SetStrings, a member of class TValueListEditor.
	StringsChanging (see page 23427)	This is StringsChanging, a member of class TValueListEditor.
	TitleCaptionsStored (see page 23427)	This is TitleCaptionsStored, a member of class TValueListEditor.

Public Methods

	Name	Description
	DeleteRow (see page 23418)	Deletes a row in the value list editor and a corresponding string from the associated TStrings object.
	FindRow (see page 23420)	Locates the row that corresponds to a specified key name.
	InsertRow (see page 23422)	Inserts a row in the value list editor and a corresponding string into the associated TStrings object.
	Refresh (see page 23424)	Updates the display to reflect the current value of the Strings (see page 23456) property.
	RestoreCurrentRow (see page 23425)	Undoes all edits to the current row.

168.1.2.4.1 TValueListEditor.AdjustColWidths Method

Pascal

```
procedure AdjustColWidths; virtual;
```

C++

```
virtual __fastcall AdjustColWidths();
```

Description

This is AdjustColWidths, a member of class TValueListEditor.

168.1.2.4.2 TValueListEditor.AdjustRowCount Method

Pascal

```
procedure AdjustRowCount; virtual;
```

C++

```
virtual __fastcall AdjustRowCount();
```

Description

This is AdjustRowCount, a member of class TValueListEditor.

168.1.2.4.3 TValueListEditor.CanEditModify Method

Indicates whether the current cell in the grid can be edited.

Pascal

```
function CanEditModify: Boolean; override;
```

C++

```
virtual __fastcall Boolean CanEditModify();
```

Description

Grid components use CanEditModify internally to determine whether to allow the user to edit the current cell. CanEditModify returns true unless the inplace editor has disallowed editing for the cell.

See Also

CanEditShow (see page 14820)

InplaceEditor (see page 14852)

168.1.2.4.4 TValueListEditor.ColWidthsChanged Method

Responds when the column widths change.

Pascal

```
procedure ColWidthsChanged; override;
```

C++

```
virtual __fastcall ColWidthsChanged();
```

Description

ColWidthsChanged is called immediately after the column widths change. The change can result from setting the ColWidths property, from setting the DefaultColWidth property, from moving one of the columns, or from resizing the columns with the mouse.

ColWidthsChanged adjusts the scroll bar and the position of the inplace editor to take into account the new column size and positions of the columns.

See Also

ColWidths (see page 14845)

DefaultColWidth (see page 14846)

InplaceEditor (see page 14852)

ScrollBars (see page 14856)

168.1.2.4.5 TValueListEditor.CreateEditor Method

Creates the inplace editor control.

Pascal

```
function CreateEditor: TInplaceEdit; override;
```

C++

```
virtual __fastcall TInplaceEdit CreateEditor();
```

Description

Grid controls call CreateEditor internally the first time the grid goes into edit mode. CreateEditor is exposed as a protected method so that descendants of TCustomGrid can substitute a specialized descendant of TInplaceEdit to handle cell editing.

See Also

EditorMode (see page 14848)

InplaceEditor (see page 14852)

ShowEditor (see page 14839)

168.1.2.4.6 TValueListEditor.CreateWnd Method

Creates the underlying window.

Pascal

```
procedure CreateWnd; override;
```

C++

```
virtual __fastcall CreateWnd();
```

Description

CreateWnd is called automatically when the control is first created or when the underlying screen object must be destroyed and recreated to reflect property changes. Override CreateWnd to pass additional initialization messages to the screen object when it is created.

See Also

CreateParams (see page 6135)

CreateWindowHandle (see page 6137)

Perform (see page 5776)

DestroyWnd (see page 6141)

168.1.2.4.7 TValueListEditor.DeleteRow Method

Deletes a row in the value list editor and a corresponding string from the associated TStrings object.

Pascal

```
procedure DeleteRow(ARow: Integer); override;
```

C++

```
virtual __fastcall DeleteRow(int ARow);
```

Description

Call DeleteRow to remove the row specified by the ARow parameter. Delete removes the corresponding string from the TStrings object being edited and updates the display.

ARow must be the index of a row that displays a name/value pair. That is, it can't be less than 0 or greater than the number of rows. If DisplayOptions (see page 23438) includes doColumnTitles, ARow can't be 0, because that is the title row, not a name/value pair in the associated TStrings object.

Note: DeleteRow deletes the specified row regardless of the value of KeyOptions (see page 23445). The keyDelete member of KeyOptions (see page 23445) controls only whether the user can delete a row by pressing the Delete key.

See Also

Cells (see page 23433)

Strings (see page 23456)

KeyOptions (see page 23445)

DisplayOptions (see page 23438)

168.1.2.4.8 TValueListEditor.DoExit Method

Hides the inplace editor when selection moves to another control in a form.

Pascal

```
procedure DoExit; override;
```

C++

```
virtual __fastcall DoExit();
```

Description

After calling the inherited method, which generates an OnExit event, DoExit hides the inplace editor unless the Options property includes goAlwaysShowEditor.

See Also

HideEditor (see page 14830)

Options (see page 14853)

OnExit (see page 6221)

168.1.2.4.9 TValueListEditor.DoOnValidate Method

Pascal

```
procedure DoOnValidate; virtual;
```

C++

```
virtual __fastcall DoOnValidate();
```

Description

This is DoOnValidate, a member of class TValueListEditor.

168.1.2.4.10 TValueListEditor.DrawCell Method

Generates an OnDrawCell event.

Pascal

```
procedure DrawCell(ACol: Longint; ARow: Longint; ARect: TRect; AState: TGridDrawState);
override;
```

C++

```
virtual __fastcall DrawCell(Longint ACol, Longint ARow, TRect ARect, TGridDrawState AState);
```

Description

DrawCell is called automatically whenever a cell in the grid is drawn. If the DefaultDrawing property is true, the background of the cell is painted before DrawCell is called, and the 3D effects of the fixed cells or the focus rectangle around the focused cell

are drawn after DrawCell. Descendants of TCustomDrawGrid can override this method to draw the contents of the cell or to block the OnDrawCell event.

See Also

DefaultDrawing (see page 14847)

FixedCols (see page 14848)

FixedRows (see page 14849)

OnDrawCell (see page 14795)

168.1.2.4.11 TValueListEditor.EditListGetItems Method

Pascal

```
procedure EditListGetItems(ACol: Integer; ARow: Integer; Items: TStrings);
```

C++

```
__fastcall EditListGetItems(int ACol, int ARow, TStrings Items);
```

Description

This is EditListGetItems, a member of class TValueListEditor.

168.1.2.4.12 TValueListEditor.FindRow Method

Locates the row that corresponds to a specified key name.

Pascal

```
function FindRow(const KeyName: string; var Row: Integer): Boolean;
```

C++

```
__fastcall Boolean FindRow(const AnsiString KeyName, int Row);
```

Description

Call FindRow to locate the row in the value list editor that has the value specified by KeyName in the first column. This corresponds to a name/value pair in the string list where the name part is KeyName.

If a row in the value list editor has the specified key name, FindRow returns true and the Row parameter returns the index of the first row found with the specified name. If the specified name does not correspond to any of the rows in the value list editor, FindRow returns false.

See Also

Keys (see page 23445)

168.1.2.4.13 TValueListEditor.GetCell Method

Pascal

```
function GetCell(ACol: Integer; ARow: Integer): string; virtual;
```

C++

```
virtual __fastcall AnsiString GetCell(int ACol, int ARow);
```

Description

This is GetCell, a member of class TValueListEditor.

168.1.2.4.14 TValueListEditor.GetColCount Method

Pascal

```
function GetColCount: Integer;
```

C++

```
__fastcall int GetColCount();
```

Description

This is GetColCount, a member of class TValueListEditor.

168.1.2.4.15 TValueListEditor.GetEditLimit Method

Provides the interface for a method that limits the number of characters the user can type into cells.

Pascal

```
function GetEditLimit: Integer; override;
```

C++

```
virtual __fastcall int GetEditLimit();
```

Description

The inplace editor calls GetEditLimit to determine if a limit should be placed on the number of characters a user can type into a cell. GetEditLimit sets no limits. Descendants of TCustomGrid override this method to limit the text for certain cells.

See Also

InplaceEditor (see page 14852)

168.1.2.4.16 TValueListEditor.GetEditMask Method

Generates an OnGetEditMask event.

Pascal

```
function GetEditMask(ACol: Longint; ARow: Longint): string; override;
```

C++

```
virtual __fastcall AnsiString GetEditMask(Longint ACol, Longint ARow);
```

Description

The inplace editor calls GetEditMask to obtain any input mask associated with the cell specified by the ACol and ARow parameters. GetEditMask returns the Value parameter set by the OnGetEditMask event handler. If there is no OnGetEditMask event handler, GetEditMask returns an empty string, indicating that there is no edit mask.

See Also

OnGetEditMask (see page 14796)

168.1.2.4.17 TValueListEditor.GetEditStyle Method

Indicates whether a specified cell has an ellipsis button or drop-down arrow.

Pascal

```
function GetEditStyle(ACol: Longint; ARow: Longint): TEditStyle; override;
```

C++

```
virtual __fastcall TEditStyle GetEditStyle(Longint ACol, Longint ARow);
```

Description

GetEditStyle indicates whether the specified cell can only be edited directly (esSimple), whether it has an ellipsis button that users can click to launch an editor for modifying field values (esEllipsis), or whether it has a drop-down arrow that users can click to display a pick list of possible values (esPickList).

ACol is the column that contains the cell. ARow is the row that contains the cell.

In TCustomGrid, GetEditStyle always returns esSimple, indicating that there is no ellipsis button or drop-down arrow. Descendant classes can override this methods if they provide a way to add pick lists or ellipsis buttons to cells.

168.1.2.4.18 TValueListEditor.GetEditText Method

Pascal

```
function GetEditText(ACol: Integer; ARow: Integer): string; override;
```

C++

```
virtual __fastcall AnsiString GetEditText(int ACol, int ARow);
```

Description

This is GetEditText, a member of class TValueListEditor.

168.1.2.4.19 TValueListEditor.GetPickList Method

Pascal

```
function GetPickList(Values: TStrings; ClearFirst: Boolean = True): Boolean;
```

C++

```
__fastcall Boolean GetPickList(TStrings Values, Boolean ClearFirst = True);
```

Description

This is GetPickList, a member of class TValueListEditor.

168.1.2.4.20 TValueListEditor.GetRowCount Method

Pascal

```
function GetRowCount: Integer;
```

C++

```
__fastcall int GetRowCount();
```

Description

This is GetRowCount, a member of class TValueListEditor.

168.1.2.4.21 TValueListEditor.InsertRow Method

Inserts a row in the value list editor and a corresponding string into the associated TStrings object.

Pascal

```
function InsertRow(const KeyName: string; const Value: string; Append: Boolean): Integer;
```

C++

```
__fastcall int InsertRow(const AnsiString KeyName, const AnsiString Value, Boolean Append);
```

Description

Call InsertRow to add a name/value pair to the value list editor and the TStrings object it is editing.

InsertRow adds a string of the form

`KeyName=Value`

to the Strings (see page 23456) property and updates the display to reflect the change.

If the current row of the value list editor is empty (has no name or value portion), InsertRow assigns the new KeyName and Value to the current row. Otherwise, if the Append parameter is true, the new string appears after the currently selected row, while if Append is false, the new string appears before the currently selected row.

Note: InsertRow inserts the specified row regardless of the value of KeyOptions (see page 23445). The keyAdd member of KeyOptions (see page 23445) controls only whether the user can add new rows by pressing the Insert key or navigating past the last row.

See Also

Cells (see page 23433)

Strings (see page 23456)

KeyOptions (see page 23445)

DisplayOptions (see page 23438)

168.1.2.4.22 TValueListEditor.IsEmptyRow Method

Pascal

```
function IsEmptyRow: Boolean;
```

C++

```
__fastcall Boolean IsEmptyRow();
```

Description

This is IsEmptyRow, a member of class TValueListEditor.

168.1.2.4.23 TValueListEditor.KeyDown Method

Provides special processing when the user presses a key.

Pascal

```
procedure KeyDown(var Key: Word; Shift: TShiftState); override;
```

C++

```
virtual __fastcall KeyDown(Word Key, TShiftState Shift);
```

Description

After generating an OnKeyDown event, KeyDown calls CanGridAcceptKey to screen out problematic key combinations. KeyDown moves to the appropriate cell in response to navigational key combinations, or sets the EditorMode property to true when the user presses F2.

See Also

CanGridAcceptKey (see page 14820)

EditorMode (see page 14848)

KeyPress (see page 14833)

OnKeyDown (see page 6225)

168.1.2.4.24 TValueListEditor.MouseDown Method

Provides special processing when the user presses a mouse button.

Pascal

```
procedure MouseDown(Button: TMouseButton; Shift: TShiftState; X: Integer; Y: Integer);
override;
```

C++

```
virtual __fastcall MouseDown(TMouseButton Button, TShiftState Shift, int X, int Y);
```

Description

MouseDown hides the editor window so that it can move selection to the cell that receives the mouse click. If the mouse lands in the hot region for beginning a move or resize of a row or column, MouseDown starts the move or resize, and provides visual feedback by changing the cursor. If the editor window was hidden, it is brought back up in its new location. Finally, MouseDown generates an OnMouseDown event.

See Also

HideEditor (see page 14830)

InplaceEditor (see page 14852)

MouseMove (see page 14834)

MouseUp (see page 14835)

ShowEditor (see page 14839)

OnMouseDown (see page 5862)

168.1.2.4.25 TValueListEditor.Refresh Method

Updates the display to reflect the current value of the Strings (see page 23456) property.

Pascal

```
procedure Refresh;
```

C++

```
__fastcall Refresh();
```

Description

Call Refresh to ensure that the value list editor accurately reflects the value of the Strings (see page 23456) property. For example, call Refresh after programmatically editing the value of the Strings (see page 23456) property.

See Also

RestoreCurrentRow (see page 23425)

Repaint (see page 6174)

Strings (see page 23456)

168.1.2.4.26 TValueListEditor.Resize Method

Respond to control resize.

Pascal

```
procedure Resize; override;
```

C++

```
virtual __fastcall Resize();
```

Description

Resize is called automatically immediately after the control's dimensions change. As implemented in TControl, Resize calls the control's OnResize event handler if it is assigned.

See Also

OnResize (see page 5870)

168.1.2.4.27 TValueListEditor.RestoreCurrentRow Method

Undoes all edits to the current row.

Pascal

```
function RestoreCurrentRow: Boolean;
```

C++

```
__fastcall Boolean RestoreCurrentRow();
```

Description

Call RestoreCurrentRow to back out edits to the current cell in the value list editor. RestoreCurrentRow backs out edits to the current cell if it is still in edit mode, or deletes a newly inserted row.

The user can accomplish the same effect by pressing the Escape key.

See Also

Cells (see page 23433)

InsertRow (see page 23422)

168.1.2.4.28 TValueListEditor.RowMoved Method

Generates an OnRowMoved event.

Pascal

```
procedure RowMoved(FromIndex: Longint; ToIndex: Longint); override;
```

C++

```
virtual __fastcall RowMoved(Longint FromIndex, Longint ToIndex);
```

Description

RowMoved is called immediately after a row in the grid changes position. It overrides the inherited method to generate an OnRowMoved event. Descendants of TCustomDrawGrid can override this method to make internal adjustments or to block the OnRowMoved event.

See Also

OnRowMoved (see page 14798)

168.1.2.4.29 TValueListEditor.SelectCell Method

Determines whether a particular cell in the grid can be selected.

Pascal

```
function SelectCell(ACol: Longint; ARow: Longint): Boolean; override;
```

C++

```
virtual __fastcall Boolean SelectCell(Longint ACol, Longint ARow);
```

Description

Grid controls call SelectCell internally before attempting to move selection to a the cell identified by the ACol and ARow parameters. ACol and ARow are the column and row indexes for the cell, where the first column has index 0, and the top row has index 0.

SelectCell generates an OnSelectCell event. This method then returns true, unless the OnSelectCell event handler indicates that the cell should not be selected. Descendants of TCustomDrawGrid can override this method to check the properties of the information displayed in the cell or block the OnSelectCell event.

See Also

OnSelectCell (see page 14798)

168.1.2.4.30 TValueListEditor.SetCell Method

Pascal

```
procedure SetCell(ACol: Integer; ARow: Integer; const Value: string); virtual;
```

C++

```
virtual __fastcall SetCell(int ACol, int ARow, const AnsiString Value);
```

Description

This is SetCell, a member of class TValueListEditor.

168.1.2.4.31 TValueListEditor.SetEditText Method

Pascal

```
procedure SetEditText(ACol: Integer; ARow: Integer; const Value: string); override;
```

C++

```
virtual __fastcall SetEditText(int ACol, int ARow, const AnsiString Value);
```

Description

This is SetEditText, a member of class TValueListEditor.

168.1.2.4.32 TValueListEditor.SetStrings Method

Pascal

```
procedure SetStrings(const Value: TStrings); virtual;
```

C++

```
virtual __fastcall SetStrings(const TStrings Value);
```

Description

This is SetStrings, a member of class TValueListEditor.

168.1.2.4.33 TValueListEditor.StringsChanging Method

Pascal

```
procedure StringsChanging; dynamic;
```

C++

```
__fastcall StringsChanging();
```

Description

This is StringsChanging, a member of class TValueListEditor.

168.1.2.4.34 TValueListEditor.TitleCaptionsStored Method

Pascal

```
function TitleCaptionsStored: Boolean;
```

C++

```
__fastcall Boolean TitleCaptionsStored();
```

Description

This is TitleCaptionsStored, a member of class TValueListEditor.

168.1.2.5 TValueListEditor Properties

The properties of the TValueListEditor class are listed here.

Protected Properties

	Name	Description
R	EditList (see page 23441)	This is EditList, a member of class TValueListEditor.

Public Properties

	Name	Description
	Cells (see page 23433)	Lists the strings for each cell in the editor.
R	ColCount (see page 23434)	Indicates the number of columns in the value list editor.
	ItemProps (see page 23445)	Specifies various constraints on the way users can enter a value for each item in the list.
	Keys (see page 23445)	Lists the strings for each cell in the name (key) column.
R	RowCount (see page 23453)	Indicates the number of rows in the value list editor.
	Values (see page 23457)	Lists the strings for each value from the value column.
	VisibleColCount (see page 23459)	Indicates the number of scrollable columns visible in the grid.
	VisibleRowCount (see page 23459)	Indicates the number of scrollable rows visible in the grid.

Published Properties

	Name	Description
	Align (see page 23428)	Determines how the control aligns within its container (parent control).
	Anchors (see page 23432)	Specifies how the control is anchored to its parent.

	BiDiMode (see page 23432)	Specifies the bi-directional mode for the control.
	BorderStyle (see page 23433)	Determines whether a single line border is drawn around the grid.
	Color (see page 23434)	Specifies the background color of the control.
	Constraints (see page 23435)	Specifies the size constraints for the control.
	Ctl3D (see page 23435)	Determines whether a control has a three-dimensional (3-D) or two-dimensional look.
	DefaultColWidth (see page 23436)	Determines the width (in pixels) of all columns that have not been explicitly resized.
	DefaultDrawing (see page 23437)	Determines whether the Cells are painted when the grid is drawn.
	DefaultRowHeight (see page 23437)	Specifies the height (in pixels) of all rows that have not been explicitly resized.
	DisplayOptions (see page 23438)	Controls (see page 5711) aspects of the value list editor's appearance.
	DragCursor (see page 23438)	Indicates the image used to represent the mouse pointer when the control is being dragged.
	DragKind (see page 23438)	Specifies whether the control is being dragged normally or for docking.
	DragMode (see page 23439)	Determines how the control initiates drag-and-drop or drag-and-dock operations.
	DropDownRows (see page 23440)	Limits the length of the drop-down list that appears for values that use a pick list.
	Enabled (see page 23441)	Controls whether the control responds to mouse, keyboard, and timer events.
	FixedColor (see page 23442)	Specifies the background color of the fixed rows and columns in the grid.
	FixedCols (see page 23442)	Specifies the number of columns on the left of the grid that cannot be scrolled.
	Font (see page 23442)	Controls the attributes of text written on or in the control.
	GridLineWidth (see page 23444)	Specifies the width (in pixels) of the lines that separate the cells of the grid.
	KeyOptions (see page 23445)	Controls (see page 5711) the way the value list editor responds to user keystrokes.
	Options (see page 23446)	Specifies various display and behavioral properties of the grid.
	ParentBiDiMode (see page 23446)	Specifies whether the control uses its parent's BiDiMode.
	ParentColor (see page 23447)	Determines where a control looks for its color information.
	ParentCtl3D (see page 23447)	Determines where a component looks to determine if it should appear three dimensional.
	ParentFont (see page 23448)	Determines where a control looks for its font information.
	ParentShowHint (see page 23448)	Determines where a control looks to find out if its Help Hint should be shown.
	PopupMenu (see page 23449)	Identifies the pop-up menu associated with the control.
	ScrollBars (see page 23454)	Specifies whether the grid includes horizontal and vertical scroll bars.
	ShowHint (see page 23454)	Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.
	Strings (see page 23456)	Provides access to the string list that is being edited.
	TabOrder (see page 23456)	Indicates the position of the control in its parent's tab order.
	TitleCaptions (see page 23457)	Specifies the captions that label the columns of the value list editor.
	Visible (see page 23458)	Determines whether the component appears onscreen.

168.1.2.5.1 TValueListEditor.Align Property

Determines how the control aligns within its container (parent control).

Pascal

```
property Align: TAlign;
```

C++

```
__property TAlign Align;
```

Description

Use Align to align a control to the top, bottom, left, or right of a form or panel and have it remain there even if the size of the form, panel, or component that contains the control changes. When the parent is resized, an aligned control also resizes so that it continues to span the top, bottom, left, or right edge of the parent.

For example, to use a panel component with various controls on it as a tool palette, change the panel's Align value to alLeft. The value of alLeft for the Align property of the panel guarantees that the tool palette remains on the left side of the form and always

equals the client height of the form.

The default value of Align is alNone, which means a control remains where it is positioned on a form or panel.

Tip: If Align is set to alClient, the control fills the entire client area so that it is impossible to select the parent form by clicking on it. In this case, select the parent by selecting the control on the form and pressing Esc, or by using the Object Inspector.

Any number of child components within a single parent can have the same Align value, in which case they stack up along the edge of the parent. The child controls stack up in z-order. To adjust the order in which the controls stack up, drag the controls into their desired positions.

Note: To cause a control to maintain a specified relationship with an edge of its parent, but not necessarily lie along one edge of the parent, use the Anchors property instead.

C++ Examples:

```
/*
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form’s implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
*/
#include <Extctrls.hpp>
#include <Filectrl.hpp>

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  TSplitter* ps = new TSplitter(Form1);
  TFileListBox* pflb = new TFileListBox(Form1);
  TDirectoryListBox* pdlb = new TDirectoryListBox(Form1);

  // Line up the directory list box on the left of the form.
  pdlb->Parent = Form1;
  pdlb->Align = alLeft;
  pdlb->Width = Form1->ClientWidth/3;

  // Now use the splitter to divide the directory pane from the file pane.
  ps->Parent = Form1;
  ps->Left = pdlb->Left + pdlb->Width + 1; // Move to right of directory list.
  ps->Align = pdlb->Align; // Give same alignment as directory list.

  // Each pane must be at least one quarter of the form's width.
  ps->MinSize = Form1->ClientWidth/4;

  // Finally, create the last pane - a file list box.
  pflb->Parent = Form1;
  pflb->Align = alClient;
  pdlb->FileList = pflb; // Link the file list box to the directory list box.
}
/*
Dynamically create a TProgressBar control and align it to
the bottom of the form.
*/

#include <ComCtrls.hpp>
#include <Controls.hpp>

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TProgressBar *ProgressBar = new TProgressBar(this);
```

```
  ProgressBar->Parent = this;
  ProgressBar->Align = alBottom;
  TButton *Button1 = new TButton(this);
  Button1->Parent = this;
}
/*
This example dynamically creates a Page Control, then a
series of Tab Sheets on the Page Control.
*/
#include <Comctrls.hpp>
TPageControl* ppc;
const int MAXTABS = 3;
TTabSheet* pts[MAXTABS];
const char * ppcTabTitles[] = { "ShortString", "Orders", "Items", "Parts" };
int iTabTitles = sizeof(ppcTabTitles)/sizeof(ppcTabTitles[0]);
const TColor colorPalette[12] = {
  clRed, clGreen, clYellow, clBlue, clWhite, clFuchsia,
  clTeal, clNavy, clMaroon, clLime, clOlive, clPurple};

void __fastcall TForm1::FormCreate(TObject *Sender)
{
    ppc = new TPageControl(this);
    ppc->Parent = this;
    ppc->Align = alClient;
    for (int i=0;i<iTabTitles;i++)
  {
        pts[i] = new TTabSheet(this);
        pts[i]->PageControl = ppc;
        pts[i]->Name = AnsiString("pts") + ppcTabTitles[i];
        pts[i]->Caption = ppcTabTitles[i];
        pts[i]->Brush->Color = colorPalette[i];
  }
}//---------------------------------------------------------------------------
void __fastcall TForm1::FormDestroy(TObject *Sender)
{
  for (int i=0;i<iTabTitles;i++)
        delete pts[i];
    delete ppc;
}
```

Delphi Examples:

```
{
This example shows how to use a splitter to divide a form
into resizable panes.  All objects on the form are created
dynamically in the OnCreate event handler of the form. To
run this example, add ExtCtrls and FileCtrl to the uses
clause of the form's implementation section.
Note that when creating a splitter dynamically at runtime,
it is important to set its position to the appropriate side
of the control it will resize.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  Split: TSplitter;
  Files: TFileListBox;
  Dirs: TDirectoryListBox;
begin
  { first add a directory list box to the form }
  Dirs := TDirectoryListBox.Create(Form1);
  { line it up on the left of the form }
  Dirs.Parent := Form1;
  Dirs.Align := alLeft;
  Dirs.Width := Form1.ClientWidth div 3;
{ now add the splitter to divide the directory pane from the file pane }
  Split := TSplitter.Create(Form1);
  Split.Parent := Form1;
```

```
    { make sure the splitter is to the right of the directory list box! }
    Split.Left := Dirs.Left + Dirs.Width + 1;
    Split.Align := Dirs.Align; { give it the same alignment as the directory }
    { each pane must be at least one quarter of the form's width }
    Split.MinSize := Form1.ClientWidth div 4;
    { Finally, create the last pane – a file list box }
    Files := TFileListBox.Create(Form1);
    Files.Parent := Form1;
    Files.Align := alClient;
    Dirs.FileList := Files; { link the file list box to the directory list box }
  end;
  {
  Dynamically create a TProgressBar control and align it to
  the bottom of the form.
  }

  var
    I: Integer;

  procedure TForm1.Button1Click(Sender: TObject);
  var
    ProgressBar: TProgressBar;

    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i]:= TTabSheet.Create(PageControl1);
      with pts[i] do
      begin
        PageControl := PageControl1;
        Name := 'ts' + TabTitles[i];
        Caption := TabTitles[i];
        Brush.Color := colorPalette[i];
     end;
    end;
  end;

  procedure TForm1.FormDestroy(Sender: TObject);
  var
```

```
    i: Integer;
  begin
    for i := Low(TabTitles) to High(TabTitles) do
    begin
      pts[i].Free;
    end;
    PageControl1.Free;
  end;
```

See Also

Parent (see page 5832)

Anchors (see page 5802)

168.1.2.5.2 TValueListEditor.Anchors Property

Specifies how the control is anchored to its parent.

Pascal

```
property Anchors: TAnchors;
```

C++

```
__property TAnchors Anchors;
```

Description

Use Anchors to ensure that a control maintains its current position relative to an edge of its parent, even if the parent is resized. When its parent is resized, the control holds its position relative to the edges to which it is anchored.

If a control is anchored to opposite edges of its parent, the control stretches when its parent is resized. For example, if a control has its Anchors property set to [akLeft, akRight], the control stretches when the width of its parent changes.

Anchors is enforced only when the parent is resized. Thus, for example, if a control is anchored to opposite edges of a form at design time and the form is created in a maximized state, the control is not stretched because the form is not resized after the control is created.

Note: If a control should maintain contact with three edges of its parent (hugging one side of the parent and stretching the length of that side), use the Align property instead. Unlike Anchors, Align allows controls to adjust to changes in the size of other aligned sibling controls as well as changes to the parent's size.

See Also

Parent (see page 5832)

Align (see page 5798)

168.1.2.5.3 TValueListEditor.BiDiMode Property

Specifies the bi-directional mode for the control.

Pascal

```
property BiDiMode: TBiDiMode;
```

C++

```
__property TBiDiMode BiDiMode;
```

Description

Use BiDiMode to enable the control to adjust its appearance and behavior automatically when the application runs in a locale that reads from right to left instead of left to right. The bi-directional mode controls the reading order for the text, the placement of

the vertical scroll bar, and whether the alignment is changed.

Alignment does not change for controls that are known to contain number, date, time, or currency values. For example, with data aware controls, the alignment does not change for the following field types: ftSmallint, ftInteger, ftWord, ftFloat, ftCurrency, ftBCD, ftDate, ftTime, ftDateTime, ftAutoInc.

See Also

UseRightToLeftAlignment (see page 5790)

UseRightToLeftReading (see page 5790)

UseRightToLeftScrollBar (see page 5791)

Including Bi-directional Functionality in Applications

168.1.2.5.4 TValueListEditor.BorderStyle Property

Determines whether a single line border is drawn around the grid.

Pascal

```
property BorderStyle: TBorderStyle;
```

C++

```
__property TBorderStyle BorderStyle;
```

Description

Set BorderStyle to bsSingle to add a single line border around the grid's image. Set BorderStyle to bsNone to omit the border.

168.1.2.5.5 TValueListEditor.Cells Property

Lists the strings for each cell in the editor.

Pascal

```
property Cells [ACol, ARow: Integer]: string;
```

C++

```
__property AnsiString Cells[int ACol, ARow];
```

Description

Use Cells to access the string in a particular cell. ACol is the column coordinate of the cell, and ARow is the row coordinate of the cell. ACol can be 0 (for the name column) or 1 (for the value column). ARow can range from 0 (for the title row) to the number of strings in the associated TStrings descendant.

To access the strings in the name column, use the Keys (see page 23445) property instead. To access the strings in the value column, use the Values (see page 23457) property instead. To access the underlying string list, use the Strings (see page 23456) property.

See Also

Keys (see page 23445)

Values (see page 23457)

Strings (see page 23456)

168.1.2.5.6 TValueListEditor.ColCount Property

Indicates the number of columns in the value list editor.

Pascal

```
property ColCount: Longint;
```

C++

```
__property Longint ColCount;
```

Description

TValueListEditor (see page 23401) redeclares the ColCount property, which it inherits from TCustomGrid, to change it to a read-only property. The value of ColCount is always 2 plus the number of fixed columns, because the value list editor is designed to display only the name and value of the strings in the associated string list.

See Also

Cells (see page 23433)

RowCount (see page 23453)

FixedCols (see page 14848)

168.1.2.5.7 TValueListEditor.Color Property

Specifies the background color of the control.

Pascal

```
property Color: TColor;
```

C++

```
__property TColor Color;
```

Description

Use Color to read or change the background color of the control.

If a control's ParentColor property is true, then changing the Color property of the control's parent automatically changes the Color property of the control. When the value of the Color property is changed, the control's ParentColor property is automatically set to false.

C++ Examples:

```
/*
The following code changes the color of a shape control
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  if (ColorDialog1->Execute())
    Shape1->Brush->Color = ColorDialog1->Color;
}
```

Delphi Examples:

```
{
The following code changes the color of a shape control
```

```
using the Color dialog box. The example displays the Color
dialog box when the Button1 button is clicked, allowing the
user to select a color with the dialog box. When a color
value is selected with the dialog box, it is assigned to
the shape control.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if ColorDialog1.Execute then
    Shape1.Brush.Color := ColorDialog1.Color;
end;
```

See Also

ParentColor (see page 5834)

168.1.2.5.8 TValueListEditor.Constraints Property

Specifies the size constraints for the control.

Pascal

```
property Constraints: TSizeConstraints;
```

C++

```
__property TSizeConstraints Constraints;
```

Description

Use Constraints to specify the minimum and maximum width and height of the control. When Constraints contains maximum or minimum values, the control cannot be resized to violate those constraints.

Note: Constraints apply to the height of the form. However, the height of the form depends on how large Windows makes the title bar. For example, Windows XP uses much larger title bars than other windowing systems. To work around this, note the ClientHeight when you design your form and set the constraints in the FormCreate event. In the following example, ClientHeight is represented by x: `Constraints.MinHeight := x + Height - ClientHeight`.

Warning: Do not set up constraints that conflict with the value of the Align or Anchors property. When these properties conflict, the response of the control to resize attempts is not well-defined.

See Also

AutoSize (see page 5803)

Align (see page 5798)

Anchors (see page 5802)

OnConstrainedResize (see page 5853)

OnCanResize (see page 5851)

168.1.2.5.9 TValueListEditor.Ctl3D Property

Determines whether a control has a three-dimensional (3-D) or two-dimensional look.

Pascal

```
property Ctl3D: Boolean;
```

C++

```
__property Boolean Ctl3D;
```

Description

Ctl3D is provided for backward compatibility. It is not used by 32-bit versions of Windows or NT4.0 and later, with the exception of Windows XP Home, where it is used on occasion.

On earlier platforms, Ctl3D controlled whether the control had a flat or beveled appearance.

See Also

ParentCtl3D (see page 6209)

BevelKind (see page 6193)

BevelInner (see page 6193)

BevelOuter (see page 6194)

BorderWidth (see page 6195)

168.1.2.5.10 TValueListEditor.DefaultColWidth Property

Determines the width (in pixels) of all columns that have not been explicitly resized.

Pascal

```
property DefaultColWidth: Integer;
```

C++

```
__property int DefaultColWidth;
```

Description

Set DefaultColWidth to change the size of all columns in the grid. When DefaultColWidth is set, columns that have been resized using the mouse or by setting the ColWidths property are given the DefaultColWidth as well.

When new columns are added to the grid using the ColCount property, they are created with a width of DefaultColWidth.

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
This example includes a draw grid on a form. When the
application runs and the form is created, the width of the
lines on the draw grid changes if the default column width of
the grid is over 90 pixels wide.  This example requires a
populated image list, or can just display an empty grid.
Set the drawgrid DefaultColWidth and GridLineWidth statically
to values the cause the button click to do something.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if DrawGrid1.DefaultColWidth > 90 then
    DrawGrid1.GridLineWidth := 2
  else
    DrawGrid1.GridLineWidth := 1;
end;

procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clBackground;
```

```
    DrawGrid1.Canvas.FillRect(Rect);
    ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
    if (gdFocused in State) then
    begin
      DrawGrid1.Canvas.DrawFocusRect(Rect);
    end;
  end;

  procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
    var CanSelect: Boolean);
  begin
    CanSelect:= True;
  end;
```

See Also

ColCount (see page 14844)

ColWidths (see page 14845)

DefaultRowHeight (see page 14847)

168.1.2.5.11 TValueListEditor.DefaultDrawing Property

Determines whether the Cells are painted when the grid is drawn.

Pascal

```
property DefaultDrawing: Boolean;
```

C++

```
__property Boolean DefaultDrawing;
```

Description

Set DefaultDrawing to true to have the grid automatically paint the cells in the grid, including adding the background color, the 3-D effects on the fixed cells, and the focus rectangle around the selected cell. Set DefaultDrawing to false to skip the painting of the cells when the grid is drawn.

When DefaultDrawing is false, the cells should be painted using the DrawCell method. For TCustomGrid, DrawCell is an abstract method. Descendants of TCustomGrid use DrawCell to provide their own customized drawing code, or to generate an OnDrawCell event.

See Also

DrawCell (see page 14826)

OnDrawCell (see page 14914)

168.1.2.5.12 TValueListEditor.DefaultRowHeight Property

Specifies the height (in pixels) of all rows that have not been explicitly resized.

Pascal

```
property DefaultRowHeight: Integer;
```

C++

```
__property int DefaultRowHeight;
```

Description

Set DefaultRowHeight to change the size of all rows in the grid. When DefaultRowHeight is set, rows that have been resized using the mouse or by setting the RowHeights property are given the DefaultRowHeight as well.

When new rows are added to the grid using the RowCount property, they are created with a height of DefaultRowHeight.

See Also

DefaultColWidth (see page 14846)

RowCount (see page 14854)

RowHeights (see page 14855)

168.1.2.5.13 TValueListEditor.DisplayOptions Property

Controls (see page 5711) aspects of the value list editor's appearance.

Pascal

```
property DisplayOptions: TDisplayOptions;
```

C++

```
__property TDisplayOptions DisplayOptions;
```

Description

Use DisplayOptions to control whether titles appear at the top of the columns in the value list editor and how the control responds when it is resized.

See Also

KeyOptions (see page 23445)

Options (see page 14853)

TitleCaptions (see page 23457)

168.1.2.5.14 TValueListEditor.DragCursor Property

Indicates the image used to represent the mouse pointer when the control is being dragged.

Pascal

```
property DragCursor: TCursor;
```

C++

```
__property TCursor DragCursor;
```

Description

Use the DragCursor property to change the cursor image presented when the control is being dragged.

Note: To make a custom cursor available for the DragCursor property, see the Cursor property.

See Also

Cursor (see page 5815)

DragKind (see page 5819)

DragMode (see page 5819)

168.1.2.5.15 TValueListEditor.DragKind Property

Specifies whether the control is being dragged normally or for docking.

Pascal

```
property DragKind: TDragKind;
```

C++

```
__property TDragKind DragKind;
```

Description

Use DragKind to get or set whether the control participates in drag-and-drop operations, or drag-and-dock operations.

See Also

DragCursor (see page 5818)

DragMode (see page 5819)

168.1.2.5.16 TValueListEditor.DragMode Property

Determines how the control initiates drag-and-drop or drag-and-dock operations.

Pascal

```
property DragMode: TDragMode;
```

C++

```
__property TDragMode DragMode;
```

Description

Use DragMode to control when the user can drag the control. Disable the drag-and-drop or drag-and-dock capability at runtime by setting the DragMode property value to dmManual. Enable automatic dragging by setting DragMode to dmAutomatic.

C++ Examples:

```
/*
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
*/
void __fastcall TForm1::TreeView1DragDrop(TObject *Sender, TObject *Source,
      int X, int Y)
{
  if (Source != (TObject *)TreeView1 || TreeView1->Selected == NULL)
    return;
  THitTests HT = TreeView1->GetHitTestInfoAt(X, Y);
  TNodeAttachMode AttachMode;
  TTreeNode *Item = TreeView1->GetNodeAt(X, Y);
  if (HT.Contains(htOnItem) || HT.Contains(htOnIcon))
    AttachMode = naAddChild;
  else if (HT.Contains(htNowhere))
    AttachMode = naAdd;
  else if (HT.Contains(htOnIndent))
    AttachMode = naInsert;
  else
    return;
  TreeView1->Selected->MoveTo(Item, AttachMode);
}

void __fastcall TForm1::TreeView1DragOver(TObject *Sender, TObject *Source,
      int X, int Y, TDragState State, bool &Accept)
{
  Accept = (Source == (TObject *)TreeView1);
```

```
}
```

Delphi Examples:

```
{
The following code uses GetNodeAt to add a dragged node as a
child of the node under the mouse when it is dropped.  This
example requires a populated TreeView.  Also, the TTreeView
DragMode property set to dmAutomatic, and the TTreeView
OnDragOver event handler must be implemented to accept the
drop.
}
procedure TForm1.TreeView1DragDrop(Sender, Source: TObject; X, Y: Integer);
var
  AnItem: TTreeNode;
  AttachMode: TNodeAttachMode;
  HT: THitTests;
begin
  if TreeView1.Selected = nil then Exit;
  HT := TreeView1.GetHitTestInfoAt(X, Y);
  AnItem := TreeView1.GetNodeAt(X, Y);
  if (HT - [htOnItem, htOnIcon, htNowhere, htOnIndent] <> HT) then
  begin
    if (htOnItem in HT) or (htOnIcon in HT) then
      AttachMode := naAddChild
    else if htNowhere in HT then AttachMode := naAdd
    else if htOnIndent in HT then AttachMode := naInsert;
    TreeView1.Selected.MoveTo(AnItem, AttachMode);
  end;
end;

procedure TForm1.TreeView1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TTreeView;
end;
```

EndDrag (see page 5757)

OnDragDrop (see page 5855)

OnDragOver (see page 5857)

OnEndDrag (see page 5860)

OnStartDrag (see page 5871)

DragKind (see page 5819)

Arranging the Order of Persistent Columns

168.1.2.5.17 TValueListEditor.DropDownRows Property

Limits the length of the drop-down list that appears for values that use a pick list.

Pascal

```
property DropDownRows: Integer;
```

C++

```
__property int DropDownRows;
```

Description

Use DropDownRows to indicate the maximum height of the drop-down list that appears when the user clicks the drop-down button on values that have a pick list. DropDownRows is an upper limit: if the pick list has fewer entries that DropDownRows, the drop-down list includes only a line for every item in the list.

DropDownRows is ignored for values that do not have a pick list. To provide a value in the value list editor with a drop-down button and pick list, you do either of the following:

For the appropriate entry in the ItemProps (see page 23445) property, set the EditStyle property to esPickList and set the PickList property to the list of items.

Write an OnGetPickList (see page 23477) event handler that supplies the items in the list.

See Also

OnGetPickList (see page 23477)

Values (see page 23457)

ItemProps (see page 23445)

168.1.2.5.18 TValueListEditor.EditList Property

Pascal

```
property EditList: TInplaceEditList;
```

C++

```
__property TInplaceEditList EditList;
```

Description

This is EditList, a member of class TValueListEditor.

168.1.2.5.19 TValueListEditor.Enabled Property

Controls whether the control responds to mouse, keyboard, and timer events.

Pascal

```
property Enabled: Boolean;
```

C++

```
__property Boolean Enabled;
```

Description

Use Enabled to change the availability of the control to the user. To disable a control, set Enabled to false. Disabled controls appear dimmed. If Enabled is false, the control ignores mouse, keyboard, and timer events.

To re-enable a control, set Enabled to true. The control is no longer dimmed, and the user can use the control.

See Also

Visible (see page 5847)

DisableControls (see page 6925)

EnableControls (see page 6934)

Enabling Mouse

168.1.2.5.20 TValueListEditor.FixedColor Property

Specifies the background color of the fixed rows and columns in the grid.

Pascal

```
property FixedColor: TColor;
```

C++

```
__property TColor FixedColor;
```

Description

Set FixedColor to specify the color for the nonscrolling cells in the grid. The scrolling region of the grid is drawn using the Color property.

See Also

Color (see page 5812)

FixedCols (see page 14848)

FixedRows (see page 14849)

168.1.2.5.21 TValueListEditor.FixedCols Property

Specifies the number of columns on the left of the grid that cannot be scrolled.

Pascal

```
property FixedCols: Integer;
```

C++

```
__property int FixedCols;
```

Description

Set FixedCols to create or get rid of nonscrolling columns. Nonscrolling columns appear at the left of the grid, and are always visible, even when the user scrolls the other columns in the grid. Use nonscrolling columns for displaying row titles or row numbers, or to implement a scroll lock that the user can set.

Nonscrolling columns are visually distinct from the scrollable columns in the grid. They are painted with a separate background color, and their cells have a raised, 3-D look.

Note: Grids must include at least one scrolling column. Do not set FixedCols to a value greater than ColCount - 1.

See Also

ColCount (see page 14844)

DefaultDrawing (see page 14847)

FixedColor (see page 14848)

FixedRows (see page 14849)

168.1.2.5.22 TValueListEditor.Font Property

Controls the attributes of text written on or in the control.

Pascal

```
property Font: TFont;
```

C++

```
__property TFont Font;
```

Description

To change to a new font, specify a new TFont object. To modify a font, change the value of the Charset, Color, Height, Name, Pitch, Size, or Style of the TFont object.

C++ Examples:

```
/*
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < Screen->Fonts->Count; i++)
   ComboBox1->Items->Add(Screen->Fonts->Strings[i]);
//  ComboBox1->Items = Screen->Fonts;  // Another way to do it.
}

void __fastcall TForm1::ComboBox1Change(TObject *Sender)
{
  RichEdit1->Font->Name = ComboBox1->Text;
}
```

Delphi Examples:

```
{
To use this example, place a TComboBox and TRichEdit or
TMemo on a form.  During form creation, a list of font names
is loaded into the combo box. When the combo box is clicked,
the memo or Rich Edit control font is set to the
corresponding font name in the combo box.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  i : Integer;
begin
  for i := 0 to Screen.Fonts.Count - 1 do
   ComboBox1.Items.Add(Screen.Fonts.Strings[i]);
//  ComboBox1.Items := Screen.Fonts;  // Another way to do it.
  RichEdit1.Lines.Text := 'How is it to be you?';
end;

procedure TForm1.ComboBox1Click(Sender: TObject);
begin
  RichEdit1.Font.Name := ComboBox1.Text;
end;
```

See Also

DesktopFont (see page 5818)

ParentFont (see page 5834)

Displaying and Editing Text in a Memo Control

168.1.2.5.23 TValueListEditor.GridLineWidth Property

Specifies the width (in pixels) of the lines that separate the cells of the grid.

Pascal

```
property GridLineWidth: Integer;
```

C++

```
__property int GridLineWidth;
```

Description

Set GridLineWidth to make the lines that separate the cells in the grid heavier or lighter. When GridLineWidth is zero, no separators are drawn between the cells of the grid.

GridLineWidth will have no effect if the Options property does not include goFixedHorzLine, goFixedVertLine, goHorzLine, or goVertLine.

Note: Values greater than 3 pixels are not recommended for applications that run on Windows 9x or Windows ME because of distortions that can appear.

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
This example includes a draw grid on a form. When the
application runs and the form is created, the width of the
lines on the draw grid changes if the default column width of
the grid is over 90 pixels wide.  This example requires a
populated image list, or can just display an empty grid.
Set the drawgrid DefaultColWidth and GridLineWidth statically
to values the cause the button click to do something.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
  if DrawGrid1.DefaultColWidth > 90 then
    DrawGrid1.GridLineWidth := 2
  else
    DrawGrid1.GridLineWidth := 1;
end;

procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clBackground;
  DrawGrid1.Canvas.FillRect(Rect);
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
  end;
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
```

See Also

FixedCols (see page 14848)

FixedRows (see page 14849)

Options (see page 14853)

168.1.2.5.24 TValueListEditor.ItemProps Property

Specifies various constraints on the way users can enter a value for each item in the list.

Pascal

```
property ItemProps [const KeyOrIndex: Variant]: TItemProp;
```

C++

```
__property TItemProp ItemProps[Variant const KeyOrIndex];
```

Description

Use ItemProps to indicate, for each item:

- Whether the item is read only.
- The maximum length of strings the user can enter.
- An edit mask that limits the strings the user can enter as a value.
- Whether the item lets users drop down a pick list or launch a dialog to enter values.
- A fixed set of values from which users select (a pick list).

See Also

OnGetPickList (see page 23477)

Values (see page 23457)

168.1.2.5.25 TValueListEditor.KeyOptions Property

Controls (see page 5711) the way the value list editor responds to user keystrokes.

Pascal

```
property KeyOptions: TKeyOptions;
```

C++

```
__property TKeyOptions KeyOptions;
```

Description

Use KeyOptions to control how users can edit name/value pairs using the value list editor.

See Also

Keys (see page 23445)

Strings (see page 23456)

168.1.2.5.26 TValueListEditor.Keys Property

Lists the strings for each cell in the name (key) column.

Pascal

```
property Keys [Index: Integer]: string;
```

C++

```
__property AnsiString Keys[int Index];
```

Description

Use Keys to access the name (or key) value for a particular row. That is, Keys assumes the strings in the associated string list have the form Name=Value, and returns the Name portion.

Index identifies the Row of the value list editor. It takes a value from 0 to the number of rows. When DisplayOptions (see page 23438) includes doColumnTitles, the value of Keys is the title of the first column when Index is 0, and is the Name portion of the string when Index is greater than 0. When DisplayOptions (see page 23438) does not include doColumnTitles, the value of Keys is the Name portion of the string in the specified row.

To access the strings in the value column, use the Values (see page 23457) property instead. To access the underlying string list, use the Strings (see page 23456) property.

See Also

Cells (see page 23433)

Values (see page 23457)

Strings (see page 23456)

DisplayOptions (see page 23438)

Names (see page 3075)

168.1.2.5.27 TValueListEditor.Options Property

Specifies various display and behavioral properties of the grid.

Pascal

```
property Options: TGridOptions;
```

C++

```
__property TGridOptions Options;
```

Description

Set Options to include the desired properties for the grid. See the type Grids.TGridOptions for definitions of these properties.

See Also

ColWidths (see page 14788)

EditorMode (see page 14848)

GridLineWidth (see page 14850)

RowHeights (see page 14855)

Selection (see page 14856)

TabStops (see page 14858)

168.1.2.5.28 TValueListEditor.ParentBiDiMode Property

Specifies whether the control uses its parent's BiDiMode.

Pascal

```
property ParentBiDiMode: Boolean;
```

C++

```
__property Boolean ParentBiDiMode;
```

Description

Use ParentBiDiMode to get or set whether the control uses its parent's BiDiMode. When ParentBiDiMode is true, the control's BiDiMode property is always equal to that of its parent. If ParentBiDiMode is false, the control uses its own BiDiMode property.

Set ParentBiDiMode to true for all controls in a form in order to ensure that the entire user interface adjusts to Middle Eastern locales in a uniform manner.

When the value of the control's BiDiMode property changes, ParentBiDiMode becomes false automatically.

See Also

Parent (see page 5832)

BiDiMode (see page 5803)

168.1.2.5.29 TValueListEditor.ParentColor Property

Determines where a control looks for its color information.

Pascal

```
property ParentColor: Boolean;
```

C++

```
__property Boolean ParentColor;
```

Description

To have a control use the same color as its parent control, set ParentColor to true. If ParentColor is false, the control uses its own Color property.

Set ParentColor to true for all controls in order to ensure that all the controls on a form have a uniform appearance. For example, if ParentColor is true for all controls in a form, changing the background color of the form to gray causes all the controls on the form to also have a gray background.

When the value of a control's Color property changes, ParentColor becomes false automatically.

See Also

Color (see page 5812)

Parent (see page 5832)

ParentFont (see page 5834)

ParentShowHint (see page 5835)

168.1.2.5.30 TValueListEditor.ParentCtl3D Property

Determines where a component looks to determine if it should appear three dimensional.

Pascal

```
property ParentCtl3D: Boolean;
```

C++

```
__property Boolean ParentCtl3D;
```

Description

ParentCtl3D is provided for backwards compatibility. It has no effect on 32-bit versions of Windows or NT 4.0 and later.

ParentCtl3D determines whether the control uses its parent's Ctl3D property.

See Also

Ctl3D (see page 6198)

168.1.2.5.31 TValueListEditor.ParentFont Property

Determines where a control looks for its font information.

Pascal

```
property ParentFont: Boolean;
```

C++

```
__property Boolean ParentFont;
```

Description

To have a control use the same font as its parent control, set ParentFont to true. If ParentFont is false, the control uses its own Font property. Many controls default ParentFont to true so that all the controls in a form or other container present a uniform appearance. When the value of a control's Font property changes, ParentFont becomes false automatically.

When ParentFont is true for a form, the form uses the default font.

See Also

Font (see page 5823)

Parent (see page 5832)

ParentColor (see page 5834)

ParentShowHint (see page 5835)

168.1.2.5.32 TValueListEditor.ParentShowHint Property

Determines where a control looks to find out if its Help Hint should be shown.

Pascal

```
property ParentShowHint: Boolean;
```

C++

```
__property Boolean ParentShowHint;
```

Description

Use ParentShowHint to ensure that all the controls on a form either uniformly show their Help Hints or uniformly do not show them.

If ParentShowHint is true, the control uses the ShowHint property value of its parent. If ParentShowHint is false, the control uses the value of its own ShowHint property.

To provide Help Hints for only selected controls on a form, set the ShowHint property for those controls that should have Help Hints to true, and ParentShowHint becomes false automatically.

Note: Enable or disable all Help Hints for the entire application using the ShowHint property of the application object.

See Also

Hint (see page 5827)

Parent (see page 5832)

ParentColor (see page 5834)

ParentFont (see page 5834)

ShowHint (see page 5840)

168.1.2.5.33 TValueListEditor.PopupMenu Property

Identifies the pop-up menu associated with the control.

Pascal

```
property PopupMenu: TPopupMenu;
```

C++

```
__property TPopupMenu PopupMenu;
```

Description

Assign a value to PopupMenu to make a pop-up menu appear when the user selects the control and clicks the right mouse button. If the TPopupMenu's AutoPopup property is true, the pop-up menu appears automatically. If the menu's AutoPopup property is false, display the menu with a call to its Popup method from the control's OnContextPopup event handler.

C++ Examples:

```
/*
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  PopupMenu1->AutoPopup = true;
  Edit1->PopupMenu = PopupMenu1;
  Edit2->PopupMenu = PopupMenu1;
}

/*
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
*/
void __fastcall TForm1::Copy1Click(TObject *Sender)
{
  TComponent *pComponent = PopupMenu1->PopupComponent;
  if (pComponent)
  {
    if (pComponent->ClassNameIs("TEdit"))
      ((TEdit *)pComponent)->CopyToClipboard();
    else
      MessageBeep(0);
  }
```

```
    else
      MessageBeep(0);
  }

  void __fastcall TForm1::Cut1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;
    if (pComponent)
    {
      if (pComponent->ClassNameIs("TEdit"))
        ((TEdit *)pComponent)->CutToClipboard();
      else
        MessageBeep(0);
    }
    else
      MessageBeep(0);
  }

  void __fastcall TForm1::Paste1Click(TObject *Sender)
  {
    TComponent *pComponent = PopupMenu1->PopupComponent;

      MessageBeep(0);
  }
  /*
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  */
  void __fastcall TForm1::AddButtonClick(TObject *Sender)
  {
      const int num_items = 4;
      for (int index = 0; index < num_items; ++index)
      {
          TMenuItem *NewItem = new TMenuItem(PopupMenu1); // create the new item
          PopupMenu1->Items->Add(NewItem);// add it to the Popupmenu
          NewItem->Caption = "Menu Item " + IntToStr(index);
          NewItem->Tag = index;
          NewItem->OnClick = PopupMenuItemsClick;// assign it an event handler
          TNotifyEvent();
      }
  }

  void __fastcall TForm1::PopupMenuItemsClick(TObject *Sender)
  {
      TMenuItem *ClickedItem = dynamic_cast<TMenuItem *>(Sender);
      if (ClickedItem)
      {
          switch (ClickedItem->Tag)
          {
              case 0:
              {
                  ShowMessage("first item clicked");
```

```
                break;
            }
            case 1:
            {
                ShowMessage("second item clicked");
                break;
            }
            case 2:
            {
                ShowMessage("third item clicked");
                break;
            }
            case 3:
            {
                ShowMessage("fourth item clicked");
                break;
            }
        }
    }
}

/*
To edit or destroy an item, grab its pointer via the Items
property.
*/
void __fastcall TForm1::EditButtonClick(TObject *Sender)
{
    const int index = 1;
    TMenuItem *ItemToEdit = PopupMenu->Items->Items[index];
    ItemToEdit->Caption = "Changed Caption";
}

void __fastcall TForm1::DestroyButtonClick(TObject *Sender)
{
    const int index = 2;
    TMenuItem *ItemToDelete = PopupMenu->Items->Items[index];
    delete ItemToDelete;
}
```

Delphi Examples:

```
{
This example uses two edit boxes and one pop-up menu on a form.
The pop-up menu contains Cut, Copy, and Paste commands. This code
makes the pop-up menu available to both edit boxes:
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  PopupMenu1.AutoPopup := True;
  Edit1.PopupMenu := PopupMenu1;
  Edit2.PopupMenu := PopupMenu1;
end;

{
These are the cut, copy, and paste OnClick events for the commands
on the pop-up menu. Double click on the pop-up menu and add three
TMenuItems.  Then set the captions to "Cut", "Copy" and "Paste".
The names will be automatically set to "Cut1", "Copy1", and
"Paste1".  Then double click on the OnClick events and they will
be named "Cut1Click", "Copy1Click" and "Paste1Click" respectively.
Note: only the selected portion of the string in the edit box will
be copied, cut or replaced.
}
procedure TForm1.Copy1Click(Sender: TObject);
begin
  if PopupMenu1.PopupComponent = Edit1 then
   Edit1.CopyToClipboard
```

```
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CopyToClipboard
    else
      Beep;
  end;

  procedure TForm1.Cut1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.CutToClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.CutToClipboard
    else
      Beep;
  end;

  procedure TForm1.Paste1Click(Sender: TObject);
  begin
    if PopupMenu1.PopupComponent = Edit1 then
      Edit1.PasteFromClipboard
    else if PopupMenu1.PopupComponent = Edit2 then
      Edit2.PasteFromClipboard
    else
      Beep;
  end;
  {
  This example demonstrates how to add and delete menu items
  to a popup menu at runtime and assign an event handler to
  the OnClick event.  Place a TPopupMenu and three buttons on
  the form named "AddButton", "EditButton",  and
  "DestroyButton" and add OnClick events to all three buttons.
  Put the TPopupMenu in the PopupMenu property of the form.
  Place the PopupMenuItemsClick procedure in the TForm1 type
  declaration so that it can be used as the method call for
  the menu item OnClick event.
  }

168.1.2.5.34 TValueListEditor.RowCount Property

Indicates the number of rows in the value list editor.

Pascal

```
property RowCount: Integer;
```

C++

```
__property int RowCount;
```

Description

TValueListEditor (see page 23401) redeclares the RowCount property, which it inherits from TCustomGrid, to change it to a read-only property. The value of RowCount is the number of strings in the Strings (see page 23456) property plus the number of fixed rows (typically one, for the column titles).

See Also

Strings (see page 23456)

ColCount (see page 23434)

FixedRows (see page 14849)

168.1.2.5.35 TValueListEditor.ScrollBars Property

Specifies whether the grid includes horizontal and vertical scroll bars.

Pascal

```
property ScrollBars: TScrollStyle;
```

C++

```
__property TScrollStyle ScrollBars;
```

Description

Use ScrollBars to give the grid horizontal or vertical scroll bars.

Note: If all the cells in the grid fit in the ClientWidth, no horizontal scroll bar appears, even if ScrollBars is ssHorizontal or ssBoth. If all the cells fit in the ClientHeight, no vertical scroll bar appears, even if ScrollBars is ssVertical or ssBoth.

See Also

ClientHeight (see page 5808)

ClientWidth (see page 5811)

168.1.2.5.36 TValueListEditor.ShowHint Property

Determines whether the control displays a Help Hint when the mouse pointer rests momentarily on the control.

Pascal

```
property ShowHint: Boolean;
```

C++

```
__property Boolean ShowHint;
```

Description

The Help Hint is the value of the Hint property, which is displayed in a box just beneath the control. Use ShowHint to determine whether a Help Hint appears for the control.

To enable Help Hint for a particular control, the application ShowHint property must be true and either

the control's own ShowHint property must be true, or

the control's ParentShowHint property must be true and its parent's ShowHint property must be true.

For example, imagine a check box within a group box. If the ShowHint property of the group box is true and the ParentShowHint property of the check box is true, but the ShowHint property of the check box is false, the check box still displays its Help Hint.

Changing the ShowHint value automatically sets the ParentShowHint property to false.

C++ Examples:

```
/*
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
*/
void __fastcall TForm1::FormCreate(TObject *Sender)
{
  Edit1->Hint = "Enter your name";
  Edit1->ShowHint = true;

  char string[10];
  char index[3];
  for(int i = 1; i <= 10; i++)
  {
    strcpy(string, "Item");
    itoa(i, index, 10);
    strcat(string, index);
    ListBox1->Items->Add(string);
  }
  ListBox1->Hint = "Select an item";
  ListBox1->ShowHint = true;
  Application->ShowHint = true;
}
/*
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
*/
```

Delphi Examples:

```
{
This example uses an edit box and a list box on a form.
Items are added to the list box and a Help Hint is assigned
to both controls. The last statement enables the Help Hints
for the entire application.
}
procedure TForm1.FormCreate(Sender: TObject);
var
  I: Integer;
begin
  Edit1.Hint := 'Enter your name';
  Edit1.ShowHint := True;
  with ListBox1 do
  begin
    for I := 1 to 10 do
      Items.Add('Item ' + IntToStr(I));
    Hint := 'Select an item';
    ShowHint := True;
  end;
  Application.ShowHint := True;
end;
{
Note: To see an example that displays the hints of controls
in some place other than in a Help Hint box, see the OnHint
example.
}

Displaying Fly-over Help

168.1.2.5.37 TValueListEditor.Strings Property

Provides access to the string list that is being edited.

Pascal

```
property Strings: TStrings;
```

C++

```
__property TStrings Strings;
```

Description

Use Strings to access the string list that the value list editor displays. Strings should be a TStrings descendant that contains strings of the form Name=Value.

At design time, add values to the Strings property using the string list editor. At runtime, you can use the methods of TStrings to add strings to the list one by one, or assign an existing TStrings descendant to the Strings property. When you set Strings at runtime, TValueListEditor (see page 23401) copies the strings from the TStrings object you assign: it does not take ownership of the object itself.

When Strings is assigned, the value list editor displays the name portion (TStrings . ::Names) of the strings in its key column and the value portion (TStrings . ::Values (see page 23457)) in the value column.

See Also

Names (see page 3075)

Values (see page 3086)

KeyOptions (see page 23445)

168.1.2.5.38 TValueListEditor.TabOrder Property

Indicates the position of the control in its parent's tab order.

Pascal

```
property TabOrder: TTabOrder;
```

C++

```
__property TTabOrder TabOrder;
```

Description

TabOrder is the order in which child windows are visited when the user presses the Tab key. The control with the TabOrder value of 0 is the control that has the focus when the form first appears.

Initially, the tab order is always the order in which the controls were added to the form. The first control added to the form has a TabOrder value of 0, the second is 1, the third is 2, and so on. Change this by changing the TabOrder property.

Each control has a unique tab-order value within its parent. If you change the TabOrder property value of one control to be the same as the value of a second control, the TabOrder value for all the other controls changes. For example, suppose a control is sixth in the tab order. If you change the control's TabOrder property value to 3 (making the control fourth in the tab order), the control that was originally fourth in the tab order now becomes fifth, and the control that was fifth becomes sixth.

Assigning TabOrder a value greater than the number of controls contained in the parent control moves the control to the end of the tab order. The control does not take on the assigned value of TabOrder, but instead is given the number that assures the control is the last in the tab order.

Note: TabOrder is meaningful only if the TabStop property is true and if the control has a parent. (The TabOrder property of a form is not used unless the form is the child of another form.) A control with a TabOrder of -1 has no parent, and therefore cannot be reached by pressing the Tab key. To remove a parented control from the Tab order, set its TabStop property to false.

See Also

FindNextControl (see page 6149)

TabStop (see page 6211)

168.1.2.5.39 TValueListEditor.TitleCaptions Property

Specifies the captions that label the columns of the value list editor.

Pascal

```
property TitleCaptions: TStrings;
```

C++

```
__property TStrings TitleCaptions;
```

Description

Use TitleCaptions to provide titles for the columns of the value list editor. TitleCaptions is a TStrings descendant that contains two strings: the first string labels the name (key) column, and the second string labels the value column. If TitleCaptions contains less than two strings, missing captions are treated as empty strings. If TitleCaptions contains more than two strings, all strings except the first two are ignored.

Note: TitleCaptions is only used when the DisplayOptions (see page 23438) property includes doColumnTitles.

See Also

DisplayOptions (see page 23438)

168.1.2.5.40 TValueListEditor.Values Property

Lists the strings for each value from the value column.

Pascal

```
property Values [const Key: string]: string;
```

C++

```
__property AnsiString Values[AnsiString const Key];
```

Description

Use Values to access the value associated with a specified name from the first (key) column. Key specifies a string that appears in the first column of the value list editor. Values is the corresponding string from the second (value) column.

To access the strings in the key column, use the Keys (see page 23445) property instead. To access the underlying string list, use the Strings (see page 23456) property.

Note: Setting Values with Key set to a name that is not in the list adds a new string to Strings (see page 23456) and a new row to the value list editor.

See Also

Cells (see page 23433)

Keys (see page 23445)

Strings (see page 23456)

Values (see page 3086)

168.1.2.5.41 TValueListEditor.Visible Property

Determines whether the component appears onscreen.

Pascal

```
property Visible: Boolean;
```

C++

```
__property Boolean Visible;
```

Description

Use the Visible property to control the visibility of the control at runtime. If Visible is true, the control appears. If Visible is false, the control is not visible.

Calling the Show method sets the control's Visible property to true. Calling the Hide method sets it to false.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}

void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
```

```
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

168.1.2.5.42 TValueListEditor.VisibleColCount Property

Indicates the number of scrollable columns visible in the grid.

Pascal

```
property VisibleColCount: Integer;
```

C++

```
__property int VisibleColCount;
```

Description

Use VisibleColCount to determine the number of scrollable columns fully visible in the grid. VisibleColCount does not include the fixed columns counted by the FixedCols property. It does not include any partially visible columns on the right edge of the grid.

See Also

ColCount (see page 14844)

FixedCols (see page 14848)

VisibleRowCount (see page 14859)

168.1.2.5.43 TValueListEditor.VisibleRowCount Property

Indicates the number of scrollable rows visible in the grid.

Pascal

```
property VisibleRowCount: Integer;
```

C++

```
__property int VisibleRowCount;
```

Description

Use VisibleRowCount to determine the number of scrollable rows fully visible in the grid. VisibleRowCount does not include the fixed rows counted by the FixedRows property. It does not include any partially visible rows on the bottom of the grid.

See Also

FixedRows (see page 14849)

RowCount (see page 14854)

VisibleColCount (see page 14859)

168.1.2.6 TValueListEditor Events

The events of the TValueListEditor class are listed here.

Published Events

	Name	Description
	OnClick (see page 23461)	Occurs when the user clicks the control.
	OnContextPopup (see page 23463)	Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).
	OnDblClick (see page 23463)	Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.
	OnDragDrop (see page 23464)	Occurs when the user drops an object being dragged.
	OnDragOver (see page 23466)	Occurs when the user drags an object over a control.
	OnDrawCell (see page 23468)	Occurs when a cell in the grid needs to be drawn.
	OnEditButtonClick (see page 23470)	Occurs when the user click the ellipsis button on a cell in the values column or types Ctrl+Enter while focus is on a value cell with an ellipsis button.
	OnEndDock (see page 23470)	Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.
	OnEndDrag (see page 23471)	Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.
	OnEnter (see page 23472)	Occurs when a control receives the input focus.
	OnExit (see page 23474)	Occurs when the input focus shifts away from one control to another.
	OnGetEditMask (see page 23476)	Occurs when the in-place editor requests an edit mask.
	OnGetEditText (see page 23476)	Occurs when the in-place editor requests the value of a cell.
	OnGetPickList (see page 23477)	Supplies a pick list for values associated with a particular key.
	OnKeyDown (see page 23478)	Occurs when a user presses any key while the control has focus.
	OnKeyPress (see page 23480)	Occurs when a key is pressed.
	OnKeyUp (see page 23481)	Occurs when the user releases a key that has been pressed.
	OnMouseActivate (see page 23483)	Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.
	OnMouseDown (see page 23484)	Occurs when the user presses a mouse button with the mouse pointer over a control.
	OnMouseEnter (see page 23486)	Occurs when the user moves the mouse into a control.
	OnMouseLeave (see page 23487)	Occurs when the user moves the mouse outside of a control.
	OnMouseMove (see page 23487)	Occurs when the user moves the mouse pointer while the mouse pointer is over a control.
	OnMouseUp (see page 23489)	Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.
	OnMouseWheelDown (see page 23492)	Occurs when the mouse wheel is rotated downward.

	OnMouseWheelUp (see page 23492)	Occurs when the mouse wheel is rotated upward.
	OnRowMoved (see page 23492)	Occurs immediately after the position of a row changes.
	OnSelectCell (see page 23493)	Occurs before a cell in the grid is selected.
	OnSetEditText (see page 23494)	Occurs when the user edits the value of a cell.
	OnStartDock (see page 23495)	Occurs when the user begins to drag a control with a DragKind of dkDock.
	OnStartDrag (see page 23495)	Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.
	OnStringsChange (see page 23496)	Occurs immediately after the names or values in the string list change.
	OnStringsChanging (see page 23496)	Occurs immediately before the names or values in the string list change.
	OnTopLeftChanged (see page 23497)	Occurs immediately after the TopRow property or the LeftCol property changes.
	OnValidate (see page 23497)	Occurs when focus shifts away from a cell in the value list editor.

168.1.2.6.1 TValueListEditor.OnClick Event

Occurs when the user clicks the control.

Pascal

```
property OnClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnClick;
```

Description

Use the OnClick event handler to respond when the user clicks the control. If the control has an associated action, and that action has an OnExecute method, the action's OnExecute method responds to click events unless it is superseded by an OnClick event handler.

Usually OnClick occurs when the user presses and releases the left mouse button with the mouse pointer over the control. This event can also occur when:

- The user selects an item in a grid, outline, list, or combo box by pressing an arrow key.
- The user presses Spacebar while a button or check box has focus.
- The user presses Enter when the active form has a default button (specified by the Default property).
- The user presses Esc when the active form has a cancel button (specified by the Cancel property).
- The user presses the accelerator key for a button or check box. For example, if the value of the Caption property of a check box is '&Bold', the B is underlined at runtime and the OnClick event of the check box is triggered when the user presses Alt+B. However, focus does not move to the control in these instances.
- The Checked property of a radio button is set to true.
- The value of the Checked property of a check box is changed.
- The Click method of a menu item is called.

For a form, an OnClick event occurs when the user clicks a blank area of the form or on a disabled component.

C++ Examples:

```
/*
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
*/
void __fastcall TForm1::PageControl1Change(TObject *Sender)
{
  CheckBox1->Checked = PageControl1->ActivePage->Visible;
}
```

```
void __fastcall TForm1::CheckBox1Click(TObject *Sender)
{
  PageControl1->ActivePage->Visible = CheckBox1->Checked;
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  for (int i = 0; i < 10; i++)
  {
    TTabSheet *pPage = new TTabSheet(this);
    pPage->PageControl = PageControl1;
    pPage->Caption = AnsiString("Page") + IntToStr(i);
    TEdit *pEdit = new TEdit(this);
    pEdit->Parent = pPage;
    pEdit->Left = random(pPage->ClientWidth - pEdit->Width);
    pEdit->Top = random(pPage->ClientHeight - pEdit->Height);
  }
  PageControl1Change(Sender);
}
```

Delphi Examples:

```
{
This examples requires a TPageControl and a TCheckBox.  The
form OnCreate event handler populates each sheet with an
edit control placed somewhere on the client area of the
sheet.  Unchecking the checkbox will cause the client area
(not the tab area) of the Tab Control to become invisible.
}
procedure TForm1.CheckBox1Click(Sender: TObject);
begin
  PageControl1.ActivePage.Visible := CheckBox1.Checked;
end;

procedure TForm1.PageControl1Change(Sender: TObject);
begin
  CheckBox1.Checked := PageControl1.ActivePage.Visible;
end;

procedure TForm1.FormCreate(Sender: TObject);
var
  i: Integer;
begin
  for i := 0 to 9 do
    with TTabSheet.Create(Self) do
    begin
      PageControl := PageControl1;
      Caption := 'TabSheet' + IntToStr(i);
      with TEdit.Create(Self) do
      begin
        Parent := PageControl1.Pages[i];
        Left := Random(PageControl1.ActivePage.ClientWidth - Width);
        Top := Random(PageControl1.ActivePage.ClientHeight - Height);
      end;
    end;
    PageControl1Change(Sender);
end;
```

168.1.2.6.2 TValueListEditor.OnContextPopup Event

Occurs when the user right-clicks the control or otherwise invokes the popup menu (such as using the keyboard).

Pascal

```
property OnContextPopup: TContextPopupEvent;
```

C++

```
__property TContextPopupEvent OnContextPopup;
```

Description

The OnContextPopup handler is called when the user uses the mouse or keyboard to request a popup menu. The OnContextPopup event is generated by a WM_CONTEXTMENU message, which is itself generated by the user clicking the right mouse button or by pressing SHIFT+F10 or the Applications key.

This event is especially useful when the control does not have an associated popup menu (the PopupMenu property is not set) or if the AutoPopup property of the control's associated popup menu is false. However, the OnContextPopup can also be used to override the automatic context menu that appears when the control has an associated popup menu with an AutoPopup property of true. In this last case, if the event handler displays its own menu, it should set the Handled parameter to true to suppress the default context menu.

The handler's MousePos parameter indicates the position of the mouse, in client coordinates.. If the event was not generated by a mouse click, MousePos is (-1,-1).

Note: Parent controls receive an OnContextPopup event before their child controls. In addition, for many child controls, the default window procedure causes the parent control to receive an OnContextPopup event after the child control. As a result, when parent controls do not set Handled to true in an OnContextPopup event handler, the event handler may be called multiple times for each context menu invocation.

168.1.2.6.3 TValueListEditor.OnDblClick Event

Occurs when the user double-clicks the left mouse button when the mouse pointer is over the control.

Pascal

```
property OnDblClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnDblClick;
```

Description

Use the OnDblClick event to respond to mouse double-clicks.

See Also

OnClick (see page 5851)

Responding to User Actions at Runtime

168.1.2.6.4 TValueListEditor.OnDragDrop Event

Occurs when the user drops an object being dragged.

Pascal

```
property OnDragDrop: TDragDropEvent;
```

C++

```
__property TDragDropEvent OnDragDrop;
```

Description

Use the OnDragDrop event handler to specify what happens when the user drops an object. The Source parameter of the OnDragDrop event is the object being dropped, and the Sender is the control the object is being dropped on. The X and Y parameters are the coordinates of the mouse positioned over the control.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

procedure TForm1.FormDragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
  ListBox1.Items.Add('Not');
  ListBox1.Items.Add('In');
  ListBox1.Items.Add('Alphabetical');
  ListBox1.Items.Add('Order');
end;

// This OnDragOver event handler permits the list box to
// accept a dropped label:

procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := Source is TLabel;
end;

// This OnDragDrop event handler implements the drop behavior.

procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  if (Sender is TListBox) and (Source is TLabel) then
  begin
    with Sender as TListBox do
    begin
      Font := (Source as TLabel).Font;
      Color := (Source as TLabel).Color;
      DoubleBuffered := true;
      Color := clWindow;
```

```
      end;
    end;
  end;
```

168.1.2.6.5 TValueListEditor.OnDragOver Event

Occurs when the user drags an object over a control.

Pascal

```
property OnDragOver: TDragOverEvent;
```

C++

```
__property TDragOverEvent OnDragOver;
```

Description

Use an OnDragOver event to signal that the control can accept a dragged object so the user can drop or dock it.

Within the OnDragOver event handler, change the Accept parameter to false to reject the dragged object. Leave Accept as true to allow the user to drop or dock the dragged object on the control.

To change the shape of the cursor, indicating that the control can accept the dragged object, change the value of the DragCursor property for the control before the OnDragOver event occurs.

The Source is the object being dragged, the Sender is the potential drop or dock site, and X and Y are screen coordinates in pixels. The State parameter specifies how the dragged object is moving over the control.

Note: Within the OnDragOver event handler, the Accept parameter defaults to true. However, if an OnDragOver event handler is not supplied, the control rejects the dragged object, as if the Accept parameter were changed to false.

C++ Examples:

```
/*
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
*/

// This OnDragOver event handler permits the list box to
// accept a dropped label:
void __fastcall TForm1::ListBox1DragOver(TObject *Sender, TObject *Source, int X, int Y,
TDragState State, bool &Accept)
```

```
{
   Accept = Source->ClassNameIs("TLabel");
}

/*
This OnDragDrop event handler implements the drop behavior.
*/
void __fastcall TForm1::ListBox1DragDrop(TObject *Sender, TObject *Source, int X, int Y)
{
  if (Sender->ClassNameIs("TListBox") && Source->ClassNameIs("TLabel"))
  {
    TListBox *DestList = (TListBox *)Sender;
    DestList->Font = ((TLabel *)Source)->Font;
    DestList->Color = ((TLabel *)Source)->Color;
    DestList->DoubleBuffered = true;
    DestList->Color = clWindow;
  }
}

void __fastcall TForm1::FormCreate(TObject *Sender)
{
  ListBox1->Items->Add("Not");
  ListBox1->Items->Add("In");
  ListBox1->Items->Add("Alphabetical");
  ListBox1->Items->Add("Order");

}
```

Delphi Examples:

```
{
This code is an OnDragOver event handler that won't allow a
label control to be dropped on a panel control and stops the
dragging of the label as soon as the user drags the label
onto the panel:
Note: Set the label's DragMode property to dmAutomatic.
}
procedure TForm1.FormDragDrop(Sender, Source: TObject; X, Y: Integer);
begin
  TForm1(Source).Left := X;
  TForm1(Source).Top := Y;
end;

begin
  Accept := Source is TLabel;
end;

procedure TForm1.Panel1DragOver(Sender, Source: TObject; X, Y: Integer;
  State: TDragState; var Accept: Boolean);
begin
  Accept := False;
  if (Source is TLabel) and (State = dsDragEnter) then
    (Source as TLabel).EndDrag(False);
end;
{
This code comes from an application that contains a list box
and three labels, each with a different font and color.  The
DragMode property for each of the labels is dmAutomatic.
The user can select a label and drag it to a list box and
drop it. When the label is dropped, the items in the list
box assume the color and font of the dropped label.
}

procedure TForm1.FormCreate(Sender: TObject);
begin
```

```
    ListBox1.Items.Add('Not');
    ListBox1.Items.Add('In');
    ListBox1.Items.Add('Alphabetical');
    ListBox1.Items.Add('Order');
  end;

  // This OnDragOver event handler permits the list box to
  // accept a dropped label:

  procedure TForm1.ListBox1DragOver(Sender, Source: TObject; X, Y: Integer;
    State: TDragState; var Accept: Boolean);
  begin
    Accept := Source is TLabel;
  end;

  // This OnDragDrop event handler implements the drop behavior.

  procedure TForm1.ListBox1DragDrop(Sender, Source: TObject; X, Y: Integer);
  begin
    if (Sender is TListBox) and (Source is TLabel) then
    begin
      with Sender as TListBox do
      begin
        Font := (Source as TLabel).Font;
        Color := (Source as TLabel).Color;
        DoubleBuffered := true;
        Color := clWindow;
      end;
    end;
  end;
```

168.1.2.6.6 TValueListEditor.OnDrawCell Event

Occurs when a cell in the grid needs to be drawn.

Pascal

```
property OnDrawCell: TDrawCellEvent;
```

C++

```
__property TDrawCellEvent OnDrawCell;
```

Description

Write an OnDrawCell event handler to draw the contents of all the cells in the grid. Draw on the cell using the methods of the Canvas property. The Rect parameter indicates the location of the cell on the canvas. The Col and Row parameters indicate the

column and row indexes of the cell that should be drawn. The State parameter indicates whether the cell has input focus, whether the cell is selected, and whether the cell is a fixed (nonscrolling) cell.

If the OnDrawCell event handler is not assigned, all cells in the draw grid will appear empty. If the DefaultDrawing property is true, the draw grid paints the background color of the cell before the OnDrawCell event, and draws a focus rectangle around the selected cell after the OnDrawCell event handler finishes drawing the contents of the cell. If the DefaultDrawing property is false, the OnDrawCell event handler should paint the background of the cell and provide all visual indication of selection and focus.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  ImageList1->Draw(DrawGrid1->Canvas,Rect.Left,Rect.Top,index);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(index) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}
//---------------------------------------------------------------------------
void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clWhite;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
```

```
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
```

168.1.2.6.7 TValueListEditor.OnEditButtonClick Event

Occurs when the user click the ellipsis button on a cell in the values column or types Ctrl+Enter while focus is on a value cell with an ellipsis button.

Pascal

```
property OnEditButtonClick: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEditButtonClick;
```

Description

Write an OnEditButtonClick to display a dialog that lets users edit a value in the Values (see page 23457) column. This event only occurs for items for which the ItemProps (see page 23445) property has an EditStyle of esEllipsis.

In the event handler, you can use the Row property to identify the row that the user is editing. The event handler (or the dialog that the event handler displays) can use the Keys (see page 23445) property to identify the current key value, and use that to get and set the corresponding entry in the Values (see page 23457) property that is being edited.

See Also

Values (see page 23457)

Keys (see page 23445)

168.1.2.6.8 TValueListEditor.OnEndDock Event

Occurs when the dragging of an object ends, either by docking the object or by canceling the dragging.

Pascal

```
property OnEndDock: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDock;
```

Description

Use OnEndDock to specify actions or special processing that when a drag-and-dock operation stops.

See Also

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

OnStartDock (see page 5871)

168.1.2.6.9 TValueListEditor.OnEndDrag Event

Occurs when the dragging of an object ends, either by dropping the object or by canceling the dragging.

Pascal

```
property OnEndDrag: TEndDragEvent;
```

C++

```
__property TEndDragEvent OnEndDrag;
```

Description

Use the OnEndDrag event handler to specify any special processing that occurs when dragging stops.

C++ Examples:

```
/*
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
*/
void __fastcall TForm1::Label1EndDrag(TObject *Sender, TObject *Target, int X,
      int Y)
{
  if (Sender->ClassNameIs("TLabel"))
  {
    AnsiString S = ((TLabel *)Sender)->Name + " was dropped and ";
    if (Target)
      S = S + "accepted!";
    else
      S = S + "rejected.";
    Status->Caption = S;
  }
}
```

Delphi Examples:

```
{
This code displays a message in a label named Status. The
message displayed depends on whether the dragged label
control was successfully dropped into and accepted by a
another control.
}
procedure TForm1.Label1EndDrag(Sender, Target: TObject; X, Y: Integer);
var
  S: string;
begin
  S := (Sender as TLabel).Name + ' was dropped... and ';
  if Target <> nil then
    S := S + 'accepted!'
  else
    S := S + 'rejected!';
  Status.Caption := S;
end;
```

OnStartDrag (see page 5871)

DragKind (see page 5819)

168.1.2.6.10 TValueListEditor.OnEnter Event

Occurs when a control receives the input focus.

Pascal

```
property OnEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnEnter;
```

Description

Use the OnEnter event handler to cause any special processing to occur when a control becomes active.

The OnEnter event does not occur when switching between forms or between another application and the application that includes the control.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnEnter event occurs for the container before the OnEnter event of the contained control.

Similarly, an OnExit event of the container occurs after the OnExit event of the control in a container when focus moves to another control outside the container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

C++ Examples:

```
/*
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
*/
TWinControl *myActiveControl;

void __fastcall TForm1::Button1Click(TObject *Sender)
{
  FontDialog1->Options << fdApplyButton;
  FontDialog1->Execute();
}

void __fastcall TForm1::FontDialog1Apply(TObject *Sender, HWND Wnd)
{
  if (myActiveControl->ClassNameIs("TEdit"))
   ((TEdit *)myActiveControl)->Font->Assign(FontDialog1->Font);
  else if (myActiveControl->ClassNameIs("TRichEdit"))
    ((TRichEdit *)myActiveControl)->SelAttributes->Assign(FontDialog1->Font);
  else
    MessageBeep(0);
```

```
}

void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  myActiveControl = ActiveControl;
}
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example takes an edit control, a button, and a rich
edit control on a form.  When the user presses the button, a
Font dialog appears.  When the user clicks the Apply (not OK)
button in the Font dialog, the currently selected font is
applied to the active control. Clicking the button sets the
ActiveControl to the button.  That is why we need to save
the ActiveControl in a shared OnEnter procedure.  In the rich
edit, only the text selected converts.
}
procedure TForm1.Button1Click(Sender: TObject);
begin
   FontDialog1.Options := FontDialog1.Options + [fdApplyButton];
   FontDialog1.Execute;
end;

procedure TForm1.Edit1Enter(Sender: TObject);
begin
  myActiveControl := ActiveControl;
end;

procedure TForm1.FontDialog1Apply(Sender: TObject; Wnd: HWND);
begin
  if myActiveControl is TEdit then
    with myActiveControl as TEdit do
       Font.Assign(TFontDialog(Sender).Font)
  else if myActiveControl is TRichEdit then
    with myActiveControl as TRichEdit do
      SelAttributes.Assign(TFontDialog(Sender).Font)
  else
    Beep;
```

```
end;
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.

168.1.2.6.11 TValueListEditor.OnExit Event

Occurs when the input focus shifts away from one control to another.

Pascal

```
property OnExit: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnExit;
```

Description

Use the OnExit event handler to provide special processing when the control ceases to be active.

The OnExit event does not occur when switching between forms or between another application and your application.

When switching between controls in separate container controls such as the TPanel and the TGroupBox controls, an OnExit event occurs for the control inside the container before the OnExit event of the container.

Similarly, an OnEnter event of the container occurs before the OnEnter event of the control in a container when focus moves to a control inside a container.

For example, consider a form with an OK button and a group box that contains three radio buttons, where focus is currently on the OK button. When the user clicks one of the radio buttons, an OnExit event of the button occurs, followed by an OnEnter event on the group box, and finally an OnEnter event on the radio button that was clicked. If the user then clicks on the OK

button, an OnExit event for the radio button occurs followed by an OnExit event for the group box, and then the button's OnEnter event occurs.

Note: In some control classes the ActiveControl property updates before the OnExit event occurs.

C++ Examples:

```
/*
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
*/
void __fastcall TForm1::Edit1Enter(TObject *Sender)
{
  Edit1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Edit1Exit(TObject *Sender)
{
  Edit1->Color = clWindow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Enter(TObject *Sender)
{
  Memo1->Color = clYellow;
}
//---------------------------------------------------------------------------
void __fastcall TForm1::Memo1Exit(TObject *Sender)
{
  Memo1->Color = clWindow;
}
```

Delphi Examples:

```
{
This example uses an edit box and a memo control on a form.
When either the edit box or the memo is the active control,
it is colored yellow. When the active control becomes
inactive, the color of the control returns to the Windows
system color for a window.  These event handlers could also
be shared.
}
procedure TForm1.Edit1Enter(Sender: TObject);
begin
  Edit1.Color := clYellow;
end;

procedure TForm1.Edit1Exit(Sender: TObject);
begin
  Edit1.Color := clWindow;
end;

procedure TForm1.Memo1Enter(Sender: TObject);
begin
  Memo1.Color := clYellow;
end;

procedure TForm1.Memo1Exit(Sender: TObject);
begin
  Memo1.Color := clWindow;
end;
```

168.1.2.6.12 TValueListEditor.OnGetEditMask Event

Occurs when the in-place editor requests an edit mask.

Pascal

```
property OnGetEditMask: TGetEditEvent;
```

C++

```
__property TGetEditEvent OnGetEditMask;
```

Description

Write an OnGetEditMask event handler to provide the in-place editor with an edit mask that describes the valid input strings a user can type into a cell. Set the Value parameter to the string that describes the edit mask for the cell specified by the ACol and ARow parameters. If the cell does not have an edit mask, set the Value parameter to an empty string.

OnGetEditMask does not occur unless the Options property includes goEditing.

Delphi Examples:

```
{
This example specifies an edit mask in a string grid to
limit the cells that contain telephone numbers, as indicated
by a label cell in the first row.  Include goEditing in the
TStringGrid Options property.  Set the title of one of the
columns to 'Phone Number'.  Set the DefaultColWidth large
enough to see a phone number.
}
procedure TForm1.FormCreate(Sender: TObject);
begin
  StringGrid1.Cells[2, 0]:= 'Phone Number';
end;

procedure TForm1.StringGrid1GetEditMask(Sender: TObject; ACol, ARow: Longint; var Value:
string);
begin
  if StringGrid1.Cells[ACol, 0] = 'Phone Number' then
    Value :=  '!\(999\)000-0000;1';
end;
```

168.1.2.6.13 TValueListEditor.OnGetEditText Event

Occurs when the in-place editor requests the value of a cell.

Pascal

```
property OnGetEditText: TGetEditEvent;
```

C++

```
__property TGetEditEvent OnGetEditText;
```

Description

Write an OnGetEditText event handler to provide the in-place editor with a string representing the contents of the cell. Set the Value parameter to the string for the cell specified by the ACol and ARow parameters. When the cell enters edit mode, the contents of the cell are drawn as the Value string returned by the OnGetEditText event handler. This image need not match the appearance of the cell when it is not in edit mode, which is drawn using the OnDrawCell event handler.

OnGetEditText does not occur unless the Options property includes goEditing.

Delphi Examples:

```
{
The following code lowercases the text for a string grid
cell when the user begins to edit it.
}
procedure TForm1.StringGrid1GetEditText(Sender: TObject; ACol, ARow: Longint; var Value:
string);
begin
  Value := AnsiLowerCase(Value);
end;
```

168.1.2.6.14 TValueListEditor.OnGetPickList Event

Supplies a pick list for values associated with a particular key.

Pascal

```
property OnGetPickList: TGetPickListEvent;
```

C++

```
__property TGetPickListEvent OnGetPickList;
```

Description

Write an OnGetPickList event handler to provide a drop-down list of values for specific names from the first (key) column. OnGetPickList is called when the value column gets focus and the name (key) column contains the string specified by KeyName.

If the ItemProps (see page 23445) property has an EditStyle of esPickList for this item, The Values (see page 23457) parameter of the event handler is initialized to the value of its PickList property for this item. Otherwise, Values (see page 23457) is initialized to an empty list. In either case, the event handler can change the list of values that appear in the drop-down pick list.

If the OnGetPickList event handler exits with a non-empty string list as the value of the Values (see page 23457) parameter, a drop-down arrow appears in the value column. The user can click this arrow button to display the pick list you supplied as the value of Values (see page 23457). This makes the Value column behave like a drop-down combo box: the user can select items from the list or type in an entirely different value.

168.1.2.6.15 TValueListEditor.OnKeyDown Event

Occurs when a user presses any key while the control has focus.

Pascal

```
property OnKeyDown: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyDown;
```

Description

Use the OnKeyDown event handler to specify special processing to occur when a key is pressed. The OnKeyDown handler can respond to keyboard keys, including function keys and keys combined with the `Shift`, `Alt`, and `Ctrl` keys, and pressed mouse buttons.

Note: TCheckBox does not fire OnKeyDown events for arrow keys.

The TKeyEvent type points to a method that handles keyboard events.

The Key parameter is the key on the keyboard. For non-alphanumeric keys, use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

```
void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
}
var
  FormColor: TColor;
procedure TForm1.FormCreate(Sender: TObject);
begin
  KeyPreview := True;
  FormColor := Form1.Color;
end;

procedure TForm1.FormKeyDown(
  Sender: TObject; var Key: Word; Shift: TShiftState);
begin
  if Key = VK_F1 then
  begin
    Form1.Color := clAqua;
    if (ComboBox1.Text = 'KeyDown') then
      ComboBox1.Text := 'KeyDown2'
    else
      ComboBox1.Text := 'KeyDown';
    WriteLn(ComboBox1.Text);
  end;
end;

procedure TForm1.FormKeyUp(
  Sender: TObject; var Key: Word; Shift: TShiftState);

  if Key = VK_F1 then
  begin
    Form1.Color := FormColor;
    if (ComboBox1.Text = 'KeyUp') then
      ComboBox1.Text := 'KeyUp2'
    else
      ComboBox1.Text := 'KeyUp';
    WriteLn(ComboBox1.Text);
  end;
end;
{
The following code aborts a print job if the user presses
Esc. Note that you should set KeyPreview to true to ensure
that the OnKeyDown event handler of Form1 is called.
}

uses Printers;
```

```
procedure TForm1.Button1Click(Sender: TObject);
var
  I, X, Y: Integer;
  Memo1 : TMemo;
  r: TRect;
begin
  Memo1 := TMemo.Create(Form1);
  Memo1.Parent := Form1;
  Memo1.Visible := True;
  Memo1.Width := 700;
  if (OpenDialog1.Execute) then
  begin
    Memo1.Lines.LoadFromFile(OpenDialog1.FileName);

    Printer.BeginDoc;
    X := 200;
    Y := 200;
    for I := 0 to 140 do
      if (not Printer.Aborted) then
      begin
        Printer.Canvas.TextOut(X, Y, Memo1.Lines[I]);
        Y := Y + 80;
        if (Y > (Printer.PageHeight - 300)) then
        begin
          Y := 200;
          Printer.NewPage;
          Sleep(1000);  // to give you time to abort!
        end;
      end;
    if (not Printer.Aborted) then Printer.EndDoc;
  end;
end;

procedure TForm1.FormCreate(Sender: TObject);
begin
   KeyPreview := True;
end;

procedure TForm1.FormKeyDown(Sender: TObject; var Key: Word; Shift: TShiftState);
begin
if (Key=VK_ESCAPE) and Printer.Printing then
  begin
  Printer.Abort;
  MessageDlg('Printing aborted', mtInformation, [mbOK],0);
  end;
end;
```

168.1.2.6.16 TValueListEditor.OnKeyPress Event

Occurs when a key is pressed.

Pascal

```
property OnKeyPress: TKeyPressEvent;
```

C++

```
__property TKeyPressEvent OnKeyPress;
```

Description

Use the OnKeyPress event handler to make something happen as a result of a single character key press.

The Key parameter in the OnKeyPress event handler is of type Char; therefore, the OnKeyPress event registers the ASCII character of the key pressed. Keys that don't correspond to an ASCII Char value (Shift or F1, for example) don't generate an OnKeyPress event. Key combinations (such as Shift+A), generate only one OnKeyPress event (for this example, Shift+A results in a Key value of "A" if Caps Lock is off). To respond to non-ASCII keys or key combinations, use the OnKeyDown or OnKeyUp event handlers.

An application gets Windows WM_KEYDOWN messages for all keys when the user presses a key. These messages indirectly fire the OnKeyDown event. If you set the Key to 0 there you prevent only any further processing of this message. But for keys that generate characters Windows also produces WM_CHAR. At the time your OnKeyDown event fires, the WM_CHAR message for the key will already be in the message queue. Setting Key to 0 does not stop it from being delivered, so it fires the OnKeyPress event. You must set the Key to #0 to prevent the control from intercepting the WM_CHAR message.

This method of organizing key processing has advantages. Code that only deals with characters, including control characters like #13 for carriage return, #3 for Ctrl-C and so on, should go into the OnKeyPress event. Code that deals with keys that do not generate characters should be put into the OnKeyDown event.

C++ Examples:

```
/*
This event handler displays a message dialog box specifying
which key was pressed:
*/

void __fastcall TForm1::FormKeyPress(TObject *Sender, char &Key)
{
  char keyString[25];
  keyString[0] = Key;
  strcpy(&keyString[1], " Was Pressed");
  TMsgDlgButtons() << mbOK;
  MessageDlg(AnsiString(keyString), TMsgDlgType(mtInformation), TMsgDlgButtons() << mbOK, 0);
}
```

Delphi Examples:

```
{
This event handler displays a message dialog box specifying
which key was pressed:
}
procedure TForm1.FormKeyPress(Sender: TObject; var Key: Char);
begin
  MessageDlg(Key + ' has been pressed', mtInformation, [mbOK], 0)
end;
```

168.1.2.6.17 TValueListEditor.OnKeyUp Event

Occurs when the user releases a key that has been pressed.

Pascal

```
property OnKeyUp: TKeyEvent;
```

C++

```
__property TKeyEvent OnKeyUp;
```

Description

Use the OnKeyUp event handler to provide special processing that occurs when a key is released. The OnKeyUp handler can respond to all keyboard keys, including function keys and keys combined with the Shift, Alt, and Ctrl keys.

The TKeyEvent type points to a method that handles keyboard events. The Key parameter is the key on the keyboard. For non-alphanumeric keys, you must use virtual key codes to determine the key pressed. For more information, see Virtual Key codes.

The Shift parameter indicates whether the Shift, Alt, or Ctrl keys are combined with the keystroke.

C++ Examples:

```
/*
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
event to FormKeyUp.  Set the KeyPreview on the form to True.
*/
void __fastcall TForm1::FormKeyDown(TObject *Sender, WORD &Key,
      TShiftState Shift)
{
  if (Key == VK_F1)
  {
    FormColor = Form1->Color;
    Form1->Color = clAqua;
    if (ComboBox1->Text == "KeyDown")
      ComboBox1->Text = "KeyDown2";
    else
      ComboBox1->Text = "KeyDown";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}

void __fastcall TForm1::FormKeyUp(TObject *Sender, WORD &Key, TShiftState Shift)
{
  if (Key == VK_F1)
  {
    Form1->Color = FormColor;
    if (ComboBox1->Text == "KeyUp")
      ComboBox1->Text = "KeyUp2";
    else
      ComboBox1->Text = "KeyUp";
    Form1->Refresh();
    Memo1->Lines->Add(ComboBox1->Text);
  }
}
```

Delphi Examples:

```
{
This example changes a form's color to aqua when the user
presses the F1 key, even when a control on the form has the
focus. When the user releases the key, the form returns to
its original color.  Set the KeyPreview on the form to True.
Set the OnKeyDown event to FormKeyDown and set the OnKeyUp
```

```
  event to FormKeyUp.  Set the KeyPreview on the form to True.
  }
  var
    FormColor: TColor;
  procedure TForm1.FormCreate(Sender: TObject);
  begin
    KeyPreview := True;
    FormColor := Form1.Color;
  end;

  procedure TForm1.FormKeyDown(
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := clAqua;
      if (ComboBox1.Text = 'KeyDown') then
        ComboBox1.Text := 'KeyDown2'
      else
        ComboBox1.Text := 'KeyDown';
      WriteLn(ComboBox1.Text);
    end;
  end;

  procedure TForm1.FormKeyUp(
    Sender: TObject; var Key: Word; Shift: TShiftState);
  begin
    if Key = VK_F1 then
    begin
      Form1.Color := FormColor;
      if (ComboBox1.Text = 'KeyUp') then
        ComboBox1.Text := 'KeyUp2'
      else
        ComboBox1.Text := 'KeyUp';
      WriteLn(ComboBox1.Text);
    end;
  end;
```

168.1.2.6.18 TValueListEditor.OnMouseActivate Event

Occurs when the user presses a mouse button with the mouse pointer over a control and the parent form is not active.

Pascal

```
property OnMouseActivate: TMouseActivateEvent;
```

C++

```
__property TMouseActivateEvent OnMouseActivate;
```

Description

Use the OnMouseActivate event handler to implement any special processing that should occur as a result of pressing a mouse button on a control when the parent top-level form is not active.

The event type is:

```
TMouseActivateEvent = procedure (Sender: TObject; Button: TMouseButton; ShiftState:
TShiftState;
X, Y: Integer; HitTest: Integer; var MouseActivate: TMouseActivate) of object;
```

When you click on a control and the parent top-level form is not active, this event fires on the control that the mouse cursor is over. MouseActivate is a protected virtual function in TControl. MouseActivate can be overridden in custom control descendants to provide special built-in processing of the OnMouseActivate events. If you leave the default value of MouseActivate as maDefault, the parent control fires the OnMouseActivate event and repeats the process all the way up to the top-level form. If no control in the chain sets the value of MouseActivate, the behavior is the same as if a control set TMouseActivate to maActivate. At any point, a control can set the value of TMouseActivate and the parent processing stops.

Some controls set focus to themselves when they get a button down message so, in some cases, setting maNoActivate appears to have no effect. For instance, a TButton control sets focus to itself in the WM_LBUTTONDOWN message regardless of whether or not TMouseActivate is set to maNoActivate. In this case, setting maNoActivateAndEat will work because the top-level form is not activated and the WM_LBUTTONDOWN message is suppressed.

The HitTest parameter is the hit test value obtained from the WM_NCHITTEST message. See Windows.pas for valid values and their meanings. In most cases this value will be HTCLIENT, which means that the user clicked in the client area of a control. However, in the case of a top-level form, this can take other values such as HTCAPTION, or HTBOTTOM. This allows the code to decide which value to set for MouseActivate, based on the HitTest code. For example, the following code in the OnMouseActivate event handler for a TForm forces the user to click into a non-client area to activate the form:

```
if HitTest = HTCLIENT then
    MouseActivate := maNoActivateAndEat;
```

Even though this event is tied to how Windows processes WM_MOUSEACTIVATE, the actual handling of the message is done at the TControl level, which is the point in the VCL hierarchy where the control has no window handle. The OnMouseActivate event is then simulated since the all TControl descendants also have OnMouseDown, OnMouseMove, and OnMouseUp events. This information is applicable to both VCL Win32 and VCL.NET.

168.1.2.6.19 TValueListEditor.OnMouseDown Event

Occurs when the user presses a mouse button with the mouse pointer over a control.

Pascal

```
property OnMouseDown: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseDown;
```

Description

Use the OnMouseDown event handler to implement any special processing that should occur as a result of pressing a mouse button.

The OnMouseDown event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
```

```
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form's unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled

168.1.2.6.20 TValueListEditor.OnMouseEnter Event

Occurs when the user moves the mouse into a control.

Pascal

```
property OnMouseEnter: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseEnter;
```

Description

Use the OnMouseEnter event handler to implement any special processing that should occur as a result of moving the mouse into a control when the parent top-level form is not active.

168.1.2.6.21 TValueListEditor.OnMouseLeave Event

Occurs when the user moves the mouse outside of a control.

Pascal

```
property OnMouseLeave: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnMouseLeave;
```

Description

Use the OnMouseLeave event handler to implement any special processing that should occur as a result of moving the mouse outside of a control when the parent top-level form is not active.

168.1.2.6.22 TValueListEditor.OnMouseMove Event

Occurs when the user moves the mouse pointer while the mouse pointer is over a control.

Pascal

```
property OnMouseMove: TMouseMoveEvent;
```

C++

```
__property TMouseMoveEvent OnMouseMove;
```

Description

Use the OnMouseMove event handler to respond when the mouse pointer moves after the control has captured the mouse.

Use the Shift parameter of the OnMouseDown event handler, to determine to the state of the shift keys and mouse buttons. Shift keys are the Shift, Ctrl, and Alt keys or shift key-mouse button combinations. X and Y are pixel coordinates of the new location of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form’s unit
```

```
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
```

```
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;
    if X > StartX then
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(StartX);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(X);
      end
    else
      begin
      StatusBar1.Panels[1].Text := 'Left: ' + IntToStr(X);
      StatusBar1.Panels[3].Text := 'Right: ' + IntToStr(StartX);
      end;
  end;
end;

168.1.2.6.23 TValueListEditor.OnMouseUp Event

Occurs when the user releases a mouse button that was pressed with the mouse pointer over a component.

Pascal

```
property OnMouseUp: TMouseEvent;
```

C++

```
__property TMouseEvent OnMouseUp;
```

Description

Use an OnMouseUp event handler to implement special processing when the user releases a mouse button.

The OnMouseUp event handler can respond to left, right, or center mouse button presses and shift key plus mouse-button combinations. Shift keys are the Shift, Ctrl, and Alt keys. X and Y are the pixel coordinates of the mouse pointer in the client area of the Sender.

C++ Examples:

```
/*
The following example requires a form with a four-paneled
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form’s canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
*/
int StartX, StartY; // Declare at the top of the form’s unit
// Use this code as the OnMouseDown event handler of the form:
void __fastcall TForm1::FormMouseDown(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  StartX = X;
  StartY = Y;
}

// Use this code as the OnMouseUp event handler of the form:
void __fastcall TForm1::FormMouseUp(TObject *Sender, TMouseButton Button, TShiftState Shift,
int X, int Y)
{
  Form1->Canvas->Rectangle(StartX, StartY, X, Y);
  StatusBar1->Panels->Items[0]->Text = "";
  StatusBar1->Panels->Items[1]->Text = "";
  StatusBar1->Panels->Items[2]->Text = "";
  StatusBar1->Panels->Items[3]->Text = "";
}

// Use this code as the OnMouseMove event handler of the form:
void __fastcall TForm1::FormMouseMove(TObject *Sender, TShiftState Shift, int X, int Y)
{
  if (Shift.Contains(ssLeft)) // make sure button is down
  {
    if (Y > StartY)
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(StartY);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(Y);
    }
    else
    {
      StatusBar1->Panels->Items[0]->Text = "Top: " + IntToStr(Y);
      StatusBar1->Panels->Items[2]->Text = "Bottom: " + IntToStr(StartY);
    }
    if (X > StartX)
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(StartX);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(X);
    }
    else
    {
      StatusBar1->Panels->Items[1]->Text = "Left: " + IntToStr(X);
      StatusBar1->Panels->Items[3]->Text = "Right: " + IntToStr(StartX);
    }
  }
}
```

Delphi Examples:

```
{
The following example requires a form with a four-paneled
```

```
status bar.  (Set the Width of the status panels to 150
before running this example).  When the user presses a mouse
button, moves the mouse, and releases the mouse button, a
rectangle is drawn on the form. When the mouse button is
released, the rectangle appears on the form's canvas. Its
top-left and bottom-right corners are defined by the
location of the mouse pointer when the user pressed and
released the mouse button.  While the user drags the mouse,
the location of the top, left, bottom, and right sides of
the rectangle are displayed in the status bar.
}
procedure TForm1.FormMouseDown(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X,
Y: Integer);
begin
  StartX := X;
  StartY := Y;
end;

procedure TForm1.FormMouseUp(Sender: TObject; Button: TMouseButton; Shift: TShiftState; X, Y:
Integer);
begin
  Form1.Canvas.Rectangle(StartX, StartY, X, Y);
  StatusBar1.Panels[0].Text := '';
  StatusBar1.Panels[1].Text := '';
  StatusBar1.Panels[2].Text := '';
  StatusBar1.Panels[3].Text := '';
end;

procedure TForm1.FormMouseMove(Sender: TObject; Shift: TShiftState; X, Y: Integer);
begin
  if ssLeft in Shift then { make sure button is down }
  begin
    if Y > StartY then
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(StartY);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(Y);
      end
    else
      begin
      StatusBar1.Panels[0].Text := 'Top: ' + IntToStr(Y);
      StatusBar1.Panels[2].Text := 'Bottom: ' + IntToStr(StartY);
      end;

Responding to a Mouse-up Action

168.1.2.6.24 TValueListEditor.OnMouseWheelDown Event

Occurs when the mouse wheel is rotated downward.

Pascal

```
property OnMouseWheelDown: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelDown;
```

Description

Write code in the OnMouseWheelDown event handler to perform actions when the mouse wheel is rotated downward. OnMouseWheelDown occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheel (see page 5869)

OnMouseWheelUp (see page 5870)

168.1.2.6.25 TValueListEditor.OnMouseWheelUp Event

Occurs when the mouse wheel is rotated upward.

Pascal

```
property OnMouseWheelUp: TMouseWheelUpDownEvent;
```

C++

```
__property TMouseWheelUpDownEvent OnMouseWheelUp;
```

Description

Write code in the OnMouseWheelUp event handler to perform actions when the mouse wheel is rotated upward. OnMouseWheelUp occurs only if the message is not already handled in an OnMouseWheel event handler.

See Also

OnMouseWheelDown (see page 5869)

OnMouseWheel (see page 5869)

168.1.2.6.26 TValueListEditor.OnRowMoved Event

Occurs immediately after the position of a row changes.

Pascal

```
property OnRowMoved: TMovedEvent;
```

C++

```
__property TMovedEvent OnRowMoved;
```

Description

Write an OnRowMoved event handler to provide special processing whenever a row in the grid changes position. Rows can be moved programmatically or by user manipulation. OnRowMoved does not occur unless the Options property includes goRowMoving.

Delphi Examples:

```
{
The following code displays the number of rows a row was
moved in a label.  To move rows in a TStringGrid, goRowMoving
must be included in the Options property.
}
procedure TForm1.StringGrid1RowMoved(Sender: TObject; FromIndex, ToIndex: Longint);
begin
  Label1.Caption := IntToStr(Abs(FromIndex-ToIndex));
end;
```

See Also

OnColumnMoved (see page 14794)

Options (see page 14853)

168.1.2.6.27 TValueListEditor.OnSelectCell Event

Occurs before a cell in the grid is selected.

Pascal

```
property OnSelectCell: TSelectCellEvent;
```

C++

```
__property TSelectCellEvent OnSelectCell;
```

Description

Write an OnSelectCell event handler to specify whether any particular cell in the grid can be selected. The Col and Row parameters indicate the column and row indexes of the cell that is about to be selected. Set the CanSelect parameter to false to prevent the cell being selected.

C++ Examples:

```
/*
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
*/
void __fastcall TForm1::DrawGrid1DrawCell(
  TObject *Sender, int ACol, int ARow, TRect &Rect, TGridDrawState State)
{
  long index = ARow * DrawGrid1->ColCount + ACol;
  DrawGrid1->Canvas->Brush->Color = clBackground;
  DrawGrid1->Canvas->FillRect(Rect);
  ImageList1->Draw(DrawGrid1->Canvas,Rect.Left,Rect.Top,index);
  if (State.Contains(gdFocused))
  {
    DrawGrid1->Canvas->DrawFocusRect(Rect);
    Label1->Caption = "Cell " + IntToStr(index) + " has the focus.";
  }
  ImageList1->Draw(
    DrawGrid1->Canvas, Rect.Left, Rect.Top, index, True);
}
//---------------------------------------------------------------------------
void __fastcall TForm1::DrawGrid1SelectCell(TObject *Sender, int ACol, int ARow,
      bool &CanSelect)
{
  CanSelect= True;
}
```

Delphi Examples:

```
{
The following code uses the bitmaps in an image list
component to draw the contents of each cell in a draw grid.
It draws a focus rectangle around the cell that has focus.
goDrawFocusSelect in the DrawGrid Options parameter must be
True to set focus on a cell.  The ImageList Draw method must
be called after DrawFocusRect. The OnSelectCell event handler
must implemented to return true.
}
procedure TForm1.DrawGrid1DrawCell(Sender: TObject; ACol, ARow: Integer;
  Rect: TRect; State: TGridDrawState);
var
  index: Integer;
begin
  index := ARow * DrawGrid1.ColCount + ACol;
  DrawGrid1.Canvas.Brush.Color := clWhite;
  DrawGrid1.Canvas.FillRect(Rect);
  if (gdFocused in State) then
  begin
    DrawGrid1.Canvas.DrawFocusRect(Rect);
    Label1.Caption:= 'Cell ' + InttoStr(index) + ' has the focus.';
  end;
  ImageList1.Draw(DrawGrid1.Canvas,Rect.Left,Rect.Top,index, True);
end;

procedure TForm1.DrawGrid1SelectCell(Sender: TObject; ACol, ARow: Integer;
  var CanSelect: Boolean);
begin
  CanSelect:= True;
end;
{
The following code ensures that the user cannot select a cell unless it is empty.
}
procedure TForm1.StringGrid1SelectCell(Sender: TObject; ACol, ARow: Longint; var CanSelect:
Boolean);
begin
  CanSelect := (StringGrid1.Cells[ACol, ARow]='')
end;
```

See Also

Col (see page 14843)

Row (see page 14854)

TabStops (see page 14858)

168.1.2.6.28 TValueListEditor.OnSetEditText Event

Occurs when the user edits the value of a cell.

Pascal

```
property OnSetEditText: TSetEditEvent;
```

C++

```
__property TSetEditEvent OnSetEditText;
```

Description

Write an OnSetEditText event handler to perform any special processing of the text edited by the user in an in-place editor. For example, use the OnSetEditText event to retrieve and store the value of a cell so that it can be displayed in an OnDrawCell event handler. OnSetEditText occurs every time the user changes the text.

The Value parameter is the new value for the cell specified by the ACol and ARow parameters.

OnSetEditText does not occur unless the Options property includes goEditing.

See Also

OnDrawCell (see page 14795)

OnGetEditText (see page 14797)

Options (see page 14853)

168.1.2.6.29 TValueListEditor.OnStartDock Event

Occurs when the user begins to drag a control with a DragKind of dkDock.

Pascal

```
property OnStartDock: TStartDockEvent;
```

C++

```
__property TStartDockEvent OnStartDock;
```

Description

Use the OnStartDock event handler to implement special processing when the user starts a drag-and-dock operation by dragging the control.

The OnStartDock event handler can create a TDragDockObjectEx object for the DragObject parameter to specify the appearance of the dragging rectangle and how the dragged control interacts with potential docking sites. If you return TDragDockObjectEx as the drag object, there is no need to call the Free method for the DragObject when dragging is over. If you use TDragDockObject, your application is responsible for freeing the drag object.

If the OnStartDock event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragDockObject object is automatically created.

Note: This information applies to Win32 applications only.

See Also

OnEndDock (see page 5859)

TDragDockObjectEx (see page 6018)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDockDrop (see page 6214)

168.1.2.6.30 TValueListEditor.OnStartDrag Event

Occurs when the user begins to drag the control or an object it contains by left-clicking on the control and holding the mouse button down.

Pascal

```
property OnStartDrag: TStartDragEvent;
```

C++

```
__property TStartDragEvent OnStartDrag;
```

Description

Use the OnStartDrag event handler to implement special processing when the user starts to drag the control or an object it contains. OnStartDrag only occurs if DragKind is dkDrag.

Sender is the control that is about to be dragged, or that contains the object about to be dragged.

The OnStartDrag event handler can create a TDragControlObjectEx instance for the DragObject parameter to specify the drag cursor, or, optionally, a drag image list. If you create a TDragControlObjectEx instance, there is no need to call the Free method for the DragObject when dragging is over. If you create, instead, a TDragControlObject instance, your application is responsible for freeing the drag object instance.

If the OnStartDrag event handler sets the DragObject parameter to nil (Delphi) or NULL (C++), a TDragControlObject object is automatically created and dragging begins on the control itself.

Note: On some controls, such as TRichEdit, the underlying Windows control handles internal drag operations. For these controls, there are no OnStartDrag or OnEndDrag events for drag operations within the control.

OnEndDrag (see page 5860)

TDragControlObjectEx (see page 6007)

DragKind (see page 5819)

OnDragOver (see page 5857)

OnDragDrop (see page 5855)

168.1.2.6.31 TValueListEditor.OnStringsChange Event

Occurs immediately after the names or values in the string list change.

Pascal

```
property OnStringsChange: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnStringsChange;
```

Description

Write an OnStringsChange event handler to respond when the strings in the list change. For example, you can use the OnStringsChange event to update your display to reflect the new values of the strings in the value list editor.

OnStringsChange occurs after the change is complete. The properties of the value list editor reflect the new values of the strings.

See Also

OnStringsChanging (see page 23496)

Strings (see page 23456)

OnSetEditText (see page 14800)

168.1.2.6.32 TValueListEditor.OnStringsChanging Event

Occurs immediately before the names or values in the string list change.

Pascal

```
property OnStringsChanging: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnStringsChanging;
```

Description

Write an OnStringsChanging event handler to prepare for changes in the list of strings. For example, you can use the OnStringsChanging event to disable repaints until the OnStringsChange (see page 23496) event when the list has finished changing..

OnStringsChanging occurs before the change occurs. The properties of the value list editor reflect the old values of the strings.

See Also

OnStringsChange (see page 23496)

Strings (see page 23456)

OnSetEditText (see page 14800)

168.1.2.6.33 TValueListEditor.OnTopLeftChanged Event

Occurs immediately after the TopRow property or the LeftCol property changes.

Pascal

```
property OnTopLeftChanged: TNotifyEvent;
```

C++

```
__property TNotifyEvent OnTopLeftChanged;
```

Description

Use OnTopLeftChanged to perform special processing when the non-fixed cells in the grid are scrolled.

See Also

LeftCol (see page 14852)

TopRow (see page 14858)

168.1.2.6.34 TValueListEditor.OnValidate Event

Occurs when focus shifts away from a cell in the value list editor.

Pascal

```
property OnValidate: TOnValidateEvent;
```

C++

```
__property TOnValidateEvent OnValidate;
```

Description

Write an OnValidate event handler to validate any edits the user enters in a cell before focus leaves it. OnValidate gives applications an opportunity to provide more validation than the EditMask property of the corresponding TItemProp (see page 23394) object can supply.

OnValidate only occurs if the user edited the value of the cell that is about to lose focus. The OnValidate event handler can verify the value the user supplied, and if it is not acceptable, raise an exception.

168.1.3 TValueListStrings Class

Class Hierarchy

System::TObject → Classes.TPersistent → Classes.TStrings → Classes.TStringList → ValEdit.TValueListStrings

Pascal

```
TValueListStrings = class(TStringList);
```

C++

```
class TValueListStrings : public TStringList;
```

File

ValEdit

Description

This is class ValEdit.TValueListStrings.

168.1.3.1 TValueListStrings Members

The following tables list the members exposed by TValueListStrings.

Protected Methods

	Name	Description
	AssignTo (see page 2931)	Copies the properties of an object to a destination object.
	Changed (see page 23504)	This is Changed, a member of class TValueListStrings.
	Changing (see page 23505)	This is Changing, a member of class TValueListStrings.
	CompareStrings (see page 3014)	Compares two strings.
	CompareStrings (see page 3048)	Compares two strings.
	DefineProperties (see page 2931)	Provides an interface for a method that reads and writes otherwise unpublished data.
	DefineProperties (see page 3049)	Reads and writes the Strings (see page 3080) property as if it were published.
	Error (see page 3052)	This is the overview for the Error method overload.
	ExtractName (see page 3053)	Returns the name portion of a string that is a name value pair.
	FindItemProp (see page 23507)	This is FindItemProp, a member of class TValueListStrings.
	Get (see page 3017)	Returns a string given its index.
	Get (see page 3053)	Returns a string given its index.
	GetCapacity (see page 3017)	Returns the currently allocated size of the list of strings.
	GetCapacity (see page 3054)	Returns the currently allocated size of the list of strings.
	GetCount (see page 3018)	Returns the number of strings in the list
	GetCount (see page 3054)	Returns the number of strings in the list
	GetObject (see page 3018)	Returns the object associated with the string at a specified index.
	GetObject (see page 3055)	Returns the object associated with the string at a specified index.
	GetOwner (see page 2932)	Returns the owner of an object.
	GetTextStr (see page 3056)	Returns the value of the Text (see page 3084) property.
	InsertItem (see page 23507)	This is InsertItem, a member of class TValueListStrings.

	Put (see page 23507)	This is Put, a member of class TValueListStrings.
	PutObject (see page 3022)	Changes the object associated with the string at a specified index.
	PutObject (see page 3065)	Changes the object associated with the string at a specified index.
	SetCapacity (see page 3022)	Changes the amount of memory allocated to hold strings in the list.
	SetCapacity (see page 3068)	Changes the amount of memory allocated to hold strings in the list.
	SetTextStr (see page 3069)	Sets the Text (see page 3084) property.
	SetUpdateState (see page 3023)	Performs internal adjustments before or after a series of updates.
	SetUpdateState (see page 3069)	Performs internal adjustments before or after a series of updates.

Protected Properties

	Name	Description
	UpdateCount (see page 3085)	Indicates the number of calls to BeginUpdate (see page 3045) that have not been matched by a call to EndUpdate (see page 3050).

Public Events

	Name	Description
	OnChange (see page 3028)	Occurs immediately after the list of strings changes.
	OnChanging (see page 3028)	Occurs immediately before the list of strings changes.

Public Methods

	Name	Description
	Add (see page 3010)	Adds a new string to the list.
	Add (see page 3033)	Adds a string at the end of the list.
	AddObject (see page 3012)	Adds a string to the list, and associates an object with the string.
	AddObject (see page 3036)	Adds a string to the list, and associates an object with the string.
	AddStrings (see page 3039)	Adds a group of strings to the list.
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	Append (see page 3041)	Adds a string to the list.
	Assign (see page 23502)	Sets the strings in the list, and possibly associated objects, from a source object.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BeginUpdate (see page 3045)	Enables the TStrings (see page 3029) object to track when the list of strings is changing.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 23505)	Deletes all the strings from the list.
	Create (see page 23501)	This is Create, a member of class TValueListStrings.
	CustomSort (see page 23505)	Sorts the strings in the list in a customized order.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Delete (see page 23506)	Removes the string specified by the Index parameter.
	Destroy (see page 23501)	Destroys an instance of TStringList.
	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	EndUpdate (see page 3050)	Enables the TStrings (see page 3029) object to keep track of when the list of strings has finished changing.
	Equals (see page 3051)	Compares the list of strings to the list from another TStrings (see page 3029) object and returns true if the two lists match.
	Exchange (see page 23506)	Swaps the position of two strings in the list.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Find (see page 3016)	Locates the index for a string in a sorted list and indicates whether a string with that value already exists in the list.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.

V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetEnumerator (see page 3054)	Returns a TStrings (see page 3029) enumerator.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	GetNamePath (see page 2932)	Returns the name of the object as it appears in the Object Inspector.
V	GetText (see page 3055)	Allocates a text buffer and fills it with the value of the Text (see page 3084) property.
V	IndexOf (see page 3019)	Returns the position of a string in the list.
V	IndexOf (see page 3056)	Returns the position of a string in the list.
V	IndexOfName (see page 3057)	Returns the position of the first name-value pair with the specified name.
V	IndexOfObject (see page 3059)	Returns the index of the first string in the list associated with a given object.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
V	Insert (see page 3019)	Inserts a string to the list at the position specified by Index.
A	Insert (see page 3059)	Introduces abstract (Delphi) or pure virtual (C++) method to insert a string at a specified position.
V	InsertObject (see page 3020)	Inserts a string into the list at the specified position, and associates it with an object.
V	InsertObject (see page 3060)	Inserts a string into the list at the specified position, and associates it with an object.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	KeyIsValid (see page 23507)	This is KeyIsValid, a member of class TValueListStrings.
V	LoadFromFile (see page 3061)	Fills the list with the lines of text in a specified file.
V	LoadFromStream (see page 3062)	Fills the list with lines of text read from a stream.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	Move (see page 3063)	Changes the position of a string in the list.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	SaveToFile (see page 3065)	Saves the strings in the list to the specified file.
V	SaveToStream (see page 3067)	Writes the value of the Text (see page 3084) property to a stream object.
V	SetText (see page 3068)	Sets the Text (see page 3084) property.
V	Sort (see page 3023)	Sorts the strings in the list in ascending order.

Public Properties

	Name	Description
	Capacity (see page 3070)	Indicates the number of strings the TStrings (see page 3029) object can hold.
	CaseSensitive (see page 3025)	Controls (see page 5711) whether strings are located, sorted, and identified as duplicates in a case-sensitive or case-insensitive manner.
	CommaText (see page 3070)	Lists the strings in the TStrings (see page 3029) object in system data format (SDF).
R	Count (see page 3071)	Introduces an abstract property to represent the number of strings in the list.
	DelimitedText (see page 3074)	Represents all the strings in the TStrings (see page 3029) object as a single delimited string.
	Delimiter (see page 3074)	Specifies the delimiter used by the DelimitedText (see page 3074) property.
	Duplicates (see page 3025)	Specifies whether duplicate strings can be added to sorted lists.
	ItemProps (see page 23508)	This is ItemProps, a member of class TValueListStrings.
	LineBreak (see page 3075)	Defines the line break character(s).
R	Names (see page 3075)	Indicates the name part of strings that are name-value pairs.
	NameValueSeparator (see page 3077)	Indicates the character used to separate names from values.
	Objects (see page 3077)	Represents a set of objects that are associated one with each of the strings in the Strings (see page 3080) property.

	QuoteChar (see page 3080)	Specifies the quote character used by the DelimitedText (see page 3074) property.
	Sorted (see page 3026)	Specifies whether the strings in the list should be automatically sorted.
	StrictDelimiter (see page 3080)	Determines how the Delimiter (see page 3074) property is used.
	Strings (see page 3080)	References the strings in the list by their positions.
	StringsAdapter (see page 3084)	Implements an IStringsAdapter (see page 3208) interface for the TStrings (see page 3029) object.
	Text (see page 3084)	Lists the strings in the TStrings (see page 3029) object as a single string with the individual strings delimited by carriage returns and line feeds.
	ValueFromIndex (see page 3085)	Represents the value part of a string with a given index, on strings that are name-value pairs.
	Values (see page 3086)	Represents the value part of a string associated with a given name, on strings that are name-value pairs.

168.1.3.2 TValueListStrings.Create Constructor

Pascal

```
constructor Create(AEditor: TValueListEditor); reintroduce;
```

C++

```
__fastcall TValueListStrings(TValueListEditor AEditor);
```

Description

This is Create, a member of class TValueListStrings.

168.1.3.3 TValueListStrings.Destroy Destructor

Destroys an instance of TStringList.

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TValueListStrings();
```

Description

Do not call Destroy directly in an application. Instead, call Free. Free verifies that the TStringList reference is not nil and only then calls Destroy.

Destroy frees the memory allocated to hold the list of strings and object references before calling the inherited destructor.

See Also

Free (see page 22300)

168.1.3.4 TValueListStrings Methods

The methods of the TValueListStrings class are listed here.

Protected Methods

	Name	Description
	Changed (see page 23504)	This is Changed, a member of class TValueListStrings.
	Changing (see page 23505)	This is Changing, a member of class TValueListStrings.
	FindItemProp (see page 23507)	This is FindItemProp, a member of class TValueListStrings.

	InsertItem (see page 23507)	This is InsertItem, a member of class TValueListStrings.
	Put (see page 23507)	This is Put, a member of class TValueListStrings.

Public Methods

	Name	Description
	Assign (see page 23502)	Sets the strings in the list, and possibly associated objects, from a source object.
	Clear (see page 23505)	Deletes all the strings from the list.
	CustomSort (see page 23505)	Sorts the strings in the list in a customized order.
	Delete (see page 23506)	Removes the string specified by the Index parameter.
	Exchange (see page 23506)	Swaps the position of two strings in the list.
	KeyIsValid (see page 23507)	This is KeyIsValid, a member of class TValueListStrings.

168.1.3.4.1 TValueListStrings.Assign Method

Sets the strings in the list, and possibly associated objects, from a source object.

Pascal

```
procedure Assign(Source: TPersistent); override;
```

C++

```
virtual __fastcall Assign(TPersistent * Source);
```

Description

Use Assign to set the value of the TStrings object from another object. If Source is of type TStrings, the list is set to the list of the source TStrings object, and if associated objects are supported, any associated objects are copied from the Source as well.

If Source is not of type TStrings, the inherited Assign will set the value of the list from any object that supports TStrings in its AssignTo method.

C++ Examples:

```
/*
This example uses a tab control to display the contents of
several files. To run the example, place a tab control on a
form and add a memo control that fits into its client area.
Be sure to leave enough room for the tabs when they appear.
Then add an OpenDialog and a button to the form.  The
"Add a file" button adds a single file to the tabcontrol.
The "Assign files" button removes previous files and can be
used to assign multiple files.  To assign multiple files,
use CNTL Select or SHIFT Select to select files in the
OpenDialog.
*/
void __fastcall TForm1::Add_a_fileClick(TObject *Sender)
{
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    int index = TabControl1->Tabs->Add(OpenDialog1->FileName);
    Memo1->Lines->LoadFromFile(TabControl1->Tabs->Strings[index]);
  }
}

void __fastcall TForm1::Assign_filesClick(TObject *Sender)
{
  OpenDialog1->Options << ofAllowMultiSelect << ofFileMustExist << ofHideReadOnly;
  if (OpenDialog1->Execute())
  {
    TabControl1->Tabs->Assign(OpenDialog1->Files);
    Memo1->Lines->LoadFromFile(TabControl1->Tabs->Strings[TabControl1->TabIndex]);
  }
```

```
}
/*
Place the following code in the tab control's OnChange event
handler:
*/
void __fastcall TForm1::TabControl1Change(TObject *Sender)
{
    Memo1->Lines->LoadFromFile(
      TabControl1->Tabs->Strings[TabControl1->TabIndex]);
}
/*
This example creates a stringlist, adds elements to it and
assigns the strings to items of a combo box.
*/
void __fastcall TForm1::Button1Click(TObject *Sender)
{
  TStrings *StringList = new TStringList();
  try
  {
    StringList->Add("This example uses A string List. ");
    StringList->Add("It is the easiest way to add strings");
    StringList->Add("to a combobox's list of strings. ");
    StringList->Add("Always remember TStrings is abstract,");
    StringList->Add("So create a TStringList instead.");
    ComboBox1->Width = 210;
    ComboBox1->Items->Assign(StringList);
    ComboBox1->ItemIndex = 0;
  }
  __finally
  {
    delete StringList;
  }
}
```

Delphi Examples:

```
{
This example uses a tab control to display the contents of
several files. To run the example, place a tab control on a
form and add a memo control that fits into its client area.
Be sure to leave enough room for the tabs when they appear.
Then add an OpenDialog and a button to the form.  The
"Add a file" button adds a single file to the tabcontrol.
The "Assign files" button removes previous files and can be
used to assign multiple files.  To assign multiple files,
use CNTL Select or SHIFT Select to select files in the
OpenDialog.
}
procedure TForm1.Add_a_fileClick(Sender: TObject);
var index : integer;
begin
  OpenDialog1.Options :=
    [ofAllowMultiSelect, ofFileMustExist, ofHideReadOnly];
  if OpenDialog1.Execute then
  begin
    index:= TabControl1.Tabs.Add(OpenDialog1.FileName);
    Memo1.Lines.LoadFromFile(TabControl1.Tabs[index]);
  end;
end;

procedure TForm1.Assign_filesClick(Sender: TObject);
var index : integer;
begin
  OpenDialog1.Options :=
    [ofAllowMultiSelect, ofFileMustExist, ofHideReadOnly];
  if OpenDialog1.Execute then
  begin
```

```
      TabControl1.Tabs.Assign(OpenDialog1.Files);
      Memo1.Lines.LoadFromFile(
        TabControl1.Tabs[TabControl1.TabIndex]);
    end;
  end;

  {
  Place the following code in the tab control's OnChange event
  handler:
  }
  procedure TForm1.TabControl1Change(Sender: TObject);
  begin
    with TabControl1 do
      Memo1.Lines.LoadFromFile(Tabs[TabIndex]);
  end;
  {
  This example creates a stringlist, adds elements to it and
  assigns the strings to items of a combo box.
  }
  procedure TForm1.Button1Click(Sender: TObject);
  var
    StringList: TStringList;
  begin
    StringList := TStringList.Create;
    try
      with StringList do begin
        Add('This example uses A string List.');
        Add('It is the easiest way to add strings');
        Add('to a combobox''s list of strings.');
        Add('Always remember TStrings.Create method');
        Add('is abstract; So use TStringList.Create');
        Add('method instead.');
      end;
      with ComboBox1 do begin
        Width := 210;
        Items.Assign(StringList);
        ItemIndex := 0;
      end;
    finally
      StringList.free;
    end;
  end;
```

See Also

AddStrings (see page 3039)

Objects (see page 3077)

Strings (see page 3080)

AssignTo (see page 2931)

168.1.3.4.2 TValueListStrings.Changed Method

Pascal

```
procedure Changed; override;
```

C++

```
virtual __fastcall Changed();
```

Description

This is Changed, a member of class TValueListStrings.

168.1.3.4.3 TValueListStrings.Changing Method

Pascal

```
procedure Changing; override;
```

C++

```
virtual __fastcall Changing();
```

Description

This is Changing, a member of class TValueListStrings.

168.1.3.4.4 TValueListStrings.Clear Method

Deletes all the strings from the list.

Pascal

```
procedure Clear; override;
```

C++

```
virtual __fastcall Clear();
```

Description

Call clear to empty the list of strings. All references to associated objects are also removed. However, the objects themselves are not freed.

See Also

Delete (see page 3015)

Objects

Strings

168.1.3.4.5 TValueListStrings.CustomSort Method

Sorts the strings in the list in a customized order.

Pascal

```
procedure CustomSort(Compare: TStringListSortCompare); override;
```

C++

```
virtual __fastcall CustomSort(TStringListSortCompare Compare);
```

Description

Use CustomSort to sort the strings in the list, where the sort order is defined by the Compare parameter.

Supply a value for the Compare function that compares two strings in the string list. The List parameter provides access to the string list, while the Index1 and Index2 parameters identify the strings to be compared.

Do not pass nil (Delphi) or NULL (C++) as the value of the Compare parameter.

Note: You must explicitly call the CustomSort method. Setting the Sorted property only sorts strings using ANSI (Windows) or UTF-8 (Linux) order, as implemented in the Sort method.

See Also

Sort (see page 3023)

Strings

Sorted (see page 3026)

168.1.3.4.6 TValueListStrings.Delete Method

Removes the string specified by the Index parameter.

Pascal

```
procedure Delete(Index: Integer); override;
```

C++

```
virtual __fastcall Delete(int Index);
```

Description

Call Delete to remove a single string from the list. If an object is associated with the string, the reference to the object is removed as well. Index gives the position of the string, where 0 is the first string, 1 is the second string, and so on.

See Also

Add (see page 3010)

AddObject (see page 3012)

Clear (see page 3013)

IndexOf (see page 3019)

InsertObject (see page 3060)

Objects

Strings

168.1.3.4.7 TValueListStrings.Exchange Method

Swaps the position of two strings in the list.

Pascal

```
procedure Exchange(Index1: Integer; Index2: Integer); override;
```

C++

```
virtual __fastcall Exchange(int Index1, int Index2);
```

Description

Call Exchange to rearrange the strings in the list. The strings are specified by their index values in the Index1 and Index2 parameters. Indexes are zero-based, so the first string in the list has an index value of 0, the second has an index value of 1, and so on.

If either string has an associated object, Exchange changes the index of the object as well.

Warning: Do not call Exchange on a sorted list except to swap two identical strings with different associated objects. Exchange does not check whether the list is sorted, and can destroy the sort order of a sorted list.

See Also

Move (see page 3063)

Objects

Sorted (see page 3026)

Strings

168.1.3.4.8 TValueListStrings.FindItemProp Method

Pascal

```
function FindItemProp(const KeyOrIndex: Variant; Create: Boolean = False): TItemProp;
```

C++

```
__fastcall TItemProp FindItemProp(const Variant KeyOrIndex, Boolean Create = False);
```

Description

This is FindItemProp, a member of class TValueListStrings.

168.1.3.4.9 TValueListStrings.InsertItem Method

Pascal

```
procedure InsertItem(Index: Integer; const S: string; AObject: TObject); override;
```

C++

```
virtual __fastcall InsertItem(int Index, const AnsiString S, TObject * AObject);
```

Description

This is InsertItem, a member of class TValueListStrings.

168.1.3.4.10 TValueListStrings.KeyIsValid Method

Pascal

```
function KeyIsValid(const Key: string; RaiseError: Boolean = True): Boolean;
```

C++

```
__fastcall Boolean KeyIsValid(const AnsiString Key, Boolean RaiseError = True);
```

Description

This is KeyIsValid, a member of class TValueListStrings.

168.1.3.4.11 TValueListStrings.Put Method

Pascal

```
procedure Put(Index: Integer; const S: String); override;
```

C++

```
virtual __fastcall Put(int Index, const AnsiString S);
```

Description

This is Put, a member of class TValueListStrings.

168.1.3.5 TValueListStrings Properties

The properties of the TValueListStrings class are listed here.

Public Properties

	Name	Description
	ItemProps (see page 23508)	This is ItemProps, a member of class TValueListStrings.

168.1.3.5.1 TValueListStrings.ItemProps Property

Pascal

```
property ItemProps [const KeyOrIndex: Variant]: TItemProp;
```

C++

```
__property TItemProp ItemProps[Variant const KeyOrIndex];
```

Description

This is ItemProps, a member of class TValueListStrings.

168.2 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TDisplayOption (see page 23509)	TDisplayOption and TDisplayOptions (see page 23511) control the appearance of a value list editor.
	TKeyOption (see page 23510)	TKeyOption and TKeyOptions (see page 23512) indicate the response of a value list editor to certain keystrokes.

168.2.1 ValEdit.TDisplayOption Enumeration

TDisplayOption and TDisplayOptions (see page 23511) control the appearance of a value list editor.

Pascal

```
TDisplayOption = (
  doColumnTitles,
  doAutoColResize,
  doKeyColFixed
);
```

C++

```
enum TDisplayOption {
  doColumnTitles,
  doAutoColResize,
  doKeyColFixed
};
```

File

ValEdit

Description

TDisplayOption is a set of TDisplayOptions (see page 23511) values. The possible values of TDisplayOptions (see page 23511) are

Option	Meaning
doColumnTitles	The first row of the value list editor is a fixed (nonscrolling) row that displays the captions specified by the TitleCaptions property.
doAutoColResize	When the editor is resized, the column widths automatically adjust so that they completely fill the new width of the editor. If DisplayOptions does not include doKeyColFixed, each column has a width equal to half the width of the editor. Otherwise, the value column takes up any space left over after the fixed (key) column.
doKeyColFixed	The first (key) column of the value list editor is fixed in width. When the value list editor is resized, only the second (value) column resizes. This option is only used when DisplayOptions includes doAutoColResize.

168.2.2 ValEdit.TKeyOption Enumeration

TKeyOption and TKeyOptions (see page 23512) indicate the response of a value list editor to certain keystrokes.

Pascal

```
TKeyOption = (
  keyEdit,
  keyAdd,
  keyDelete,
  keyUnique
);
```

C++

```
enum TKeyOption {
  keyEdit,
  keyAdd,
  keyDelete,
  keyUnique
};
```

File

ValEdit

Description

TKeyOption is a set of TKeyOptions (see page 23512) values. The possible values of TKeyOptions (see page 23512) are

Option	Meaning
keyEdit	The user can select and edit values in the first (key) column. That is, the user can specify the name in a name/value pair.
keyAdd	The user can add new name/value pairs. When included, the user can create new entries by pressing the Insert key or using the down arrow key when positioned on the last name/value pair. keyAdd requires that keyEdit is also included.
keyDelete	The user can delete the selected name/value pair by pressing the Delete key.
keyUnique	The user can't create name/value pairs where the name portion is the same as the name in another name/value pair. Attempting to add a duplicate name causes the value list editor to raise an exception. keyUnique requires that keyEdit is also included.

168.3 Types

The following table lists types in this documentation.

Types

Name	Description
TDisplayOptions (see page 23511)	This is type ValEdit.TDisplayOptions.
TGetPickListEvent (see page 23511)	This is type ValEdit.TGetPickListEvent.
TItemProps (see page 23512)	This is type ValEdit.TItemProps.
TKeyOptions (see page 23512)	This is type ValEdit.TKeyOptions.
TOnValidateEvent (see page 23512)	This is type ValEdit.TOnValidateEvent.

168.3.1 ValEdit.TDisplayOptions Type

Pascal

```
TDisplayOptions = set of TDisplayOption;
```

C++

```
TDisplayOption TDisplayOptions;
```

File

ValEdit

Description

This is type ValEdit.TDisplayOptions.

168.3.2 ValEdit.TGetPickListEvent Type

Pascal

```
TGetPickListEvent = procedure (Sender: TObject; const KeyName: string; Values: TStrings) of
object;
```

C++

```
(Sender: TObject; const KeyName: string; Values: TStrings) ( TGetPickListEvent)();
```

File

ValEdit

Description

This is type ValEdit.TGetPickListEvent.

168.3.3 ValEdit.TItemProps Type

Pascal

```
TItemProps = array of TItemProp;
```

C++

```
array of TItemProp TItemProps;
```

File

ValEdit

Description

This is type ValEdit.TItemProps.

168.3.4 ValEdit.TKeyOptions Type

Pascal

```
TKeyOptions = set of TKeyOption;
```

C++

```
TKeyOption TKeyOptions;
```

File

ValEdit

Description

This is type ValEdit.TKeyOptions.

168.3.5 ValEdit.TOnValidateEvent Type

Pascal

```
TOnValidateEvent = procedure (Sender: TObject; ACol, ARow: Longint; const KeyName, KeyValue:
string) of object;
```

C++

```
(Sender: TObject; ACol, ARow: Longint; const KeyName, KeyValue: string) ( TOnValidateEvent)();
```

File

ValEdit

Description

This is type ValEdit.TOnValidateEvent.

169 VarCmplx Namespace

This is namespace VarCmplx.

Topics

Name	Description
Functions (see page 23515)	The following table lists functions in this documentation.
Variables (see page 23559)	The following table lists variables in this documentation.

Functions

	Name	Description
	VarAsComplex (see page 23516)	Casts an arbitrary Variant so that it is a custom Variant representing a complex number.
	VarComplex (see page 23516)	Returns the Variant type code for custom Variants (see page 23567) that represent complex numbers.
	VarComplexAbs (see page 23517)	Returns the absolute value of a complex number.
	VarComplexAbsSqr (see page 23518)	Returns the square of the absolute value of a complex number.
	VarComplexAngle (see page 23518)	Returns the angle made by a complex number.
	VarComplexArcCos (see page 23519)	Returns the inverse cosine of a complex number.
	VarComplexArcCosH (see page 23520)	Returns the hyperbolic inverse cosine of a complex number.
	VarComplexArcCot (see page 23521)	Returns the inverse cotangent of a complex number.
	VarComplexArcCotH (see page 23522)	Returns the hyperbolic inverse cotangent of a complex number.
	VarComplexArcCsc (see page 23523)	Returns the inverse cosecant of a complex number.
	VarComplexArcCscH (see page 23524)	Returns the hyperbolic inverse cosecant of a complex number.
	VarComplexArcSec (see page 23525)	Returns the inverse secant of a complex number.
	VarComplexArcSecH (see page 23527)	Returns the hyperbolic inverse secant of a complex number.
	VarComplexArcSin (see page 23528)	Returns the inverse sine of a complex number.
	VarComplexArcSinH (see page 23529)	Returns the hyperbolic inverse sine of a complex number.
	VarComplexArcTan (see page 23530)	Returns the inverse tangent of a complex number.
	VarComplexArcTanH (see page 23531)	Returns the hyperbolic inverse tangent of a complex number.
	VarComplexConjugate (see page 23532)	Returns the conjugate of a complex number.
	VarComplexCos (see page 23533)	Returns the cosine of a complex number.
	VarComplexCosH (see page 23534)	Returns the hyperbolic cosine of a complex number.
	VarComplexCot (see page 23535)	Returns the cotangent of a complex number.
	VarComplexCotH (see page 23536)	Returns the hyperbolic cotangent of a complex number.
	VarComplexCreate (see page 23537)	Returns a custom Variant that represents a complex number.
	VarComplexCreate (see page 23537)	Returns a custom Variant that represents a complex number.

	VarComplexCreate (see page 23537)	Returns a custom Variant that represents a complex number.
	VarComplexCreate (see page 23537)	Returns a custom Variant that represents a complex number.
	VarComplexCsc (see page 23538)	Returns the cosecant of a complex number.
	VarComplexCscH (see page 23539)	Returns the hyperbolic cosecant of a complex number.
	VarComplexExp (see page 23540)	Returns the exponential of a complex number.
	VarComplexFromPolar (see page 23541)	Converts a set of polar coordinates to a complex number.
	VarComplexInverse (see page 23541)	Returns the inverse of a complex number.
	VarComplexLn (see page 23542)	Returns the natural log of a complex number.
	VarComplexLog10 (see page 23543)	Returns the log base 10 of a complex number.
	VarComplexLog2 (see page 23543)	Returns the log base 2 of a complex number.
	VarComplexLogN (see page 23544)	Returns the log base N of a complex number.
	VarComplexPower (see page 23545)	Returns the value of a complex number raised to a specified power.
	VarComplexSec (see page 23545)	Returns the secant of a complex number.
	VarComplexSecH (see page 23546)	Returns the hyperbolic secant of a complex number.
	VarComplexSign (see page 23548)	This is function VarCmplx.VarComplexSign.
	VarComplexSimplify (see page 23548)	Reduces a Variant that represents a complex number to one that represents a real value, if possible.
	VarComplexSin (see page 23548)	Returns the sine of a complex number.
	VarComplexSinH (see page 23550)	Returns the hyperbolic sine of a complex number.
	VarComplexSqr (see page 23551)	Returns the square of a complex number.
	VarComplexSqrt (see page 23551)	Returns the square root of a complex number.
	VarComplexTan (see page 23552)	Returns the tangent of a complex number.
	VarComplexTanH (see page 23553)	Returns the hyperbolic tangent of a complex number.
	VarComplexTimesImaginary (see page 23554)	Returns the value of a complex number multiplied by an imaginary number.
	VarComplexTimesNegI (see page 23555)	Returns the value of a complex number multiplied by –i.
	VarComplexTimesPosI (see page 23555)	Returns the value of a complex number multiplied by i.
	VarComplexTimesReal (see page 23556)	Returns the value of a complex number multiplied by a real number.
	VarComplexToPolar (see page 23556)	Computes the polar coordinates that correspond to a custom Variant that represents a complex number.
	VarIsComplex (see page 23557)	Indicates whether a Variant stores its data internally as a complex number.

Variables

Name	Description
ComplexNumberDefuzzAtZero (see page 23559)	This is variable VarCmplx.ComplexNumberDefuzzAtZero.
ComplexNumberSymbol (see page 23559)	This is variable VarCmplx.ComplexNumberSymbol.
ComplexNumberSymbolBeforeImaginary (see page 23560)	This is variable VarCmplx.ComplexNumberSymbolBeforeImaginary.

169.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	VarAsComplex (see page 23516)	Casts an arbitrary Variant so that it is a custom Variant representing a complex number.
	VarComplex (see page 23516)	Returns the Variant type code for custom Variants (see page 23567) that represent complex numbers.
	VarComplexAbs (see page 23517)	Returns the absolute value of a complex number.
	VarComplexAbsSqr (see page 23518)	Returns the square of the absolute value of a complex number.
	VarComplexAngle (see page 23518)	Returns the angle made by a complex number.
	VarComplexArcCos (see page 23519)	Returns the inverse cosine of a complex number.
	VarComplexArcCosH (see page 23520)	Returns the hyperbolic inverse cosine of a complex number.
	VarComplexArcCot (see page 23521)	Returns the inverse cotangent of a complex number.
	VarComplexArcCotH (see page 23522)	Returns the hyperbolic inverse cotangent of a complex number.
	VarComplexArcCsc (see page 23523)	Returns the inverse cosecant of a complex number.
	VarComplexArcCscH (see page 23524)	Returns the hyperbolic inverse cosecant of a complex number.
	VarComplexArcSec (see page 23525)	Returns the inverse secant of a complex number.
	VarComplexArcSecH (see page 23527)	Returns the hyperbolic inverse secant of a complex number.
	VarComplexArcSin (see page 23528)	Returns the inverse sine of a complex number.
	VarComplexArcSinH (see page 23529)	Returns the hyperbolic inverse sine of a complex number.
	VarComplexArcTan (see page 23530)	Returns the inverse tangent of a complex number.
	VarComplexArcTanH (see page 23531)	Returns the hyperbolic inverse tangent of a complex number.
	VarComplexConjugate (see page 23532)	Returns the conjugate of a complex number.
	VarComplexCos (see page 23533)	Returns the cosine of a complex number.
	VarComplexCosH (see page 23534)	Returns the hyperbolic cosine of a complex number.
	VarComplexCot (see page 23535)	Returns the cotangent of a complex number.
	VarComplexCotH (see page 23536)	Returns the hyperbolic cotangent of a complex number.
	VarComplexCreate (see page 23537)	Returns a custom Variant that represents a complex number.
	VarComplexCreate (see page 23537)	Returns a custom Variant that represents a complex number.
	VarComplexCreate (see page 23537)	Returns a custom Variant that represents a complex number.
	VarComplexCreate (see page 23537)	Returns a custom Variant that represents a complex number.
	VarComplexCsc (see page 23538)	Returns the cosecant of a complex number.
	VarComplexCscH (see page 23539)	Returns the hyperbolic cosecant of a complex number.
	VarComplexExp (see page 23540)	Returns the exponential of a complex number.
	VarComplexFromPolar (see page 23541)	Converts a set of polar coordinates to a complex number.
	VarComplexInverse (see page 23541)	Returns the inverse of a complex number.
	VarComplexLn (see page 23542)	Returns the natural log of a complex number.
	VarComplexLog10 (see page 23543)	Returns the log base 10 of a complex number.
	VarComplexLog2 (see page 23543)	Returns the log base 2 of a complex number.
	VarComplexLogN (see page 23544)	Returns the log base N of a complex number.
	VarComplexPower (see page 23545)	Returns the value of a complex number raised to a specified power.
	VarComplexSec (see page 23545)	Returns the secant of a complex number.
	VarComplexSecH (see page 23546)	Returns the hyperbolic secant of a complex number.
	VarComplexSign (see page 23548)	This is function VarCmplx.VarComplexSign.
	VarComplexSimplify (see page 23548)	Reduces a Variant that represents a complex number to one that represents a real value, if possible.
	VarComplexSin (see page 23548)	Returns the sine of a complex number.
	VarComplexSinH (see page 23550)	Returns the hyperbolic sine of a complex number.

	VarComplexSqr (see page 23551)	Returns the square of a complex number.
	VarComplexSqrt (see page 23551)	Returns the square root of a complex number.
	VarComplexTan (see page 23552)	Returns the tangent of a complex number.
	VarComplexTanH (see page 23553)	Returns the hyperbolic tangent of a complex number.
	VarComplexTimesImaginary (see page 23554)	Returns the value of a complex number multiplied by an imaginary number.
	VarComplexTimesNegI (see page 23555)	Returns the value of a complex number multiplied by –i.
	VarComplexTimesPosI (see page 23555)	Returns the value of a complex number multiplied by i.
	VarComplexTimesReal (see page 23556)	Returns the value of a complex number multiplied by a real number.
	VarComplexToPolar (see page 23556)	Computes the polar coordinates that correspond to a custom Variant that represents a complex number.
	VarIsComplex (see page 23557)	Indicates whether a Variant stores its data internally as a complex number.

169.1.1 VarCmplx.VarAsComplex Function

Casts an arbitrary Variant so that it is a custom Variant representing a complex number.

Pascal

```
function VarAsComplex(const AValue: Variant): Variant;
```

C++

```
Variant VarAsComplex(const Variant AValue);
```

File

VarCmplx

Description

VarAsComplex converts the Variant specified by AValue to a custom Variant representing the corresponding complex number. It returns the custom Variant.

If VarAsComplex can't perform the conversion, it raises an EInvalidCast exception.

Complex Variants (see page 23567) are custom Variants (see page 23567) that represent complex numbers. The Variant type supports direct manipulation using the addition, subtraction, multiplication, division (but not integer division), and negation operators. They have 5 published properties: Real, Imaginary, Radius, Theta, and FixedTheta. They can be cast to and from integer types, floating point types, string types, TDateTime values, and boolean values. In addition, the VarCmplx (see page 23513) unit implements a number of global functions for operating on complex Variants (see page 23567).

VarComplexSimplify (see page 23548)

VarAsType

169.1.2 VarCmplx.VarComplex Function

Returns the Variant type code for custom Variants (see page 23567) that represent complex numbers.

Pascal

```
function VarComplex: TVarType;
```

C++

```
TVarType VarComplex();
```

File

VarCmplx

Description

Use VarComplex to obtain the variant type code for custom Variants (see page 23567) that represent complex numbers. The Variant type codes for custom Variants (see page 23567) are dynamically allocated when the application loads the unit that implements them. VarComplex allows the application to identify the Variant type code that is currently used for custom Variants (see page 23567) that represent complex numbers. This type code, however, may not match the type code used by another application that uses a different set of custom Variant types.

Complex Variants (see page 23567) are custom Variants (see page 23567) that represent complex numbers. The Variant type supports direct manipulation using the addition, subtraction, multiplication, division (but not integer division), and negation operators. They have 5 published properties: Real, Imaginary, Radius, Theta, and FixedTheta. They can be cast to and from integer types, floating point types, string types, TDateTime values, and boolean values. In addition, the VarCmplx (see page 23513) unit implements a number of global functions for operating on complex Variants (see page 23567).

VarType

169.1.3 VarCmplx.VarComplexAbs Function

Returns the absolute value of a complex number.

Pascal

```
function VarComplexAbs(const AValue: Variant): Double;
```

C++

```
Double VarComplexAbs(const Variant AValue);
```

File

VarCmplx

Description

Use VarComplexAbs to take the absolute value (length) of a complex number.

AValue is a Variant whose value represents the complex number.

VarComplexAbs returns the absolute value of AValue.

See Also

VarComplexAbsSqr (see page 23518)

VarComplexAngle (see page 23518)

VarComplexConjugate (see page 23532)

VarComplexInverse (see page 23541)

VarComplexTimesPosI (see page 23555)

VarComplexTimesNegI (see page 23555)

169.1.4 VarCmplx.VarComplexAbsSqr Function

Returns the square of the absolute value of a complex number.

Pascal

```
function VarComplexAbsSqr(const AValue: Variant): Double;
```

C++

```
Double VarComplexAbsSqr(const Variant AValue);
```

File

VarCmplx

Description

Use VarComplexAbsSqr to obtain the square of a complex number's absolute value.

AValue is a Variant whose value represents the complex number.

VarComplexAbs (see page 23517) returns the absolute value of AValue, squared.

See Also

VarComplexAbs (see page 23517)

VarComplexAngle (see page 23518)

VarComplexConjugate (see page 23532)

VarComplexInverse (see page 23541)

VarComplexTimesPosI (see page 23555)

VarComplexTimesNegI (see page 23555)

VarComplexLn (see page 23542)

VarComplexExp (see page 23540)

VarComplexSqr (see page 23551)

VarComplexSqrt (see page 23551)

VarComplexPower (see page 23545)

169.1.5 VarCmplx.VarComplexAngle Function

Returns the angle made by a complex number.

Pascal

```
function VarComplexAngle(const AValue: Variant): Double;
```

C++

```
Double VarComplexAngle(const Variant AValue);
```

File

VarCmplx

Description

Use VarComplexAngle to obtain the angle of a complex number.

AValue is a Variant whose value represents the complex number.

VarComplexAbs (see page 23517) returns the angle that corresponds to AValue.

See Also

VarComplexToPolar (see page 23556)

VarComplexAbs (see page 23517)

169.1.6 VarCmplx.VarComplexArcCos Function

Returns the inverse cosine of a complex number.

Pascal

```
function VarComplexArcCos(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCos(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCos computes the inverse cosine of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcCos returns a Variant whose value is the inverse cosine of AValue.

VarComplexTanH (see page 23553)

169.1.7 VarCmplx.VarComplexArcCosH Function

Returns the hyperbolic inverse cosine of a complex number.

Pascal

```
function VarComplexArcCosH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCosH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCosH computes the hyperbolic inverse cosine of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcCosH returns a Variant whose value is the hyperbolic inverse cosine of AValue.

VarComplexTanH (see page 23553)

169.1.8 VarCmplx.VarComplexArcCot Function

Returns the inverse cotangent of a complex number.

Pascal

```
function VarComplexArcCot(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCot(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCot computes the inverse cotangent of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcCot returns a Variant whose value is the inverse cotangent of AValue.

See Also

169.1.9 VarCmplx.VarComplexArcCotH Function

Returns the hyperbolic inverse cotangent of a complex number.

Pascal

```
function VarComplexArcCotH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCotH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCot (see page 23521) computes the hyperbolic inverse cotangent of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcCot (see page 23521) returns a Variant whose value is the hyperbolic inverse cotangent of AValue.

See Also

VarComplexTanH (see page 23553)

169.1.10 VarCmplx.VarComplexArcCsc Function

Returns the inverse cosecant of a complex number.

Pascal

```
function VarComplexArcCsc(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCsc(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCsc computes the inverse cosecant of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcCsc returns a Variant whose value is the inverse cosecant of AValue.

See Also

VarComplexArcCosH (see page 23520)

169.1.11 VarCmplx.VarComplexArcCscH Function

Returns the hyperbolic inverse cosecant of a complex number.

Pascal

```
function VarComplexArcCscH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcCscH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcCsc (see page 23523) computes the hyperbolic inverse cosecant of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcCsc (see page 23523) returns a Variant whose value is the hyperbolic inverse cosecant of AValue.

See Also

VarComplexTanH (see page 23553)

169.1.12 VarCmplx.VarComplexArcSec Function

Returns the inverse secant of a complex number.

Pascal

```
function VarComplexArcSec(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcSec(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcSec computes the inverse secant of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcSec returns a Variant whose value is the inverse secant of AValue.

169.1.13 VarCmplx.VarComplexArcSecH Function

Returns the hyperbolic inverse secant of a complex number.

Pascal

```
function VarComplexArcSecH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcSecH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcSec (see page 23525) computes the hyperbolic inverse secant of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcSec (see page 23525) returns a Variant whose value is the hyperbolic inverse secant of AValue.

169.1.14 VarCmplx.VarComplexArcSin Function

Returns the inverse sine of a complex number.

Pascal

```
function VarComplexArcSin(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcSin(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcSin computes the inverse sine of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcSin returns a Variant whose value is the inverse sine of AValue.

169.1.15 VarCmplx.VarComplexArcSinH Function

Returns the hyperbolic inverse sine of a complex number.

Pascal

```
function VarComplexArcSinH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcSinH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcSinH computes the hyperbolic inverse sine of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcSinH returns a Variant whose value is the hyperbolic inverse sine of AValue.

169.1.16 VarCmplx.VarComplexArcTan Function

Returns the inverse tangent of a complex number.

Pascal

```
function VarComplexArcTan(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcTan(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcTan computes the inverse tangent of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcTan returns a Variant whose value is the inverse tangent of AValue.

169.1.17 VarCmplx.VarComplexArcTanH Function

Returns the hyperbolic inverse tangent of a complex number.

Pascal

```
function VarComplexArcTanH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexArcTanH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexArcTanH computes the hyperbolic inverse tangent of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexArcTanH returns a Variant whose value is the hyperbolic inverse tangent of AValue.

169.1.18 VarCmplx.VarComplexConjugate Function

Returns the conjugate of a complex number.

Pascal

```
function VarComplexConjugate(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexConjugate(const Variant AValue);
```

File

VarCmplx

Description

VarComplexConjugate returns the conjugate of a complex number. The conjugate is the value that has the same real part and the inverse of the imaginary part.

AValue is a Variant whose value represents the complex number.

VarComplexConjugate returns a Variant whose value is the conjugate of AValue.

169.1.19 VarCmplx.VarComplexCos Function

Returns the cosine of a complex number.

Pascal

```
function VarComplexCos(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCos(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCos computes the cosine of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexCos returns a Variant whose value is the cosine of AValue.

169.1.20 VarCmplx.VarComplexCosH Function

Returns the hyperbolic cosine of a complex number.

Pascal

```
function VarComplexCosH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCosH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCosH computes the hyperbolic cosine of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexCosH returns a Variant whose value is the hyperbolic cosine of AValue.

169.1.21 VarCmplx.VarComplexCot Function

Returns the cotangent of a complex number.

Pascal

```
function VarComplexCot(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCot(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCot computes the cotangent of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexCot returns a Variant whose value is the cotangent of AValue.

169.1.22 VarCmplx.VarComplexCotH Function

Returns the hyperbolic cotangent of a complex number.

Pascal

```
function VarComplexCotH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCotH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCot (see page 23535) computes the hyperbolic cotangent of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexCot (see page 23535) returns a Variant whose value is the hyperbolic cotangent of AValue.

169.1.23 VarCmplx.VarComplexCreate Function

Returns a custom Variant that represents a complex number.

Pascal

```
function VarComplexCreate: Variant; overload;
function VarComplexCreate(const AReal: Double): Variant; overload;
function VarComplexCreate(const AReal: Double; const AImaginary: Double): Variant; overload;
function VarComplexCreate(const AText: string): Variant; overload;
```

C++

```
Variant VarComplexCreate();
Variant VarComplexCreate(const Double AReal);
Variant VarComplexCreate(const Double AReal, const Double AImaginary);
Variant VarComplexCreate(const AnsiString AText);
```

File

VarCmplx

Description

Call VarComplexCreate to create a Variant whose value is a complex number.

AReal is the real part of the complex number.

AImaginary is the imaginary part of the complex number.

Using the first three versions of the constructor, omitting AReal or AImaginary results in a real or imaginary part of 0.

Using the last syntax, AText is parsed using the ComplexNumberSymbol (see page 23559) and ComplexNumberSymbolBeforeImaginary (see page 23560) global variables and, if the string represents a complex value, that becomes the value of the new Variant. If the string can't be parsed into a complex number, VarComplexCreate raises an EConvertError exception.

Complex Variants (see page 23567) are custom Variants (see page 23567) that represent complex numbers. The Variant type supports direct manipulation using the addition, subtraction, multiplication, division (but not integer division), and negation operators. They have 5 published properties: Real, Imaginary, Radius, Theta, and FixedTheta. They can be cast to and from integer types, floating point types, string types, TDateTime values, and boolean values. In addition, the VarCmplx (see page 23513) unit implements a number of global functions for operating on complex Variants (see page 23567).

169.1.24 VarCmplx.VarComplexCsc Function

Returns the cosecant of a complex number.

Pascal

```
function VarComplexCsc(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCsc(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCsc computes the cosecant of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexCsc returns a Variant whose value is the cosecant of AValue.

169.1.25 VarCmplx.VarComplexCscH Function

Returns the hyperbolic cosecant of a complex number.

Pascal

```
function VarComplexCscH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexCscH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexCsc (see page 23538) computes the hyperbolic cosecant of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexCsc (see page 23538) returns a Variant whose value is the hyperbolic cosecant of AValue.

169.1.26 VarCmplx.VarComplexExp Function

Returns the exponential of a complex number.

Pascal

```
function VarComplexExp(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexExp(const Variant AValue);
```

File

VarCmplx

Description

VarComplexExp returns value of e raised to the power of a specified complex number, where e is the base of the natural logarithms.

AValue is a Variant whose value represents the complex number.

VarComplexExp returns a Variant whose value is the exponential of AValue.

See Also

169.1.27 VarCmplx.VarComplexFromPolar Function

Converts a set of polar coordinates to a complex number.

Pascal

```
function VarComplexFromPolar(const ARadius: Double; const ATheta: Double): Variant;
```

C++

```
Variant VarComplexFromPolar(const Double ARadius, const Double ATheta);
```

File

VarCmplx

Description

VarComplexFromPolar returns the complex number that corresponds to the radius (length) and angle specified by the ARadius and ATheta parameters, respectively. The result is returned as a Variant whose value is the corresponding complex number.

See Also

VarComplexCreate (see page 23537)

VarComplexToPolar (see page 23556)

169.1.28 VarCmplx.VarComplexInverse Function

Returns the inverse of a complex number.

Pascal

```
function VarComplexInverse(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexInverse(const Variant AValue);
```

File

VarCmplx

Description

VarComplexInverse returns the inverse of a complex number. The inverse is the value that results when you divide 1 by the complex number.

AValue is a Variant whose value represents the complex number.

VarComplexInverse returns a Variant whose value is the inverse of AValue.

See Also

VarComplexAbs (see page 23517)

VarComplexSqrt (see page 23551)

VarComplexPower (see page 23545)

169.1.29 VarCmplx.VarComplexLn Function

Returns the natural log of a complex number.

Pascal

```
function VarComplexLn(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexLn(const Variant AValue);
```

File

VarCmplx

Description

VarComplexLn returns the natural logarithm of a complex number. The natural logarithm is the power to which you must raise e to get the complex number.

AValue is a Variant whose value represents the complex number.

VarComplexLn returns a Variant whose value is the natural log of AValue.

VarComplexPower (see page 23545)

169.1.30 VarCmplx.VarComplexLog10 Function

Returns the log base 10 of a complex number.

Pascal

```
function VarComplexLog10(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexLog10(const Variant AValue);
```

File

VarCmplx

Description

VarComplexLog10 returns the base 10 logarithm of a complex number. The base 10 logarithm is the power to which you must raise 10 to get the complex number.

AValue is a Variant whose value represents the complex number.

VarComplexLog10 returns a Variant whose value is the log base 10 of AValue.

See Also

VarComplexLn (see page 23542)

VarComplexLog2 (see page 23543)

VarComplexLogN (see page 23544)

169.1.31 VarCmplx.VarComplexLog2 Function

Returns the log base 2 of a complex number.

Pascal

```
function VarComplexLog2(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexLog2(const Variant AValue);
```

File

VarCmplx

Description

VarComplexLog2 returns the base 2 logarithm of a complex number. The base 2 logarithm is the power to which you must raise 2 to get the complex number.

AValue is a Variant whose value represents the complex number.

VarComplexLog2 returns a Variant whose value is the log base 2 of AValue.

See Also

VarComplexLn (see page 23542)

VarComplexLog10 (see page 23543)

VarComplexLogN (see page 23544)

169.1.32 VarCmplx.VarComplexLogN Function

Returns the log base N of a complex number.

Pascal

```
function VarComplexLogN(const AValue: Variant; const X: Double): Variant;
```

C++

```
Variant VarComplexLogN(const Variant AValue, const Double X);
```

File

VarCmplx

Description

VarComplexLogN returns the base N logarithm of a complex number. The base N logarithm is the power to which you must raise an exponent N to get the complex number.

AValue is a Variant whose value represents the complex number.

X is the logarithm exponent.

VarComplexLogN returns a Variant whose value is the log base N of AValue.

See Also

VarComplexLn (see page 23542)

VarComplexLog2 (see page 23543)

VarComplexLog10 (see page 23543)

169.1.33 VarCmplx.VarComplexPower Function

Returns the value of a complex number raised to a specified power.

Pascal

```
function VarComplexPower(const AValue: Variant; const APower: Variant): Variant;
```

C++

```
Variant VarComplexPower(const Variant AValue, const Variant APower);
```

File

VarCmplx

Description

VarComplexPower returns the result of raising AValue to the power APower.

AValue is a Variant whose value represents the complex number.

APower is a Variant that specifies the power to which you want to raise AValue. It can also be a complex number.

VarComplexPower returns a Variant whose value is AValue raised to the APower power.

169.1.34 VarCmplx.VarComplexSec Function

Returns the secant of a complex number.

Pascal

```
function VarComplexSec(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSec(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSec computes the secant of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexSec returns a Variant whose value is the secant of AValue.

169.1.35 VarCmplx.VarComplexSecH Function

Returns the hyperbolic secant of a complex number.

Pascal

```
function VarComplexSecH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSecH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSec (see page 23545) computes the hyperbolic secant of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexSec (see page 23545) returns a Variant whose value is the hyperbolic secant of AValue.

169.1.36 VarCmplx.VarComplexSign Function

Pascal

```
function VarComplexSign(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSign(const Variant AValue);
```

File

VarCmplx

Description

This is function VarCmplx.VarComplexSign.

169.1.37 VarCmplx.VarComplexSimplify Function

Reduces a Variant that represents a complex number to one that represents a real value, if possible.

Pascal

```
function VarComplexSimplify(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSimplify(const Variant AValue);
```

File

VarCmplx

Description

Use VarComplexSimplify to convert a complex number to a real value when possible. VarComplexSimplify checks whether the Variant specified by AValue represents a complex number that has no imaginary part. If so, it returns a Variant whose value is simply a real number. If AValue does not represent a complex number, or if AValue represents a complex number with a nonzero imaginary part, VarComplexSimplify returns AValue.

169.1.38 VarCmplx.VarComplexSin Function

Returns the sine of a complex number.

Pascal

```
function VarComplexSin(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSin(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSin computes the sine of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexSin returns a Variant whose value is the sine of AValue.

169.1.39 VarCmplx.VarComplexSinH Function

Returns the hyperbolic sine of a complex number.

Pascal

```
function VarComplexSinH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSinH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSinH computes the hyperbolic sine of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexSinH returns a Variant whose value is the hyperbolic sine of AValue.

169.1.40 VarCmplx.VarComplexSqr Function

Returns the square of a complex number.

Pascal

```
function VarComplexSqr(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSqr(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSqr returns the square of AValue.

AValue is a Variant whose value represents the complex number.

See Also

VarComplexAbs (see page 23517)

169.1.41 VarCmplx.VarComplexSqrt Function

Returns the square root of a complex number.

Pascal

```
function VarComplexSqrt(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexSqrt(const Variant AValue);
```

File

VarCmplx

Description

VarComplexSqrt returns the square root of AValue.

AValue is a Variant whose value represents the complex number.

See Also

VarComplexAbs (see page 23517)

VarComplexAngle (see page 23518)

169.1.42 VarCmplx.VarComplexTan Function

Returns the tangent of a complex number.

Pascal

```
function VarComplexTan(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexTan(const Variant AValue);
```

File

VarCmplx

Description

VarComplexTan computes the tangent of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexTan returns a Variant whose value is the tangent of AValue.

169.1.43 VarCmplx.VarComplexTanH Function

Returns the hyperbolic tangent of a complex number.

Pascal

```
function VarComplexTanH(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexTanH(const Variant AValue);
```

File

VarCmplx

Description

VarComplexTanH computes the hyperbolic tangent of a complex number and returns the result.

AValue is a Variant whose value represents the complex number.

VarComplexTanH returns a Variant whose value is the hyperbolic tangent of AValue.

VarComplexTanH

169.1.44 VarCmplx.VarComplexTimesImaginary Function

Returns the value of a complex number multiplied by an imaginary number.

Pascal

```
function VarComplexTimesImaginary(const AValue: Variant; const AFactor: Double): Variant;
```

C++

```
Variant VarComplexTimesImaginary(const Variant AValue, const Double AFactor);
```

File

VarCmplx

Description

VarComplexTimesImaginary returns a complex value times an imaginary number.

AValue is a Variant whose value represents the complex number.

AFactor is a real number that represents the imaginary number. That is, the imaginary number is AFactor times i.

VarComplexTimesImaginary returns a variant whose value is AValue times AFactor times i.

See Also

VarComplexTimesNegI (see page 23555)

VarComplexTimesPosI (see page 23555)

VarComplexTimesReal (see page 23556)

169.1.45 VarCmplx.VarComplexTimesNegI Function

Returns the value of a complex number multiplied by –i.

Pascal

```
function VarComplexTimesNegI(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexTimesNegI(const Variant AValue);
```

File

VarCmplx

Description

VarComplexTimesNegI returns AValue times –i.

AValue is a Variant whose value represents the complex number.

See Also

VarComplexTimesImaginary (see page 23554)

VarComplexTimesPosI (see page 23555)

VarComplexTimesReal (see page 23556)

169.1.46 VarCmplx.VarComplexTimesPosI Function

Returns the value of a complex number multiplied by i.

Pascal

```
function VarComplexTimesPosI(const AValue: Variant): Variant;
```

C++

```
Variant VarComplexTimesPosI(const Variant AValue);
```

File

VarCmplx

Description

VarComplexTimesPosI returns AValue times i.

AValue is a Variant whose value represents the complex number.

See Also

VarComplexTimesNegI (see page 23555)

VarComplexTimesImaginary (see page 23554)

VarComplexTimesReal (see page 23556)

169.1.47 VarCmplx.VarComplexTimesReal Function

Returns the value of a complex number multiplied by a real number.

Pascal

```
function VarComplexTimesReal(const AValue: Variant; const AFactor: Double): Variant;
```

C++

```
Variant VarComplexTimesReal(const Variant AValue, const Double AFactor);
```

File

VarCmplx

Description

VarComplexTimesReal returns a complex value times a real number.

AValue is a Variant whose value represents the complex number.

AFactor is a real number.

VarComplexTimesReal returns a variant whose value is AValue times AFactor.

See Also

VarComplexTimesNegI (see page 23555)

VarComplexTimesPosI (see page 23555)

VarComplexTimesReal

169.1.48 VarCmplx.VarComplexToPolar Function

Computes the polar coordinates that correspond to a custom Variant that represents a complex number.

Pascal

```
procedure VarComplexToPolar(const AValue: Variant; var ARadius: Double; var ATheta: Double;
AFixTheta: Boolean = True);
```

C++

```
VarComplexToPolar(const Variant AValue, Double ARadius, Double ATheta, Boolean AFixTheta =
True);
```

File

VarCmplx

Description

Call VarComplexToPolar to obtain the polar coordinates for a complex number.

AValue is a Variant whose value represents the complex number.

ARadius returns the radius of the corresponding polar coordinates.

ATheta returns the angle (Theta) of the corresponding polar coordinates.

AFixTheta indicates whether VarComplexToPolar should normalize the angle (ATheta). When AFixTheta is true, VarComplexToPolar always returns an angle between – pi and pi.

See Also

VarComplexAngle (see page 23518)

VarComplexFromPolar (see page 23541)

VarComplexAbs (see page 23517)

169.1.49 VarCmplx.VarIsComplex Function

Indicates whether a Variant stores its data internally as a complex number.

Pascal

```
function VarIsComplex(const AValue: Variant): Boolean;
```

C++

```
Boolean VarIsComplex(const Variant AValue);
```

File

VarCmplx

Description

VarIsComplex returns true if AValue represents a complex number (that is, if it has a VarType of VarComplex (see page 23516)).

Complex Variants (see page 23567) are custom Variants (see page 23567) that represent complex numbers. The Variant type supports direct manipulation using the addition, subtraction, multiplication, division (but not integer division), and negation operators. They have 5 published properties: Real, Imaginary, Radius, Theta, and FixedTheta. They can be cast to and from integer types, floating point types, string types, TDateTime values, and boolean values. In addition, the VarCmplx (see page 23513) unit implements a number of global functions for operating on complex Variants (see page 23567).

169.2 Variables

The following table lists variables in this documentation.

Variables

Name	Description
ComplexNumberDefuzzAtZero (see page 23559)	This is variable VarCmplx.ComplexNumberDefuzzAtZero.
ComplexNumberSymbol (see page 23559)	This is variable VarCmplx.ComplexNumberSymbol.
ComplexNumberSymbolBeforeImaginary (see page 23560)	This is variable VarCmplx.ComplexNumberSymbolBeforeImaginary.

169.2.1 VarCmplx.ComplexNumberDefuzzAtZero Variable

Pascal

```
ComplexNumberDefuzzAtZero: Boolean = True;
```

C++

```
Boolean ComplexNumberDefuzzAtZero = True;
```

File

VarCmplx

Description

This is variable VarCmplx.ComplexNumberDefuzzAtZero.

169.2.2 VarCmplx.ComplexNumberSymbol Variable

Pascal

```
ComplexNumberSymbol: string = 'i';
```

C++

```
AnsiString ComplexNumberSymbol = 'i';
```

File

VarCmplx

Description

This is variable VarCmplx.ComplexNumberSymbol.

169.2.3 VarCmplx.ComplexNumberSymbolBeforeImaginary Variable

Pascal

```
ComplexNumberSymbolBeforeImaginary: Boolean = False;
```

C++

```
Boolean ComplexNumberSymbolBeforeImaginary = False;
```

File

VarCmplx

Description

This is variable VarCmplx.ComplexNumberSymbolBeforeImaginary.

170 VarConv Namespace

This is namespace VarConv.

Topics

Name	Description
Functions (see page 23562)	The following table lists functions in this documentation.

Functions

	Name	Description
	VarAsConvert (see page 23562)	Casts an arbitrary Variant so that it is a custom Variant representing a measurement.
	VarAsConvert (see page 23562)	Casts an arbitrary Variant so that it is a custom Variant representing a measurement.
	VarConvert (see page 23563)	Returns the Variant type code for custom Variants (see page 23567) that represent measurements.
	VarConvertCreate (see page 23564)	Returns a custom Variant that represents a measurement.
	VarConvertCreate (see page 23564)	Returns a custom Variant that represents a measurement.
	VarIsConvert (see page 23565)	Indicates whether a Variant is a custom Variant that represents a measurement.

170.1 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	VarAsConvert (see page 23562)	Casts an arbitrary Variant so that it is a custom Variant representing a measurement.
	VarAsConvert (see page 23562)	Casts an arbitrary Variant so that it is a custom Variant representing a measurement.
	VarConvert (see page 23563)	Returns the Variant type code for custom Variants (see page 23567) that represent measurements.
	VarConvertCreate (see page 23564)	Returns a custom Variant that represents a measurement.
	VarConvertCreate (see page 23564)	Returns a custom Variant that represents a measurement.
	VarIsConvert (see page 23565)	Indicates whether a Variant is a custom Variant that represents a measurement.

170.1.1 VarConv.VarAsConvert Function

Casts an arbitrary Variant so that it is a custom Variant representing a measurement.

Pascal

```
function VarAsConvert(const AValue: Variant): Variant; overload;
function VarAsConvert(const AValue: Variant; const AType: TConvType): Variant; overload;
```

C++

```
Variant VarAsConvert(const Variant AValue);
Variant VarAsConvert(const Variant AValue, const TConvType AType);
```

File

VarConv

Description

VarAsConvert converts the Variant specified by AValue to a VarConvert (see page 23563) custom Variant.

Using the first syntax, AValue is interpreted as the numeric portion (the number of units), and AType identifies the units.

Using the second syntax, AValue should be a Variant that can be parsed into a VarConv (see page 23561) custom Variant (for example, a variant whose value is a string such as '1.5 miles').

If VarAsConvert can't perform the conversion, it raises an EInvalidCast exception.

VarConvert (see page 23563) custom Variants (see page 23567) represent measurements (that is, a type of measurement units and the number of those units). The units must be registered measurement units such as those used by the ConvUtils (see page 6379) unit. You can use the negation operator on VarConv (see page 23561) variants, and use the addition, subtraction, multiplication, division, and comparison operators on a VarConv (see page 23561) Variant with a real number. You can use the addition, subtraction, division, and comparison operators on two VarConv (see page 23561) Variants (see page 23567). VarConv (see page 23561) custom Variants (see page 23567) also support the following properties:

Value is the numeric portion (the number of units). (read/write)

Type is units. (read-only)

TypeName is the name of the units. (read-only).

Family is the conversion family of the units (the thing measured). (read-only).

FamilyName is the name of the conversion family. (read-only)

Depending on the Family, each Variant has a set of conversion properties with names of the form As<Unit>, where <Unit> is the name of another type of unit in the same conversion family.

EInvalidCast

VarIsConvert (see page 23565)

VarConvertCreate (see page 23564)

VarAsType

TVarData

170.1.2 VarConv.VarConvert Function

Returns the Variant type code for custom Variants (see page 23567) that represent measurements.

Pascal

```
function VarConvert: TVarType;
```

C++

```
TVarType VarConvert();
```

File

VarConv

Description

Use VarConvert to obtain the variant type code for custom Variants (see page 23567) that represent measurements. The Variant type codes for custom Variants (see page 23567) are dynamically allocated when the application loads the unit that implements them. VarConvert allows the application to identify the Variant type code that is currently used for custom Variants (see page 23567) that represent VarConvert custom Variants (see page 23567). This type code, however, may not match the type code used by another application that uses a different set of custom Variant types.

VarConvert custom Variants (see page 23567) represent measurements (that is, a type of measurement units and the number of those units). The units must be registered measurement units such as those used by the ConvUtils (see page 6379) unit. You can use the negation operator on VarConv (see page 23561) variants, and use the addition, subtraction, multiplication, division, and comparison operators on a VarConv (see page 23561) Variant with a real number. You can use the addition, subtraction, division, and comparison operators on two VarConv (see page 23561) Variants (see page 23567). VarConv (see page 23561) custom Variants (see page 23567) also support the following properties:

Value is the numeric portion (the number of units). (read/write)

Type is units. (read-only)

TypeName is the name of the units. (read-only).

Family is the conversion family of the units (the thing measured). (read-only).

FamilyName is the name of the conversion family. (read-only)

Depending on the Family, each Variant has a set of conversion properties with names of the form As<Unit>, where <Unit> is the name of another type of unit in the same conversion family.

VarType

170.1.3 VarConv.VarConvertCreate Function

Returns a custom Variant that represents a measurement.

Pascal

```
function VarConvertCreate(const AValue: Double; const AType: TConvType): Variant; overload;
function VarConvertCreate(const AValue: string): Variant; overload;
```

C++

```
Variant VarConvertCreate(const Double AValue, const TConvType AType);
Variant VarConvertCreate(const AnsiString AValue);
```

File

VarConv

Description

Call VarConvertCreate to create a Variant whose value is a measurement.

Using the first syntax, AType indicates the measurement units, and AValue is the number of those units. AType must represent a registered conversion unit.

Using the second syntax, AValue is a string that can be parsed by the TryStrToConvUnit function. (For example '1.5 liters'.)

If the string can't be parsed into a measurement, VarConvertCreate raises an EInvalidCast exception.

VarConvert (see page 23563) custom Variants (see page 23567) represent measurements (that is, a type of measurement units and the number of those units). The units must be registered measurement units such as those used by the ConvUtils (see page 6379) unit. You can use the negation operator on VarConv (see page 23561) variants, and use the addition, subtraction, multiplication, division, and comparison operators on a VarConv (see page 23561) Variant with a real number. You can use the addition, subtraction, division, and comparison operators on two VarConv (see page 23561) Variants (see page 23567). VarConv (see page 23561) custom Variants (see page 23567) also support the following properties:

Value is the numeric portion (the number of units). (read/write)

Type is units. (read-only)

TypeName is the name of the units. (read-only).

Family is the conversion family of the units (the thing measured). (read-only).

FamilyName is the name of the conversion family. (read-only)

Depending on the Family, each Variant has a set of conversion properties with names of the form As<Unit>, where <Unit> is the name of another type of unit in the same conversion family.

EInvalidCast

170.1.4 VarConv.VarIsConvert Function

Indicates whether a Variant is a custom Variant that represents a measurement.

Pascal

```
function VarIsConvert(const AValue: Variant): Boolean;
```

C++

```
Boolean VarIsConvert(const Variant AValue);
```

File

VarConv

Description

VarIsConvert returns true if AValue represents a measurement (that is, if it has a VarType of VarConvert (see page 23563)).

VarConvert (see page 23563) custom Variants (see page 23567) represent measurements (that is, a type of measurement units and the number of those units). The units must be registered measurement units such as those used by the ConvUtils (see page 6379) unit. You can use the negation operator on VarConv (see page 23561) variants, and use the addition, subtraction, multiplication, division, and comparison operators on a VarConv (see page 23561) Variant with a real number. You can use the addition, subtraction, division, and comparison operators on two VarConv (see page 23561) Variants (see page 23567). VarConv (see page 23561) custom Variants (see page 23567) also support the following properties:

Value is the numeric portion (the number of units). (read/write)

Type is units. (read-only)

TypeName is the name of the units. (read-only).

Family is the conversion family of the units (the thing measured). (read-only).

FamilyName is the name of the conversion family. (read-only)

Depending on the Family, each Variant has a set of conversion properties with names of the form As<Unit>, where <Unit> is the name of another type of unit in the same conversion family.

Classes

	Name	Description
	EVariantArrayCreateError (see page 23572)	EVariantArrayCreateError is the exception class for failure to create or resize a variant array.
	EVariantArrayLockedError (see page 23573)	EVariantArrayLockedError is the exception class for errors that occur because a variant array is locked or fixed.
	EVariantBadIndexError (see page 23574)	EVariantBadIndexError is the exception class for errors that occur because a variant array index is out of bounds.
	EVariantBadVarTypeError (see page 23574)	EVariantBadVarTypeError is the exception class for variant type errors.
	EVariantDispatchError (see page 23575)	EVariantDispatchError is the exception class for failed dispatch attempts.
	EVariantInvalidArgError (see page 23575)	EVariantInvalidArgError is the exception class for operations that fail due to invalid variant data.
	EVariantInvalidNullOpError (see page 23576)	EVariantInvalidNullOpError is the exception class for invalid Null (see page 23641) variant operations.
	EVariantInvalidOpError (see page 23577)	EVariantInvalidOpError is the exception class for invalid variant operations.
	EVariantNotAnArrayError (see page 23577)	EVariantNotAnArrayError is the exception class inappropriate variant array operations.
	EVariantNotImplError (see page 23578)	EVariantNotImplError is the exception class for unimplemented variant operations.
	EVariantOutOfMemoryError (see page 23578)	EVariantOutOfMemoryError is the exception class for variant operations that cannot allocate necessary memory.
	EVariantOverflowError (see page 23579)	EVariantOverflowError is the exception class for overflow in a variant operation.
	EVariantRangeCheckError (see page 23580)	EVariantRangeCheckError is the exception class for out-of-range errors in a variant operation.
	EVariantTypeCastError (see page 23580)	EVariantTypeCastError is the exception class for variant type cast errors.
	EVariantUnexpectedError (see page 23581)	EVariantUnexpectedError is the exception class for unexpected variant errors.

	TCustomVariantType (see page 23581)	TCustomVariantType is the base class for Delphi custom variant types.
	TInvokeableVariantType (see page 23606)	TInvokeableVariantType is the base class for custom Variant types that implement custom Variants with properties and methods.

Functions

	Name	Description
	_DispInvoke (see page 23619)	This is function Variants._DispInvoke.
	_OleVarFromInt (see page 23620)	This is function Variants._OleVarFromInt.
	_OleVarFromInt64 (see page 23620)	This is function Variants._OleVarFromInt64.
	_OleVarFromLStr (see page 23620)	This is function Variants._OleVarFromLStr.
	_OleVarFromPStr (see page 23621)	This is function Variants._OleVarFromPStr.
	_OleVarFromVar (see page 23621)	This is function Variants._OleVarFromVar.
	_VarAdd (see page 23621)	This is function Variants._VarAdd.
	_VarAddRef (see page 23622)	This is function Variants._VarAddRef.
	_VarAnd (see page 23622)	This is function Variants._VarAnd.
	_VarArrayGet (see page 23622)	This is function Variants._VarArrayGet.
	_VarArrayPut (see page 23623)	This is function Variants._VarArrayPut.
	_VarArrayRedim (see page 23623)	This is function Variants._VarArrayRedim.
	_VarCast (see page 23623)	This is function Variants._VarCast.
	_VarCastOle (see page 23624)	This is function Variants._VarCastOle.
	_VarClear (see page 23624)	This is function Variants._VarClear.
	_VarClr (see page 23624)	This is function Variants._VarClr.
	_VarCmpEQ (see page 23625)	This is function Variants._VarCmpEQ.
	_VarCmpGE (see page 23625)	This is function Variants._VarCmpGE.
	_VarCmpGT (see page 23625)	This is function Variants._VarCmpGT.
	_VarCmpLE (see page 23626)	This is function Variants._VarCmpLE.
	_VarCmpLT (see page 23626)	This is function Variants._VarCmpLT.
	_VarCmpNE (see page 23626)	This is function Variants._VarCmpNE.
	_VarCopy (see page 23627)	This is function Variants._VarCopy.
	_VarCopyNoInd (see page 23627)	This is function Variants._VarCopyNoInd.
	_VarDiv (see page 23627)	This is function Variants._VarDiv.
	_VarFromBool (see page 23628)	This is function Variants._VarFromBool.
	_VarFromCurr (see page 23628)	This is function Variants._VarFromCurr.
	_VarFromDisp (see page 23628)	This is function Variants._VarFromDisp.
	_VarFromDynArray (see page 23629)	This is function Variants._VarFromDynArray.
	_VarFromInt (see page 23629)	This is function Variants._VarFromInt.
	_VarFromInt64 (see page 23629)	This is function Variants._VarFromInt64.
	_VarFromIntf (see page 23630)	This is function Variants._VarFromIntf.
	_VarFromLStr (see page 23630)	This is function Variants._VarFromLStr.
	_VarFromPStr (see page 23630)	This is function Variants._VarFromPStr.
	_VarFromReal (see page 23631)	This is function Variants._VarFromReal.
	_VarFromTDateTime (see page 23631)	This is function Variants._VarFromTDateTime.
	_VarFromWStr (see page 23631)	This is function Variants._VarFromWStr.
	_VarMod (see page 23632)	This is function Variants._VarMod.
	_VarMul (see page 23632)	This is function Variants._VarMul.
	_VarNeg (see page 23632)	This is function Variants._VarNeg.
	_VarNot (see page 23633)	This is function Variants._VarNot.
	_VarOr (see page 23633)	This is function Variants._VarOr.
	_VarRDiv (see page 23633)	This is function Variants._VarRDiv.
	_VarShl (see page 23634)	This is function Variants._VarShl.
	_VarShr (see page 23634)	This is function Variants._VarShr.
	_VarSub (see page 23634)	This is function Variants._VarSub.
	_VarToBool (see page 23635)	This is function Variants._VarToBool.
	_VarToCurrency (see page 23635)	This is function Variants._VarToCurrency.
	_VarToDisp (see page 23635)	This is function Variants._VarToDisp.

	_VarToDynArray (see page 23636)	This is function Variants._VarToDynArray.
	_VarToInt64 (see page 23636)	This is function Variants._VarToInt64.
	_VarToInteger (see page 23636)	This is function Variants._VarToInteger.
	_VarToIntf (see page 23637)	This is function Variants._VarToIntf.
	_VarToLStr (see page 23637)	This is function Variants._VarToLStr.
	_VarToPStr (see page 23637)	This is function Variants._VarToPStr.
	_VarToReal (see page 23638)	This is function Variants._VarToReal.
	_VarToWStr (see page 23638)	This is function Variants._VarToWStr.
	_VarXor (see page 23638)	This is function Variants._VarXor.
	DynArrayFromVariant (see page 23639)	Creates a dynamic array from a Variant.
	DynArrayToVariant (see page 23639)	Creates a Variant array from a dynamic array.
	FindCustomVariantType (see page 23640)	Retrieves the object that implements a custom Variant type.
	FindCustomVariantType (see page 23640)	Retrieves the object that implements a custom Variant type.
	FindVarData (see page 23640)	Returns pointer to variant's data.
	HandleConversionException (see page 23641)	Handles exceptions during variant type conversions.
	Null (see page 23641)	Returns a Null variant.
	Unassigned (see page 23643)	Returns an "empty" variant.
	VarArrayAsPSafeArray (see page 23643)	This is function Variants.VarArrayAsPSafeArray.
	VarArrayCreate (see page 23644)	Creates a variant array.
	VarArrayCreateError (see page 23645)	Indicates an array creation error.
	VarArrayDimCount (see page 23645)	Returns number of dimensions of a variant array.
	VarArrayGet (see page 23645)	Returns a Variant that represents a single value from a multi-dimensional Variant array.
	VarArrayHighBound (see page 23646)	Returns high bound for a dimension in a variant array.
	VarArrayLock (see page 23646)	Locks a variant array and returns a pointer to the data.
	VarArrayLowBound (see page 23647)	Returns the low bound of a dimension in a variant array.
	VarArrayOf (see page 23648)	Creates and fills a one-dimensional variant array.
	VarArrayPut (see page 23648)	Sets the value of a single cell in a multi-dimensional Variant array.
	VarArrayRef (see page 23649)	Returns a reference to the specified variant array.
	VarArrayUnlock (see page 23649)	Unlocks a variant array.
	VarAsError (see page 23650)	Converts a HRESULT into an Error variant.
	VarAsType (see page 23650)	Converts a variant to specified type.
	VarCastError (see page 23651)	Raises an EVariantTypeCastError (see page 23580) exception.
	VarCastError (see page 23651)	Raises an EVariantTypeCastError (see page 23580) exception.
	VarCheckEmpty (see page 23651)	Raises an exception if a specified variant's value is Unassigned (see page 23643).
	VarCompareValue (see page 23652)	Returns the relationship between Variants.
	VarCopyNoInd (see page 23652)	Copies a Variant.
	VarEnsureRange (see page 23653)	Returns a Variant with a value in a specified range.
	VarFromDateTime (see page 23653)	Returns a variant containing a specified data and time.
	VarInRange (see page 23654)	Indicates whether a Variant's value is in a specified range.
	VarInvalidNullOp (see page 23654)	Indicate variant operation on null.
	VarInvalidOp (see page 23655)	Indicate invalid variant operation.
	VarIsArray (see page 23655)	Indicates whether the specified variant is an array.
	VarIsArray (see page 23655)	Indicates whether the specified variant is an array.
	VarIsByRef (see page 23656)	Indicates whether the specified variant's value is by reference.
	VarIsClear (see page 23656)	Indicates whether the specified variant has an undefined value.
	VarIsCustom (see page 23657)	Indicates whether the specified variant is a custom variant.
	VarIsEmpty (see page 23657)	Indicates whether the specified variant is unassigned.
	VarIsEmptyParam (see page 23658)	Indicates whether the specified variant represents an unassigned optional parameter.
	VarIsError (see page 23659)	Indicates whether the specified variant is an error variant; optionally converts variant back to HRESULT.
	VarIsError (see page 23659)	Indicates whether the specified variant is an error variant; optionally converts variant back to HRESULT.
	VarIsFloat (see page 23659)	Indicates whether the specified variant represents a floating-point value.

	VarIsNull (see page 23660)	Indicates whether the specified variant is Null (see page 23641).
	VarIsNumeric (see page 23660)	Indicates whether the specified variant represents a numeric value.
	VarIsOrdinal (see page 23661)	Indicates whether the specified variant represents an ordinal value.
	VarIsStr (see page 23661)	Indicates whether the specified variant represents a string value.
	VarIsType (see page 23662)	Indicates whether the specified variant represents a specified type.
	VarIsType (see page 23662)	Indicates whether the specified variant represents a specified type.
	VarOverflowError (see page 23662)	Raises an EVariantOverflowError (see page 23579) exception.
	VarRangeCheckError (see page 23663)	Raises an EVariantRangeCheckError (see page 23580) exception.
	VarResultCheck (see page 23663)	Raises variant exception based on HRESULT value.
	VarResultCheck (see page 23663)	Raises variant exception based on HRESULT value.
	VarSameValue (see page 23664)	Indicates whether two Variants have equivalent values.
	VarSupports (see page 23664)	Indicates whether the Variant's value is an interface that supports a specified interface.
	VarSupports (see page 23664)	Indicates whether the Variant's value is an interface that supports a specified interface.
	VarToDateTime (see page 23665)	Converts a specified variant to a TDateTime value.
	VarToStr (see page 23665)	Converts a variant's value to a string.
	VarToStrDef (see page 23666)	Converts a variant's value to a string.
	VarToWideStr (see page 23666)	Converts a variant's value to a WideString.
	VarToWideStrDef (see page 23667)	Converts a variant's value to a WideString.
	VarType (see page 23667)	Returns the type code of a specified variant.
	VarTypeAsText (see page 23668)	Returns variant type descriptive string.
	VarTypeIsValidArrayType (see page 23669)	Indicates whether a Variant type code represents a type that can be used for the elements in a Variant array.
	VarTypeIsValidElementType (see page 23669)	Indicates whether a Variant type code represents a type that can be used for the elements in a Variant array.

Interfaces

	Name	Description
	IVarInstanceReference (see page 23614)	This is class Variants.IVarInstanceReference.
	IVarInvokeable (see page 23615)	This is class Variants.IVarInvokeable.

Structs, Records, Enums

	Name	Description
	TBooleanToStringRule (see page 23671)	TBooleanToStringRule enumerates possible rules for BooleanToStringRule (see page 23676).
	TNullCompareRule (see page 23671)	TNullCompareRule enumerates possible rules for comparing variant nulls with other values.
	TVarCompareResult (see page 23672)	This is record Variants.TVarCompareResult.
	TVariantRelationship (see page 23672)	TVariantRelationship describes the results of comparing two Variants.

Types

Name	Description
TAnyProc (see page 23674)	This is type Variants.TAnyProc.
TCustomVariantTypeClass (see page 23674)	This is type Variants.TCustomVariantTypeClass.
TVarDataArray (see page 23675)	This is type Variants.TVarDataArray.
TVarDispProc (see page 23675)	This is type Variants.TVarDispProc.

Variables

Name	Description
BooleanToStringRule (see page 23676)	Specifies rule fixing up Boolean values converted to strings.
ChangeAnyProc (see page 23677)	This is variable Variants.ChangeAnyProc.
ClearAnyProc (see page 23677)	This is variable Variants.ClearAnyProc.
EmptyParam (see page 23677)	Contains an OleVariant that represents an unused optional parameter on a dual interface.
NullAsStringValue (see page 23678)	Specifies string value of Null (see page 23641) variants.
NullEqualityRule (see page 23678)	Specifies rule for Null (see page 23641) variant equality comparison.

NullMagnitudeRule (see page 23679)	Specifies rule for Null (see page 23641) variant magnitude comparison.
NullStrictConvert (see page 23679)	Specifies whether Null (see page 23641) conversion is an error.
OleVariantInt64AsDouble (see page 23680)	This is variable Variants.OleVariantInt64AsDouble.
PackVarCreation (see page 23680)	Specifies whether space-efficient Variant Types (see page 23293) are preferred.
RefAnyProc (see page 23681)	This is variable Variants.RefAnyProc.
VarDispProc (see page 23681)	Provides the support for IDispatch-based Automation.

171.1 Classes

The following table lists classes in this documentation.

Classes

	Name	Description
	EVariantArrayCreateError (see page 23572)	EVariantArrayCreateError is the exception class for failure to create or resize a variant array.
	EVariantArrayLockedError (see page 23573)	EVariantArrayLockedError is the exception class for errors that occur because a variant array is locked or fixed.
	EVariantBadIndexError (see page 23574)	EVariantBadIndexError is the exception class for errors that occur because a variant array index is out of bounds.
	EVariantBadVarTypeError (see page 23574)	EVariantBadVarTypeError is the exception class for variant type errors.
	EVariantDispatchError (see page 23575)	EVariantDispatchError is the exception class for failed dispatch attempts.
	EVariantInvalidArgError (see page 23575)	EVariantInvalidArgError is the exception class for operations that fail due to invalid variant data.
	EVariantInvalidNullOpError (see page 23576)	EVariantInvalidNullOpError is the exception class for invalid Null (see page 23641) variant operations.
	EVariantInvalidOpError (see page 23577)	EVariantInvalidOpError is the exception class for invalid variant operations.
	EVariantNotAnArrayError (see page 23577)	EVariantNotAnArrayError is the exception class inappropriate variant array operations.
	EVariantNotImplError (see page 23578)	EVariantNotImplError is the exception class for unimplemented variant operations.
	EVariantOutOfMemoryError (see page 23578)	EVariantOutOfMemoryError is the exception class for variant operations that cannot allocate necessary memory.
	EVariantOverflowError (see page 23579)	EVariantOverflowError is the exception class for overflow in a variant operation.
	EVariantRangeCheckError (see page 23580)	EVariantRangeCheckError is the exception class for out-of-range errors in a variant operation.
	EVariantTypeCastError (see page 23580)	EVariantTypeCastError is the exception class for variant type cast errors.
	EVariantUnexpectedError (see page 23581)	EVariantUnexpectedError is the exception class for unexpected variant errors.
	TCustomVariantType (see page 23581)	TCustomVariantType is the base class for Delphi custom variant types.
	TInvokeableVariantType (see page 23606)	TInvokeableVariantType is the base class for custom Variant types that implement custom Variants (see page 23567) with properties and methods.

171.1.1 EVariantArrayCreateError Class

EVariantArrayCreateError is the exception class for failure to create or resize a variant array.

Class Hierarchy

Pascal

```
EVariantArrayCreateError = class(EVariantError);
```

C++

```
class EVariantArrayCreateError : public EVariantError;
```

File

Variants

Description

EVariantArrayCreateError is raised when an attempt to create or resize a variant array fails. To raise this exception programmatically, call VarArrayCreateError (see page 23645)

See Also

VarArrayCreateError (see page 23645)

TVarData (see page 22571)

VarArrayCreate (see page 23644)

VarArrayOf (see page 23648)

VarArrayRedim

TCustomVariantType (see page 23581)

VarArrayCreateError (see page 23645)

171.1.2 EVariantArrayLockedError Class

EVariantArrayLockedError is the exception class for errors that occur because a variant array is locked or fixed.

Class Hierarchy

Pascal

```
EVariantArrayLockedError = class(EVariantError);
```

C++

```
class EVariantArrayLockedError : public EVariantError;
```

File

Variants

Description

EVariantArrayLockedError is raised when an operation on a variant array fails because the array is locked or fixed.

See Also

TVarData (see page 22571)

TVariantManager

VarAsType (see page 23650)

VarArrayLock (see page 23646)

VarArrayUnlock (see page 23649)

VarArrayOf (see page 23648)

VarArrayRedim

171.1.3 EVariantBadIndexError Class

EVariantBadIndexError is the exception class for errors that occur because a variant array index is out of bounds.

Class Hierarchy

Pascal

```
EVariantBadIndexError = class(EVariantError);
```

C++

```
class EVariantBadIndexError : public EVariantError;
```

File

Variants

Description

EVariantBadIndexError is raised when an operation on a variant array fails because an index value is out of bounds.

See Also

TVarData (see page 22571)

TVariantManager

VarAsType (see page 23650)

VarArrayCreate (see page 23644)

VarArrayHighBound (see page 23646)

VarArrayLowBound (see page 23647)

VarArrayOf (see page 23648)

VarArrayRedim

TCustomVariantType (see page 23581)

171.1.4 EVariantBadVarTypeError Class

EVariantBadVarTypeError is the exception class for variant type errors.

Class Hierarchy

Pascal

```
EVariantBadVarTypeError = class(EVariantError);
```

C++

```
class EVariantBadVarTypeError : public EVariantError;
```

File

Variants

Description

EVariantBadVarTypeError is raised when a variant operation fails because of a value that isn't a valid variant type.

See Also

TVarData (see page 22571)

TVariantManager

VarAsType (see page 23650)

TCustomVariantType (see page 23581)

171.1.5 EVariantDispatchError Class

EVariantDispatchError is the exception class for failed dispatch attempts.

Class Hierarchy

Pascal

```
EVariantDispatchError = class(EVariantError);
```

C++

```
class EVariantDispatchError : public EVariantError;
```

File

Variants

Description

EVariantDispatchError is raised when a variant type is unable to dispatch a method call. Do not directly instantiate EVariantDispatchError. Instead call the RaiseDispError method of TCustomVariant.

See Also

TVarData (see page 22571)

171.1.6 EVariantInvalidArgError Class

EVariantInvalidArgError is the exception class for operations that fail due to invalid variant data.

Class Hierarchy

Pascal

```
EVariantInvalidArgError = class(EVariantError);
```

C++

```
class EVariantInvalidArgError : public EVariantError;
```

File

Variants

Description

EVariantInvalidArgError is raised when a variant operation fails because it was passed an inappropriate value.

See Also

TVarData (see page 22571)

TVariantManager

VarAsType (see page 23650)

TCustomVariantType (see page 23581)

171.1.7 EVariantInvalidNullOpError Class

EVariantInvalidNullOpError is the exception class for invalid Null (see page 23641) variant operations.

Class Hierarchy

Pascal

```
EVariantInvalidNullOpError = class(EVariantInvalidOpError);
```

C++

```
class EVariantInvalidNullOpError : public EVariantInvalidOpError;
```

File

Variants

Description

EVariantInvalidNullOpError is raised when a variant operation fails because the operation is not valid for Null (see page 23641) variants. To raise this exception programmatically, call VarInvalidNullOp (see page 23654).

Note: Do not raise EVariantInvalidNullOpError unless NullEqualityRule (see page 23678) or NullMagnitudeRule (see page 23679) is ncrError, and a corresponding operation has been attempted.

NullMagnitudeRule (see page 23679)

171.1.8 EVariantInvalidOpError Class

EVariantInvalidOpError is the exception class for invalid variant operations.

Class Hierarchy

Pascal

```
EVariantInvalidOpError = class(EVariantError);
```

C++

```
class EVariantInvalidOpError : public EVariantError;
```

File

Variants

Description

EVariantInvalidOpError is raised when a variant operation fails because the operands are incompatible with the specific operation. To raise this exception programmatically, call VarInvalidOp (see page 23655).

See Also

TVarData (see page 22571)

TCustomVariantType (see page 23581)

VarInvalidOp (see page 23655)

171.1.9 EVariantNotAnArrayError Class

EVariantNotAnArrayError is the exception class inappropriate variant array operations.

Class Hierarchy

Pascal

```
EVariantNotAnArrayError = class(EVariantError);
```

C++

```
class EVariantNotAnArrayError : public EVariantError;
```

File

Variants

Description

EVariantNotAnArrayError is raised when an array operation is attempted on a variant that does not contain an array.

See Also

VarArrayCreateError (see page 23645)

TVarData (see page 22571)

VarArrayCreate (see page 23644)

VarArrayCreateError (see page 23645)

171.1.10 EVariantNotImplError Class

EVariantNotImplError is the exception class for unimplemented variant operations.

Class Hierarchy

Pascal

```
EVariantNotImplError = class(EVariantError);
```

C++

```
class EVariantNotImplError : public EVariantError;
```

File

Variants

Description

EVariantNotImplError is raised when an operation is attempted on a variant type that does not implement that operation.

TCustomVariantType (see page 23581)

171.1.11 EVariantOutOfMemoryError Class

EVariantOutOfMemoryError is the exception class for variant operations that cannot allocate necessary memory.

Class Hierarchy

Pascal

```
EVariantOutOfMemoryError = class(EVariantError);
```

C++

```
class EVariantOutOfMemoryError : public EVariantError;
```

File

Variants

Description

EVariantOutOfMemoryError is raised when a variant operation fails because of a failure to allocate necessary memory.

171.1.12 EVariantOverflowError Class

EVariantOverflowError is the exception class for overflow in a variant operation.

Class Hierarchy

Pascal

```
EVariantOverflowError = class(EVariantError);
```

C++

```
class EVariantOverflowError : public EVariantError;
```

File

Variants

Description

EVariantOverflowError is raised when a variant operation fails because the result was too large. To raise this exception programmatically, call VarOverflowError (see page 23662).

See Also

TVarData (see page 22571)

TVariantManager

171.1.13 EVariantRangeCheckError Class

EVariantRangeCheckError is the exception class for out-of-range errors in a variant operation.

Class Hierarchy

Pascal

```
EVariantRangeCheckError = class(EVariantOverflowError);
```

C++

```
class EVariantRangeCheckError : public EVariantOverflowError;
```

File

Variants

Description

EVariantRangeCheckError is raised when a variant operation fails because the result is out-of-range for the destination variant type. To raise this exception programmatically, call VarRangeCheckError (see page 23663).

171.1.14 EVariantTypeCastError Class

EVariantTypeCastError is the exception class for variant type cast errors.

Class Hierarchy

Pascal

```
EVariantTypeCastError = class(EVariantError);
```

C++

```
class EVariantTypeCastError : public EVariantError;
```

File

Variants

Description

EVariantTypeCastError is raised when a variant operation fails because a value could not be cast to the destination variant type. To raise this exception programmatically, call VarCastError (see page 23651).

171.1.15 EVariantUnexpectedError Class

EVariantUnexpectedError is the exception class for unexpected variant errors.

Class Hierarchy

Pascal

```
EVariantUnexpectedError = class(EVariantError);
```

C++

```
class EVariantUnexpectedError : public EVariantError;
```

File

Variants

Description

EVariantUnexpectedError is raised when a variant operation generates an unexpected error.

171.1.16 TCustomVariantType Class

TCustomVariantType is the base class for Delphi custom variant types.

Class Hierarchy

Pascal

```
TCustomVariantType = class(TObject, IInterface);
```

C++

```
class TCustomVariantType : public TObject, public IInterface;
```

File

Variants

Description

Use TCustomVariantType to define new data types for Delphi Variants (see page 23567). TCustomVariantType descendants do not represent the Variants (see page 23567) themselves. Rather, they act as utility classes that the custom Variants (see page 23567) call on to perform their operations.

To create a Variant type,

1.Map the storage of the Variant's data on to the TVarData record.

2.Write a method that creates instances of your custom Variant. This fills in the Variant's data as defined in step 1.

3.Declare a class that descends from TCustomVariantType.

4.Implement all required behavior (including type conversion rules) in the new class. This involves overriding the appropriate virtual methods (typically BinaryOp (see page 23587), UnaryOp (see page 23598), CompareOp (see page 23590) or Compare (see page 23590), Cast (see page 23588), CastTo (see page 23589), Clear (see page 23589), Copy (see page 23591), IsClear (see page 23592), LeftPromotion (see page 23593), and RightPromotion (see page 23596)).

5.In the initialization section of the unit that defines your TCustomVariantType descendant, create an instance of your class. When you instantiate your object, it automatically registers itself with the Variant-handling system so that the new Variant type is enabled.

6.In the finalization section of the unit that defines your TCustomVariantType descendant, free the instance of your class. This automatically unregisters the Variant type.

Note: C++ can use Custom Variant types, but TCustomVariantType descendants must be implemented in Delphi.

For an example, see the FMTBcd (see page 13627) unit, which implements a custom Variant type for binary-coded decimal.

Tip: To create a custom Variant that allows users to call methods or procedures and to get or set property values, use TInvokeableVariantType (see page 23606) as a base class instead.

TInvokeableVariantType (see page 23606)

Creating a Class to Enable the Custom Variant Type

171.1.16.1 TCustomVariantType Members

The following tables list the members exposed by TCustomVariantType.

Protected Methods

	Name	Description
	_AddRef (see page 23586)	Increments the reference count for this interface.
	_Release (see page 23587)	Decrements the reference count for this interface.
	DispInvoke (see page 23592)	Invokes a method call when the Variant supports such operations.

	LeftPromotion (see page 23593)	Indicates whether the left argument to a binary operation should be coerced to a different type.
	OlePromotion (see page 23594)	Indicates the type to which a Variant value must be cast to make it Automation-compatible.
	QueryInterface (see page 23594)	Returns a reference to a specified interface if the object supports that interface.
	RaiseCastError (see page 23595)	Generates a system error that indicates an invalid cast.
	RaiseDispError (see page 23595)	Generates a system error indicating an invalid dispatch attempt.
	RaiseInvalidOp (see page 23596)	Generates a system error indicating an invalid operation.
	RightPromotion (see page 23596)	Indicates whether the right argument to a binary operation should be coerced to a different type.
	SimplisticClear (see page 23597)	Clears a TVarData record by re-initializing it.
	SimplisticCopy (see page 23598)	Performs a simple block copy of one TVarData record to another.
	VarDataCast (see page 23599)	Performs a cast from one Variant type to another.
	VarDataCastTo (see page 23599)	This is the overview for the VarDataCastTo method overload.
	VarDataCastToOleStr (see page 23600)	Performs a cast to a Variant type of varOleStr.
	VarDataClear (see page 23600)	Clears the data from a built-in Variant type.
	VarDataCopy (see page 23601)	Copies the data from one built-in Variant type to another.
	VarDataCopyNoInd (see page 23601)	Copies the data from one built-in Variant type to another.
	VarDataFromOleStr (see page 23602)	Creates a TVarData record to represent a Unicode string.
	VarDataFromStr (see page 23602)	Creates a TVarData record to represent a string.
	VarDataInit (see page 23602)	Initializes a TVarData record.
	VarDataIsArray (see page 23603)	Indicates whether a TVarData record represents the data from a Variant array.
	VarDataIsByRef (see page 23603)	Indicates whether a TVarData record stores its data indirectly.
	VarDataIsEmptyParam (see page 23603)	Indicates whether a TVarData record represents an unassigned optional parameter.
	VarDataIsFloat (see page 23604)	Indicates whether a TVarData record represents a floating-point value.
	VarDataIsNumeric (see page 23604)	Indicates whether a TVarData record represents a numeric value.
	VarDataIsOrdinal (see page 23605)	Indicates whether a TVarData record represents a ordinal value.
	VarDataIsStr (see page 23605)	Indicates whether a TVarData record represents a string (normal or Unicode).
	VarDataToStr (see page 23605)	Returns a string that represents the value from a TVarData record.

Public Methods

	Name	Description
	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
	BinaryOp (see page 23587)	Implements any binary operations of which the custom Variant type is capable.
	Cast (see page 23588)	Converts the data from another Variant type so that it represents this custom type's data format.
	CastTo (see page 23589)	This is CastTo, a member of class TCustomVariantType.
	CastToOle (see page 23589)	This is CastToOle, a member of class TCustomVariantType.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.
	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
	Clear (see page 23589)	Sets the data for this custom Variant type to a blank or unassigned value.
	Compare (see page 23590)	Implements comparisons that involve the custom Variant type.
	CompareOp (see page 23590)	Implements any comparison operations of which the custom Variant type is capable.
	Copy (see page 23591)	Copies the data from a Variant of this custom type.
	Create (see page 23584)	This is the overview for the Create constructor overload.
	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
	Destroy (see page 23585)	Frees an instance of TCustomVariantType (see page 23581).

	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
	IsClear (see page 23592)	Indicates whether the data from a custom Variant represents a blank or unassigned value.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
	UnaryOp (see page 23598)	Implements any unary operations of which the custom Variant type is capable.

Public Properties

	Name	Description
	VarType (see page 23606)	Indicates the Variant type code for the custom Variant type.

171.1.16.2 Create Constructor

This is the overview for the Create constructor overload.

Overload List

	Name	Description
	TCustomVariantType.Create () (see page 23584)	Creates an instance of TCustomVariantType (see page 23581).
	TCustomVariantType.Create (TVarType) (see page 23584)	Creates an instance of TCustomVariantType (see page 23581).

171.1.16.2.1 TCustomVariantType.Create Constructor ()

Creates an instance of TCustomVariantType (see page 23581).

Pascal

```
constructor Create; overload;
constructor Create(RequestedVarType: TVarType); overload;
```

C++

```
__fastcall TCustomVariantType();
__fastcall TCustomVariantType(TVarType RequestedVarType);
```

Description

Call Create in the initialization section of the unit that defines your TCustomVariantType (see page 23581) descendant to instantiate a single instance of the custom Variant type. This single instance automatically registers itself with the Variant system so that the custom Variant type is enabled in the application.

The RequestedVarType parameter specifies a type code for the new custom Variant type. It must be in the range from $010F to $0FFF.

When called with no parameters, the constructor generates a new type code for the custom Variant type.

The TCustomVariantType (see page 23581) constructor raises an exception if there is a problem with the new Variant type code. Such problems include

The RequestedVarType parameter specifies a type code that is already used by another Variant type.

The RequestedVarType parameter specifies a type code that is not in the valid range for custom Variants (see page 23567).

There are too many custom Variants (see page 23567) already defined to allow another one.

See Also

VarType (see page 23606)

171.1.16.3 TCustomVariantType.Destroy Destructor

Frees an instance of TCustomVariantType (see page 23581).

Pascal

```
destructor Destroy; override;
```

C++

```
virtual __fastcall ~TCustomVariantType();
```

Description

To free a TCustomVariantType (see page 23581) instance, use the Free method instead. Free checks that the instance is not already nil before calling Destroy.

Free the single instance of a TCustomVariantType (see page 23581) descendant from the finalization section of the unit that implements the class.

See Also

Create (see page 23584)

Free (see page 22300)

171.1.16.4 TCustomVariantType Methods

The methods of the TCustomVariantType class are listed here.

Protected Methods

	Name	Description
	_AddRef (see page 23586)	Increments the reference count for this interface.
	_Release (see page 23587)	Decrements the reference count for this interface.
V	DispInvoke (see page 23592)	Invokes a method call when the Variant supports such operations.
V	LeftPromotion (see page 23593)	Indicates whether the left argument to a binary operation should be coerced to a different type.
V	OlePromotion (see page 23594)	Indicates the type to which a Variant value must be cast to make it Automation-compatible.
V	QueryInterface (see page 23594)	Returns a reference to a specified interface if the object supports that interface.
	RaiseCastError (see page 23595)	Generates a system error that indicates an invalid cast.
	RaiseDispError (see page 23595)	Generates a system error indicating an invalid dispatch attempt.

	RaiseInvalidOp (see page 23596)	Generates a system error indicating an invalid operation.
V	RightPromotion (see page 23596)	Indicates whether the right argument to a binary operation should be coerced to a different type.
	SimplisticClear (see page 23597)	Clears a TVarData record by re-initializing it.
	SimplisticCopy (see page 23598)	Performs a simple block copy of one TVarData record to another.
	VarDataCast (see page 23599)	Performs a cast from one Variant type to another.
	VarDataCastTo (see page 23599)	This is the overview for the VarDataCastTo method overload.
	VarDataCastToOleStr (see page 23600)	Performs a cast to a Variant type of varOleStr.
	VarDataClear (see page 23600)	Clears the data from a built-in Variant type.
	VarDataCopy (see page 23601)	Copies the data from one built-in Variant type to another.
	VarDataCopyNoInd (see page 23601)	Copies the data from one built-in Variant type to another.
	VarDataFromOleStr (see page 23602)	Creates a TVarData record to represent a Unicode string.
	VarDataFromStr (see page 23602)	Creates a TVarData record to represent a string.
	VarDataInit (see page 23602)	Initializes a TVarData record.
	VarDataIsArray (see page 23603)	Indicates whether a TVarData record represents the data from a Variant array.
	VarDataIsByRef (see page 23603)	Indicates whether a TVarData record stores its data indirectly.
	VarDataIsEmptyParam (see page 23603)	Indicates whether a TVarData record represents an unassigned optional parameter.
	VarDataIsFloat (see page 23604)	Indicates whether a TVarData record represents a floating-point value.
	VarDataIsNumeric (see page 23604)	Indicates whether a TVarData record represents a numeric value.
	VarDataIsOrdinal (see page 23605)	Indicates whether a TVarData record represents a ordinal value.
	VarDataIsStr (see page 23605)	Indicates whether a TVarData record represents a string (normal or Unicode).
	VarDataToStr (see page 23605)	Returns a string that represents the value from a TVarData record.

Public Methods

	Name	Description
V	BinaryOp (see page 23587)	Implements any binary operations of which the custom Variant type is capable.
V	Cast (see page 23588)	Converts the data from another Variant type so that it represents this custom type's data format.
V	CastTo (see page 23589)	This is CastTo, a member of class TCustomVariantType.
V	CastToOle (see page 23589)	This is CastToOle, a member of class TCustomVariantType.
A	Clear (see page 23589)	Sets the data for this custom Variant type to a blank or unassigned value.
V	Compare (see page 23590)	Implements comparisons that involve the custom Variant type.
V	CompareOp (see page 23590)	Implements any comparison operations of which the custom Variant type is capable.
A	Copy (see page 23591)	Copies the data from a Variant of this custom type.
V	IsClear (see page 23592)	Indicates whether the data from a custom Variant represents a blank or unassigned value.
V	UnaryOp (see page 23598)	Implements any unary operations of which the custom Variant type is capable.

171.1.16.4.1 TCustomVariantType._AddRef Method

Increments the reference count for this interface.

Pascal

```
function _AddRef: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _AddRef();
```

Description

The Delphi compiler automatically generates a call to __AddRef for every reference to this interface. For most implementations, __AddRef increments the reference count for the interface and returns the new reference count. When the caller is through with the interface, the compiler generates a call to the _Release method, which decrements the reference count. When the reference count drops to zero, the object is automatically freed.

Note: Implementation objects can implement __AddRef and _Release so that they do not perform any reference counting. For such objects, the reference count never drops to zero and the object is not automatically freed. In these cases, it is the application's responsibility to free the object.

See Also

_Release (see page 22397)

171.1.16.4.2 TCustomVariantType._Release Method

Decrements the reference count for this interface.

Pascal

```
function _Release: Integer; stdcall;
```

C++

```
__fastcall __stdcall int _Release();
```

Description

The Delphi compiler automatically generates a call to __Release whenever a reference to this interface goes out of scope. For most implementations, __Release decrements the reference count for the interface and returns the new reference count. When the reference count drops to zero, the object is automatically freed.

Note: Implementation objects can implement __Release so that it does not perform any reference counting. For such objects, the reference count never drops to zero and the object is not automatically freed. In these cases, it is the application's responsibility to free the object.

See Also

_AddRef (see page 22397)

171.1.16.4.3 TCustomVariantType.BinaryOp Method

Implements any binary operations of which the custom Variant type is capable.

Pascal

```
procedure BinaryOp(var Left: TVarData; const Right: TVarData; const Operator: TVarOp); virtual;
```

C++

```
virtual __fastcall BinaryOp(TVarData Left, const TVarData Right, const TVarOp Operator);
```

Description

Override BinaryOp to implement any binary operators the custom Variant type supports.

Left is the value that appears to the left of the operator. BinaryOp changes this value to indicate the result of the operation.

Right is the value that appears to the right of the operator.

Operator identifies the operator that appears between Left and Right. It can be any of the following values:

Value	Operation
opAdd	addition
opSubtract	subtraction
opMultiply	multiplication
opDivide	floating-point division

opIntDivide	integer division
opModulus	remainder
opShiftLeft	bitwise left shift
opShiftRight	bitwise right shift
opAnd	bitwise and
opOr	bitwise or
opXor	bitwise exclusive or

As implemented in TCustomVariantType (see page 23581), BinaryOp raises a system error indicating an invalid operation.

See Also

UnaryOp (see page 23598)

CompareOp (see page 23590)

LeftPromotion (see page 23593)

RightPromotion (see page 23596)

Implementing Binary Operations

171.1.16.4.4 TCustomVariantType.Cast Method

Converts the data from another Variant type so that it represents this custom type's data format.

Pascal

```
procedure Cast(var Dest: TVarData; const Source: TVarData); virtual;
```

C++

```
virtual __fastcall Cast(TVarData Dest, const TVarData Source);
```

Description

Override Cast to enable other types of Variants (see page 23567) to be cast to this custom Variant type.

Dest is a TVarData record that returns the Variant's data stored in the format used by this custom Variant type. The Cast method fills out this record from the information in Source.

Source is a TVarData record that contains the data from another Variant type. Check the VType field of Source to identify how it currently stores its data. Then use the other fields to fetch the data and convert it to the format used by this Variant type.

As implemented in TCustomVariantType (see page 23581), Cast checks whether Source is another custom Variant type. If so, it calls its CastTo (see page 23589) method, to convert it to this Variant type. If not, it raises a system error indicating an invalid cast.

See Also

castto (see page 23589)

VarDataCast (see page 23599)

Enabling Casting

171.1.16.4.5 TCustomVariantType.CastTo Method

Pascal

```
procedure CastTo(var Dest: TVarData; const Source: TVarData; const AVarType: TVarType);
virtual;
```

C++

```
virtual __fastcall CastTo(TVarData Dest, const TVarData Source, const TVarType AVarType);
```

Description

This is CastTo, a member of class TCustomVariantType.

171.1.16.4.6 TCustomVariantType.CastToOle Method

Pascal

```
procedure CastToOle(var Dest: TVarData; const Source: TVarData); virtual;
```

C++

```
virtual __fastcall CastToOle(TVarData Dest, const TVarData Source);
```

Description

This is CastToOle, a member of class TCustomVariantType.

171.1.16.4.7 TCustomVariantType.Clear Method

Sets the data for this custom Variant type to a blank or unassigned value.

Pascal

```
procedure Clear(var V: TVarData); virtual; abstract;
```

C++

```
virtual __fastcall Clear(TVarData V) = 0;
```

Description

Override Clear to implement the way this custom Variant type represents a blank or unassigned value.

V is a TVarData record that represents the data from a Variant of this custom type that needs to be cleared.

In TCustomVariantType (see page 23581), Clear is an abstract method. Descendant classes must override this method to provide an implementation. If the custom Variant type stores its data in a manner that includes memory that needs to be freed, Clear should free that memory. Once any memory is freed, Clear can call the SimplisticClear (see page 23597) method, which re-initializes the TVarData record, or set the VType field to varEmpty.

See Also

Unassigned (see page 23643)

IsClear (see page 23592)

SimplisticClear (see page 23597)

VarDataClear (see page 23600)

Copying and Clearing Custom Variants

171.1.16.4.8 TCustomVariantType.Compare Method

Implements comparisons that involve the custom Variant type.

Pascal

```
procedure Compare(const Left: TVarData; const Right: TVarData; var Relationship:
TVarCompareResult); virtual;
```

C++

```
virtual __fastcall Compare(const TVarData Left, const TVarData Right, TVarCompareResult
Relationship);
```

Description

Override Compare to implement any comparison operators the custom Variant type supports. Descendants can implement comparison operators by overriding either the Compare or the CompareOp (see page 23590) method.

Left is the value that appears to the left of the operator.

Right is the value that appears to the right of the operator.

Relationship returns a value indicating the relationship between Left and Right, as indicated in the following table:

Value	Operation
crLessThan	Left is less than Right.
crEqual	Left is equal to Right.
crGreaterThan	Left is greater than Right.

As implemented in TCustomVariantType (see page 23581), CompareOp (see page 23590) raises a system error indicating an invalid operation.

Tip: For custom Variants (see page 23567) that support a test of inequality, but not ordering, it makes more sense to override the CompareOp (see page 23590) method instead.

See Also

CompareOp (see page 23590)

CompareValue (see page 15938)

Implementing Comparison Operations

171.1.16.4.9 TCustomVariantType.CompareOp Method

Implements any comparison operations of which the custom Variant type is capable.

Pascal

```
function CompareOp(const Left: TVarData; const Right: TVarData; const Operator: TVarOp):
Boolean; virtual;
```

C++

```
virtual __fastcall Boolean CompareOp(const TVarData Left, const TVarData Right, const TVarOp
Operator);
```

Description

Override CompareOp to implement any comparison operators the custom Variant type supports. Descendants can implement comparison operators by overriding either the Compare (see page 23590) or the CompareOp method.

Left is the value that appears to the left of the operator.

Right is the value that appears to the right of the operator.

Operator identifies the operator that appears between Left and Right. It can be any of the following values:

Value	Operation
opCmpEQ	equality comparison
opCmpNE	inequality comparison
opCmpLT	less than
opCmpLE	less than or equal
opCmpGT	greater than
opCmpGE	greater than or equal

CompareOp returns true if the comparison is true as specified. It returns false if the specified comparison does not hold true.

As implemented in TCustomVariantType (see page 23581), CompareOp raises a system error indicating an invalid operation.

See Also

UnaryOp (see page 23598)

BinaryOp (see page 23587)

LeftPromotion (see page 23593)

RightPromotion (see page 23596)

Compare (see page 23590)

Implementing Comparison Operations

171.1.16.4.10 TCustomVariantType.Copy Method

Copies the data from a Variant of this custom type.

Pascal

```
procedure Copy(var Dest: TVarData; const Source: TVarData; const Indirect: Boolean); virtual;
abstract;
```

C++

```
virtual __fastcall Copy(TVarData Dest, const TVarData Source, const Boolean Indirect) = 0;
```

Description

Override Copy to enable the custom Variant type to be copied (assigned) to another Variant.

Dest is the TVarData record from the Variant whose value is to be a copy of the source Variant.

Source is the TVarData record from a Variant of this custom type that is to be copied to Dest.

Indirect indicates whether the copy is direct or indirect. When Indirect is true, the source TVarData record contains an indirect reference to its data (the VarDataIsByRef (see page 23603) method should return true for Source). When making an indirect copy, it is not necessary to reallocate records or objects, because the Variant does not "own" the data, it merely points to it. When making a direct copy, Copy must allocate new memory for any allocated records or objects, so that Dest can "own" its own copy of the data.

In TCustomVariantType (see page 23581), Copy is an abstract method. Descendant classes must override this method to provide an implementation.

See Also

VarDataCopy (see page 23601)

VarDataCopyNoInd (see page 23601)

SimplisticCopy (see page 23598)

VarDataIsByRef (see page 23603)

Copying and Clearing Custom Variants

171.1.16.4.11 TCustomVariantType.DispInvoke Method

Invokes a method call when the Variant supports such operations.

Pascal

```
procedure DispInvoke(Dest: PVarData; const Source: TVarData; CallDesc: PCallDesc; Params:
Pointer); virtual;
```

C++

```
virtual __fastcall DispInvoke(PVarData Dest, const TVarData Source, PCallDesc CallDesc, void *
Params);
```

Description

When the application tries to call a method, set a property, or read a property using a Variant of the custom Variant type, the system automatically generates a call to DispInvoke. TCustomVariantType (see page 23581) responds by generating a system error indicating an invalid dispatch attempt.

To create a custom Variant type that allows applications to call methods or use properties, use TInvokeableVariantType (see page 23606) as a base class instead of TCustomVariantType (see page 23581). TInvokeableVariantType (see page 23606) introduces methods for executing method calls and implementing properties, and overrides the DispInvoke method so that it dispatches method calls to the appropriate methods.

Dest is a TVarData record that receives the return value of any function calls.

Source is the TVarData record that holds the data from the custom Variant whose property or method was invoked.

CallDesc identifies the method that was called, including the type and number of its arguments.

Params points to an array of parameter values that were passed in the method call.

See Also

TInvokeableVariantType (see page 23606)

171.1.16.4.12 TCustomVariantType.IsClear Method

Indicates whether the data from a custom Variant represents a blank or unassigned value.

Pascal

```
function IsClear(const V: TVarData): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean IsClear(const TVarData V);
```

Description

Override IsClear to identify when data from a Variant of the custom Variant type represents a blank or unassigned value. The global VarIsClear (see page 23656) method calls IsClear when given a custom Variant of this type.

As Implemented in TCustomVariantType (see page 23581), IsClear always returns false. Override this method to return true for invalid values or special values set by the Clear (see page 23589) method.

See Also

Clear (see page 23589)

VarIsClear (see page 23656)

Copying and Clearing Custom Variants

171.1.16.4.13 TCustomVariantType.LeftPromotion Method

Indicates whether the left argument to a binary operation should be coerced to a different type.

Pascal

```
function LeftPromotion(const V: TVarData; const Operator: TVarOp; out RequiredVarType:
TVarType): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean LeftPromotion(const TVarData V, const TVarOp Operator, TVarType
RequiredVarType);
```

Description

Override LeftPromotion to indicate when the left argument for a binary or comparison operation should be implicitly cast to another type before performing the operation. LeftPromotion is called when the right-hand Variant in a binary or comparison operation is of this Variant type and

The left-hand argument is a built-in Variant type.

The left-hand argument is a custom Variant type that does not indicate any problem with this Variant type for the right-hand argument.

V is the TVarData record for the left-hand argument of the operation.

Operator indicates the type of operation. It can be any of the operators in the following table:

Value	Operation
opAdd	addition
opSubtract	subtraction
opMultiply	multiplication
opDivide	floating-point division
opIntDivide	integer division
opModulus	remainder
opShiftLeft	left shift
opShiftRight	right shift
opAnd	bitwise and
opOr	bitwise or
opXor	bitwise exclusive or
opCompare	any comparison operation

RequiredVarType returns the Variant type code for the type to which the left-hand argument should be cast before performing the operation. If the operation can proceed with the left-hand argument left as-is, RequiredVarType returns the VType field of V.

LeftPromotion returns true if the TCustomVariantType (see page 23581) descendant can perform the operation (using the BinaryOp (see page 23587), CompareOp (see page 23590), or Compare (see page 23590) method) assuming the left-hand argument can be cast to RequiredVarType. It returns false if the TCustomVariantType (see page 23581) descendant can't perform the operation.

As implemented in TCustomVariantType (see page 23581), LeftPromotion returns the VarType (see page 23606) property as RequiredVarType, and returns true.

See Also

BinaryOp (see page 23587)

CompareOp (see page 23590)

Compare (see page 23590)

VarType (see page 23606)

RightPromotion (see page 23596)

Implementing Binary Operations

171.1.16.4.14 TCustomVariantType.OlePromotion Method

Indicates the type to which a Variant value must be cast to make it Automation-compatible.

Pascal

```
function OlePromotion(const V: TVarData; out RequiredVarType: TVarType): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean OlePromotion(const TVarData V, TVarType RequiredVarType);
```

Description

Override OlePromotion to indicate when a Variant of this custom Variant type must be cast to another type before it can be auto-marshaled using an Automation interface.

V is the TVarData record for the custom Variant that the application wants to marshal.

RequiredVarType returns the type to which V must be cast before it is Automation-compatible.

OlePromotion returns true if V can be cast to an Automation-compatible type, false if there is no type to which V can be cast.

As implemented in TCustomVariantType (see page 23581), OlePromotion sets RequiredVarType to varOleStr and returns true if V does not already represent a Unicode string.

See Also

casttoole (see page 23589)

171.1.16.4.15 TCustomVariantType.QueryInterface Method

Returns a reference to a specified interface if the object supports that interface.

Pascal

```
function QueryInterface(const IID: TGUID; out Obj): HResult; virtual; stdcall;
```

C++

```
virtual __fastcall __stdcall HRESULT QueryInterface(const TGUID IID,  Obj);
```

Description

QueryInterface checks whether the TCustomVariantType (see page 23581) object supports the interface specified by IID. If so, QueryInterface

increments the reference count.

sets the Obj parameter so that it points to an instance of the specified interface.

returns 0 to indicate success.

If the object does not support the interface, QueryInterface returns a nonzero error code such as E_NoInterface.

See Also

_addref (see page 23586)

_release (see page 23587)

171.1.16.4.16 TCustomVariantType.RaiseCastError Method

Generates a system error that indicates an invalid cast.

Pascal

```
procedure RaiseCastError;
```

C++

```
__fastcall RaiseCastError();
```

Description

Call RaiseCastError from the implementation of a TCustomVariantType (see page 23581) descendant when an operation fails because a Variant value could not be cast to a necessary type.

See Also

Cast (see page 23588)

castto (see page 23589)

171.1.16.4.17 TCustomVariantType.RaiseDispError Method

Generates a system error indicating an invalid dispatch attempt.

Pascal

```
procedure RaiseDispError;
```

C++

```
__fastcall RaiseDispError();
```

Description

Call RaiseDispError from the implementation of a TCustomVariantType (see page 23581) descendant when an operation fails because the variant can't execute a method call. This raises EVariantDispatchError (see page 23575).

See Also

DispInvoke (see page 23592)

EVariantDispatchError (see page 23575)

171.1.16.4.18 TCustomVariantType.RaiseInvalidOp Method

Generates a system error indicating an invalid operation.

Pascal

```
procedure RaiseInvalidOp;
```

C++

```
__fastcall RaiseInvalidOp();
```

Description

Call RaiseInvalidOp from the implementation of a TCustomVariantType (see page 23581) descendant when it can't perform an operation.

See Also

BinaryOp (see page 23587)

UnaryOp (see page 23598)

CompareOp (see page 23590)

Compare (see page 23590)

171.1.16.4.19 TCustomVariantType.RightPromotion Method

Indicates whether the right argument to a binary operation should be coerced to a different type.

Pascal

```
function RightPromotion(const V: TVarData; const Operator: TVarOp; out RequiredVarType:
TVarType): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean RightPromotion(const TVarData V, const TVarOp Operator, TVarType
RequiredVarType);
```

Description

Override RightPromotion to indicate when the right-hand argument for a binary or comparison operation should be implicitly cast to another type before performing the operation. RightPromotion is called when the right-hand Variant in a binary or comparison operation is of this Variant type.

Note: In operations that involve two custom Variants (see page 23567), the left-hand argument's RightPromotion method is called first. The right-hand argument's LeftPromotion (see page 23593) method is then called only if the left-hand argument's RightPromotion method returns false.

V is the TVarData record for the left-hand argument of the operation.

Operator indicates the type of operation. It can be any of the operators in the following table:

Value	Operation
opAdd	addition
opSubtract	subtraction
opMultiply	multiplication
opDivide	floating-point division
opIntDivide	integer division

opModulus	remainder
opShiftRight	right shift
opShiftRight	right shift
opAnd	bitwise and
opOr	bitwise or
opXor	bitwise exclusive or
opCompare	any comparison operation

RequiredVarType returns the Variant type code for the type to which the right-hand argument should be cast before performing the operation. If the operation can proceed with the right-hand argument left as-is, RequiredVarType returns the VType field of V.

RightPromotion returns true if the TCustomVariantType (see page 23581) descendant can perform the operation (using the BinaryOp (see page 23587), CompareOp (see page 23590), or Compare (see page 23590) method) assuming the right-hand argument can be cast to RequiredVarType. It returns false if the TCustomVariantType (see page 23581) descendant can't perform the operation.

As implemented in TCustomVariantType (see page 23581), RightPromotion returns the VarType (see page 23606) property as RequiredVarType, and returns true.

See Also

BinaryOp (see page 23587)

CompareOp (see page 23590)

Compare (see page 23590)

VarType (see page 23606)

LeftPromotion (see page 23593)

Implementing Binary Operations

171.1.16.4.20 TCustomVariantType.SimplisticClear Method

Clears a TVarData record by re-initializing it.

Pascal

```
procedure SimplisticClear(var V: TVarData);
```

C++

```
__fastcall SimplisticClear(TVarData V);
```

Description

Call SimplisticClear from the implementation of a TCustomVariantType (see page 23581) descendant to clear the TVarData record of a Variant of the custom type. This method should only be called if the TVarData record does not contain any members that must be freed.

SimplisticClear simply calls the VarDataInit (see page 23602) method, which reinitializes the TVarData record passed as V.

See Also

Clear (see page 23589)

VarDataClear (see page 23600)

VarDataInit (see page 23602)

171.1.16.4.21 TCustomVariantType.SimplisticCopy Method

Performs a simple block copy of one TVarData record to another.

Pascal

```
procedure SimplisticCopy(var Dest: TVarData; const Source: TVarData; const Indirect: Boolean =
False);
```

C++

```
__fastcall SimplisticCopy(TVarData Dest, const TVarData Source, const Boolean Indirect =
False);
```

Description

Call SimplisticCopy from the implementation of a TCustomVariantType (see page 23581) descendant to block copy one TVarData record to another.

Dest is the TVarData record that receives the copy.

Source is the TVarData record to copy.

Indirect indicates whether Source represents the data (false) or merely a reference to the data (true).

See Also

Copy (see page 23591)

VarDataCopy (see page 23601)

VarDataCopyNoInd (see page 23601)

Copying and Clearing Custom Variants

171.1.16.4.22 TCustomVariantType.UnaryOp Method

Implements any unary operations of which the custom Variant type is capable.

Pascal

```
procedure UnaryOp(var Right: TVarData; const Operator: TVarOp); virtual;
```

C++

```
virtual __fastcall UnaryOp(TVarData Right, const TVarOp Operator);
```

Description

Override UnaryOp to implement any unary operators the custom Variant type supports.

Right is the value that appears to the right of the operator. UnaryOp changes this value to indicate the result of the operation.

Operator identifies the operator that appears before Right. It can be any of the following values:

Value	Operation
opNegate	unary minus
opNot	logical negation

As implemented in TCustomVariantType (see page 23581), UnaryOp raises a system error indicating an invalid operation.

See Also

BinaryOp (see page 23587)

CompareOp (see page 23590)

Implementing Unary Operations

171.1.16.4.23 TCustomVariantType.VarDataCast Method

Performs a cast from one Variant type to another.

Pascal

```
procedure VarDataCast(var Dest: TVarData; const Source: TVarData);
```

C++

```
__fastcall VarDataCast(TVarData Dest, const TVarData Source);
```

Description

Call VarDataCast from the implementation of a TCustomVariantType (see page 23581) descendant to perform casts on the data from another Variant type to the type specified by the VarType (see page 23606) property. Do not use VarDataCast as the entire implementation of the Cast (see page 23588) method, as this will lead to a circular reference.

Dest returns the result of the cast.

Source is the TVarData record of another Variant type that is to be converted.

See Also

Cast (see page 23588)

castto (see page 23589)

VarDataCastTo (see page 23599)

VarType (see page 23606)

171.1.16.4.24 VarDataCastTo Method

This is the overview for the VarDataCastTo method overload.

Overload List

	Name	Description
	TCustomVariantType.VarDataCastTo (TVarData, TVarData, TVarType) (see page 23599)	Performs a cast from one Variant type to another.
	TCustomVariantType.VarDataCastTo (TVarData, TVarType) (see page 23599)	Performs a cast from one Variant type to another.

171.1.16.4.24.1 TCustomVariantType.VarDataCastTo Method (TVarData, TVarData, TVarType)

Performs a cast from one Variant type to another.

Pascal

```
procedure VarDataCastTo(var Dest: TVarData; const Source: TVarData; const AVarType: TVarType);
overload;
procedure VarDataCastTo(var Dest: TVarData; const AVarType: TVarType); overload;
```

C++

```
__fastcall VarDataCastTo(TVarData Dest, const TVarData Source, const TVarType AVarType);
```

```
__fastcall VarDataCastTo(TVarData Dest, const TVarType AVarType);
```

Description

Call VarDataCastTo from the implementation of a TCustomVariantType (see page 23581) descendant to perform casts on the data from one Variant type to another. Do not use VarDataCastTo as the entire implementation of the CastTo (see page 23589) method, as this will lead to a circular reference.

Dest returns the result of the cast. If VarDataCastTo is called with no Source parameter, it also provides the source data to be cast.

Source is the TVarData record to be cast.

VarType (see page 23606) is the type code of the Variant type to which the data should be cast.

See Also

castto (see page 23589)

171.1.16.4.25 TCustomVariantType.VarDataCastToOleStr Method

Performs a cast to a Variant type of varOleStr.

Pascal

```
procedure VarDataCastToOleStr(var Dest: TVarData);
```

C++

```
__fastcall VarDataCastToOleStr(TVarData Dest);
```

Description

Call VarDataCastToOleStr from the implementation of a TCustomVariantType (see page 23581) descendant to perform casts to a TVarData record with Variant type code of varOleStr (Unicode string).

Dest is the TVarData record of a Variant, and returns the result of the cast.

See Also

VarDataFromOleStr (see page 23602)

VarDataToStr (see page 23605)

171.1.16.4.26 TCustomVariantType.VarDataClear Method

Clears the data from a built-in Variant type.

Pascal

```
procedure VarDataClear(var Dest: TVarData);
```

C++

```
__fastcall VarDataClear(TVarData Dest);
```

Description

Call VarDataClear from the implementation of a TCustomVariantType (see page 23581) descendant to clear the data in the TVarData record of a Variant. Do not use VarDataClear as the entire implementation of the Clear (see page 23589) method, as this will lead to a circular reference.

Dest is the TVarData record of a Variant type, and returns the result after clearing the data.

See Also

SimplisticClear (see page 23597)

Clear (see page 23589)

171.1.16.4.27 TCustomVariantType.VarDataCopy Method

Copies the data from one built-in Variant type to another.

Pascal

```
procedure VarDataCopy(var Dest: TVarData; const Source: TVarData);
```

C++

```
__fastcall VarDataCopy(TVarData Dest, const TVarData Source);
```

Description

Call VarDataCopy from the implementation of a TCustomVariantType (see page 23581) descendant to clear the data from a destination Variant and then copy the TVarData record from another Variant. VarDataCopy can handle data that is stored indirectly (when the VType field includes varByRef). Do not use VarDataCopy as the entire implementation of the Copy (see page 23591) method, as this will lead to a circular reference.

Dest is the TVarData record that receives the copy.

Source is the TVarData record to be copied.

See Also

SimplisticCopy (see page 23598)

VarDataCopyNoInd (see page 23601)

Copy (see page 23591)

171.1.16.4.28 TCustomVariantType.VarDataCopyNoInd Method

Copies the data from one built-in Variant type to another.

Pascal

```
procedure VarDataCopyNoInd(var Dest: TVarData; const Source: TVarData);
```

C++

```
__fastcall VarDataCopyNoInd(TVarData Dest, const TVarData Source);
```

Description

Call VarDataCopyNoInd from the implementation of a TCustomVariantType (see page 23581) descendant to clear the data from a destination Variant and then copy the TVarData record from another Variant. Unlike the VarDataCopy (see page 23601) method, it can't handle data that is stored indirectly (when the VType field includes varByRef). However, it is often more efficient than VarDataCopy (see page 23601).

Dest is the TVarData record that receives the copy.

Source is the TVarData record to be copied.

See Also

VarDataCopy (see page 23601)

Copy (see page 23591)

171.1.16.4.29 TCustomVariantType.VarDataFromOleStr Method

Creates a TVarData record to represent a Unicode string.

Pascal

```
procedure VarDataFromOleStr(var V: TVarData; const Value: WideString);
```

C++

```
__fastcall VarDataFromOleStr(TVarData V, const BSTR Value);
```

Description

Call VarDataCopy (see page 23601) from the implementation of a TCustomVariantType (see page 23581) descendant to fill out a TVarData record so that it represents a specified Unicode string.

V is the TVarData record to be filled out.

Value is a Unicode string that becomes the value of V.

See Also

VarDataCastToOleStr (see page 23600)

VarDataFromStr (see page 23602)

171.1.16.4.30 TCustomVariantType.VarDataFromStr Method

Creates a TVarData record to represent a string.

Pascal

```
procedure VarDataFromStr(var V: TVarData; const Value: string);
```

C++

```
__fastcall VarDataFromStr(TVarData V, const AnsiString Value);
```

Description

Call VarDataCopy (see page 23601) from the implementation of a TCustomVariantType (see page 23581) descendant to fill out a TVarData record so that it represents a specified string.

V is the TVarData record to be filled out.

Value is a string that becomes the value of V.

See Also

VarDataFromOleStr (see page 23602)

VarDataIsStr (see page 23605)

VarDataToStr (see page 23605)

171.1.16.4.31 TCustomVariantType.VarDataInit Method

Initializes a TVarData record.

Pascal

```
procedure VarDataInit(var Dest: TVarData);
```

C++

```
__fastcall VarDataInit(TVarData Dest);
```

Description

Call VarDataInit from the implementation of a TCustomVariantType (see page 23581) descendant to initialize a newly-allocated TVarData record.

See Also

VarDataClear (see page 23600)

171.1.16.4.32 TCustomVariantType.VarDataIsArray Method

Indicates whether a TVarData record represents the data from a Variant array.

Pascal

```
function VarDataIsArray(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsArray(const TVarData V);
```

Description

VarDataIsArray returns true if the VType field of V contains the varArray bit.

See Also

VarDataIsByRef (see page 23603)

VarType (see page 23667)

171.1.16.4.33 TCustomVariantType.VarDataIsByRef Method

Indicates whether a TVarData record stores its data indirectly.

Pascal

```
function VarDataIsByRef(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsByRef(const TVarData V);
```

Description

VarDataIsArray (see page 23603) returns true if the VType field of V contains the varByRef bit.

See Also

VarDataIsArray (see page 23603)

VarType (see page 23667)

171.1.16.4.34 TCustomVariantType.VarDataIsEmptyParam Method

Indicates whether a TVarData record represents an unassigned optional parameter.

Pascal

```
function VarDataIsEmptyParam(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsEmptyParam(const TVarData V);
```

Description

VarDataIsEmptyParam returns true if the given TVarData record represents an unassigned optional parameter.

See Also

VarDataIsArray (see page 23603)

VarType (see page 23667)

171.1.16.4.35 TCustomVariantType.VarDataIsFloat Method

Indicates whether a TVarData record represents a floating-point value.

Pascal

```
function VarDataIsFloat(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsFloat(const TVarData V);
```

Description

VarDataIsFloat returns true if the given TVarData record comes from a built-in Variant type that represents a floating-point value (Single, Double, or Currency). VarDataIsFloat does not return true for data from Custom Variant types.

See Also

VarDataIsNumeric (see page 23604)

VarType (see page 23667)

VarDataIsOrdinal (see page 23605)

VarDataIsStr (see page 23605)

171.1.16.4.36 TCustomVariantType.VarDataIsNumeric Method

Indicates whether a TVarData record represents a numeric value.

Pascal

```
function VarDataIsNumeric(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsNumeric(const TVarData V);
```

Description

VarDataIsNumeric returns true if the given TVarData record represents a numeric value of some sort. This can be either a floating-point value or an ordinal value. VarDataIsNumeric does not return true for data from Custom Variant types.

See Also

VarDataIsFloat (see page 23604)

VarType (see page 23667)

VarDataIsOrdinal (see page 23605)

VarDataIsStr (see page 23605)

171.1.16.4.37 TCustomVariantType.VarDataIsOrdinal Method

Indicates whether a TVarData record represents a ordinal value.

Pascal

```
function VarDataIsOrdinal(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsOrdinal(const TVarData V);
```

Description

VarDataIsOrdinal returns true if the given TVarData record comes from a built-in Variant type that represents a ordinal value (such as an integer or Boolean type). VarDataIsOrdinal does not return true for data from Custom Variant types.

See Also

VarDataIsNumeric (see page 23604)

VarType (see page 23667)

VarDataIsFloat (see page 23604)

VarDataIsStr (see page 23605)

171.1.16.4.38 TCustomVariantType.VarDataIsStr Method

Indicates whether a TVarData record represents a string (normal or Unicode).

Pascal

```
function VarDataIsStr(const V: TVarData): Boolean;
```

C++

```
__fastcall Boolean VarDataIsStr(const TVarData V);
```

Description

VarDataIsStr returns true if the given TVarData record has a VType field of varString or varOleStr.

See Also

VarDataIsNumeric (see page 23604)

VarType (see page 23667)

VarDataIsFloat (see page 23604)

VarDataIsStr

171.1.16.4.39 TCustomVariantType.VarDataToStr Method

Returns a string that represents the value from a TVarData record.

Pascal

```
function VarDataToStr(const V: TVarData): string;
```

C++

```
__fastcall AnsiString VarDataToStr(const TVarData V);
```

Description

Call VarDataToStr from the implementation of a TCustomVariantType (see page 23581) descendant to extract a string that represents the value of a Variant.

V is the TVarData record that represents the value of the Variant.

See Also

VarDataCastToOleStr (see page 23600)

VarDataFromStr (see page 23602)

171.1.16.5 TCustomVariantType Properties

The properties of the TCustomVariantType class are listed here.

Public Properties

	Name	Description
R	VarType (see page 23606)	Indicates the Variant type code for the custom Variant type.

171.1.16.5.1 TCustomVariantType.VarType Property

Indicates the Variant type code for the custom Variant type.

Pascal

```
property VarType: TVarType;
```

C++

```
__property TVarType VarType;
```

Description

The VarType property provides read-only access to the type code that identifies a custom Variant data type.

The value of VarType is set in the constructor. This can be an automatically generated value, or it can be a value explicitly passed to the constructor. Note that if the VarType is automatically-generated, it may not remain the same for every application that uses the custom Variant type: its value will depend on the other custom Variants (see page 23567) also used in the application.

Enabling Casting

171.1.17 TInvokeableVariantType Class

TInvokeableVariantType is the base class for custom Variant types that implement custom Variants (see page 23567) with properties and methods.

Class Hierarchy

Pascal

```
TInvokeableVariantType = class(TCustomVariantType, IVarInvokeable);
```

C++

```
class TInvokeableVariantType : public TCustomVariantType, public IVarInvokeable;
```

File

Variants

Description

Use TInvokeableVariantType to define new data types for Delphi Variants (see page 23567) with properties and methods. TInvokeableVariantType descendants do not represent the Variants (see page 23567) themselves. Rather, they act as utility classes that the custom Variants (see page 23567) call on to perform their operations.

Note: Do not define TInvokeableVariantType descendants in C++. The logic for custom Variant types must be defined in Delphi code.

To create a Variant type that supports properties and methods,

1. Map the storage of the Variant's data on to the TVarData record.
2. Write a method that creates instances of your custom Variant. This fills in the Variant's data as defined in step 1.
3. Declare a class that descends from TInvokeableVariantType.
4. Implement all required behavior (including type conversion rules) in the new class. This involves overriding the appropriate virtual methods (typically DoFunction (see page 23610), DoProcedure (see page 23611), GetProperty (see page 23612), SetProperty (see page 23613), BinaryOp (see page 23587), UnaryOp (see page 23598), CompareOp (see page 23590) or Compare (see page 23590), Cast (see page 23588), CastTo (see page 23589), Clear (see page 23589), Copy (see page 23591), IsClear (see page 23592), LeftPromotion (see page 23593), and RightPromotion (see page 23596)).
5. In the initialization section of the unit that defines your TInvokeableVariantType descendant, create an instance of your class. When you instantiate your object, it automatically registers itself with the Variant-handling system so that the new Variant type is enabled.
6. In the finalization section of the unit that defines your TInvokeableVariantType descendant, free the instance of your class. This automatically unregisters the Variant type.

For an example, see the VarConv (see page 23561) unit, which implements a custom Variant type for measurements.

Tip: If the custom Variant type uses an object instance to store its data, you can automatically implement the published properties of that object by deriving your custom Variant type from TPublishableVariantType instead.

Supporting Properties and Methods in Custom Variants

171.1.17.1 TInvokeableVariantType Members

The following tables list the members exposed by TInvokeableVariantType.

Protected Methods

	Name	Description
	_AddRef (see page 23586)	Increments the reference count for this interface.
	_Release (see page 23587)	Decrements the reference count for this interface.
V	DispInvoke (see page 23610)	Invokes a method call by dispatching it to the appropriate TInvokeableVariantType (see page 23606) method.
V	FixupIdent (see page 23612)	Fixes up dispatch identifier.
V	LeftPromotion (see page 23593)	Indicates whether the left argument to a binary operation should be coerced to a different type.
V	OlePromotion (see page 23594)	Indicates the type to which a Variant value must be cast to make it Automation-compatible.
V	QueryInterface (see page 23594)	Returns a reference to a specified interface if the object supports that interface.
	RaiseCastError (see page 23595)	Generates a system error that indicates an invalid cast.
	RaiseDispError (see page 23595)	Generates a system error indicating an invalid dispatch attempt.
	RaiseInvalidOp (see page 23596)	Generates a system error indicating an invalid operation.
V	RightPromotion (see page 23596)	Indicates whether the right argument to a binary operation should be coerced to a different type.
	SimplisticClear (see page 23597)	Clears a TVarData record by re-initializing it.
	SimplisticCopy (see page 23598)	Performs a simple block copy of one TVarData record to another.
	VarDataCast (see page 23599)	Performs a cast from one Variant type to another.
	VarDataCastTo (see page 23599)	This is the overview for the VarDataCastTo method overload.
	VarDataCastToOleStr (see page 23600)	Performs a cast to a Variant type of varOleStr.
	VarDataClear (see page 23600)	Clears the data from a built-in Variant type.
	VarDataCopy (see page 23601)	Copies the data from one built-in Variant type to another.
	VarDataCopyNoInd (see page 23601)	Copies the data from one built-in Variant type to another.
	VarDataFromOleStr (see page 23602)	Creates a TVarData record to represent a Unicode string.
	VarDataFromStr (see page 23602)	Creates a TVarData record to represent a string.
	VarDataInit (see page 23602)	Initializes a TVarData record.
	VarDataIsArray (see page 23603)	Indicates whether a TVarData record represents the data from a Variant array.
	VarDataIsByRef (see page 23603)	Indicates whether a TVarData record stores its data indirectly.
	VarDataIsEmptyParam (see page 23603)	Indicates whether a TVarData record represents an unassigned optional parameter.
	VarDataIsFloat (see page 23604)	Indicates whether a TVarData record represents a floating-point value.
	VarDataIsNumeric (see page 23604)	Indicates whether a TVarData record represents a numeric value.
	VarDataIsOrdinal (see page 23605)	Indicates whether a TVarData record represents a ordinal value.
	VarDataIsStr (see page 23605)	Indicates whether a TVarData record represents a string (normal or Unicode).
	VarDataToStr (see page 23605)	Returns a string that represents the value from a TVarData record.

Public Methods

	Name	Description
	_AddRef (see page 22397)	Increments the reference count for this interface.
	_Release (see page 22397)	Decrements the reference count for this interface.
V	AfterConstruction (see page 22289)	Responds after the last constructor has executed.
V	BeforeDestruction (see page 22289)	Responds before the first destructor executes.
V	BinaryOp (see page 23587)	Implements any binary operations of which the custom Variant type is capable.
V	Cast (see page 23588)	Converts the data from another Variant type so that it represents this custom type's data format.
V	CastTo (see page 23589)	This is CastTo, a member of class TCustomVariantType.
V	CastToOle (see page 23589)	This is CastToOle, a member of class TCustomVariantType.
	ClassInfo (see page 22290)	Returns a pointer to the runtime type information (RTTI) table for the object type.

	ClassName (see page 22290)	Returns a string indicating the type of the object instance (as opposed to the type of the variable passed as an argument).
	ClassNameIs (see page 22293)	Determines whether an object is of a specific type.
	ClassParent (see page 22293)	Returns the type of the immediate ancestor of a class.
	ClassType (see page 22295)	Returns the class reference for the object's class.
	CleanupInstance (see page 22298)	Performs finalization on long strings, variants, and interface variables within a class.
A	Clear (see page 23589)	Sets the data for this custom Variant type to a blank or unassigned value.
V	Compare (see page 23590)	Implements comparisons that involve the custom Variant type.
V	CompareOp (see page 23590)	Implements any comparison operations of which the custom Variant type is capable.
A	Copy (see page 23591)	Copies the data from a Variant of this custom type.
	Create (see page 22287)	Constructs an object and initializes its data before the object is first used.
	Create (see page 23584)	This is the overview for the Create constructor overload.
V	DefaultHandler (see page 22299)	Provides the interface for a method that processes message records.
V	Destroy (see page 22287)	Disposes of an object instance.
V	Destroy (see page 23585)	Frees an instance of TCustomVariantType (see page 23581).
V	Dispatch (see page 22299)	Calls message-handling methods for the object, based on the contents of the Message parameter.
V	DoFunction (see page 23610)	Implements all methods that return values.
V	DoProcedure (see page 23611)	Implements all methods that do not return values.
	FieldAddress (see page 22299)	Returns the address of a published object field.
	Free (see page 22300)	Destroys an object and frees its associated memory, if necessary.
V	FreeInstance (see page 22303)	Deallocates memory allocated by a previous call to the System::TObject::NewInstance (see page 22306) method.
	GetInterface (see page 22303)	Retrieves a specified interface.
	GetInterfaceEntry (see page 22304)	Returns the entry for a specific interface implemented in a class.
	GetInterfaceTable (see page 22304)	Returns a pointer to a structure containing all of the interfaces implemented by a given class.
V	GetProperty (see page 23612)	Returns the value for any property this Variant type supports.
	InheritsFrom (see page 22305)	Determines the relationship of two object types.
	InitInstance (see page 22305)	Initializes a newly allocated object instance to all zeros and initializes the instance's virtual method table pointer.
	InstanceSize (see page 22306)	Returns the size in bytes of each instance of the object type.
V	IsClear (see page 23592)	Indicates whether the data from a custom Variant represents a blank or unassigned value.
	MethodAddress (see page 22306)	This is MethodAddress, a member of class TObject.
	MethodName (see page 22306)	This is MethodName, a member of class TObject.
V	NewInstance (see page 22306)	Allocates memory for an instance of an object type and returns a pointer to that new instance.
	QueryInterface (see page 22398)	Returns a reference to a specified interface if the object supports that interface.
V	SafeCallException (see page 22307)	Handles exceptions in methods declared using the safecall calling convention.
V	SetProperty (see page 23613)	Sets the value for any property this Variant type supports.
V	UnaryOp (see page 23598)	Implements any unary operations of which the custom Variant type is capable.

Public Properties

	Name	Description
R	VarType (see page 23606)	Indicates the Variant type code for the custom Variant type.

171.1.17.2 TInvokeableVariantType Methods

The methods of the TInvokeableVariantType class are listed here.

Protected Methods

	Name	Description
	DispInvoke (see page 23610)	Invokes a method call by dispatching it to the appropriate TInvokeableVariantType (see page 23606) method.
	FixupIdent (see page 23612)	Fixes up dispatch identifier.

Public Methods

	Name	Description
	DoFunction (see page 23610)	Implements all methods that return values.
	DoProcedure (see page 23611)	Implements all methods that do not return values.
	GetProperty (see page 23612)	Returns the value for any property this Variant type supports.
	SetProperty (see page 23613)	Sets the value for any property this Variant type supports.

171.1.17.2.1 TInvokeableVariantType.DispInvoke Method

Invokes a method call by dispatching it to the appropriate TInvokeableVariantType (see page 23606) method.

Pascal

```
procedure DispInvoke(Dest: PVarData; const Source: TVarData; CallDesc: PCallDesc; Params:
Pointer); override;
```

C++

```
virtual __fastcall DispInvoke(PVarData Dest, const TVarData Source, PCallDesc CallDesc, void *
Params);
```

Description

When the application tries to call a method, set a property, or read a property using a Variant of the custom Variant type, the system automatically generates a call to DispInvoke. TInvokeableVariantType (see page 23606) responds by generating a call to the GetProperty (see page 23612), SetProperty (see page 23613), DoProcedure (see page 23611), or DoFunction (see page 23610) method, as appropriate.

Dest is a TVarData record that receives the return value of any function calls.

Source is the TVarData record that holds the data from the custom Variant whose property or method was invoked.

CallDesc identifies the method that was called, including the type and number of its arguments.

Params points to an array of parameter values that were passed in the method call.

See Also

GetProperty (see page 23612)

SetProperty (see page 23613)

DoProcedure (see page 23611)

DoFunction (see page 23610)

171.1.17.2.2 TInvokeableVariantType.DoFunction Method

Implements all methods that return values.

Pascal

```
function DoFunction(var Dest: TVarData; const V: TVarData; const Name: string; const
Arguments: TVarDataArray): Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoFunction(TVarData Dest, const TVarData V, const AnsiString Name,
const TVarDataArray Arguments);
```

Description

Override DoFunction to provide the implementation for method calls that return values. When the application invokes a Variant member function (Delphi) or calls the Variant's Exec method (C++) a call is automatically generated to DoFunction.

Dest is a TVarData record that receives the value that the function returns.

V is the TVarData record from the Variant instance that was used to call the function.

Name is the name of the function.

Arguments is a dynamic array of TVarData records, where each one represents the value of an argument passed to the function.

DoFunction returns true if it executes the method call, false if it does not implement the specified function.

As implemented in TInvokeableVariant, DoFunction always returns false, because it does not implement any function calls.

See Also

GetProperty (see page 23612)

DoProcedure (see page 23611)

SetProperty (see page 23613)

Exec

Supporting Properties and Methods in Custom Variants

171.1.17.2.3 TInvokeableVariantType.DoProcedure Method

Implements all methods that do not return values.

Pascal

```
function DoProcedure(const V: TVarData; const Name: string; const Arguments: TVarDataArray):
Boolean; virtual;
```

C++

```
virtual __fastcall Boolean DoProcedure(const TVarData V, const AnsiString Name, const
TVarDataArray Arguments);
```

Description

Override DoProcedure to provide the implementation for methods calls that do not return values. When the application invokes a Variant member procedure (Delphi) or calls the Variant's Exec method (C++) a call is automatically generated to DoProcedure that allows the TInvokeableVariant descendant to implement the call.

V is the TVarData record from the Variant instance that was used to call the procedure.

Name is the name of the procedure.

Arguments is a dynamic array of TVarData records, where each one represents the value of an argument passed to the procedure.

DoProcedure returns true if it executes the procedure call, false if it does not implement the specified procedure.

As implemented in TInvokeableVariant, DoProcedure always returns false, because it does not implement any procedure calls.

See Also

GetProperty (see page 23612)

DoFunction (see page 23610)

SetProperty (see page 23613)

Exec

Supporting Properties and Methods in Custom Variants

171.1.17.2.4 TInvokeableVariantType.FixupIdent Method

Fixes up dispatch identifier.

Pascal

```
function FixupIdent(const AText: string): string; virtual;
```

C++

```
virtual __fastcall AnsiString FixupIdent(const AnsiString AText);
```

Description

FixupIdent is called internally to determine the final fixup for the dispatch identifier. As defined in TInvokeableVariantType (see page 23606), this fixup consists of converting the identifier to all upper case.

171.1.17.2.5 TInvokeableVariantType.GetProperty Method

Returns the value for any property this Variant type supports.

Pascal

```
function GetProperty(var Dest: TVarData; const V: TVarData; const Name: string): Boolean;
virtual;
```

C++

```
virtual __fastcall Boolean GetProperty(TVarData Dest, const TVarData V, const AnsiString Name);
```

Description

Override GetProperty to provide the read implementations for properties of instances of the Variant. When the application reads a Variant property (Delphi) or calls the Variant's Exec method (C++) a call is automatically generated to GetProperty that allows the TInvokeableVariant descendant to implement the call.

Dest is a TVarData record that receives the property value.

V is the TVarData record from the Variant instance whose property is being read.

Name is the name of the property.

GetProperty returns true if it returns a property value, false if it does not implement the specified property.

As implemented in TInvokeableVariant, GetProperty always returns false, because it does not implement any properties.

DoFunction (see page 23610)

DoProcedure (see page 23611)

SetProperty (see page 23613)

Exec

Supporting Properties and Methods in Custom Variants

171.1.17.2.6 TInvokeableVariantType.SetProperty Method

Sets the value for any property this Variant type supports.

Pascal

```
function SetProperty(const V: TVarData; const Name: string; const Value: TVarData): Boolean;
virtual;
```

C++

```
virtual __fastcall Boolean SetProperty(const TVarData V, const AnsiString Name, const TVarData
Value);
```

Description

Override SetProperty to provide the write implementation for the properties of instances of the invokeable Variant type. When the application writes to a Variant property (Delphi) or calls the Variant's Exec method (C++) a call is automatically generated to SetProperty that allows the TInvokeableVariant descendant to implement the call.

Name is the name of the property.

Value is a TVarData record that contains the new property value.

GetProperty (see page 23612) returns true if it sets a property value, false if it does not implement the specified property or if the specified property is read-only.

As implemented in TInvokeableVariant, GetProperty (see page 23612) always returns false, because it does not implement any properties.

171.2 Interfaces

The following table lists interfaces in this documentation.

Interfaces

	Name	Description
	IVarInstanceReference (see page 23614)	This is class Variants.IVarInstanceReference.
	IVarInvokeable (see page 23615)	This is class Variants.IVarInvokeable.

171.2.1 IVarInstanceReference Interface

Class Hierarchy

Variants.IVarInstanceReference

Pascal

```
IVarInstanceReference = interface;
```

C++

```
__interface IVarInstanceReference;
```

File

Variants

Description

This is class Variants.IVarInstanceReference.

171.2.1.1 IVarInstanceReference Members

The following tables list the members exposed by IVarInstanceReference.

Public Methods

	Name	Description
	GetInstance (see page 23615)	This is GetInstance, a member of class IVarInstanceReference.

171.2.1.2 IVarInstanceReference Methods

The methods of the IVarInstanceReference class are listed here.

Public Methods

	Name	Description
	GetInstance (see page 23615)	This is GetInstance, a member of class IVarInstanceReference.

171.2.1.2.1 IVarInstanceReference.GetInstance Method

Pascal

```
function GetInstance(const V: TVarData): TObject;
```

C++

```
__fastcall TObject * GetInstance(const TVarData V);
```

Description

This is GetInstance, a member of class IVarInstanceReference.

171.2.2 IVarInvokeable Interface

Class Hierarchy

Variants.IVarInvokeable

Pascal

```
IVarInvokeable = interface;
```

C++

```
__interface IVarInvokeable;
```

File

Variants

Description

This is class Variants.IVarInvokeable.

171.2.2.1 IVarInvokeable Members

The following tables list the members exposed by IVarInvokeable.

Public Methods

	Name	Description
	DoFunction (see page 23616)	This is DoFunction, a member of class IVarInvokeable.
	DoProcedure (see page 23616)	This is DoProcedure, a member of class IVarInvokeable.
	GetProperty (see page 23616)	This is GetProperty, a member of class IVarInvokeable.
	SetProperty (see page 23616)	This is SetProperty, a member of class IVarInvokeable.

171.2.2.2 IVarInvokeable Methods

The methods of the IVarInvokeable class are listed here.

Public Methods

	Name	Description
	DoFunction (see page 23616)	This is DoFunction, a member of class IVarInvokeable.
	DoProcedure (see page 23616)	This is DoProcedure, a member of class IVarInvokeable.
	GetProperty (see page 23616)	This is GetProperty, a member of class IVarInvokeable.

	SetProperty (see page 23616)	This is SetProperty, a member of class IVarInvokeable.

171.2.2.2.1 IVarInvokeable.DoFunction Method

Pascal

```
function DoFunction(var Dest: TVarData; const V: TVarData; const Name: string; const
Arguments: TVarDataArray): Boolean;
```

C++

```
__fastcall Boolean DoFunction(TVarData Dest, const TVarData V, const AnsiString Name, const
TVarDataArray Arguments);
```

Description

This is DoFunction, a member of class IVarInvokeable.

171.2.2.2.2 IVarInvokeable.DoProcedure Method

Pascal

```
function DoProcedure(const V: TVarData; const Name: string; const Arguments: TVarDataArray):
Boolean;
```

C++

```
__fastcall Boolean DoProcedure(const TVarData V, const AnsiString Name, const TVarDataArray
Arguments);
```

Description

This is DoProcedure, a member of class IVarInvokeable.

171.2.2.2.3 IVarInvokeable.GetProperty Method

Pascal

```
function GetProperty(var Dest: TVarData; const V: TVarData; const Name: string): Boolean;
```

C++

```
__fastcall Boolean GetProperty(TVarData Dest, const TVarData V, const AnsiString Name);
```

Description

This is GetProperty, a member of class IVarInvokeable.

171.2.2.2.4 IVarInvokeable.SetProperty Method

Pascal

```
function SetProperty(const V: TVarData; const Name: string; const Value: TVarData): Boolean;
```

C++

```
__fastcall Boolean SetProperty(const TVarData V, const AnsiString Name, const TVarData Value);
```

Description

This is SetProperty, a member of class IVarInvokeable.

171.3 Functions

The following table lists functions in this documentation.

Functions

	Name	Description
	_DispInvoke (see page 23619)	This is function Variants._DispInvoke.
	_OleVarFromInt (see page 23620)	This is function Variants._OleVarFromInt.
	_OleVarFromInt64 (see page 23620)	This is function Variants._OleVarFromInt64.
	_OleVarFromLStr (see page 23620)	This is function Variants._OleVarFromLStr.
	_OleVarFromPStr (see page 23621)	This is function Variants._OleVarFromPStr.
	_OleVarFromVar (see page 23621)	This is function Variants._OleVarFromVar.
	_VarAdd (see page 23621)	This is function Variants._VarAdd.
	_VarAddRef (see page 23622)	This is function Variants._VarAddRef.
	_VarAnd (see page 23622)	This is function Variants._VarAnd.
	_VarArrayGet (see page 23622)	This is function Variants._VarArrayGet.
	_VarArrayPut (see page 23623)	This is function Variants._VarArrayPut.
	_VarArrayRedim (see page 23623)	This is function Variants._VarArrayRedim.
	_VarCast (see page 23623)	This is function Variants._VarCast.
	_VarCastOle (see page 23624)	This is function Variants._VarCastOle.
	_VarClear (see page 23624)	This is function Variants._VarClear.
	_VarClr (see page 23624)	This is function Variants._VarClr.
	_VarCmpEQ (see page 23625)	This is function Variants._VarCmpEQ.
	_VarCmpGE (see page 23625)	This is function Variants._VarCmpGE.
	_VarCmpGT (see page 23625)	This is function Variants._VarCmpGT.
	_VarCmpLE (see page 23626)	This is function Variants._VarCmpLE.
	_VarCmpLT (see page 23626)	This is function Variants._VarCmpLT.
	_VarCmpNE (see page 23626)	This is function Variants._VarCmpNE.
	_VarCopy (see page 23627)	This is function Variants._VarCopy.
	_VarCopyNoInd (see page 23627)	This is function Variants._VarCopyNoInd.
	_VarDiv (see page 23627)	This is function Variants._VarDiv.
	_VarFromBool (see page 23628)	This is function Variants._VarFromBool.
	_VarFromCurr (see page 23628)	This is function Variants._VarFromCurr.
	_VarFromDisp (see page 23628)	This is function Variants._VarFromDisp.
	_VarFromDynArray (see page 23629)	This is function Variants._VarFromDynArray.
	_VarFromInt (see page 23629)	This is function Variants._VarFromInt.
	_VarFromInt64 (see page 23629)	This is function Variants._VarFromInt64.
	_VarFromIntf (see page 23630)	This is function Variants._VarFromIntf.
	_VarFromLStr (see page 23630)	This is function Variants._VarFromLStr.
	_VarFromPStr (see page 23630)	This is function Variants._VarFromPStr.
	_VarFromReal (see page 23631)	This is function Variants._VarFromReal.
	_VarFromTDateTime (see page 23631)	This is function Variants._VarFromTDateTime.
	_VarFromWStr (see page 23631)	This is function Variants._VarFromWStr.
	_VarMod (see page 23632)	This is function Variants._VarMod.
	_VarMul (see page 23632)	This is function Variants._VarMul.
	_VarNeg (see page 23632)	This is function Variants._VarNeg.
	_VarNot (see page 23633)	This is function Variants._VarNot.
	_VarOr (see page 23633)	This is function Variants._VarOr.
	_VarRDiv (see page 23633)	This is function Variants._VarRDiv.
	_VarShl (see page 23634)	This is function Variants._VarShl.

	_VarShr (see page 23634)	This is function Variants._VarShr.
	_VarSub (see page 23634)	This is function Variants._VarSub.
	_VarToBool (see page 23635)	This is function Variants._VarToBool.
	_VarToCurrency (see page 23635)	This is function Variants._VarToCurrency.
	_VarToDisp (see page 23635)	This is function Variants._VarToDisp.
	_VarToDynArray (see page 23636)	This is function Variants._VarToDynArray.
	_VarToInt64 (see page 23636)	This is function Variants._VarToInt64.
	_VarToInteger (see page 23636)	This is function Variants._VarToInteger.
	_VarToIntf (see page 23637)	This is function Variants._VarToIntf.
	_VarToLStr (see page 23637)	This is function Variants._VarToLStr.
	_VarToPStr (see page 23637)	This is function Variants._VarToPStr.
	_VarToReal (see page 23638)	This is function Variants._VarToReal.
	_VarToWStr (see page 23638)	This is function Variants._VarToWStr.
	_VarXor (see page 23638)	This is function Variants._VarXor.
	DynArrayFromVariant (see page 23639)	Creates a dynamic array from a Variant.
	DynArrayToVariant (see page 23639)	Creates a Variant array from a dynamic array.
	FindCustomVariantType (see page 23640)	Retrieves the object that implements a custom Variant type.
	FindCustomVariantType (see page 23640)	Retrieves the object that implements a custom Variant type.
	FindVarData (see page 23640)	Returns pointer to variant's data.
	HandleConversionException (see page 23641)	Handles exceptions during variant type conversions.
	Null (see page 23641)	Returns a Null variant.
	Unassigned (see page 23643)	Returns an "empty" variant.
	VarArrayAsPSafeArray (see page 23643)	This is function Variants.VarArrayAsPSafeArray.
	VarArrayCreate (see page 23644)	Creates a variant array.
	VarArrayCreateError (see page 23645)	Indicates an array creation error.
	VarArrayDimCount (see page 23645)	Returns number of dimensions of a variant array.
	VarArrayGet (see page 23645)	Returns a Variant that represents a single value from a multi-dimensional Variant array.
	VarArrayHighBound (see page 23646)	Returns high bound for a dimension in a variant array.
	VarArrayLock (see page 23646)	Locks a variant array and returns a pointer to the data.
	VarArrayLowBound (see page 23647)	Returns the low bound of a dimension in a variant array.
	VarArrayOf (see page 23648)	Creates and fills a one-dimensional variant array.
	VarArrayPut (see page 23648)	Sets the value of a single cell in a multi-dimensional Variant array.
	VarArrayRef (see page 23649)	Returns a reference to the specified variant array.
	VarArrayUnlock (see page 23649)	Unlocks a variant array.
	VarAsError (see page 23650)	Converts a HRESULT into an Error variant.
	VarAsType (see page 23650)	Converts a variant to specified type.
	VarCastError (see page 23651)	Raises an EVariantTypeCastError (see page 23580) exception.
	VarCastError (see page 23651)	Raises an EVariantTypeCastError (see page 23580) exception.
	VarCheckEmpty (see page 23651)	Raises an exception if a specified variant's value is Unassigned (see page 23643).
	VarCompareValue (see page 23652)	Returns the relationship between Variants (see page 23567).
	VarCopyNoInd (see page 23652)	Copies a Variant.
	VarEnsureRange (see page 23653)	Returns a Variant with a value in a specified range.
	VarFromDateTime (see page 23653)	Returns a variant containing a specified data and time.
	VarInRange (see page 23654)	Indicates whether a Variant's value is in a specified range.
	VarInvalidNullOp (see page 23654)	Indicate variant operation on null.
	VarInvalidOp (see page 23655)	Indicate invalid variant operation.
	VarIsArray (see page 23655)	Indicates whether the specified variant is an array.
	VarIsArray (see page 23655)	Indicates whether the specified variant is an array.
	VarIsByRef (see page 23656)	Indicates whether the specified variant's value is by reference.
	VarIsClear (see page 23656)	Indicates whether the specified variant has an undefined value.
	VarIsCustom (see page 23657)	Indicates whether the specified variant is a custom variant.
	VarIsEmpty (see page 23657)	Indicates whether the specified variant is unassigned.

	VarIsEmptyParam (see page 23658)	Indicates whether the specified variant represents an unassigned optional parameter.
	VarIsError (see page 23659)	Indicates whether the specified variant is an error variant; optionally converts variant back to HRESULT.
	VarIsError (see page 23659)	Indicates whether the specified variant is an error variant; optionally converts variant back to HRESULT.
	VarIsFloat (see page 23659)	Indicates whether the specified variant represents a floating-point value.
	VarIsNull (see page 23660)	Indicates whether the specified variant is Null (see page 23641).
	VarIsNumeric (see page 23660)	Indicates whether the specified variant represents a numeric value.
	VarIsOrdinal (see page 23661)	Indicates whether the specified variant represents an ordinal value.
	VarIsStr (see page 23661)	Indicates whether the specified variant represents a string value.
	VarIsType (see page 23662)	Indicates whether the specified variant represents a specified type.
	VarIsType (see page 23662)	Indicates whether the specified variant represents a specified type.
	VarOverflowError (see page 23662)	Raises an EVariantOverflowError (see page 23579) exception.
	VarRangeCheckError (see page 23663)	Raises an EVariantRangeCheckError (see page 23580) exception.
	VarResultCheck (see page 23663)	Raises variant exception based on HRESULT value.
	VarResultCheck (see page 23663)	Raises variant exception based on HRESULT value.
	VarSameValue (see page 23664)	Indicates whether two Variants (see page 23567) have equivalent values.
	VarSupports (see page 23664)	Indicates whether the Variant's value is an interface that supports a specified interface.
	VarSupports (see page 23664)	Indicates whether the Variant's value is an interface that supports a specified interface.
	VarToDateTime (see page 23665)	Converts a specified variant to a TDateTime value.
	VarToStr (see page 23665)	Converts a variant's value to a string.
	VarToStrDef (see page 23666)	Converts a variant's value to a string.
	VarToWideStr (see page 23666)	Converts a variant's value to a WideString.
	VarToWideStrDef (see page 23667)	Converts a variant's value to a WideString.
	VarType (see page 23667)	Returns the type code of a specified variant.
	VarTypeAsText (see page 23668)	Returns variant type descriptive string.
	VarTypeIsValidArrayType (see page 23669)	Indicates whether a Variant type code represents a type that can be used for the elements in a Variant array.
	VarTypeIsValidElementType (see page 23669)	Indicates whether a Variant type code represents a type that can be used for the elements in a Variant array.

171.3.1 Variants._DispInvoke Function

Pascal

```
procedure _DispInvoke(Dest: PVarData; const Source: TVarData; CallDesc: PCallDesc; Params:
Pointer); cdecl;
```

C++

```
__cdecl _DispInvoke(PVarData Dest, const TVarData Source, PCallDesc CallDesc, void * Params);
```

File

Variants

Description

This is function Variants._DispInvoke.

171.3.2 Variants._OleVarFromInt Function

Pascal

```
procedure _OleVarFromInt(var V: TVarData; const Value: Integer; const Range: ShortInt);
```

C++

```
_OleVarFromInt(TVarData V, const int Value, const ShortInt Range);
```

File

Variants

Description

This is function Variants._OleVarFromInt.

171.3.3 Variants._OleVarFromInt64 Function

Pascal

```
procedure _OleVarFromInt64(var V: TVarData; const Value: Int64);
```

C++

```
_OleVarFromInt64(TVarData V, const Int64 Value);
```

File

Variants

Description

This is function Variants._OleVarFromInt64.

171.3.4 Variants._OleVarFromLStr Function

Pascal

```
procedure _OleVarFromLStr(var V: TVarData; const Value: string);
```

C++

```
_OleVarFromLStr(TVarData V, const AnsiString Value);
```

File

Variants

Description

This is function Variants._OleVarFromLStr.

171.3.5 Variants._OleVarFromPStr Function

Pascal

```
procedure _OleVarFromPStr(var V: TVarData; const Value: ShortString);
```

C++

```
_OleVarFromPStr(TVarData V, const ShortString Value);
```

File

Variants

Description

This is function Variants._OleVarFromPStr.

171.3.6 Variants._OleVarFromVar Function

Pascal

```
procedure _OleVarFromVar(var Dest: TVarData; const Source: TVarData);
```

C++

```
_OleVarFromVar(TVarData Dest, const TVarData Source);
```

File

Variants

Description

This is function Variants._OleVarFromVar.

171.3.7 Variants._VarAdd Function

Pascal

```
procedure _VarAdd(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarAdd(TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarAdd.

171.3.8 Variants._VarAddRef Function

Pascal

```
procedure _VarAddRef(var V: TVarData);
```

C++

```
_VarAddRef(TVarData V);
```

File

Variants

Description

This is function Variants._VarAddRef.

171.3.9 Variants._VarAnd Function

Pascal

```
procedure _VarAnd(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarAnd(TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarAnd.

171.3.10 Variants._VarArrayGet Function

Pascal

```
function _VarArrayGet(var A: TVarData; IndexCount: Integer; const Indices:
TVarArrayCoorArray): TVarData; cdecl;
```

C++

```
__cdecl TVarData _VarArrayGet(TVarData A, int IndexCount, const TVarArrayCoorArray Indices);
```

File

Variants

Description

This is function Variants._VarArrayGet.

171.3.11 Variants._VarArrayPut Function

Pascal

```
procedure _VarArrayPut(var A: TVarData; const Value: TVarData; IndexCount: Integer; const
Indices: TVarArrayCoorArray); cdecl;
```

C++

```
__cdecl _VarArrayPut(TVarData A, const TVarData Value, int IndexCount, const
TVarArrayCoorArray Indices);
```

File

Variants

Description

This is function Variants._VarArrayPut.

171.3.12 Variants._VarArrayRedim Function

Pascal

```
procedure _VarArrayRedim(var A: TVarData; HighBound: Integer);
```

C++

```
_VarArrayRedim(TVarData A, int HighBound);
```

File

Variants

Description

This is function Variants._VarArrayRedim.

171.3.13 Variants._VarCast Function

Pascal

```
procedure _VarCast(var Dest: TVarData; const Source: TVarData; AVarType: Integer);
```

C++

```
_VarCast(TVarData Dest, const TVarData Source, int AVarType);
```

File

Variants

Description

This is function Variants._VarCast.

171.3.14 Variants._VarCastOle Function

Pascal

```
procedure _VarCastOle(var Dest: TVarData; const Source: TVarData; AVarType: Integer);
```

C++

```
_VarCastOle(TVarData Dest, const TVarData Source, int AVarType);
```

File

Variants

Description

This is function Variants._VarCastOle.

171.3.15 Variants._VarClear Function

Pascal

```
procedure _VarClear(var V: TVarData);
```

C++

```
_VarClear(TVarData V);
```

File

Variants

Description

This is function Variants._VarClear.

171.3.16 Variants._VarClr Function

Pascal

```
procedure _VarClr(var V: TVarData);
```

C++

```
_VarClr(TVarData V);
```

File

Variants

Description

This is function Variants._VarClr.

171.3.17 Variants._VarCmpEQ Function

Pascal

```
procedure _VarCmpEQ(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpEQ(const TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarCmpEQ.

171.3.18 Variants._VarCmpGE Function

Pascal

```
procedure _VarCmpGE(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpGE(const TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarCmpGE.

171.3.19 Variants._VarCmpGT Function

Pascal

```
procedure _VarCmpGT(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpGT(const TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarCmpGT.

171.3.20 Variants._VarCmpLE Function

Pascal

```
procedure _VarCmpLE(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpLE(const TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarCmpLE.

171.3.21 Variants._VarCmpLT Function

Pascal

```
procedure _VarCmpLT(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpLT(const TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarCmpLT.

171.3.22 Variants._VarCmpNE Function

Pascal

```
procedure _VarCmpNE(const Left: TVarData; const Right: TVarData);
```

C++

```
_VarCmpNE(const TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarCmpNE.

171.3.23 Variants._VarCopy Function

Pascal

```
procedure _VarCopy(var Dest: TVarData; const Source: TVarData);
```

C++

```
_VarCopy(TVarData Dest, const TVarData Source);
```

File

Variants

Description

This is function Variants._VarCopy.

171.3.24 Variants._VarCopyNoInd Function

Pascal

```
procedure _VarCopyNoInd(var Dest: TVarData; const Source: TVarData);
```

C++

```
_VarCopyNoInd(TVarData Dest, const TVarData Source);
```

File

Variants

Description

This is function Variants._VarCopyNoInd.

171.3.25 Variants._VarDiv Function

Pascal

```
procedure _VarDiv(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarDiv(TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarDiv.

171.3.26 Variants._VarFromBool Function

Pascal

```
procedure _VarFromBool(var V: TVarData; const Value: Boolean);
```

C++

```
_VarFromBool(TVarData V, const Boolean Value);
```

File

Variants

Description

This is function Variants._VarFromBool.

171.3.27 Variants._VarFromCurr Function

Pascal

```
procedure _VarFromCurr;
```

C++

```
_VarFromCurr();
```

File

Variants

Description

This is function Variants._VarFromCurr.

171.3.28 Variants._VarFromDisp Function

Pascal

```
procedure _VarFromDisp(var V: TVarData; const Value: IDispatch);
```

C++

```
_VarFromDisp(TVarData V, const IDispatch Value);
```

File

Variants

Description

This is function Variants._VarFromDisp.

171.3.29 Variants._VarFromDynArray Function

Pascal

```
procedure _VarFromDynArray(var V: TVarData; const DynArray: Pointer; TypeInfo: Pointer);
```

C++

```
_VarFromDynArray(TVarData V, const void * DynArray, void * TypeInfo);
```

File

Variants

Description

This is function Variants._VarFromDynArray.

171.3.30 Variants._VarFromInt Function

Pascal

```
procedure _VarFromInt(var V: TVarData; const Value: Integer; const Range: ShortInt);
```

C++

```
_VarFromInt(TVarData V, const int Value, const ShortInt Range);
```

File

Variants

Description

This is function Variants._VarFromInt.

171.3.31 Variants._VarFromInt64 Function

Pascal

```
procedure _VarFromInt64(var V: TVarData; const Value: Int64);
```

C++

```
_VarFromInt64(TVarData V, const Int64 Value);
```

File

Variants

Description

This is function Variants._VarFromInt64.

171.3.32 Variants._VarFromIntf Function

Pascal

```
procedure _VarFromIntf(var V: TVarData; const Value: IInterface);
```

C++

```
_VarFromIntf(TVarData V, const IInterface Value);
```

File

Variants

Description

This is function Variants._VarFromIntf.

171.3.33 Variants._VarFromLStr Function

Pascal

```
procedure _VarFromLStr(var V: TVarData; const Value: string);
```

C++

```
_VarFromLStr(TVarData V, const AnsiString Value);
```

File

Variants

Description

This is function Variants._VarFromLStr.

171.3.34 Variants._VarFromPStr Function

Pascal

```
procedure _VarFromPStr(var V: TVarData; const Value: ShortString);
```

C++

```
_VarFromPStr(TVarData V, const ShortString Value);
```

File

Variants

Description

This is function Variants._VarFromPStr.

171.3.35 Variants._VarFromReal Function

Pascal

```
procedure _VarFromReal;
```

C++

```
_VarFromReal();
```

File

Variants

Description

This is function Variants._VarFromReal.

171.3.36 Variants._VarFromTDateTime Function

Pascal

```
procedure _VarFromTDateTime;
```

C++

```
_VarFromTDateTime();
```

File

Variants

Description

This is function Variants._VarFromTDateTime.

171.3.37 Variants._VarFromWStr Function

Pascal

```
procedure _VarFromWStr(var V: TVarData; const Value: WideString);
```

C++

```
_VarFromWStr(TVarData V, const BSTR Value);
```

File

Variants

Description

This is function Variants._VarFromWStr.

171.3.38 Variants._VarMod Function

Pascal

```
procedure _VarMod(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarMod(TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarMod.

171.3.39 Variants._VarMul Function

Pascal

```
procedure _VarMul(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarMul(TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarMul.

171.3.40 Variants._VarNeg Function

Pascal

```
procedure _VarNeg(var Dest: TVarData);
```

C++

```
_VarNeg(TVarData Dest);
```

File

Variants

Description

This is function Variants._VarNeg.

171.3.41 Variants._VarNot Function

Pascal

```
procedure _VarNot(var Dest: TVarData);
```

C++

```
_VarNot(TVarData Dest);
```

File

Variants

Description

This is function Variants._VarNot.

171.3.42 Variants._VarOr Function

Pascal

```
procedure _VarOr(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarOr(TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarOr.

171.3.43 Variants._VarRDiv Function

Pascal

```
procedure _VarRDiv(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarRDiv(TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarRDiv.

171.3.44 Variants._VarShl Function

Pascal

```
procedure _VarShl(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarShl(TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarShl.

171.3.45 Variants._VarShr Function

Pascal

```
procedure _VarShr(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarShr(TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarShr.

171.3.46 Variants._VarSub Function

Pascal

```
procedure _VarSub(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarSub(TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarSub.

171.3.47 Variants._VarToBool Function

Pascal

```
function _VarToBool(const V: TVarData): LongBool;
```

C++

```
LongBool _VarToBool(const TVarData V);
```

File

Variants

Description

This is function Variants._VarToBool.

171.3.48 Variants._VarToCurrency Function

Pascal

```
function _VarToCurrency(const V: TVarData): Currency;
```

C++

```
Currency _VarToCurrency(const TVarData V);
```

File

Variants

Description

This is function Variants._VarToCurrency.

171.3.49 Variants._VarToDisp Function

Pascal

```
procedure _VarToDisp(var Dispatch: IDispatch; const V: TVarData);
```

C++

```
_VarToDisp(IDispatch Dispatch, const TVarData V);
```

File

Variants

Description

This is function Variants._VarToDisp.

171.3.50 Variants._VarToDynArray Function

Pascal

```
procedure _VarToDynArray(var DynArray: Pointer; const V: TVarData; TypeInfo: Pointer);
```

C++

```
_VarToDynArray(void * DynArray, const TVarData V, void * TypeInfo);
```

File

Variants

Description

This is function Variants._VarToDynArray.

171.3.51 Variants._VarToInt64 Function

Pascal

```
function _VarToInt64(const V: TVarData): Int64;
```

C++

```
Int64 _VarToInt64(const TVarData V);
```

File

Variants

Description

This is function Variants._VarToInt64.

171.3.52 Variants._VarToInteger Function

Pascal

```
function _VarToInteger(const V: TVarData): Integer;
```

C++

```
int _VarToInteger(const TVarData V);
```

File

Variants

Description

This is function Variants._VarToInteger.

171.3.53 Variants._VarToIntf Function

Pascal

```
procedure _VarToIntf(var Intf: IInterface; const V: TVarData);
```

C++

```
_VarToIntf(IInterface Intf, const TVarData V);
```

File

Variants

Description

This is function Variants._VarToIntf.

171.3.54 Variants._VarToLStr Function

Pascal

```
procedure _VarToLStr(var S: string; const V: TVarData);
```

C++

```
_VarToLStr(AnsiString S, const TVarData V);
```

File

Variants

Description

This is function Variants._VarToLStr.

171.3.55 Variants._VarToPStr Function

Pascal

```
procedure _VarToPStr(var S; const V: TVarData);
```

C++

```
_VarToPStr( S, const TVarData V);
```

File

Variants

Description

This is function Variants._VarToPStr.

171.3.56 Variants._VarToReal Function

Pascal

```
function _VarToReal(const V: TVarData): Extended;
```

C++

```
Extended _VarToReal(const TVarData V);
```

File

Variants

Description

This is function Variants._VarToReal.

171.3.57 Variants._VarToWStr Function

Pascal

```
procedure _VarToWStr(var S: WideString; const V: TVarData);
```

C++

```
_VarToWStr(BSTR S, const TVarData V);
```

File

Variants

Description

This is function Variants._VarToWStr.

171.3.58 Variants._VarXor Function

Pascal

```
procedure _VarXor(var Left: TVarData; const Right: TVarData);
```

C++

```
_VarXor(TVarData Left, const TVarData Right);
```

File

Variants

Description

This is function Variants._VarXor.

171.3.59 Variants.DynArrayFromVariant Function

Creates a dynamic array from a Variant.

Pascal

```
procedure DynArrayFromVariant(var DynArray: Pointer; const V: Variant; TypeInfo: Pointer);
```

C++

```
DynArrayFromVariant(void * DynArray, const Variant V, void * TypeInfo);
```

File

Variants

Description

Call DynArrayFromVariant to copy the contents of a variant (V) to an existing dynamic array variable (DynArray).

DynArray is a dynamic array variable whose value is assigned from the Variant.

V is the Variant to copy. Its value must be an array.

TypeInfo points to the runtime type information that identifies the type of array elements. You can obtain this pointer using the TypeInfo function (Delphi) or the __delphirtti function (C++).

See Also

DynArrayToVariant (see page 23639)

TypeInfo

171.3.60 Variants.DynArrayToVariant Function

Creates a Variant array from a dynamic array.

Pascal

```
procedure DynArrayToVariant(var V: Variant; const DynArray: Pointer; TypeInfo: Pointer);
```

C++

```
DynArrayToVariant(Variant V, const void * DynArray, void * TypeInfo);
```

File

Variants

Description

Call DynArrayToVariant to assign the contents of a dynamic array as the value of a Variant variable.

V is the Variant whose value is assigned by DynArrayToVariant.

DynArray is a dynamic array to copy.

TypeInfo points to the runtime type information that identifies the type of array elements. You can obtain this pointer using the TypeInfo function (Delphi) or the __delphirtti function (C++).

See Also

DynArrayFromVariant (see page 23639)

TypeInfo

171.3.61 Variants.FindCustomVariantType Function

Retrieves the object that implements a custom Variant type.

Pascal

```
function FindCustomVariantType(const AVarType: TVarType; out CustomVariantType:
TCustomVariantType): Boolean; overload;
function FindCustomVariantType(const TypeName: string; out CustomVariantType:
TCustomVariantType): Boolean; overload;
```

C++

```
Boolean FindCustomVariantType(const TVarType AVarType, TCustomVariantType CustomVariantType);
Boolean FindCustomVariantType(const AnsiString TypeName, TCustomVariantType CustomVariantType);
```

File

Variants

Description

Use FindCustomVariantType to obtain a reference to the object that implements a custom Variant type.

TypeName is the name of the TCustomVariantType (see page 23581) descendant class you want to retrieve.

AVarType is the type code of Variant whose implementation class you want to retrieve. If you have an instance of a Variant whose value is a custom Variant Type, you can obtain a value for this parameter using the VarType (see page 23667) function.

CustomVariantType returns an instance of the TCustomVariantType (see page 23581) descendant that implements the indicated custom Variant type.

See Also

VarType (see page 23667)

VarIsCustom (see page 23657)

171.3.62 Variants.FindVarData Function

Returns pointer to variant's data.

Pascal

```
function FindVarData(const V: Variant): PVarData;
```

C++

```
PVarData FindVarData(const Variant V);
```

File

Variants

Description

FindVarData returns a pointer to the Variant data contained referenced by a Variant. If the Variant contains another Variant, FindVarData follows the chain of references until it finds the actual data.

See Also

VarType (see page 23667)

171.3.63 Variants.HandleConversionException Function

Handles exceptions during variant type conversions.

Pascal

```
procedure HandleConversionException(const ASourceType: TVarType; const ADestType: TVarType);
```

C++

```
HandleConversionException(const TVarType ASourceType, const TVarType ADestType);
```

File

Variants

Description

HandleConversionException handles exceptions resulting from attempts to convert between variant types. Code that implements such conversions should call HandleConversionException when a conversion throws an exception.

ASourceType and ADestType indicate the variant types of the source and destination. HandleConversionException uses these to format an appropriate error string. If the current exception corresponds to a variant exception, HandleConversionException raises that exception. Otherwise, HandleConversionException simply re-raises the original exception.

See Also

VarResultCheck (see page 23663)

EVariantError

171.3.64 Variants.Null Function

Returns a Null variant.

Pascal

```
function Null: Variant;
```

C++

```
Variant Null();
```

File

Variants

Description

Use Null to obtain a Null variant that can indicate unknown or missing data. Null Variants (see page 23567) can be assigned to variant variables in an application that must contain a null value. Assigning Null to a variant variable does not cause an error, and

Null can be returned from any function with a variant return value.

Assigning Null to a variable of any type other than Variant causes either a compile-time error or raises an EVariantTypeMismatch exception. For example, in the following code the assignment of v, the Null variant, to variant q is successful; whereas the conversion of variant v, which is now Null, to the integer return type of the Test function, raises an exception.

function Test(v: Variant): Integer;

```
var
  q: Variant;
  msg: string;
begin
  q := v; { this is ok, since q is a variant }
  if VarIsNull(q) then
    msg := 'q is a null variant'
  else
    msg := 'q is not a null variant';
  ShowMessage(msg);

  Result := v; { this raises an exception!!!}
```

end;

procedure TForm1.Button1Click(Sender: TObject);

```
begin
  Test(Null);
```

end;

int Test(Variant v)

```
{
  Variant q = v; // this is ok, since q is a variant
  AnsiString msg;
  if (VarIsNull(q))
    msg = "q is a null variant";
  else
    msg = "q is not a null variant";
  ShowMessage(msg);

   return v; // this throws an exception!!!
```

}

void __fastcall TForm1::Button1Click(TObject *Sender)

{

```
  Test(Null());
```

}

Except for comparisons, which always result in Boolean values, expressions involving Null variants always result in Null variants.

Note: The Null variant returned by the Null function is different from the nil constant in Delphi code and the NULL macro in C++ code. Neither nil nor NULL is a variant. The nil constant is an object reference that does not refer to any actual object. The NULL macro is a pointer that does not refer to any actual object or value.

See Also

Unassigned (see page 23643)

VarIsNull (see page 23660)

VarType (see page 23667)

NullEqualityRule (see page 23678)

NullMagnitudeRule (see page 23679)

171.3.65 Variants.Unassigned Function

Returns an "empty" variant.

Pascal

```
function Unassigned: Variant;
```

C++

```
Variant Unassigned();
```

File

Variants

Description

A variant variable can be "empty", meaning it has not yet been assigned to. The Unassigned function returns an empty variant, which can be assigned to a variant variable to restore the variable to its initial state.

Use the VarIsEmpty (see page 23657) function to test whether a variant is empty. When used on an empty variant, the VarType (see page 23667) standard function returns varEmpty.

If an empty variant is cast to another type (for example, by assigning to a non-variant variable or calling VarAsType (see page 23650)) the following conversions occur:

Destination	Conversion result
Numeric type	Zero
String type	Empty string
Boolean	False.

Note: Unassigned is useful with variants referencing OLE Automation Objects that you want to keep "alive" until another value is assigned to the variant.

There's corresponding functionality under Linux. Should document when time permits.

See Also

Null (see page 23641)

VarIsEmpty (see page 23657)

VarType (see page 23667)

VarAsType (see page 23650)

171.3.66 Variants.VarArrayAsPSafeArray Function

Pascal

```
function VarArrayAsPSafeArray(const A: Variant): PVarArray;
```

C++

```
PVarArray VarArrayAsPSafeArray(const Variant A);
```

File

Variants

Description

This is function Variants.VarArrayAsPSafeArray.

171.3.67 Variants.VarArrayCreate Function

Creates a variant array.

Pascal

```
function VarArrayCreate(const Bounds: array of Integer; AVarType: TVarType): Variant;
```

C++

```
Variant VarArrayCreate(const array of Integer Bounds, TVarType AVarType);
```

File

Variants

Description

VarArrayCreate creates a variant array with the bounds given by Bounds and the element type given by VarType (see page 23667).

The Bounds parameter must contain an even number of values, where each pair of values specifies the upper and lower bounds of one dimension of the array.

Note: The Bounds_size parameter is the index of the last value in the Bounds array. This is one less than the total number of values. Thus, Bounds_size must always be an odd number.

The element type of the array, given by the VarType (see page 23667) parameter, is a variant type code. This must be one of the constants defined in the System (see page 22079) unit. It cannot include the varArray or varByRef bits. The element type cannot be varString or a custom Variant type. To create a variant array of strings use the varOleStr type code. If the element type is varVariant, the elements of the array are themselves variants and can in turn contain variant arrays.

If VarArrayCreate is unable to create the array, an EVariantArrayCreateError (see page 23572) is raised.

Note: :Variant arrays with an element type of varByte are the preferred method of passing binary data between OLE Automation controllers and servers. Such arrays are subject to no translation of their data, and can be efficiently accessed using the VarArrayLock (see page 23646) and VarArrayUnlock (see page 23649) routines.

There's corresponding functionality under Linux. Should document when time permits.

See Also

VarArrayOf (see page 23648)

VarArrayLock (see page 23646)

VarArrayUnlock (see page 23649)

EVariantArrayCreateError (see page 23572)

171.3.68 Variants.VarArrayCreateError Function

Indicates an array creation error.

Pascal

```
procedure VarArrayCreateError;
```

C++

```
VarArrayCreateError();
```

File

Variants

See Also

EVariantArrayCreateError (see page 23572)

171.3.69 Variants.VarArrayDimCount Function

Returns number of dimensions of a variant array.

Pascal

```
function VarArrayDimCount(const A: Variant): Integer;
```

C++

```
int VarArrayDimCount(const Variant A);
```

File

Variants

Description

VarArrayDimCount returns the number of dimensions of the given variant. The resulting value is zero if the given variant is not a variant array.

See Also

VarArrayHighBound (see page 23646)

VarArrayLowBound (see page 23647)

171.3.70 Variants.VarArrayGet Function

Returns a Variant that represents a single value from a multi-dimensional Variant array.

Pascal

```
function VarArrayGet(const A: Variant; const Indices: array of Integer): Variant;
```

C++

```
Variant VarArrayGet(const Variant A, const array of Integer Indices);
```

File

Variants

Description

Use VarArrayGet to obtain the value of a single cell from a multi-dimensional Variant array.

A is the Variant array that contains the desired value.

Indices is an array of index values, one for each dimension of the array.

Note: Indices_Size is the index of the last value in Indices (one less than the number of dimensions in the array).

If the values specified by Indices are out of bounds, VarArrayGet raises an EVariantBadIndexError (see page 23574).

See Also

VarArrayPut (see page 23648)

EVariantBadIndexError (see page 23574)

171.3.71 Variants.VarArrayHighBound Function

Returns high bound for a dimension in a variant array.

Pascal

```
function VarArrayHighBound(const A: Variant; Dim: Integer): Integer;
```

C++

```
int VarArrayHighBound(const Variant A, int Dim);
```

File

Variants

Description

VarArrayHighBound returns the high bound of the given dimension in the given variant array. The Dim parameter should be 1 for the leftmost dimension, 2 for the second leftmost dimension, and so on. An exception is raised if the variant given by A is not an array (EVariantInvalidArgError (see page 23575)), or if the dimension specified by Dim does not exist (EVariantBadIndexError (see page 23574)).

See Also

VarArrayDimCount (see page 23645)

VarArrayLowBound (see page 23647)

EVariantInvalidArgError (see page 23575)

EVariantBadIndexError (see page 23574)

171.3.72 Variants.VarArrayLock Function

Locks a variant array and returns a pointer to the data.

Pascal

```
function VarArrayLock(const A: Variant): Pointer;
```

C++

```
void * VarArrayLock(const Variant A);
```

File

Variants

Description

VarArrayLock locks the given variant array and returns a pointer to the data stored in the array. While locked, a variant array can not be resized and any calls to VarArrayRedim will fail. Once locked, a variant array must later be unlocked using VarArrayUnlock (see page 23649). An EVariantInvalidArgError (see page 23575) exception is raise if the variant given by A is not an array.

The pointer returned by VarArrayLock points to an array of elements in which the leftmost dimension increases first. In other words, the dimensions of the returned array pointer are reversed from the dimensions of the variant array.

Once it is verified that a variant array has the correct bounds and dimensions, VarArrayLock can be used to gain direct access to the array data, which results in improved performance.

See Also

VarArrayUnlock (see page 23649)

VarArrayRedim

171.3.73 Variants.VarArrayLowBound Function

Returns the low bound of a dimension in a variant array.

Pascal

```
function VarArrayLowBound(const A: Variant; Dim: Integer): Integer;
```

C++

```
int VarArrayLowBound(const Variant A, int Dim);
```

File

Variants

Description

VarArrayLowBound returns the low bound of the given dimension in the given variant array. The Dim parameter should be 1 for the leftmost dimension, 2 for the second leftmost dimension, and so on. An exception is raised if the variant given by A is not an array (EVariantInvalidArgError (see page 23575)), or if the dimension specified by Dim does not exist (EVariantBadIndexError (see page 23574))..

See Also

VarArrayDimCount (see page 23645)

VarArrayHighBound (see page 23646)

EVariantInvalidArgError (see page 23575)

EVariantBadIndexError (see page 23574)

171.3.74 Variants.VarArrayOf Function

Creates and fills a one-dimensional variant array.

Pascal

```
function VarArrayOf(const Values: array of Variant): Variant;
```

C++

```
Variant VarArrayOf(const array of Variant Values);
```

File

Variants

Description

VarArrayOf returns a one-dimensional variant array with the elements given by the Values parameter

Values is an array of Variant values to convert into a Variant array.

Note: Values_Size indicates the index of the last value in the Values array (one less than the number of values).

The low bound of the returned array is zero, the high bound is the number of values given by the Values parameter less one (Values_Size), and the element type is Variant.

See Also

VarArrayCreate (see page 23644)

171.3.75 Variants.VarArrayPut Function

Sets the value of a single cell in a multi-dimensional Variant array.

Pascal

```
procedure VarArrayPut(var A: Variant; const Value: Variant; const Indices: array of Integer);
```

C++

```
VarArrayPut(Variant A, const Variant Value, const array of Integer Indices);
```

File

Variants

Description

Use VarArrayPut to set the value of a single cell in a multi-dimensional Variant array.

A is the Variant array that contains the cell to set.

Value is the value to assign to the specified cell.

Indices is an array of index values, one for each dimension of the array.

Note: Indices_Size is the index of the last value in Indices (one less than the number of dimensions in the array).

If the values specified by Indices are out of bounds, VarArrayPut raises an EVariantBadIndexError (see page 23574).

See Also

VarArrayGet (see page 23645)

EVariantBadIndexError (see page 23574)

171.3.76 Variants.VarArrayRef Function

Returns a reference to the specified variant array.

Pascal

```
function VarArrayRef(const A: Variant): Variant;
```

C++

```
Variant VarArrayRef(const Variant A);
```

File

Variants

Description

Use VarArrayRef to reference a variant array when a referenced variant array is expected in an API call. VarArrayRef creates a new variant array of the same type as A, but with an extra level of indirection if A does not include the varByRef type bit. The returned variant includes the varByRef type bit.

If A is not an array, VarArrayRef raises an EVariantInvalidArgError (see page 23575) exception.

See Also

VarArrayCreate (see page 23644)

TVarType

VarCopyNoInd (see page 23652)

EVariantInvalidArgError (see page 23575)

171.3.77 Variants.VarArrayUnlock Function

Unlocks a variant array.

Pascal

```
procedure VarArrayUnlock(const A: Variant);
```

C++

```
VarArrayUnlock(const Variant A);
```

File

Variants

Description

VarArrayUnlock unlocks a variant array that was previously locked by VarArrayLock (see page 23646). If the variant given by A is not an array, VarArrayUnlock raises an EVariantInvalidArtgError exception.

See Also

VarArrayLock (see page 23646)

171.3.78 Variants.VarAsError Function

Converts a HRESULT into an Error variant.

Pascal

```
function VarAsError(AResult: HRESULT): Variant;
```

C++

```
Variant VarAsError(HRESULT AResult);
```

File

Variants

Description

VarAsError converts an HRESULT result code into an equivalent variant of type varError.

See Also

VarType (see page 23667)

171.3.79 Variants.VarAsType Function

Converts a variant to specified type.

Pascal

```
function VarAsType(const V: Variant; AVarType: TVarType): Variant;
```

C++

```
Variant VarAsType(const Variant V, TVarType AVarType);
```

File

Variants

Description

VarAsType converts a variant to a specified type and returns a new Variant that has the specified type.

V is the Variant to convert.

VarType (see page 23667) is a variant type code that indicates the type to which V should be converted. This can be one of the constants defined in the System (see page 22079) unit, or it can be the type code for a custom variant type. It cannot include the varArray or varByRef bits.

VarAsType raises an exception if the variant cannot be converted to the given type. This will be EVariantError or one of its descendants, such as EVariantOverflowError (see page 23579) or EVariantTypeMismatchError.

See Also

VarType (see page 23667)

171.3.80 Variants.VarCastError Function

Raises an EVariantTypeCastError (see page 23580) exception.

Pascal

```
procedure VarCastError; overload;
procedure VarCastError(const ASourceType: TVarType; const ADestType: TVarType); overload;
```

C++

```
VarCastError();
VarCastError(const TVarType ASourceType, const TVarType ADestType);
```

File

Variants

Description

Call VarCastError to indicate that a variant operation has failed due to cast error. VarCastError raises EVariantTypeCastError (see page 23580). If no arguments are specified, the error string is a general error message. If ASourceType and ADestType are specified, the error string incorporates the names of the specified Variant Types (see page 23293).

See Also

EVariantTypeCastError (see page 23580)

TVarData

VarType (see page 23667)

171.3.81 Variants.VarCheckEmpty Function

Raises an exception if a specified variant's value is Unassigned (see page 23643).

Pascal

```
procedure VarCheckEmpty(const V: Variant);
```

C++

```
VarCheckEmpty(const Variant V);
```

File

Variants

Description

Call VarCheckEmpty when your code requires that a Variant have a value, and you want to raise an exception if it doesn't. VarCheckEmpty checks whether the Variant specified by V has a value of Unassigned (see page 23643). If so, it raises an EVariantTypeMismatchError exception.

To check whether the Variant is Unassigned (see page 23643) without raising an exception, use the VarIsEmpty (see page 23657) function instead. To check whether the Variant's value is undefined, use the VarIsClear (see page 23656) function instead.

Note: Do not confuse an Unassigned (see page 23643) variant with a Variant whose value is Null (see page 23641). A Null (see page 23641) variant is still assigned, but has the value Null (see page 23641). Unlike unassigned variants, Null (see

page 23641) variants can be used in expressions and can be converted to other types of variants.

See Also

VarIsEmpty (see page 23657)

Unassigned (see page 23643)

VarType (see page 23667)

VarIsNull (see page 23660)

VarIsClear (see page 23656)

EVariantTypeMismatchError

171.3.82 Variants.VarCompareValue Function

Returns the relationship between Variants (see page 23567).

Pascal

```
function VarCompareValue(const A: Variant; const B: Variant): TVariantRelationship;
```

C++

```
TVariantRelationship VarCompareValue(const Variant A, const Variant B);
```

File

Variants

Description

Call VarCompareValue to determine the relationship between two Variants (see page 23567).

A and B are the values to compare.

VarCompareValue returns a value that indicates whether A and B are equal (vrEqual), whether one is greater than the other (vrLessThan or vrGreaterThan), or whether the two values can't be ordered relative to each other (vrNotEqual).

See Also

VarSameValue (see page 23664)

CompareValue

171.3.83 Variants.VarCopyNoInd Function

Copies a Variant.

Pascal

```
procedure VarCopyNoInd(var Dest: Variant; const Source: Variant);
```

C++

```
VarCopyNoInd(Variant Dest, const Variant Source);
```

File

Variants

Description

VarCopyNoInd copies the variant given by Source into the variant given by Dest. Calling VarCopyNoInd in C++ or Delphi code is equivalent to a simple variant assignment in Delphi code.

Dest can be a Variant or an OleVariant, and it must be possible to assign a value to it.

Source is defined as a Variant, but an OleVariant is also allowed because it is a compatible type. However, Source can't have a VarType (see page 23667) that includes the varByRef bit.

The following table lists the expected behavior when using Variant and OleVariant types as parameters:

Dest	Source	Behavior
Variant	OleVariant	Works as expected.
Variant	Variant	Works as expected.
OleVariant	OleVariant	Works as expected.
OleVariant	Variant	Source should be implicitly cast to an OleVariant.

171.3.84 Variants.VarEnsureRange Function

Returns a Variant with a value in a specified range.

Pascal

```
function VarEnsureRange(const AValue: Variant; const AMin: Variant; const AMax: Variant):
Variant;
```

C++

```
Variant VarEnsureRange(const Variant AValue, const Variant AMin, const Variant AMax);
```

File

Variants

Description

VarEnsureRange returns a Variant whose value is guaranteed to be within a specified range.

AValue is a Variant with the value you want as long as it is in range. If AValue is in range, VarEnsureRange returns AValue.

AMin is a Variant with the minimum acceptable value. If AValue is less than AMin, VarEnsureRange returns AMin.

AMax is a Variant with the maximum acceptable value. If AValue is greater than AMax, VarEnsureRange returns AMax.

See Also

VarInRange (see page 23654)

171.3.85 Variants.VarFromDateTime Function

Returns a variant containing a specified data and time.

Pascal

```
function VarFromDateTime(const DateTime: TDateTime): Variant;
```

C++

```
Variant VarFromDateTime(const TDateTime DateTime);
```

File

Variants

Description

VarFromDateTime returns a Variant that represents the date and time of the given TDateTime value, DateTime. The type code of the resulting variant is varDate.

See Also

VarToDateTime (see page 23665)

VarType (see page 23667)

171.3.86 Variants.VarInRange Function

Indicates whether a Variant's value is in a specified range.

Pascal

```
function VarInRange(const AValue: Variant; const AMin: Variant; const AMax: Variant): Boolean;
```

C++

```
Boolean VarInRange(const Variant AValue, const Variant AMin, const Variant AMax);
```

File

Variants

Description

VarInRange checks whether a Variant has a value in a specified range.

AValue is a Variant to check.

AMin is a Variant with the minimum acceptable value.

AMax is a Variant with the maximum acceptable value.

VarInRange returns true if AValue is greater than or equal to AMin and less than or equal to AMax. Otherwise, it returns false.

See Also

VarEnsureRange (see page 23653)

171.3.87 Variants.VarInvalidNullOp Function

Indicate variant operation on null.

Pascal

```
procedure VarInvalidNullOp;
```

C++

```
VarInvalidNullOp();
```

File

Variants

See Also

EVariantInvalidOpError (see page 23577)

171.3.88 Variants.VarInvalidOp Function

Indicate invalid variant operation.

Pascal

```
procedure VarInvalidOp;
```

C++

```
VarInvalidOp();
```

File

Variants

See Also

EVariantInvalidOpError (see page 23577)

171.3.89 Variants.VarIsArray Function

Indicates whether the specified variant is an array.

Pascal

```
function VarIsArray(const A: Variant): Boolean; overload;
function VarIsArray(const A: Variant; AResolveByRef: Boolean): Boolean; overload;
```

C++

```
Boolean VarIsArray(const Variant A);
Boolean VarIsArray(const Variant A, Boolean AResolveByRef);
```

File

Variants

Description

VarIsArray returns true if the given variant is an array. Otherwise, the function result is false.

A is the Variant to check.

AResolveByRef indicates how VarIsArray should handle the case when A is a reference to a Variant (when the VarType (see page 23667) of A is varByRef or varVariant).When AResolveByRef is true, VarIsArray checks whether A is an array or A points to an array. When AResolveByRef is false, VarIsArray returns false when A has a VarType (see page 23667) of varByRef or varVariant.

See Also

VarArrayCreate (see page 23644)

VarType (see page 23667)

VarIsType (see page 23662)

171.3.90 Variants.VarIsByRef Function

Indicates whether the specified variant's value is by reference.

Pascal

```
function VarIsByRef(const V: Variant): Boolean;
```

C++

```
Boolean VarIsByRef(const Variant V);
```

File

Variants

Description

VarIsByRef returns true if the given variant's type code includes the includes the varByRef bit. Otherwise, the function result is false.

See Also

VarType (see page 23667)

VarIsType (see page 23662)

171.3.91 Variants.VarIsClear Function

Indicates whether the specified variant has an undefined value.

Pascal

```
function VarIsClear(const V: Variant): Boolean;
```

C++

```
Boolean VarIsClear(const Variant V);
```

File

Variants

Description

VarIsClear returns true if the given variant's value is undefined. The value can be undefined for any of several reasons:

The Variant may have had its value set to Unassigned (see page 23643).

The Variant's value may be an interface type that has been set to nil (Delphi) or NULL (C++).

The Variant may be a custom variant that returns true from its IsClear method.

In all other cases, the function result is false.

Note: Do not confuse an unassigned variant with a Null (see page 23641) variant. A Null (see page 23641) variant is still assigned, but has the value Null (see page 23641). Unlike unassigned variants, Null (see page 23641) variants can be used in expressions and can be converted to other types of variants.

See Also

Unassigned (see page 23643)

VarType (see page 23667)

VarCheckEmpty (see page 23651)

VarIsNull (see page 23660)

VarIsEmpty (see page 23657)

VarIsType (see page 23662)

TCustomVariantType (see page 23581)

171.3.92 Variants.VarIsCustom Function

Indicates whether the specified variant is a custom variant.

Pascal

```
function VarIsCustom(const V: Variant): Boolean;
```

C++

```
Boolean VarIsCustom(const Variant V);
```

File

Variants

Description

VarIsCustom returns true if the given variant represents a custom variant type. Otherwise, the function result is false.

See Also

VarType (see page 23667)

FindCustomVariantType (see page 23640)

VarIsType (see page 23662)

171.3.93 Variants.VarIsEmpty Function

Indicates whether the specified variant is unassigned.

Pascal

```
function VarIsEmpty(const V: Variant): Boolean;
```

C++

```
Boolean VarIsEmpty(const Variant V);
```

File

Variants

Description

VarIsEmpty returns true if the given variant contains the value Unassigned (see page 23643). If the variant contains any other value, the function result is false.

Note: VarIsEmpty does not indicate when a Variant that represents an interface has had the interface pointer cleared or when a custom Variant is clear. If either of these situations may exist, use the VarIsClear (see page 23656) method instead.

Note: Do not confuse an unassigned variant with a Null (see page 23641) variant. A Null (see page 23641) variant is still assigned, but has the value Null (see page 23641). Unlike unassigned variants, Null (see page 23641) variants can be used in expressions and can be converted to other types of variants.

See Also

Unassigned (see page 23643)

VarType (see page 23667)

VarCheckEmpty (see page 23651)

VarIsNull (see page 23660)

VarIsClear (see page 23656)

VarIsEmptyParam (see page 23658)

VarIsType (see page 23662)

171.3.94 Variants.VarIsEmptyParam Function

Indicates whether the specified variant represents an unassigned optional parameter.

Pascal

```
function VarIsEmptyParam(const V: Variant): Boolean;
```

C++

```
Boolean VarIsEmptyParam(const Variant V);
```

File

Variants

Description

VarIsEmptyParam returns true if the given variant represents an unassigned optional parameter. If the variant contains any other value, the function result is false.

See Also

VarIsClear (see page 23656)

VarIsEmpty (see page 23657)

VarIsNull (see page 23660)

EmptyParam (see page 23677)

VarIsType (see page 23662)

171.3.95 Variants.VarIsError Function

Indicates whether the specified variant is an error variant; optionally converts variant back to HRESULT.

Pascal

```
function VarIsError(const V: Variant; out AResult: HRESULT): Boolean; overload;
function VarIsError(const V: Variant): Boolean; overload;
```

C++

```
Boolean VarIsError(const Variant V, HRESULT AResult);
Boolean VarIsError(const Variant V);
```

File

Variants

Description

VarIsError returns true if the given variant is an Error variant (type varError). If AResult is specified, it is set to the corresponding result code.

See Also

VarType (see page 23667)

VarIsType (see page 23662)

171.3.96 Variants.VarIsFloat Function

Indicates whether the specified variant represents a floating-point value.

Pascal

```
function VarIsFloat(const V: Variant): Boolean;
```

C++

```
Boolean VarIsFloat(const Variant V);
```

File

Variants

Description

VarIsFloat returns true if the given variant represents a floating-point value (In Delphi: Single, Double, or Currency; In C++: float, double, or Currency). If the variant contains any other type of value, the function result is false.

See Also

VarIsOrdinal (see page 23661)

VarIsNumeric (see page 23660)

VarIsStr (see page 23661)

VarType (see page 23667)

VarIsType (see page 23662)

171.3.97 Variants.VarIsNull Function

Indicates whether the specified variant is Null (see page 23641).

Pascal

```
function VarIsNull(const V: Variant): Boolean;
```

C++

```
Boolean VarIsNull(const Variant V);
```

File

Variants

Description

VarIsNull returns true if the given variant contains the value Null (see page 23641). If the variant contains any other value, the function result is false.

Note: Do not confuse a Null (see page 23641) variant with an unassigned variant. A Null (see page 23641) variant is still assigned, but has the value Null (see page 23641). Unlike unassigned variants, Null (see page 23641) variants can be used in expressions and can be converted to other types of variants.

See Also

Null (see page 23641)

VarType (see page 23667)

VarIsEmpty (see page 23657)

VarIsClear (see page 23656)

VarIsEmptyParam (see page 23658)

VarIsType (see page 23662)

171.3.98 Variants.VarIsNumeric Function

Indicates whether the specified variant represents a numeric value.

Pascal

```
function VarIsNumeric(const V: Variant): Boolean;
```

C++

```
Boolean VarIsNumeric(const Variant V);
```

File

Variants

Description

VarIsNumeric returns true if the given variant's type code indicates a numeric value of some sort. This can be either a floating-point value or an ordinal value. If the variant contains any other type of value, the function result is false.

See Also

VarIsOrdinal (see page 23661)

VarIsFloat (see page 23659)

VarIsStr (see page 23661)

VarType (see page 23667)

VarIsType (see page 23662)

171.3.99 Variants.VarIsOrdinal Function

Indicates whether the specified variant represents an ordinal value.

Pascal

```
function VarIsOrdinal(const V: Variant): Boolean;
```

C++

```
Boolean VarIsOrdinal(const Variant V);
```

File

Variants

Description

VarIsOrdinal returns true if the given variant represents an ordinal value (such as an integer or boolean type). If the variant contains any other type of value, the function result is false.

See Also

VarIsNumeric (see page 23660)

VarIsFloat (see page 23659)

VarIsStr (see page 23661)

VarType (see page 23667)

VarIsType (see page 23662)

171.3.100 Variants.VarIsStr Function

Indicates whether the specified variant represents a string value.

Pascal

```
function VarIsStr(const V: Variant): Boolean;
```

C++

```
Boolean VarIsStr(const Variant V);
```

File

Variants

Description

VarIsStr returns true if the given variant's type code is varString or varOleStr. If the variant contains any other type of value, the function result is false.

See Also

VarIsNumeric (see page 23660)

VarIsFloat (see page 23659)

VarIsOrdinal (see page 23661)

VarType (see page 23667)

VarIsType (see page 23662)

171.3.101 Variants.VarIsType Function

Indicates whether the specified variant represents a specified type.

Pascal

```
function VarIsType(const V: Variant; AVarType: TVarType): Boolean; overload;
function VarIsType(const V: Variant; const AVarTypes: array of TVarType): Boolean; overload;
```

C++

```
Boolean VarIsType(const Variant V, TVarType AVarType);
Boolean VarIsType(const Variant V, const array of TVarType AVarTypes);
```

File

Variants

Description

VarIsType checks whether the type code for the Variant specified by V matches the specified type code or one of the type codes in the specified array.

V is the Variant to check.

AVarType is the type code against which to check V.

AVarTypes is an array of valid type codes against which to check V.

AVarTypes_size is the index of the last entry in AVarTypes (one less than the number of entries).

VarIsType returns true if the given variant's type code matches the supplied type code or codes, false otherwise.

See Also

VarType (see page 23667)

171.3.102 Variants.VarOverflowError Function

Raises an EVariantOverflowError (see page 23579) exception.

Pascal

```
procedure VarOverflowError(const ASourceType: TVarType; const ADestType: TVarType);
```

C++

```
VarOverflowError(const TVarType ASourceType, const TVarType ADestType);
```

File

Variants

Description

Call VarOverflowError to indicate that a variant operation has failed due to numeric overflow. ASourceType and ADestType should contain the variant type codes for the source and destination variant types. VarOverflowError uses this information to compose an error string and raise EVariantOverflowError (see page 23579).

See Also

EVariantOverflowError (see page 23579)

TVarType

171.3.103 Variants.VarRangeCheckError Function

Raises an EVariantRangeCheckError (see page 23580) exception.

Pascal

```
procedure VarRangeCheckError(const ASourceType: TVarType; const ADestType: TVarType);
```

C++

```
VarRangeCheckError(const TVarType ASourceType, const TVarType ADestType);
```

File

Variants

Description

Call VarRangeCheckError to indicate that a variant operation has failed because the result is not in the allowed range for the destination variant type. ASourceType and ADestType are the variant types of the source and destination.

See Also

EVariantRangeCheckError (see page 23580)

171.3.104 Variants.VarResultCheck Function

Raises variant exception based on HRESULT value.

Pascal

```
procedure VarResultCheck(AResult: HRESULT); overload;
procedure VarResultCheck(AResult: HRESULT; ASourceType: TVarType; ADestType: TVarType);
overload;
```

C++

```
VarResultCheck(HRESULT AResult);
VarResultCheck(HRESULT AResult, TVarType ASourceType, TVarType ADestType);
```

File

Variants

Description

VarResultCheck examines the HRESULT value returned by many variant routines. If AResult is S_OK, VarResultCheck does nothing. Otherwise, VarResultCheck attempts to map AResult to a variant exception and raise that exception. If VarResultCheck is unable to map AResult to a specific variant Exception, it raises EVariantError.

Specify ASourceType and ADestType when the operation involves conversion between two variant types.

See Also

EVariantError

171.3.105 Variants.VarSameValue Function

Indicates whether two Variants (see page 23567) have equivalent values.

Pascal

```
function VarSameValue(const A: Variant; const B: Variant): Boolean;
```

C++

```
Boolean VarSameValue(const Variant A, const Variant B);
```

File

Variants

Description

VarSameValue returns true when A has the same value as B, false if the two values are not equivalent.

If A and B can't be compared, VarSameValue raises an exception.

See Also

VarCompareValue (see page 23652)

SameValue

171.3.106 Variants.VarSupports Function

Indicates whether the Variant's value is an interface that supports a specified interface.

Pascal

```
function VarSupports(const V: Variant; const IID: TGUID; out Intf): Boolean; overload;
function VarSupports(const V: Variant; const IID: TGUID): Boolean; overload;
```

C++

```
Boolean VarSupports(const Variant V, const TGUID IID,  Intf);
Boolean VarSupports(const Variant V, const TGUID IID);
```

File

Variants

Description

VarSupports returns the lower twelve bits of a variant type code. These indicate the type of the variant. For a list of possible variant type codes, see VarType (see page 23667).

Call VarSupports to determine whether the Variant represents an interface that supports the interface identified by the IID parameter. If V supports the interface, VarSupports returns the interface as the Intf parameter (if using the first syntax) and returns true (both versions). If the interface specified by IID is not supported, VarSupports returns false.

Unlike calling the QueryInterface method of the interface, VarSupports handles the case when the Variant's value is nil (Delphi) or NULL (C++).

See Also

Supports

171.3.107 Variants.VarToDateTime Function

Converts a specified variant to a TDateTime value.

Pascal

```
function VarToDateTime(const V: Variant): TDateTime;
```

C++

```
TDateTime VarToDateTime(const Variant V);
```

File

Variants

Description

VarToDateTime converts the given variant to a TDateTime value. VarToDateTime raises an exception if the conversion fails.

See Also

VarFromDateTime (see page 23653)

171.3.108 Variants.VarToStr Function

Converts a variant's value to a string.

Pascal

```
function VarToStr(const V: Variant): string;
```

C++

```
AnsiString VarToStr(const Variant V);
```

File

Variants

Description

VarToStr converts the data in the variant V to a string and returns the result. If the variant has a null value, VarToStr returns an empty string.

See Also

VarToStrDef (see page 23666)

VarToWideStr (see page 23666)

VarToWideStrDef (see page 23667)

171.3.109 Variants.VarToStrDef Function

Converts a variant's value to a string.

Pascal

```
function VarToStrDef(const V: Variant; const ADefault: string): string;
```

C++

```
AnsiString VarToStrDef(const Variant V, const AnsiString ADefault);
```

File

Variants

Description

VarToStrDef converts the data in the variant V to a string and returns the result. If the variant has a null value, VarToStrDef returns ADefault.

See Also

VarToStr (see page 23665)

VarToWideStr (see page 23666)

VarToWideStrDef (see page 23667)

171.3.110 Variants.VarToWideStr Function

Converts a variant's value to a WideString.

Pascal

```
function VarToWideStr(const V: Variant): WideString;
```

C++

```
BSTR VarToWideStr(const Variant V);
```

File

Variants

Description

VarToWideStr converts the data in the variant V to a WideString and returns the result. If the variant has a null value, VarToWideStr returns an empty string.

See Also

VarToStrDef (see page 23666)

VarToStr (see page 23665)

VarToWideStrDef (see page 23667)

171.3.111 Variants.VarToWideStrDef Function

Converts a variant's value to a WideString.

Pascal

```
function VarToWideStrDef(const V: Variant; const ADefault: WideString): WideString;
```

C++

```
BSTR VarToWideStrDef(const Variant V, const BSTR ADefault);
```

File

Variants

Description

VarToWideStrDef converts the data in the variant V to a WideString and returns the result. If the variant has a null value, VarToWideStrDef returns ADefault.

See Also

VarToStr (see page 23665)

VarToWideStr (see page 23666)

VarToStrDef (see page 23666)

171.3.112 Variants.VarType Function

Returns the type code of a specified variant.

Pascal

```
function VarType(const V: Variant): TVarType;
```

C++

```
TVarType VarType(const Variant V);
```

File

Variants

Description

VarType returns the type code of the given variant. The resulting value is either the type code for a custom Variant type, or it is constructed from the constants declared in the System (see page 22079) unit.

The lower twelve bits of a variant type code (the bits defined by the varTypeMask bit mask) define the type of the variant. The varArray bit is set if the variant is an array of the given type. The varByRef bit is set if the variant is a reference to a value of the given type as opposed to an actual value.

The following table describes the meaning of each of the variant type codes defined in the System (see page 22079) unit:

VarType	Contents of variant
varEmpty	The variant is Unassigned (see page 23643).
varNull	The variant is Null (see page 23641).
varSmallint	16-bit signed integer (type Smallint in Delphi, short in C++).
varInteger	32-bit signed integer (type Integer in Delphi, int in C++).
varSingle	Single-precision floating-point value (type Single in Delphi, float in C++).
varDouble	Double-precision floating-point value (type double).
varCurrency	Currency floating-point value (type Currency).
varDate	Date and time value (type TDateTime).
varOleStr	Reference to a dynamically allocated UNICODE string.
varDispatch	Reference to an Automation object (an IDispatch interface pointer).
varError	Operating system error code.
varBoolean	16-bit boolean (type WordBool).
varVariant	A variant.
varUnknown	Reference to an unknown object (an IInterface or IUnknown interface pointer).
varShortInt	8-bit signed integer (type ShortInt in Delphi or signed char in C++)
varByte	A Byte
varWord	unsigned 16-bit value (Word)
varLongWord	unsigned 32-bit value (type LongWord in Delphi or unsigned long in C++)
varInt64	64-bit signed integer (Int64 in Delphi or __int64 in C++)
varStrArg	COM-compatible string.
varString	Reference to a dynamically allocated string (not COM compatible).

The value returned by VarType corresponds to the VType field of a TVarData record.

The type of a variant can be changed using VarAsType (see page 23650).

See Also

TVarData

VarAsType (see page 23650)

VarTypeToDataType

VarTypeAsText (see page 23668)

171.3.113 Variants.VarTypeAsText Function

Returns variant type descriptive string.

Pascal

```
function VarTypeAsText(const AType: TVarType): string;
```

C++

```
AnsiString VarTypeAsText(const TVarType AType);
```

File

Variants

Description

VarTypeAsText returns a short string that names the variant type indicated by AType.

See Also

TVarData

VarAsType (see page 23650)

VarTypeToDataType

VarType (see page 23667)

171.3.114 Variants.VarTypeIsValidArrayType Function

Indicates whether a Variant type code represents a type that can be used for the elements in a Variant array.

Pascal

```
function VarTypeIsValidArrayType(const AVarType: TVarType): Boolean;
```

C++

```
Boolean VarTypeIsValidArrayType(const TVarType AVarType);
```

File

Variants

Description

VarTypeIsValidArrayType indicates whether AVarType is the type code for a Variant type that can represent the elements of a Variant array. This function is only intended for use with built-in Variant types. It returns false for custom Variant types, although they can be used for the elements of Variant arrays.

See Also

VarArrayCreate (see page 23644)

VarTypeIsValidElementType (see page 23669)

171.3.115 Variants.VarTypeIsValidElementType Function

Indicates whether a Variant type code represents a type that can be used for the elements in a Variant array.

Pascal

```
function VarTypeIsValidElementType(const AVarType: TVarType): Boolean;
```

C++

```
Boolean VarTypeIsValidElementType(const TVarType AVarType);
```

File

Variants

Description

VarTypeIsValidElementType indicates whether AVarType is the type code for a Variant type that can represent the elements of a Variant array. Unlike the VarTypeIsValidArrayType (see page 23669) function, this function returns true for custom Variant types.

See Also

VarArrayCreate (see page 23644)

VarTypeIsValidArrayType (see page 23669)

171.4 Structs, Records, Enums

The following table lists structs, records, enums in this documentation.

Enumerations

	Name	Description
	TBooleanToStringRule (see page 23671)	TBooleanToStringRule enumerates possible rules for BooleanToStringRule (see page 23676).
	TNullCompareRule (see page 23671)	TNullCompareRule enumerates possible rules for comparing variant nulls with other values.
	TVarCompareResult (see page 23672)	This is record Variants.TVarCompareResult.
	TVariantRelationship (see page 23672)	TVariantRelationship describes the results of comparing two Variants (see page 23567).

171.4.1 Variants.TBooleanToStringRule Enumeration

TBooleanToStringRule enumerates possible rules for BooleanToStringRule (see page 23676).

Pascal

```
TBooleanToStringRule = (
  bsrAsIs,
  bsrLower,
  bsrUpper
);
```

C++

```
enum TBooleanToStringRule {
  bsrAsIs,
  bsrLower,
  bsrUpper
};
```

File

Variants

Description

TBooleanToStringRule enumerates the values that can be assigned to the global variables NullEqualityRule (see page 23678) and NullMagnitudeRule (see page 23679).

171.4.2 Variants.TNullCompareRule Enumeration

TNullCompareRule enumerates possible rules for comparing variant nulls with other values.

Pascal

```
TNullCompareRule = (
  ncrError,
  ncrStrict,
  ncrLoose
);
```

C++

```
enum TNullCompareRule {
  ncrError,
  ncrStrict,
  ncrLoose
};
```

File

Variants

Description

TNullCompareRule enumerates the values that can be assigned to the global variables NullEqualityRule (see page 23678) and NullMagnitudeRule (see page 23679).

171.4.3 Variants.TVarCompareResult Enumeration

Pascal

```
TVarCompareResult = (
  crLessThan,
  crEqual,
  crGreaterThan
);
```

C++

```
enum TVarCompareResult {
  crLessThan,
  crEqual,
  crGreaterThan
};
```

File

Variants

Description

This is record Variants.TVarCompareResult.

171.4.4 Variants.TVariantRelationship Enumeration

TVariantRelationship describes the results of comparing two Variants (see page 23567).

Pascal

```
TVariantRelationship = (
  vrEqual,
  vrLessThan,
  vrGreaterThan,
  vrNotEqual
);
```

C++

```
enum TVariantRelationship {
  vrEqual,
  vrLessThan,
```

```
    vrGreaterThan,
    vrNotEqual
  };
```

File

Variants

Description

TVariantRelationship describes the relationship between two Variant values. The following table lists the possible values:

Value	Meaning
vrEqual	A is equivalent to B. Note that two NULL Variants (see page 23567) are considered equal, and two empty Variants (see page 23567) are considered equal, but a NULL Variant does not equal an empty Variant.
vrLessThan	A is less than B.
vrGreaterThan	A is larger than B.
vrNotEqual	A and B are not equal, but the values are such that they can't be ordered relative to each other. For example, this describes the relationship when either A or B is empty or NULL, and the other one is not.

See Also

VarCompareValue

171.5 Types

The following table lists types in this documentation.

Types

Name	Description
TAnyProc (see page 23674)	This is type Variants.TAnyProc.
TCustomVariantTypeClass (see page 23674)	This is type Variants.TCustomVariantTypeClass.
TVarDataArray (see page 23675)	This is type Variants.TVarDataArray.
TVarDispProc (see page 23675)	This is type Variants.TVarDispProc.

171.5.1 Variants.TAnyProc Type

Pascal

```
TAnyProc = procedure (var V: TVarData);
```

C++

```
(var V: TVarData) ( TAnyProc)();
```

File

Variants

Description

This is type Variants.TAnyProc.

171.5.2 Variants.TCustomVariantTypeClass Type

Pascal

```
TCustomVariantTypeClass = class of TCustomVariantType;
```

C++

```
TCustomVariantType TCustomVariantTypeClass;
```

File

Variants

Description

This is type Variants.TCustomVariantTypeClass.

171.5.3 Variants.TVarDataArray Type

Pascal

```
TVarDataArray = array of TVarData;
```

C++

```
array of TVarData TVarDataArray;
```

File

Variants

Description

This is type Variants.TVarDataArray.

171.5.4 Variants.TVarDispProc Type

Pascal

```
TVarDispProc = procedure (Dest: PVariant; const Source: Variant; CallDesc: PCallDesc; Params:
Pointer);
```

C++

```
(Dest: PVariant; const Source: Variant; CallDesc: PCallDesc; Params: Pointer) (
TVarDispProc)();
```

File

Variants

Description

This is type Variants.TVarDispProc.

171.6 Variables

The following table lists variables in this documentation.

Variables

Name	Description
BooleanToStringRule (see page 23676)	Specifies rule fixing up Boolean values converted to strings.
ChangeAnyProc (see page 23677)	This is variable Variants.ChangeAnyProc.
ClearAnyProc (see page 23677)	This is variable Variants.ClearAnyProc.
EmptyParam (see page 23677)	Contains an OleVariant that represents an unused optional parameter on a dual interface.
NullAsStringValue (see page 23678)	Specifies string value of Null (see page 23641) variants.
NullEqualityRule (see page 23678)	Specifies rule for Null (see page 23641) variant equality comparison.
NullMagnitudeRule (see page 23679)	Specifies rule for Null (see page 23641) variant magnitude comparison.
NullStrictConvert (see page 23679)	Specifies whether Null (see page 23641) conversion is an error.
OleVariantInt64AsDouble (see page 23680)	This is variable Variants.OleVariantInt64AsDouble.
PackVarCreation (see page 23680)	Specifies whether space-efficient Variant Types (see page 23293) are preferred.
RefAnyProc (see page 23681)	This is variable Variants.RefAnyProc.
VarDispProc (see page 23681)	Provides the support for IDispatch-based Automation.

171.6.1 Variants.BooleanToStringRule Variable

Specifies rule fixing up Boolean values converted to strings.

Pascal

```
BooleanToStringRule: TBooleanToStringRule = bsrAsIs;
```

C++

```
TBooleanToStringRule BooleanToStringRule = bsrAsIs;
```

File

Variants

Description

BooleanToStringRule determines the rule for fixing up the string generated by a conversion from Boolean to string.

Constant	Meaning
bsrAsIs	(Default.) The value obtained from the locale is left as is.
bsrUpper	The string is converted to all upper case.
bsrLower	The string is converted to all lower case.

171.6.2 Variants.ChangeAnyProc Variable

Pascal

```
ChangeAnyProc: TAnyProc;
```

C++

```
TAnyProc ChangeAnyProc;
```

File

Variants

Description

This is variable Variants.ChangeAnyProc.

171.6.3 Variants.ClearAnyProc Variable

Pascal

```
ClearAnyProc: TAnyProc;
```

C++

```
TAnyProc ClearAnyProc;
```

File

Variants

Description

This is variable Variants.ClearAnyProc.

171.6.4 Variants.EmptyParam Variable

Contains an OleVariant that represents an unused optional parameter on a dual interface.

Pascal

```
EmptyParam: OleVariant;
```

C++

```
OleVariant EmptyParam;
```

File

Variants

Description

EmptyParam can be used for Variants (see page 23567) that represent optional parameters whose value is unassigned. This is useful when the code that marshals method calls requires a fixed number of parameters, even if some of them are optional.

When marshaling interface calls that include optional parameters, COM requires a value for those parameters even when they are not used. EmptyParam returns an OleVariant you can pass as that value to indicate that the parameter is not used.

Marshaling interfaces also exist under Linux, but we can't spare the resources to document them right now.

See Also

VarIsEmptyParam (see page 23658)

171.6.5 Variants.NullAsStringValue Variable

Specifies string value of Null (see page 23641) variants.

Pascal

```
NullAsStringValue: string = '';
```

C++

```
AnsiString NullAsStringValue = '';
```

File

Variants

Description

NullAsStringValue specifies the string that is the result of a conversion from a Null (see page 23641) variant to a string type. By default, NullAsStringValue is the empty string.

NullAsStringValue is only used when the NullStrictConvert (see page 23679) global variable is set to false.

See Also

NullStrictConvert (see page 23679)

Null (see page 23641)

171.6.6 Variants.NullEqualityRule Variable

Specifies rule for Null (see page 23641) variant equality comparison.

Pascal

```
NullEqualityRule: TNullCompareRule = ncrLoose;
```

C++

```
TNullCompareRule NullEqualityRule = ncrLoose;
```

File

Variants

Description

NullEqualityRule determines the rule for handling equality comparisons (equals or not-equals) when one of the values compared is a variant containing a null value. NullEqualityRule can have the following values:

Constant	Meaning
ncrLoose	(Default.) A variant containing a null is treated as a unique value that is only equal to another variant containing a null.
ncrStrict	An equality comparison of a variant containing a null is always false, regardless of the other value.

ncrError	An equality comparison raises an EVariantInvalidNullOpError (see page 23576) if either value is a variant containing a null.

See Also

Null (see page 23641)

NullMagnitudeRule (see page 23679)

NullStrictConvert (see page 23679)

EVariantInvalidNullOpError (see page 23576)

171.6.7 Variants.NullMagnitudeRule Variable

Specifies rule for Null (see page 23641) variant magnitude comparison.

Pascal

```
NullMagnitudeRule: TNullCompareRule = ncrLoose;
```

C++

```
TNullCompareRule NullMagnitudeRule = ncrLoose;
```

File

Variants

Description

NullMagnitudeRule determines the rule for handling magnitude comparisons (one value is greater than, greater than or equals, less than, or less than or equals to another) when one of the values compared is a variant containing a null value. NullMagnitudeRule can have the following values:

Constant	Meaning
ncrLoose	(Default.) A variant containing a null is treated as a unique value that is less than any other value, but equal to another variant containing a null.
ncrStrict	A magnitude comparison of a variant containing a null is always false, regardless of the other value.
ncrError	A magnitude comparison raises an EVariantInvalidNullOpError (see page 23576) if either value is a variant containing a null.

See Also

Null (see page 23641)

NullMagnitudeRule

NullStrictConvert (see page 23679)

EVariantInvalidNullOpError (see page 23576)

171.6.8 Variants.NullStrictConvert Variable

Specifies whether Null (see page 23641) conversion is an error.

Pascal

```
NullStrictConvert: Boolean = True;
```

C++

```
Boolean NullStrictConvert = True;
```

File

Variants

Description

NullStrictConvert determines the outcome of attempts to convert Null (see page 23641) variants to other types. If NullStrictConvert is true (default), attempting to convert a Null (see page 23641) variant raises a EVariantTypeCastError (see page 23580), unless the conversion is to a custom variant that defines a conversion from Null (see page 23641). If NullStrictConvert is false, then conversion from Null (see page 23641) follows the following rules:

Destination	Conversion result
Numeric type	Zero
String type	Value of NullAsStringValue (see page 23678) global variable. (Default: empty string.)
Boolean	False.

TVarData

VarType (see page 23667)

NullAsStringValue (see page 23678)

EVariantTypeCastError (see page 23580)

171.6.9 Variants.OleVariantInt64AsDouble Variable

Pascal

```
OleVariantInt64AsDouble: Boolean = False;
```

C++

```
Boolean OleVariantInt64AsDouble = False;
```

File

Variants

Description

This is variable Variants.OleVariantInt64AsDouble.

171.6.10 Variants.PackVarCreation Variable

Specifies whether space-efficient Variant Types (see page 23293) are preferred.

Pascal

```
PackVarCreation: Boolean = True;
```

C++

```
Boolean PackVarCreation = True;
```

File

Variants
