

Digital Spectrum Analyzer

Model AT5010D

User's Guide

Safety Summary

The following safety precautions apply to both operating and maintenance personnel and must be observed during all phases of operation, service, and repair of this instrument. Before applying power, follow the installation instructions and become familiar with the operating instructions for this instrument.

Failure to comply with these precautions or with specific warnings elsewhere in this manual violates safety standards of design, manufacture, and intended use of the instrument. Atten Instruments assumes no liability for a customer's failure to comply with these requirements. This is a Safety Class I instrument.

The most sensitive component of the AT5010D is the input section of the Spectrum Analyzer. It consists of the signal attenuator and the first mixer. Without input attenuation, the voltage at the input must not exceed +10 dB (0.7 Vrms) AC or +25 volt DC. With a maximum input attenuation of 40dB the AC voltage must not exceed +20dBm(2.2Vrms). These limits must not be exceeded otherwise the input attenuator and/or the first mixer would be destroyed. When measuring via a LISN (line impedance stabilization network) the input of the Spectrum Analyzer must be protected by means of a transient limiter.

GROUND THE INSTRUMENT

To minimize shock hazard, the instrument chassis and cabinet must be connected to an electrical ground. This instrument is grounded through the ground conductor of the supplied, three-conductor ac power cable. The power cable must be plugged into an approved three-conductor electrical outlet. Do not alter the ground connection. Without the protective ground connection, all accessible conductive parts (including control knobs) can render an electric shock. The power jack and mating plug of the power cable meet IEC safety standards.

Prior to examining unidentified signals, the presence of unacceptable high voltages has to be checked. It is also recommended to start measurements with the highest possible attenuation and a maximum frequency range (1000MHz). The user should also consider the possibility of excessively high signal amplitudes outside the covered frequency range, although not displayed (e.g. 1200MHz). The frequency range of 0Hz~150KHz is not specified for the AT5010D Spectrum Analyzers. Spectral lines within this range would be displayed with incorrect amplitude. A particularly high intensity setting shall be avoided. The way signals are displayed on the spectrum analyzer typically allows for any signal to be recognized easily, even with low intensity.

Due to the frequency conversion principle, a spectral line is visible at 0Hz. It is called If-feedthrough. The line appears when the 1st LO frequency passes the If amplifiers and filters. The level of this spectral line is different in each instrument. A deviation from the full screen does not indicate a malfunctioning instrument.

DO NOT OPERATE IN AN EXPLOSIVE ATMOSPHERE

Do not operate the instrument in the presence of flammable gases or fumes. Operation of any electrical instrument in such an environment constitutes a definite safety hazard.

KEEP AWAY FROM LIVE CIRCUITS

Instrument covers must not be removed by operating personnel. Component replacement and internal adjustments must be made by qualified maintenance personnel. Disconnect the power cord before removing the instrument covers and replacing components. Under certain conditions, even with the power cable removed, dangerous voltages may exist. To avoid injuries, always disconnect power and discharge circuits before touching them.

Product Introduction

Description

AT5010D is the perfect instrument for analyzing any kind of signal within the frequency range of 0.15 to 1050 MHz, and is best suited for meeting the RF measurement needs of education and industry. Also a great tool for professionals in the cable TV industry as well as in the telecommunication. It is a value packed service tool for signals up to 1.05GHz. Both models are suitable for pre-compliance testing during development prior to third party testing.

An optional near-field sniffer probe set can be used to locate cable and PC board emission "hot spots" and evaluate EMC problems at the breadboard and prototype level. The spectrum analyzer/ sniffer probe combination is an excellent solution for RF leakage/ radiation investigation, CATV/MATV system troubleshooting, cellular telephone/pocket pager test and EMI diagnostics.

The spectrum analyzer permits the detection of spectrum components of electrical signals in the frequency range of 0.15 to 1050MHz. The detected signal and its content have to be repetitive. In contrast to an oscilloscope operated in Yt mode, where the amplitude is displayed on the time domain, the spectrum analyzer displays amplitude on the frequency domain (Yf). The individual spectrum components of "a signal" become visible on a spectrum analyzer. The oscilloscope would display the same signal as one resulting waveform.

The spectrum analyzer works according to the triple superhetro receiver principle. The signal to be measured ($f_{in} = 0.15\text{MHz to } 1050\text{MHz}$) is applied in to the 1st mixer it is mixed with the signal of a variable voltage controlled oscillator ($f_{LO} = 1350\text{MHz} \sim 2350\text{MHz}$). This oscillator is called the 1st LO (local oscillator). The difference between the oscillator and the input frequency ($f_{LO} - f_{in} = 1st\ IF$) is the first LO in intermediate frequency, which passes through a waveband filter tuned to a center frequency of 1350MHz. It then enters an amplifier, and this is followed by two additional mixing stages, oscillators and amplifiers. The second IF is 35MHz and the third is 2.875MHz. in the third IF stage, the signal can be selectively transferred through a filter with 400KHz or 20KHz bandwidth before arriving at an AM demodulator.

Applications

- AT5010D spectrum analyzer can carry out good inspection to the faults of cable system and wireless system including remote control, cordless phone, cable TV and communication equipment, as well as good comparison and analysis to frequency of signals.
- AT5010D spectrum analyzers can test mobile phone, RF circuits, for example, control signal of logic circuit, baseband signal; local oscillator signal of RF circuit, IF signal and transmission signal, It is very quick and accurate to use AT5000 series spectrum analyzers to overhaul the fault of mobile phone which cannot enter the network, and determine the fault point.
- Spectrum analyzers can display the information of un-processed original signals, such as the voltage, power, period, waveform, sideband, and frequency.
- The commonplace measurement modes of spectrum analyzers include: harmonic distortion, dual-tone crosstalk distortion, and clutter investigation etc.

- Electromagnetic Compatible (EMC) Testing: measure the function of harmful electromagnetic wave to be transmitted by various electronic equipments. In addition, it can output AM/FM demodulation signal from socket PHONE, identify the broadcast signal affected by noise. From authorization aspect, it is very effective measurement function for the evaluation and research in advance to carry out the measurement of radioactive noise.
- Widely used for production, development, education and scientific research. True form of signal (such as RF pulse signal) can be observed from ATTEN spectrum analyzer clearly, where figures are expanded by Fourier series, good for apprehend in education and research.

Specifications

Frequency Characteristics

Frequency	Range:	0.15 ~ 1050MHz
	Display Resolution	10kHz
	Display accuracy	$\leq \pm(10\text{kHz} + \text{span} \times \text{span accuracy} + 50\% \text{ of RBW})$
Stability		$\pm 5\text{ppm per year}$
Aging		$\pm 1\text{ppm per year}$
Frequency generation		TCXO , DDS
Span	Range	Zero-Span and 1 to 1000MHz(steps 1-2-5)
	Accuracy	$\pm 10\%$ of the indicated span width
Sweep time		50ms

Amplitude Characteristics

Amplitude	Range	-100dBm ~ +10dBm
	Display	7" TFT 800(H)×480(V) , 8×10 Division
	Display calibration	10dB/div. , logarithmic
	Display range	80dB(10dB/div)
Amplitude frequency response		+2dB ~ -10dB
input attenuator	Range	0 to 40dB in 10dB steps
	Accuracy	$\leq \pm 2\text{dB at } 10\text{dB}$, $\leq \pm 3\text{dB at } 40\text{dB}$
Reference level	Range	-90dBm ~ +10dBm
	Resolution	0.5dB step
	Accuracy(Freq. 50MHz, -40dBm, zero span, RBW 400kHz)	$\leq \pm 2\text{dB}$
Min. Average noise floor		< -100dBm (at RBW 20kHz, VBW 4kHz)
3rd order intermodulation (2 signals at -30dBm, >3MHz apart)		> 70dBc
2nd harmonic suppression(-30dBm, 0dB atten, at >3MHz)		> 50dBc
Resolution bandwidth(RBW)	Selections	20kHz, 200kHz
	Accuracy	$\pm 50\%$

Selectivity	60dB/3dB ratio < 15:1
Switching Error	$\leq \pm 2\text{dB}$
Video filter bandwidth(VBW)	4kHz

Inputs and Outputs

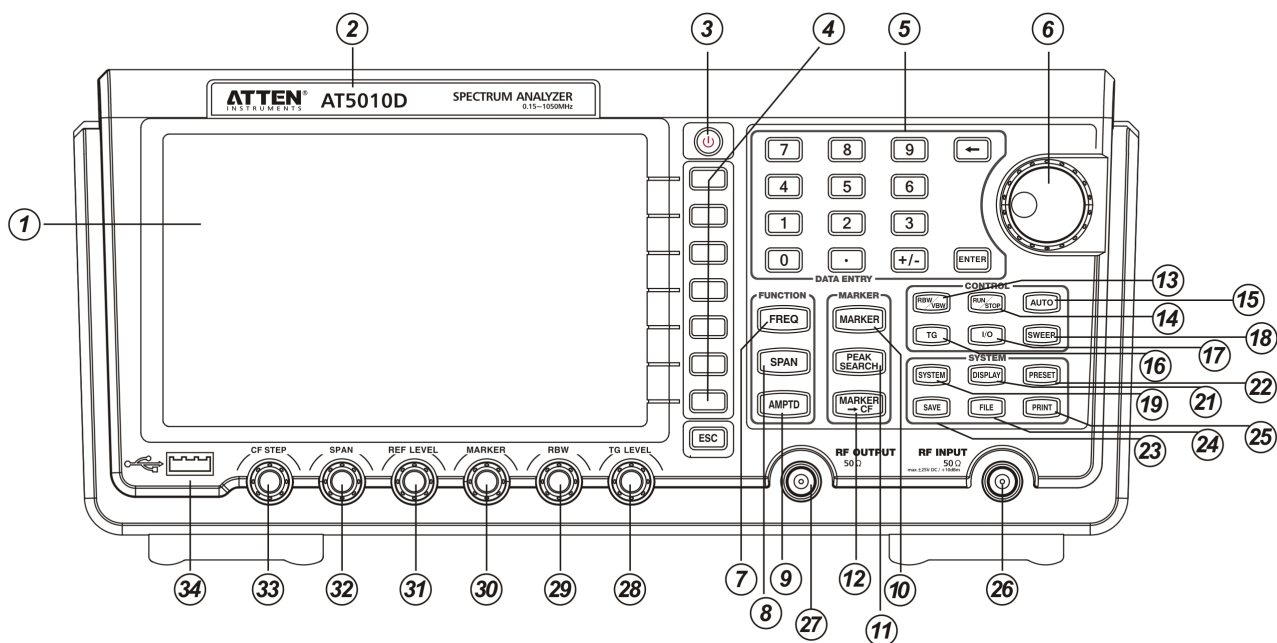

RF input	Connector	BNC female
	Impedance	50 Ω
	Max. DC input voltage	$\pm 25\text{V}$
	Max. continuous RF input level	+20dBm(10 ~40dB attenuator), +10dBm(0dB attenuator)
	VSWR (atten $\geq 10\text{dB}$)	typ. 1.5:1
Test signal output	Connector	BNC female
	Frequency	50MHz
	Impedance	50 Ω
	Level	-40dBm $\pm 2\text{dB}$
Power supply for ATTEN field probes		DC +6 $\pm 0.5\text{V}$
Audio(phone)output		$\phi 3.5\text{mm}$,phone connector

General Characteristics

Warming-up Time	More than 20 minutes for precise measurement
Working temperature	0 $^{\circ}\text{C}$ ~ 40 $^{\circ}\text{C}$
Storage temperature	-20 $^{\circ}\text{C}$ ~ 70 $^{\circ}\text{C}$
Line voltage range	DC 10.5V ~ 26V,AC adaptor
Consumption power	< 15W
Dimensions(W×H×D)	140 x 350 x 160mm
Weight	approx. 4kg

Panel description

Front Panel

Overview of Keys

(1)	7" Widescreen TFT display.	
(2)	Brand and model	
(3)	Power (Power ON and OFF)	The power button will turn red after the instrument is plugged in. Press the button for 1-2 seconds to switch ON, and the button will turn blue. Press the button for 3-5 seconds to switch OFF, and the button will turn back to red. If the button flickers, it means the input voltage is not within acceptable range, and the instrument cannot be opened. In this case, please check the power supply.
(4)	Function Buttons	Used to select the function menu
(5)	Number Buttons	Used to input numbers
(6)	Center Frequency adjusting knob	Used to adjust center frequency
(7)	FREQ.	Used to set the center freq and CF step
(8)	SPAN.	Used to set Span, Full Span and Zero Span
(9)	AMPTD	Used to set Ref Level and Attenuator
(10)	MARKER	Used to control ON/OFF of Marker function, and ON/OFF of Cont Peak function.
(11)	PEAK SEARCH	

(12)	MARKER → CF.	Short-circuit button used to marker the center frequency
(13)	RBW/VBW.	Used to set the Res Bw and Video Bw
(14)	RUN/STOP	
(15)	AUTO	For automatic configuration
(16)	TG	Used to set tracking generator, only for AT5010D
(17)	I/O	Used to control the volume of Phone and ON/OFF of 50MHz Ref Level
(18)	SWEEP	
(19)	SYSTEM	
(20)	ESC	
(21)	DISPLAY	Used to set display model and brightness.
(22)	PRESET	
(23)	SAVE	
(24)	FILE	
(25)	PRINT	
(26)	RF INPUT	Used to input signals.
(27)	RF OUTPUT	The output channel of tracking generator signals, only for AT5010D
(28)	TG LEVEL knob	Used to adjust tracking generator level, only for AT5010D
(29)	RBW knob	Used to adjust Res Bw
(30)	MARKER knob	Used to adjust markers
(31)	REF LEVEL knob	Used to adjust ref level
(32)	SPAN knob	Used to adjust span
(33)	CF STEP knob	Used to adjust center frequency step
(34)	USB interface	

Rear Panel

(1)	Probe Power	Output +6V DC voltage for AZ530 near-field sniffer probes exclusively. Accessory cables are provided along with AZ530.
(2)	Phone	3.5mm socket, for loudhailer and earphone of which the impedance exceeds +16Ω When the spectrum analyzer have gradated a certain spectral line, some audio frequencies will be demodulated. It is realized by IF amplitude demodulator, which will demodulate any amplitude-modulated signals and single sideband frequency-modulated signals.
(3)	DC Input	
(4)	USB interface.	
(5)	LAN interface	
(6)	RS232 interfac	
(7)	Reference source output 50MHz/-40dBm	

Introduction to Spectrum Analysis

The analysis of electrical signals is a fundamental problem for many engineers and scientists. Even if the immediate problem is not electrical, the basic parameters of interest are often changed into electrical signals by means of transducers. The rewards for transforming physical parameters to electrical signals are great, as many instruments are available for the analysis of electrical signals in the time and frequency domains.

The traditional way of observing electrical signals is to view them in the time domain using an oscilloscope. The time domain is used to recover relative timing and phase information which is needed to characterize electric circuit behavior.

However, not all circuits can be uniquely characterized from just time domain information.

Circuit elements such as amplifiers, oscillators, mixers, modulators, detectors and filters are best characterized by their frequency response information. This frequency information is best obtained by viewing electrical signals in the frequency domain. To display the frequency domain requires a device that can discriminate between frequencies while measuring the power level at each. One instrument which displays the frequency domain is the spectrum analyzer. It graphically displays voltage or power as a function of frequency.

In the time domain, frequency components of a signal are seen summed together. In the frequency domain, complex signals (i.e. signals composed of more than one frequency) are separated into their frequency components, and the power level at each frequency is displayed. The frequency domain is a graphical representation of signal amplitude as a function of frequency. The frequency domain contains information not found in the time domain and therefore, the spectrum analyzer has certain advantages compared with an oscilloscope.

The analyzer is more sensitive to low level distortion than a scope. Sine waves may look in the time domain, but in the frequency domain, harmonic distortion can be seen. The sensitivity and wide dynamic range of the spectrum analyzer is useful for measuring low-level modulation. It can be used to measure AM, FM and pulsed RF. The analyzer can be used to measure carrier frequency, modulation frequency, modulation level, and modulation distortion. Frequency conversion devices can be easily characterized. Such parameters as conversion loss, isolation, and distortion are readily determined from the display.

The spectrum analyzer can be used to measure long and short term stability. Parameters such as noise sidebands on an oscillator, residual FM of a source and frequency drift during warm-up can be measured using the spectrum analyzer's calibrated scans. The swept frequency responses of a filter or amplifier are examples of swept frequency measurements possible with a spectrum analyzer.

These measurements are simplified by using a tracking generator.

Types of Spectrum Analyzers

There are two basic types of spectrum analyzers, swept-tuned and real-time analyzers. The swept tuned analyzers are tuned by electrically sweeping them over their frequency range. Therefore, the frequency components of a spectrum are sampled sequentially in time. This enables periodic and random signals to be displayed, but makes it impossible to display transient responses. Real-time analyzers, on the other hand, simultaneously display the amplitude of all signals in the frequency range of the analyzer; hence the name real-time. This preserves the time dependency between signals which permits phase information to be displayed. Real-time analyzers are capable of displaying transient responses as well as periodic and random signals.

The swept-tuned analyzers of the TRF (tuned radio frequency) or superheterodyne type. A TRF analyzer consists of a bandpass filter whose center frequency is tunable over a desired frequency range, a detector to produce vertical deflection on a CRT, and a horizontal scan generator used to synchronize the tuned frequency to the CRT horizontal deflection. It is a simple, inexpensive analyzer with wide frequency coverage, but lacks resolution and sensitivity. Because trf analyzers have a swept filter they are limited in sweep width depending on the frequency range (usually one decade or less). The resolution is determined by the filter bandwidth, and since tunable filters don't usually have constant bandwidth, is dependent on frequency.

The most common type of spectrum analyzer differs from the TRF spectrum analyzers in that the spectrum is swept through a fixed bandpass filter instead of sweeping the filter through the spectrum. The analyzer is swept through a narrowband receiver which is electronically tuned in frequency by applying a saw-tooth voltage to the frequency control element of a voltage tuned local oscillator.

This same saw-tooth voltage is simultaneously applied to the horizontal deflection plates of the CRT. The output from the receiver is synchronously applied to the vertical deflection plates of the CRT and a plot of amplitude versus frequency is displayed. In the digital spectrum analyzer the data from these deflection plates are displayed over the TFT or LCD screen

The analyzer is tuned through its frequency range by varying the voltage on the LO (local oscillator).

The LO frequency is mixed with the input signal to produce an IF (intermediate frequency) which can be detected and displayed. When the frequency difference between the input signal and the LO frequency is equal to the IF frequency, then there is a response on the analyzer. The advantages of the superheterodyne technique are considerable.

It obtains high sensitivity through the use of IF amplifiers, and many decades in frequency can be tuned.

Also, the resolution can be varied by changing the bandwidth of the IF filters. However, the super heterodyne analyzer is not real-time and sweep rates must be consistent with the IF filter time constant. A peak at the left edge of the CRT is sometimes called the "zero frequency indicator" or "local oscillator feedthrough". It occurs when the analyzer is tuned to zero frequency, and the local oscillator passes directly through IF creating a peak on the Display even when no input signal is present. (For zero frequency tuning, $FLO = FIF$). This effectively limits the lower tuning limit.

Spectrum Analyzer requirements

To accurately display the frequency and amplitude of a signal on a spectrum analyzer, the analyzer itself must be properly calibrated. A spectrum analyzer properly designed for accurate frequency and amplitude measurements has to satisfy many requirements:

- Wide tuning range
- Wide frequency display range
- Stability
- Resolution
- Flat frequency response
- High sensitivity
- Low internal distortion

Frequency Measurements

The frequency scale can be scanned in three different modes full, per division, and zero scan. The full scan mode is used to locate signals because the widest frequency ranges are displayed in this mode. *(Not all spectrum analyzers offer this mode)*. The per-division mode is used to zoom-in on a particular signal. In per division, the center frequency of the display is set by the Tuning control and the scale factor is set by the Frequency Span or Scan Width control. In the zero scan mode, the analyzer acts as a fixed-tuned receiver with selectable bandwidths.

Absolute frequency measurements are usually made from the spectrum analyzer tuning dial. Relative frequency measurements require a linear frequency scan. By measuring the relative separation of two signals on the display, the frequency difference can be determined.

It is important that the spectrum analyzer be more stable than the signals being measured. The stability of the analyzer depends on the frequency stability of its local oscillators. Stability is usually characterized as either short term or long term.

Residual FM is a measure of the short term stability which is usually specified in Hz peak-to-peak. Short term stability is also characterized by noise sidebands which are a measure of the analyzers spectral purity. Noise sidebands are specified in terms of dB down and Hz away from a carrier in a specific bandwidth. Long term stability is characterized by the frequency drift of the analyzers Los. Frequency drift is a measure of how much the frequency changes during a specified time. *(i.e., Hz/hr)*

Resolution

Before the frequency of a signal can be measured on a spectrum analyzer it must first be re-solved.

Resolving a signal means distinguishing it from its nearest neighbors. The resolution of a spectrum analyzer is determined by its IF bandwidth. The IF bandwidth is usually the 3dB bandwidth of the IF filter. The ratio of the 60dB bandwidth (in Hz) to the 3dB bandwidth (in Hz) is known as the shape factor of the filter. The smaller the shape factor, the greater is the analyzers capability to resolve closely spaced signals of unequal amplitude. If the shape factor of a filter is 15, then two signals whose amplitudes differ by 60dB must differ in frequency by 7.5 times the IF bandwidth before they can be distinguished separately. Otherwise, they will appear as one signal on the spectrum analyzer display.

The ability of a spectrum analyzer to resolve closely spaced signals of unequal amplitude is not a function of the IF filter shape factor only. Noise sidebands can also reduce the resolution. They appear above the skirt of the IF filter and reduce the offband rejection of the filter. This limits the resolution when measuring signals of unequal amplitude.

The resolution of the spectrum analyzer is limited by its narrowest IF bandwidth. For example, if the narrowest bandwidth is 10KHz then the nearest any two signals can be and still be resolved is 10KHz.

This is because the analyzer traces out its own IF band-pass shape as it sweeps through a CW signal.

Since the resolution of the analyzer is limited by bandwidth, it seems that by reducing the IF bandwidth infinitely, infinite resolution will be achieved. The fallacy here is that the usable IF bandwidth is limited by the stability (residual Fm) of the analyzer. If the internal frequency deviation of the analyzer is 10 KHz, then the narrowest bandwidth that can be used to distinguish a single input signal is 10 KHz. Any narrower IF-filter will result in more than one response or an intermittent response for a single input frequency. A practical limitation exists on the IF bandwidth as well, since narrow filters have long time constants and would require excessive scan time.

Sensitivity

Sensitivity is a measure of the analyzer's ability to detect small signals. The maximum sensitivity of an analyzer is limited by its internally generated noise.

The noise is basically of two types: thermal (or Johnson) and nonthermal noise. Thermal noise power can be expressed as:

$$P_n = K \cdot T \cdot B$$

Where:

P_n = Noise power in watts

K = Boltzmann's Constant (1.38×10^{-23} Joule/K)

T = absolute temperature, K

B = bandwidth of system in Hertz

As seen from this equation, the noise level is directly proportional to bandwidth. Therefore, a decade decrease in bandwidth results in a 10dB decrease in noise level and consequently 10dB better sensitivity. Nonthermal noise accounts for all noise produced within the analyzer that is not temperature dependent. Spurious emissions due to nonlinearities of active elements, impedance mismatch, etc. are sources of non-thermal noise. A figure of merit, or noise figure, is usually assigned to this non-thermal noise which when added to the thermal noise gives the total noise of the analyzer system. This system noise which is measured on the Display unit, determines the maximum sensitivity of the spectrum analyzer. Because noise level changes with bandwidth it is important, when comparing the sensitivity of two analyzers, to compare sensitivity specifications for equal bandwidths. A spectrum analyzer sweeps over a wide frequency range, but is really a narrow band instrument. All of the signals that appear in the frequency range of the analyzer are converted to a single IF frequency which must pass through an IF filter; the detector sees only this noise at any time. Therefore, the noise displayed on the analyzer is only that which is contained in the IF passband. When measuring discrete signals, maximum sensitivity is obtained by using the narrowest IF bandwidth.

Video Filtering

Measuring small signals can be difficult when they are approximately the same amplitude as the average internal noise level of the analyzer. To facilitate the measurement, it is best to use video filtering. A video filter is a post-detection low pass filter which averages the internal noise of the analyzer. When the noise is averaged, the input signal may be seen. If the resolution bandwidth is very narrow for the span, the video filter should not be selected, as this will not allow the amplitude of the analyzed signals to reach full amplitude due to its video bandwidth limiting property.

Spectrum Analyzer Sensitivity

Specifying sensitivity on a spectrum analyzer is somewhat arbitrary. One way of specifying sensitivity is to define it as the signal level when signal power = average noise power. The analyzer always measures signal plus noise. Therefore, when the input signal is equal to the internal noise level, the signal will appear 3dB above the noise. When the signal power is added to the average noise power, the power level on the CRT is doubled (increased by 3dB) because the signal power = average noise power.

The maximum input level to the spectrum analyzer is the damage level or burn-out level of the input circuit. This is (for the AT5010D) +10dB for the input mixer and +20dB for the input attenuator. Before reaching the damage level of the analyzer, the analyzer will begin to gain compress the input signal.

This gain compression is not considered serious until it reaches 1dB. The maximum input signal level which will always result in less than 1dB gain compression is called the linear input level. Above 1dB gain compression the analyzer is considered to be operating non-linearly because the signal amplitude displayed in the CRT is not an accurate measure of the input signal level.

Whenever a signal is applied to the input of the analyzer, distortions are produced within the analyzer itself. Most of these are caused by the non-linear behavior of the input mixer. For the AT5010D these distortions are typically 70dB below the input signal level for signal levels not exceeding -30dBm at the input of the first mixer. To accommodate larger input signal levels, an attenuator is placed in the input circuit before the first mixer. The largest input signal that can be applied, at each setting of the input attenuator, while maintaining the internally generated distortions below a certain level, is called the optimum input level of the analyzer. The signal is attenuated before the first mixer because the input to the mixer must not exceed -30dB, or the analyzer distortion products may exceed the specified 70dB range. This 70dB distortion-free range is called the spurious-free dynamic range of the analyzer. The display dynamic range is defined as the ratio of the largest signal to the smallest signal that can be displayed simultaneously with no analyzer distortions present.

Dynamic range requires several things then. The display range must be adequate, no spurious or unidentified response can occur, and the sensitivity must be sufficient to eliminate noise from the displayed amplitude range.

The maximum dynamic range for a spectrum analyzer can be easily determined from its specifications. First check the distortion spec. For example, this might be "all spurious products 70dB down for -30dBm at the input mixer". Then, determine that adequate sensitivity exists. For example, 70dB down from -30dBm is -100dB. This is the level we must be able to detect, and the bandwidth required for this sensitivity must not be too narrow or it will be useless. Last, the display range must be adequate.

Notice that the spurious-free measurement range can be extended by reducing the level at the input mixer. The only limitation, then, is sensitivity. To ensure a maximum dynamic range on the CRT display, check to see that the following requirements are satisfied.

- The largest input signal does not exceed the optimum input level of the analyzer (typically -30dBm with 0dB input attenuation).
- The peak of the largest input signal rests at the top of the top of the CRT display (reference level).

Frequency Response

The frequency response of an analyzer is the amplitude linearity of the analyzer over its frequency range. If a spectrum analyzer is to display equal amplitudes for input signals of equal amplitude, independent of frequency, then the conversion (power) loss of the input mixer must not depend on frequency. If the voltage from the LO is too large compared to the input signal voltage then the conversion loss of the input mixer is frequency dependent and the frequency response of the system is nonlinear. For accurate amplitude measurements, a spectrum analyzer should be as flat as possible over its frequency range. Flatness is usually the limiting factor in amplitude accuracy since it is extremely difficult to calibrate out. And, since the primary function of the spectrum analyzer is to compare signal levels at different frequencies, a lack of flatness can seriously limit its usefulness.

The 1dB gain compression level is a point of convenience, but it is nonetheless considered the upper limit of the dynamic range. The lower limit, on the other hand, is dictated by the analyzer sensitivity which, as we know, is bandwidth dependent. The narrowest usable bandwidth in turn is limited by the tracking generator residual FM and any tracking drift between the analyzer tuning and the tracking generator signal.

Supporting products

Near Field Sniffer Probes AZ530 (Optional)

The AZ530 is the ideal toolkit for the investigation of RF electromagnetic fields. It is indispensable for EMI pre-compliance testing during product development, prior to third party testing. The set includes 3 hand-held probes with a built-in pre-amplifier covering the frequency range from 100kHz to over 1000MHz. The probes include a magnetic field probe, one electric field probe, and one high impedance probe. All are matched to the 50 Ω inputs of Spectrum analyzers or RF-receivers. The power can be supplied either from batteries, Ni-Cads or through a power cord directly connected to AT5000 series spectrum analyzers. Signal is fed via a 1.5m BNC-cable. When used in conjunction with a spectrum analyzer or measuring receiver, the probes can be used to locate and qualify EMI sources, as well as evaluate EMC problems at the breadboard and prototype level. They enable the user to evaluate radiated fields and perform shield effectiveness comparisons. Mechanical screening performance and immunity tests on cables and components are easily performed.

Specifications

Frequency range	0.1MHz to 1000MHz (lower frequency limit depends on probe type)
Output impedance	50 Ω
Output connector	BNC
Input capacitance	2pF (high imped Probe)
Max. Input Level	+10dBm (without destruction)
DC-input voltage	20V max
Supply Voltage	6V DC, 4AA size batteries, Supply-power of Analyzer
Supply Current	8mA (H-Field Probe), 5mA (E-Field probe), 24mA (High imp probe)
Probe Dimensions	195 x 40 x 19 (L*W*H) mm
Housing	Plastic (electrically shielded internally)

The H-Field Near-Field probe

The H-Field probe provides a voltage to the connected measurement system which is proportional to the magnetic radio frequency (RF) field strength existing at the probe location, with this probe, circuit RF sources may be localized in close proximity of each other.

The H-Field will decrease as the cube of the distance from the source, A doubling of the distance will reduce the H-field by a factor of eight ($H=1/d^3$), where d is the distance.

In the actual use of the H-field sensor one observes therefore a rapid increase of the probe's output voltage as the interference source is approached.

While investigating a circuit board, the sources are immediately obvious. It is easily noticed which component (*i.e.* IC) causes interference and which does not. In addition, by use of a spectrum analyzer the maximum amplitude as a function of frequency is easily identified. Therefore, one can

eliminate early in the development components which are not suitable for EMC purposes. The effectiveness of countermeasures can be judged easily. One can investigate shields for "leaking" areas and cables or wires for conducted interference.

The High-Impedance probe

The High-impedance probe (*Hi-Z*) permits the determination of the radio frequency interference (*RFI*) on individual contacts or printed circuit traces.

It is a direct-contact probe. The probe is of very high impedance (near the insulation resistance of the printed circuit material) and is loading the test point with only 2pF (80Ω at 1GHz).

Thereby one can measure directly in a circuit without significantly influencing the relationships in the circuit with the probe. One can, for example, measure the quantitative effectiveness of filters or other or other blocking measures.

Individual pins of ICs can be identified. With this Hi-Z probe individual test points of a circuit can be connected to the 50W impedance of spectrum analyzer.

The E-Field Monopole Probe

The E-field monopole probe has the highest sensitivity of the three probes. It is sensitive enough to be used as an antenna for radio or TV reception.

With this probe the entire radiation from a circuit or an equipment can be measured. It is used, for example, to determine the effectiveness of shielding measures. With this probe, the entire effectiveness of filters can be measured by measuring the RFI which is conducted along cables that leave the equipment and may influence the total radiation. In addition, the E-field probe may be used to perform relative measurements for certification tests. This makes it possible to apply remedial suppression measures so that any re-qualification results will be positive. In addition, pre-testing for certification tests may be performed so that no surprises are encountered during the certification tests.

Frequency Expander AT5000F Series (Optional)

Since the prices of 3GHz spectrum analyzers are all above several ten thousands USD, it is not affordable for most radio fans, service men and even medium or small sized enterprises. Meantime, there are many signals above 1000MHz in communication field, such as LO (*local oscillator*) signals of mobile phone usually between 1GHz to 2GHz, some are exceed 2GHz, and 1800MHz, 2400MHz or more. Based on above situations, favorable frequency expanders have been developed by Shenzhen ATTEN Electronics Co., Ltd.

AT5000F1 operating accompany with AT5010B spectrum analyzer of 1000MHz, frequency can be expanded to 1050MHz to 2050MHz.

Example: Connect AT5000F1 to AT5010D spectrum analyzers, if a 800MHz signal display in spectrum analyzer, then the tested signal should be added 1000MHz, so the frequency of tested signal must be 1800MHz.
Frequency of AT5000F2 can be expanded to 2050MHz to 3050MHz, the tested frequency is the display frequency add 2000MHz.
Frequency of AT5000F3 can be expanded to 3050MHz to 4050MHz, the tested frequency is the display frequency add 3000MHz.

Service & Support

Maintenance and repair

Various important properties of the Spectrum Analyzer should be carefully checked at certain intervals. Only in this it largely certain that all signals are displayed with the accuracy on which the technical data are based. The exterior of the instrument should be cleaned regularly with a dusting brush. Dirt which is difficult to remove on the casing and handle, the plastic and aluminum parts, can be removed with a moistened cloth (99% water +1% mild detergent).

Spirit or washing benzine (petroleum ether) can be used to remove greasy dirt. The screen may be cleaned with water or washing benzene [but not with spirit (alcohol) or solvents]; it must then be wiped with a dry clean lint-free cloth.

Under no circumstances may the cleaning fluid get into the instrument. The use of other cleaning agents can attack the plastic and paint surfaces.

Never repair the instrument with power on. As soon as the power cord is plugged into the power socket, the power supply unit and the crystal oscillator in the instrument are powered. Unplug the power cord before soldering.

When repairing, in general, first locate the external faults and visual faults, such as open circuit, short circuit or unreasonable settings parameters, etc. Secondly measure the voltage of each group to see whether it is normal. If all the voltages are normal, check the static working point of faulted circuit and check if there are any faults soldered points. Special carefulness should be paid to determine a fault IC. In repairing, the probe of oscilloscope or the pen of multimeter should not touch the test points and the adjacent point in order to avoid causing more troubles.

Contact our special agents for instant repair when the user is unable to repair by itself.

Accessories

AT5010D Spectrum Analyzer	1 set
BNC-double-clip cable	1 pc
Crocodile grounding clip (double sided)	1 pc
Antenna	1 pc
Probe (for cell phone testing)	1 pc
Power cable	1 pc
User Guide	1 copy
Warranty card and user registration form	1 pc
0.5A/220V fuse (already installed)	2 pcs
