 Los Angeles, Calif.*

WE thank M.B. Callaham for his interest in our work and his comment. He has correctly stated that our result is valid if the measurement noise is white. Indeed, our result is based on the previous assumption solely. It is not necessary to assume white noise always, but we wanted to examine this case. It is true that for colored noise we do not obtain white measurement residuals. However, colored noise is not our

assumption. Furthermore, we have nowhere stated that whiteness is physical, as can be seen by a careful reading of our work.

It is well known¹ that a continuous process can be represented by a discrete process which is statistically the same at the sampling points. Therefore, the samples of the noise process in our work are uncorrelated and independent. Now, the argument of the bandpass filter was used to give an intuitive feeling of the sampling procedure. In Ref. 2 the same argument is used for band-limited white noise. The sampling points are exactly the ones that produce uncorrelated samples. No mention of aliasing is made there. In Ref. 3 it is stated that aliasing occurs because the sampled signals are not strictly band-limited. But here we considered an ideal bandpass filter since the whole argument was used for illustrative purposes only. Finally, the sampling rate is the Nyquist rate which ideally does not produce aliasing.

OUTER PLANET ENTRY HEATING AND THERMAL PROTECTION—v. 64

THERMOPHYSICS AND THERMAL CONTROL—v. 65

Edited by Raymond Viskanta, Purdue University

The growing need for the solution of complex technological problems involving the generation of heat and its absorption, and the transport of heat energy by various modes, has brought together the basic sciences of thermodynamics and energy transfer to form the modern science of thermophysics.

Thermophysics is characterized also by the exactness with which solutions are demanded, especially in the application to temperature control of spacecraft during long flights and to the questions of survival of re-entry bodies upon entering the atmosphere of Earth or one of the other planets.

More recently, the body of knowledge we call thermophysics has been applied to problems of resource planning by means of remote detection techniques, to the solving of problems of air and water pollution, and to the urgent problems of finding and assuring new sources of energy to supplement our conventional supplies.

Physical scientists concerned with thermodynamics and energy transport processes, with radiation emission and absorption, and with the dynamics of these processes as well as steady states, will find much in these volumes which affects their specialties; and research and development engineers involved in spacecraft design, tracking of pollutants, finding new energy supplies, etc., will find detailed expositions of modern developments in these volumes which may be applicable to their projects.
