

**Discussion.** Two alanine groups and two  $\text{Ag}^+$  ions form a centrosymmetric dimer. Within this dimer the  $\text{Ag}-\text{Ag}$  separation of 2.855 (4) Å is comparable to the smallest distance of 2.88 Å found in metallic silver (Griffith, 1943). The nitrate groups are in a *trans* configuration. The  $\text{Ag}-\text{O}$  bond distances are 2.210 (19) and 2.198 (19) Å, which are comparable to those reported, respectively, for silver perfluorobutyrate and silver oxalate (Blakeslee & Hoard, 1956; Griffith, 1943). The  $\text{O}-\text{Ag}-\text{O}$  angle is 161.6 (8)°, which is comparable to the usual value of 160–163° (Blakeslee & Hoard, 1956; Rao & Viswamitra, 1972). Two independent  $\text{Ag}-\text{O}$  distances to the nitro groups are 2.58 (3) and 2.57 (3) Å. There are hydrogen bonds of type  $\text{N}-\text{H}\cdots\text{O}$  between the alanine and the nitro groups which stabilize the crystal packing.

One of us (MEK) is deeply indebted and wishes to express his gratitude to Dr J.-P. Declercq and Professor G. S. D. King for their invaluable advice given to him during his short stay at Louvain-la-Neuve, Belgium.

The authors wish to thank Messrs S. M. Murad and Syed Ahmed respectively, for their artistic and

photographic work and Mrs Sabariah Saito for typing the manuscript.

(Received 20 February 1984; accepted 10 April 1984)

**Abstract.**  $M_r = 518.3$ , orthorhombic,  $P2_12_1$ ,  $a = 11.088$  (3),  $b = 12.050$  (4),  $c = 13.839$  (5) Å,  $V = 1849$  (1) Å<sup>3</sup>,  $Z = 4$ ,  $D_x = 1.862$  (1) Mg m<sup>-3</sup>,  $\lambda(\text{Mo } \text{Ka}) = 0.71069$  Å,  $\mu(\text{Mo } \text{Ka}) = 8.0$  mm<sup>-1</sup>,  $F(000) = 992$ ,  $R = 0.028$ , 3055 reflections. Isostructural with  $\text{Ph}_3\text{PAuCl}$  and  $\text{Ph}_3\text{AsAuBr}$ . The  $\text{Au}-\text{O}$  bond length is 2.063 (6) Å, with a short  $\text{Au}-\text{P}$  bond of 2.207 (3) Å. The second acetate O is not involved in bonding at the metal [Au–O 2.93 (1) Å], which thus shows a linear coordination geometry [P–Au–O 177.3 (2)°].

**Introduction.** We have begun a systematic study of gold carboxylate complexes and here report the structure of  $\text{Ph}_3\text{PAuOCOCH}_3$ , (1). This is one of the few gold carboxylate complexes to have been chemically characterized (Nichols & Charleston, 1969). Colourless

prisms were obtained by diffusion of petroleum ether (40°–60° C) into a dichloromethane solution of (1).

**Experimental.**  $D_m$  not determined. Crystal 0.6 × 0.25 × 0.1 mm, elongated along **b**. 3247 profile-fitted intensities (Clegg, 1981) recorded on a Stoe–Siemens four-circle diffractometer. Monochromated Mo  $\text{Ka}$  radiation,  $2\theta_{\max} 50^\circ$ , octants  $hkl$  and  $\bar{h}\bar{k}\bar{l}$  (no equivalents). Three standard reflections, no intensity change. Lp and empirical absorption corrections ( $\psi$  scans: transmissions 0.61–0.96), 3055 reflections with  $F > 4\sigma(F)$  used for all calculations (program system *SHELXTL*, Sheldrick, 1978). Cell constants refined from  $2\theta$  values of 48 reflections in the range 20–24°. Structure solution by heavy-atom method. Refinement on  $F$  to  $R = 0.028$ ,  $R_w = 0.028$  [all non-H atoms anisotropic; phenyl H atoms using riding model with C–H 0.96 Å, H on external bisector of appropriate C–C–C angle; methyl H not included: 217

\* Carboxylate and Related Complexes of Gold. 2. Part 1: Jones (1984).

parameters, weighting scheme  $w^{-1} = \sigma^2(F) + 0.0002F^2$ ,  $S = 1.28$ , slope of normal probability plot 1.18]. Max.  $\Delta/\sigma$  0.01. Max. and min. heights in final  $\Delta\rho$  map +1.4 (near Au), -0.9 e Å<sup>-3</sup>. Rogers's (1981)  $\eta$  refinement gave  $\eta = 1.04$  (2), thus showing that the correct enantiomorph had been chosen [although (1) itself is achiral].

**Discussion.** Final atomic coordinates and derived parameters are given in Tables 1 and 2.\* Fig. 1 shows the atom numbering.

The similarity of cell constants to those of Ph<sub>3</sub>PAuCl (Baenziger, Bennett & Soboroff, 1976) and Ph<sub>3</sub>AsAuBr (Einstein & Restivo, 1975) suggested that (1) might be isostructural; this indeed proves to be the case, presumably because the crystal packing is determined by the bulky Ph<sub>3</sub>E ligands.

The Au atom shows the expected linear coordination, with P—Au—O(1) 177.3 (2)°; the Au...O(2) contact of 2.93 (1) Å may be regarded as non-bonding [consistent with the high thermal motion of O(2)], although it is not always clear where to draw the line between two- and three-coordination for Au<sup>I</sup> (Jones, 1981). The Au—O(1) bond length is 2.063 (6) Å, which is the first accurate Au<sup>I</sup>—O bond length to be determined; in [(Ph<sub>3</sub>PAu)<sub>3</sub>O]<sup>+</sup>BF<sub>4</sub><sup>-</sup> (Nesmeyanov, Perevalova, Struchkov, Antipin, Grandberg & Dyadchenko, 1980) the average Au—O distance is 1.97 Å, but the structure is of low accuracy (e.s.d.'s 0.07–0.08 Å for Au—O). Au<sup>I</sup> has little affinity for O ligands (Puddephatt, 1978); this is reflected in the shortness of the Au—P bond [2.207 (3) Å], compared with the usual range of 2.235–2.29 Å for Ph<sub>3</sub>PAuX complexes (Jones, 1981).

\* Lists of structure factors, anisotropic thermal parameters, H-atom parameters and bond distances and angles have been deposited with the British Library Lending Division as Supplementary Publication No. SUP 39392 (24 pp.). Copies may be obtained through The Executive Secretary, International Union of Crystallography, 5 Abbey Square, Chester CH1 2HU, England.

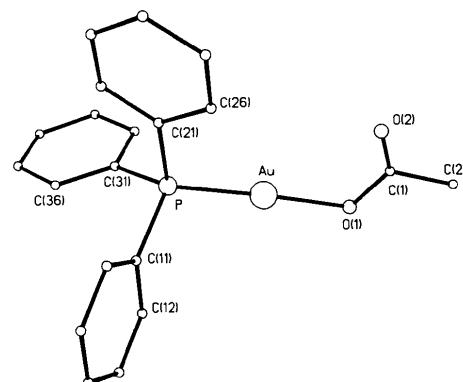

Fig. 1. A molecule of (1), showing the atom-numbering scheme.

O(2)—C(1)—C(2)	121.8 (8)		

In the Au<sup>III</sup> acetate complex SrAu<sub>2</sub>(OCOCH<sub>3</sub>)<sub>8</sub> the Au—O bonds are, as expected from the increased charge, shorter than in (1); indeed, most Au<sup>III</sup>—O bond lengths lie in the range 1.97–2.02 Å (Jones, 1981, 1984). In both complexes the acetate ligands show a marked asymmetry of C—O bond lengths, since the main bonding interactions involve only one O atom.

(1) shows no unusually short intermolecular contacts and, in particular, no Au...Au interactions of the kind often observed in Au<sup>I</sup> complexes (Jones, 1981).

I thank the Fonds der Chemischen Industrie for financial support and Mr A. Vielmäder for synthesizing the title compound.

## Structure of Bis(L-histidinato-*O,N,N'*)chromium(III) Nitrate, $[\text{Cr}(\text{C}_6\text{H}_8\text{N}_3\text{O}_2)_2]\text{NO}_3$

BY W. T. PENNINGTON AND A. W. CORDES\*

Department of Chemistry, University of Arkansas, Fayetteville, Arkansas 72701, USA

AND D. KYLE AND E. W. WILSON JR

Department of Physical Science, Harding University, Searcy, Arkansas 72143, USA

(Received 18 November 1983; accepted 9 April 1984)

**Abstract.**  $M_r = 422.3$ , monoclinic,  $P2_1$ ,  $a = 7.404$  (2),  $b = 7.209$  (3),  $c = 15.663$  (5) Å,  $\beta = 100.68$  (2)°,  $V = 821.5$  (9) Å<sup>3</sup>,  $Z = 2$ ,  $D_x = 1.707$  g cm<sup>-3</sup>, Mo  $K\alpha$ ,  $\lambda = 0.71073$  Å,  $\mu = 7.32$  cm<sup>-1</sup>,  $F(000) = 434$ ,  $T = 294$  K, final  $R = 0.036$  for 1812 observed reflections. The L-histidinate anions function as tridentate ligands, with the two imidazole rings in the *trans* orientation. The imidazole rings are planar with the Cr atom out of these planes. Hydrogen bonding occurs between amine groups and nitrate oxygen atoms and also between amine and carboxylate groups.

**Introduction.** Histidine is frequently found to be a metal-binding site in metalloproteins (Ibers & Holm, 1980) and metal complexes of the histidine anion are important for metal-ion transport in blood plasma (Lau & Sarkar, 1971). The L-histidine anion generally functions as either a bidentate or a tridentate ligand (Martin, 1979); several isomers have been reported for octahedral complexes involving two tridentate histidine ligands around Cr<sup>III</sup> (Bagger, Gibson & Sorensen, 1972) and Cr<sup>III</sup> (Hoggard, 1981). We report here the structure of the bis(L-histidinato)chromium(III) isomer with *trans* imidazole rings, which was determined in order to verify the spectroscopic structural assignment for this most dominant product of the Cr<sup>III</sup>–histidine reaction and also to provide structural data for comparisons with future structural work on binuclear chromium complexes with histidine.

**Experimental.** Title compound prepared by general method reported by Hoggard (1981); orange-red crystal used for data collection, dimensions 0.2 × 0.2 × 0.3 mm, mounted with epoxy on a glass fiber; all data collected using Enraf–Nonius CAD-4 diffractometer, graphite-monochromated Mo  $K\alpha$  radiation; 25 reflections with  $2\theta$  between 17 and 32° used for least-squares determination of cell constants. 2753 reflections measured,  $\omega$ – $2\theta$  scans,  $2\theta$  from 4 to 60° ( $h = 0$  to 10,  $k = \bar{1}\bar{0}$  to 0,  $l = \bar{2}\bar{2}$  to 22).  $R_{\text{int}} = 0.028$ . Scan range (1.00 + 0.35 tanθ)°, scan speeds 4–20° min<sup>-1</sup>. Intensities of three reflections (132, 036 and 116) measured periodically during 30.0 h of data collection varied by 1.9%, indicating crystal and electronic stability; 801 reflections with  $I \leq 3\sigma(I)$  considered unobserved; systematic absences of  $0k0$  for  $k$  odd indicate space group  $P2_1$  or  $P2_1/m$ ; however, statistical tests of intensity distribution of data set and chemical composition of the cation which precludes crystallographically imposed symmetry (a necessary condition for  $P2_1/m$ ,  $Z = 2$ ) confirmed space group  $P2_1$ . Structure solved by Patterson methods and refined by full-matrix least squares based on  $(|F_o| - |F_c|)^2$ . H atoms constrained to idealized positions (C–H = 0.95 Å, N–H = 0.90 Å). Anisotropic refinement of non-hydrogen atoms gave 243 parameters for parameter/reflection ratio 1:7.5. No absorption or secondary-extinction corrections; 112 and 103 reflections given zero weight due to evidence of extinction problems. Final  $R = 0.036$ ,  $R_w = 0.044$ ,  $S = 0.98$ ; weighting scheme based on counting statistics  $\{\sigma(F^2)\}$
