

Hydrogen-Bonded Complex

Direct EPR Detection of a Hydrogen-Bonded Complex between a Semiquinone Radical Anion and a Protonated Amino Acid, and Electron Transfer Driven by Hydrogen Bonding**

Junpei Yuasa, Shunsuke Yamada, and Shunichi Fukuzumi*

In the photosynthetic reaction center (RC), two quinones denoted Q_A and Q_B act as electron acceptors.^[1] The RC catalyzes light-induced two-electron reduction of Q_B with two protons to yield hydroquinone Q_BH_2 , which is released from the RC and replaced by another quinone molecule from the pool.^[2] Although the first electron transfer, $Q_A^{\cdot-} \rightarrow Q_B^{\cdot-}$, does not involve direct protonation of $Q_B^{\cdot-}$,^[3,4] the electron transfer (ET) is coupled with protonation of a nearby amino acid residue through hydrogen-bond formation with $Q_B^{\cdot-}$.^[5-7] Specific hydrogen bonds with nearby amino acid residues enable the quinone to perform a specific function, and hence differences in the nature of the hydrogen-bonding interactions of Q_A and Q_B have been suggested to result in their differing functions.^[8] Since hydrogen bonds are largely electrostatic in nature,^[9] protonation of amino acids that leads to a change in fractional charge on one of the components in a hydrogen bond will remarkably affect the strength of hydrogen bonding. Such a change in hydrogen-bonding strength would have a significant effect on the one-electron reduction potential of the quinone.^[10-13] Direct EPR detection of a hydrogen-bonded complex between a semiquinone radical anion and a protonated amino acid would afford valuable insight into the hydrogen-bond strength and electronic structure of the hydrogen-bonded complex. However, protonation of singly reduced species of carbonyl compounds acting as strong bases is generally too fast to detect any intermediate in organic solvent in the presence of proton donors.^[14]

We report herein the first successful EPR detection of a hydrogen-bonded complex between a semiquinone radical anion and protonated histidine ($\text{His}\cdot 2\text{H}^+$)^[15] using 1-(*p*-tolylsulfanyl)-2,5-benzoquinone (TolSQ). Effects of hydrogen bonding between TolSQ $^{\cdot-}$ and $\text{His}\cdot 2\text{H}^+$ on the one-electron reduction potential of TolSQ and the rate of ET reduction were examined to reveal how the ET rate is controlled by hydrogen bonding.

The EPR spectrum of a hydrogen-bonded complex of a semiquinone radical anion with protonated histidine (TolSQ $^{\cdot-}$ /His·2H⁺) was detected in photoinduced ET from 10,10'-dimethyl-9,9'-biacridine [(AcrH)₂] to TolSQ in the presence of His·2HClO₄ in MeCN at 298 K [Eq. (1); see experimental details in the Supporting Information].^[16] Biacridine (AcrH)₂ is known to act as a two electron donor to produce two equivalents of the radical anion of an electron acceptor.^[17] Since the TolSQ $^{\cdot-}$ /His·2H⁺ complex is unstable, the EPR spectrum of a solution of (AcrH)₂ (1.6×10^{-2} M) and TolSQ (4.0×10^{-3} M) in MeCN in the presence of His·2H⁺ (4.0×10^{-3} M) was measured under steady-state photoirradiation (Figure 1 a). The EPR spectrum is well reproduced by a simulated spectrum with hfc values of $a(3\text{H}) = 0.88, 5.31$, and 6.08 G and superhyperfine splitting due to one nitrogen atom and three equivalent protons [$a(\text{N}) = 1.35$ G and $a(3\text{H}) = 2.97$ G] of His·2H⁺ (Figure 1 b). The complete agreement of the observed EPR spectrum (Figure 1 a) with the simulated spectrum (Figure 1 b) clearly indicates formation of the TolSQ $^{\cdot-}$ /His·2H⁺ complex. The g value (2.0026) and the hfc values [$a(3\text{H}) = 0.88, 5.31$, and 6.08 G] of TolSQ $^{\cdot-}$ /His·2H⁺ are drastically changed from those of TolSQ $^{\cdot-}$ in the absence of His·2H⁺, which are $g = 2.0057$ and $a(3\text{H}) = 2.00, 2.20$, and 3.35 G.^[18,19]

The optimized structure of TolSQ $^{\cdot-}$ /His·2H⁺ was obtained by density functional calculations with the BLYP/6-31G** basis set (see experimental details in the Supporting Information).^[20] Hydrogen bonds are found between the C=O oxygen atom of TolSQ $^{\cdot-}$ and the COOH proton as well as the NH₃⁺ protons of His·2H⁺, and also between the S=O oxygen atom of TolSQ $^{\cdot-}$ and the NH⁺ proton of the imidazole ring of His·2H⁺ (Figure 1 c; for hydrogen-bond lengths, see the

Supporting information for this article is available on the WWW under <http://www.angewandte.org> or from the author.

Figure 1. a) EPR spectrum of TolSQ^{•-}/His-2H⁺ produced by photoinduced ET from (AcrH)₂ (1.6 × 10⁻² M) to TolSQ (4.0 × 10⁻³ M) in the presence of His (4.0 × 10⁻³ M) and HClO₄ (8.0 × 10⁻³ M) in deaerated MeCN at 298 K. b) Spectrum simulated with the hfc values of TolSQ^{•-}/His-2H⁺. ΔH_{msl}(maximum slope linewidth) = 30 G. c) Optimized structure of TolSQ^{•-}/His-2H⁺ calculated by DFT at the BLYP/6-31G** level (calculated hfc values are given in parentheses).

Supporting Information).^[21] Such multiple hydrogen bonding between TolSQ^{•-} and His-2H⁺ may stabilize TolSQ^{•-}/His-2H⁺. The hfc values calculated with the optimized structure are given in parentheses in Figure 1c. The superhyperfine coupling due to the hydrogen-bonded NH₃⁺ proton of His-2H⁺ is estimated as 6.61 G. The average of the calculated hfc values (2.20 G) due to the three NH₃⁺ protons agrees with the observed value.^[22] This indicates that the hydrogen-bonded proton is rapidly exchanged among the NH₃⁺ protons on the EPR time-scale. The existence of superhyperfine coupling due to the hydrogen-bonded protons and nitrogen atoms of NH₃⁺ (Figure 1) strongly supports the presence of a strong hydrogen bond.

When TolSQ is replaced by *p*-benzoquinone (Q), only the protonated species (semiquinone radical QH[•]) is detected by EPR in photoinduced ET from (AcrH)₂ to Q in the presence of His-2H⁺ (see the Supporting Information). Thus, the S=O oxygen atom in TolSQ plays a crucial role in multiple hydrogen bonding between TolSQ^{•-} and His-2H⁺.

The strong hydrogen bonding between TolSQ^{•-} and His-2H⁺ is expected to increase the electron-acceptor ability of TolSQ.^[11] The positive shift of the one-electron reduction potential E_{red} of TolSQ in the presence of His-2H⁺ (5.0 × 10⁻² M) was verified by electrochemical measurements. The cyclic voltammogram of TolSQ exhibits a reversible redox wave (Figure 2a). In contrast, the cyclic voltammogram of TolSQ in the presence of His-2H⁺ exhibits an irreversible cathodic wave due to the instability of the TolSQ^{•-}/His-2H⁺ complex (Figure 2b). Thus, the E_{red} value of TolSQ in the presence of His-2H⁺ was determined by second-harmonic alternating-current voltammetry (Figure 2c). The E_{red} value of TolSQ [-0.26 V vs saturated calomel electrode (SCE)] is shifted to 0.29 V versus SCE in the presence of 5.0 × 10⁻² M of His-2H⁺. In contrast to the strong hydrogen bonding between TolSQ^{•-} and His-2H⁺, there is virtually no interaction

Figure 2. a) Cyclic voltammogram of TolSQ (1.0 × 10⁻² M) in the absence of His-2H⁺. b) Cyclic voltammogram and c) second-harmonic alternating-current voltammogram of TolSQ (5.0 × 10⁻³ M) in the presence of His-2H⁺ (5.0 × 10⁻² M) in deaerated MeCN containing tetrabutylammonium perchlorate (TBAP, 0.10 M) with a Pt working electrode at 298 K. d) Dependence of k_{et} on [His-2H⁺] for ET from Me₂Fc (1.0 × 10⁻⁴ M) to TolSQ in the presence of His-2H⁺ in deaerated MeCN at 298 K.

between neutral TolSQ and His-2H⁺. In such a case, the positive shift in the one-electron reduction potential of TolSQ in the presence of His-2H⁺ is expressed by Equation (2),

$$E_{\text{red}} = E_{\text{red}}^0 + (2.3 RT/F) \log \{K_{\text{red}}[\text{His} \cdot 2\text{H}^+]\} \quad (2)$$

where E_{red}^0 is the reduction potential of TolSQ in the absence of His-2H⁺, and K_{red} the formation constant of the TolSQ^{•-}/His-2H⁺ complex. The K_{red} value was determined as 4.2 × 10¹⁰ M⁻¹ from the E_{red} value of TolSQ in the presence of 5.0 × 10⁻² M of His-2H⁺. Such a large K_{red} value of the TolSQ^{•-}/His-2H⁺ complex clearly indicates strong hydrogen bonding between TolSQ^{•-} and His-2H⁺.

The positive shift of the E_{red} value of TolSQ should enhance ET from an electron donor to TolSQ.^[12,13] This was confirmed by ET from 1,1'-dimethylferrocene (Me₂Fc) to TolSQ in the presence of His-2H⁺. No ET from Me₂Fc ($E_{\text{ox}} = 0.26$ V vs SCE) to TolSQ ($E_{\text{red}} = -0.26$ V vs SCE) occurs, because the free-energy change of ET is highly endergonic ($\Delta G_{\text{et}} = 0.52$ eV). In the presence of 5.0 × 10⁻² M of His-2H⁺, however, efficient ET from Me₂Fc to TolSQ occurs to yield Me₂Fc⁺ [Eq. (3)], as expected from the negative free-energy change of electron transfer ($\Delta G_{\text{et}} = -0.03$ eV).

The ET rates obeyed pseudo-first-order kinetics in the presence of a large excess TolSQ and His·2H⁺ relative to the concentration of Me₂Fc (see the first-order plot in the Supporting Information). The observed pseudo-first-order rate constant k_{obs} increases proportionally with increasing TolSQ concentration. The second-order rate constant k_{et} also increases linearly with [His·2H⁺] (Figure 2d).

Since His·2H⁺ has no effect on the oxidation potential of Me₂Fc, the free-energy change of ET from Me₂Fc to TolSQ in the presence of His·2H⁺ (ΔG_{et}) can be expressed by Equation (4), where ΔG_{et}^0 is the free-energy change in the

$$\Delta G_{\text{et}} = \Delta G_{\text{et}}^0 - (2.3 RT/F) \log \{K_{\text{red}}[\text{His} \cdot 2\text{H}^+]\} \quad (4)$$

absence of His·2H⁺. Such a change in ΔG_{et} has previously been reported for metal-ion-promoted ET from Fc to the naphthoquinone (NQ) moiety of a ferrocene–naphthoquinone (Fc–NQ) linked dyad.^[23] The dependence of k_{et} of metal-ion-promoted ET on driving force is well evaluated in terms of the Marcus theory of electron transfer^[24] when the k_{et} value increases linearly with increasing metal ion concentration.^[23] In the case of His·2H⁺ too, the k_{et} value increases linearly with [His·2H⁺] (Figure 2d).

In summary, we have detected a hydrogen-bonded complex of a semiquinone radical anion with protonated histidine (TolSQ^{·-}/His·2H⁺) by EPR, which reveals strong hydrogen bonding between TolSQ^{·-} and His·2H⁺. This finding provides valuable insight into the specific function of quinones in the photosynthetic RC. Strong hydrogen bonding between semiquinone radical anion and protonated amino acid residues would result in a positive shift in the one-electron reduction potential of quinones and facilitate the ET reduction of quinones in the RC.

- [19] The smaller g value of TolSQ^{·-}/His·2H⁺ compared to TolSQ^{·-} (2.0057) indicates that the spin density on oxygen nuclei in TolSQ^{·-} is reduced significantly due to strong hydrogen bonding with His·2H⁺.
- [20] The hfc values of semiquinone radical (QH[·]) calculated by using BLYP methods were in good agreement with experimental data: M. Nonella, *J. Phys. Chem. B* **1997**, *101*, 1235–1246.
- [21] The hydrogen-bonded proton of NH₃⁺ is not covalently bound to TolSQ^{·-} but electrostatically bound to TolSQ^{·-} through the hydrogen bond. The N–H bond length in NH₃⁺ (1.57 Å) is longer than that between the NH₃⁺ proton and the C=O oxygen atom of TolSQ^{·-} (1.05 Å) in the optimized structure of TolSQ^{·-}/His·2H⁺ (see the Supporting Information). This indicates that binding of the N–H bond in NH₃⁺ is significantly weakened by formation of strong hydrogen bonds with TolSQ^{·-}. The presence of the strong hydrogen bond is supported by the existence of superhyperfine coupling due to the hydrogen-bonded protons and nitrogen atom of NH₃⁺ (Figure 1).
- [22] The calculated hfc values of TolSQ^{·-}/His·2H⁺ agree well with the observed hfc values within the errors due to the imperfect density functional method (BLYP/6-31G**).
