Regioselective Radical Aminofluorination of Styrenes**

Hongwei Zhang, Yongcheng Song, Jinbo Zhao, Jingping Zhang,* and Qian Zhang*

Abstract: The copper-catalyzed radical aminofluorination of styrenes with *N*-fluorobenzenesulfonimide (NFSI) is realized with high regioselectivity, thus affording aminofluorination products with regioselectivities opposite that of the palladium-catalyzed and noncatalyzed processes. Preliminary mechanistic studies suggested the reaction went through a radical pathway and was supported by DFT calculations. In these reactions, NFSI is utilized as both a radical nitrogen source and radical fluorine source, thus rendering it an attractive reagent.

Molecules containing vicinal amino and fluorine moieties constitute key building blocks for the synthesis of anticancer, anticholinergic, and anti-inflammatory drugs, as well as therapeutic β -peptides.^[1] Tandem intramolecular amination cyclization followed by intermolecular fluorination of unsaturated carbon–carbon bonds has been proven to be an efficient way to construct nitrogen-containing heterocycles with vicinal amino and fluorine moieties.^[2] In contrast, the addition reaction between unsaturated carbon–carbon bonds and compounds containing N–F bonds might provide a highly attractive strategy for direct and efficient construction, in an intermolecular fashion, of molecules containing vicinal amino and fluorine moieties.

N-Fluorobenzenesulfonimide (NFSI) contains a N–F bond and is widely used as an electrophilic fluorination agent.^[3] Radical fluorine atom transfer reactions of NFSI have been also developed.^[4] With NFSI as a nitrogen source, interesting amination reactions were discovered through possible nucleophilic,^[5] electrophilic,^[6] and radical^[7] amination processes. Given the multiple reaction modes of NFSI and our work on employing NFSI as a nitrogen source,^[5b–d,7a,b] we were prompted to investigate the challenging regioselective aminofluorination directly from unsaturated carbon–carbon bonds and NFSI. Recently, Liu and co-workers developed an efficient palladium-catalyzed aminofluorination of styrenes with NFSI by fluoropalladation (Scheme 1).^[8] Herein, we report an efficient and highly regioselective copper-catalyzed radical aminofluorination reaction of styrenes with NFSI,

Scheme 1. Aminofluorination of styrene with NFSI.

wherein the regioselectivity is complementary to that of palladium catalysis (Scheme 1).

Novel synthetic methods for fluorine incorporation have been significantly developed because of the widespread use of fluorine-containing compounds in pharmaceutical and agrochemical industries.^[1c,9] In comparison with nucleophilic or electrophilic fluorination, radical fluorination under benign conditions is far less explored. Very recently, the electrophilic fluorine sources NFSI and Selectfluor were effectively used to construct C–F bonds by radical fluorination, during which the generation of a C(sp³)-centered radical was necessary.^[10] Accordingly, intermolecular hydrofluorination,^[10a] phosphonofluorination,^[10b] as well as intramolecular aminofluorination^[10h] of alkenes were realized. However, to the best of our knowledge, intermolecular radical aminofluorination of alkenes has not been documented, and might be attributed to the lack of a convenient route for the generation of relatively stable nitrogen-centered radical species.^[11–14] More recently, we developed copper-catalyzed aminocyanation and diamination reaction of alkenes by the efficient generation of nitrogen-centered radicals from NFSI, and subsequent radical addition reactions with alkenes.^[7a] With this methodology, six-membered-ring sultams^[7c] were constructed and aminoazidation reaction of alkenes were also developed.^[7e] Therefore, we reasoned that if fluorine transfer between the in situ generated C-centered radical intermediate and NFSI could occur, a novel radical amination initiated aminofluorination of styrenes would lead to a unique regioselectivity which would be different from previous work^[8] (Scheme 1).

Initially, the aminofluorination reaction between styrene (**1a**) and NFSI was investigated without employing a catalyst.^[15] When the reaction of **1a** (0.5 mmol) and NFSI (1.2 equiv) was performed at 135 °C in 1,2-dichloroethane (DCE, 2 mL) for 10 hours, the aminofluorination product **2a** (same regioselectivity as with palladium as catalyst^[8]) was obtained in 23 % yield upon isolation [Eq. (1)]. The aminofluorination product **3a** was not detected. In contrast, the reaction catalyzed by CuBr and bathocuproine (BC), as the ligand, delivered the aminofluorination product **3a** having the opposite regioselectivity.

[a] Reactions were carried out with **1a** (0.5 mmol) and NFSI (1.4 equiv) in 2 mL DCE under N₂ atmosphere at 70 °C, unless otherwise noted.

[b] Yield of the isolated product. [c] Catalyst (10 mol %), ligand (5 mol %), B₂pin₂ (10 mol %), AgF (10 mol %). [d] Catalyst (5 mol %), ligand (2.5 mol %), B₂pin₂ (5 mol %)/AgF (10 mol %). [e] Catalyst (5 mol %), ligand (2.5 mol %), B₂pin₂ (5 mol %)/AgF (100 mol %). [f] Catalyst (5 mol %), ligand (2.5 mol %), additive (5 mol %). [g] Catalyst (5 mol %), ligand (2.5 mol %), *n*BuBF₃K (10 mol %).

in 28 % with neocuproin as the ligand, however, **3a** was not detected with 1,10-phenanthroline (Phen) or pyridine as ligands (entries 2–4). Intrigued by the reports on stabilization effects of Lewis acids on nitrogen-centered radicals,^[16a] some Lewis acids were evaluated as additives to the reaction. It was discovered that addition of bis(pinacolato)diboron (B₂pin₂,^[16b–d] 10 mol %) to the above reaction dramatically improved the yield of **3a** to 60 % (entry 5). A control experiment in which CuBr was not present failed to afford any of the desired product (entry 6). With CuCl, CuCN, and Cu(OTf)₂ as the catalyst, **3a** was provided in 56, 48, and 35 % yield, respectively (entries 7–9). With other metals, such as AgF, Pd(OAc)₂ and Mn(OAc)₃, **3a** was not observed (entries 10–12). Because of the observation of haloamination products (roughly the same amount compared to catalyst

loading), AgF (10 mol %) was used to eliminate halide ions from the solution. Indeed, the yield of **3a** could be increased to 75 % (entry 13). The yield was not affected by lowering the catalyst loading to 5 mol % copper and 2.5 mol % BC and B₂pin₂ (entry 14). Interestingly, when 1.0 equivalent of AgF was added, instead of 0.1 equivalents, **3a** was obtained in only 5 % yield (entry 15). Other additives, such as ZnCl₂, ZnBr₂, and ZnI₂, also exhibited the corresponding Lewis acid effect with yields of **3a** ranging from 62 to 68 % (entries 16–18). Of note is *n*-butyl fluoroborate, which also remarkably improved the yield to as high as 72 % (entry 19).

With the optimized reaction conditions in hand (Table 1, entries 14 and 19), we then explored the scope and limitations of the above aminofluorination reaction and the results are summarized in Table 2. The reaction of NFSI with various

[a] Yield is that of the isolated product. [b] Conditions A: **1** (0.5 mmol), NFSI (1.4 equiv), CuBr (5 mol %), BC (2.5 mol %), B₂pin₂ (5 mol %), AgF (10 mol %) and 2 mL DCE in sealed tube for 4 h under N₂ atmosphere. [c] Conditions B: **1** (0.5 mmol), NFSI (1.4 equiv), CuBr (5 mol %), BC (2.5 mol %), 10 mol % *n*BuBF₃K and 2 mL DCE in sealed tube for 4 h under N₂ atmosphere. [d] The ratio of the two diastereoisomers is given within parentheses.

styrene derivatives afforded the desired aminofluorination products **3b–r** in yields within the range of 32–85 %. In these reactions, the *ortho*-, *meta*-, and *para*-methyl styrenes afforded the corresponding **3b** (45 %), **3c** (62 %), and **3d** (70 %). Other electron-donating groups such as *para-tert*-butyl, *para*-OAc, and *meta*-OMe styrenes afforded **3e** (50 %), **3f** (32 %), and **3v** (46 %). Halo-substituted styrenes were tolerated in the aminofluorination reaction, thus affording the corresponding products (**3g–o**, **3q**, and **3s**) in good yields, even for the benzylic chloride **3u** (72 %), which could be used for additional transformations. The electron-withdrawing 4-cyano styrene afforded **3p** in 73 % yield. Starting from either (*E*)-prop-1-enylbenzene (**1r**) or (*Z*)-prop-1-enylbenzene (**1r'**), loss of configurational integrity was observed in the product, as both *trans*- and *cis*-aminofluorination products were obtained in a 1:1 ratio. 1,3-Enynes produced the alkynylated products **3w** and **3x**, in 42 and 40 % yield, respectively, thus allowing further elaborations. However, for unactivated olefins, such as 1-octene and allylbenzene, the desired products were not formed as the six-membered-ring sultam^[7c] products were predominant.

To gain insight into the mechanism of this transformation, some mechanistic experiments were performed. In the presence of 1.0 equivalent of 2,6-di-*tert*-butyl-4-methylphenol (BHT), under the optimal reaction conditions A (Table 2), the reaction of **1a** failed to give any desired product. Moreover, when 1.0 equivalent of 2,2,6,6-tetramethyl-1-piperidinyloxy (TEMPO) was added instead of BHT, the aminoxygenation product **4** was isolated in 20 % yield [Eq. (2)]. In addition, under the standard reaction conditions A (Table 2), but using an O₂ atmosphere, the aminofluorination reaction of **1j** was investigated. After performing the reaction for 18 hours, the desired aminofluorination product **3j** was not observed and 30 % 4-bromobenzaldehyde was obtained.^[7a] Further evidence for a radical mechanism was demonstrated by the radical clock experiment with (1-

cyclopropylvinyl)benzene (**5**) as the substrate.^[17] The reaction of **5** under the standard reaction conditions B (Table 2) produced the ring-opened products **6** and **7** in 30 and 4 % yield, respectively [Eq. (3)]. These results supported the generation of a benzylic carbon radical intermediate.

To gain more understanding of the mechanism of this process, we sought to use density functional theory (DFT) calculations. Recently, an interesting hydrofluorination of alkenylarenes, which proceeds through a Pd^{II/IV} catalytic manifold, for the preparation of benzylic fluorides was developed by Gouverneur and co-workers.^[18] Therefore, two mechanisms were proposed for this process, the radical mechanism mentioned above and a copper(III)-mediated pathway.^[19] The possibilities of these mechanisms were interrogated computationally (Figure 1). The complex **Com** is formed from ligand, catalyst, and NFSI, thus setting the stage for the initial oxidative addition. The oxidative addition of copper(I) to the N–F bond gives a hexacoordinate copper(III) intermediate (**Int A**) with a barrier of 13.5 kcal mol^{–1}, and it could generate the copper(II)-stabilized radical **Int B** through a fast equilibration. The geometry of the corresponding transition-state **TS 1** is provided in Figure S1 in the Supporting Information. Upon fast complexation of styrene,
