ANGEWANDTE CHEMIE

A Journal of the
Gesellschaft
Deutscher Chemiker

International Edition in English

1996
23/24
Pages 2689–2944

COVER PICTURE

The cover picture shows the principle of the "Self-Regeneration of Stereocenters (SRS), a synthetic method in which a stereogenic center is temporarily destroyed with formation of an intermediate having a trigonal center. A subsequent diastereoselective reaction results in the formation of the stereogenic center once more. The additional center of chirality essential for the diastereoselective reaction is generated by acetalization (with an aldehyde) of the functional groups X and Y in the chiral starting material. The reaction sequence leads to a dissociative, enantioselecitve substitution at a single stereogenic center in a chiral compound without the use of a chiral auxiliary—hence the name "self-regeneration".
The general formula of typical glycine derivatives is shown in yellow in the center of the scheme. These are easily prepared in enantiomerically pure form by resolution of the appropriate racemate and have been shown to be particularly useful for the synthesis of α,α-disubstituted amino acids. As these compounds are prepared from chiral starting materials, they also represent the abandonment of the synthetic principle. D. Seebach et al. report more on SRS on p. 2708 ff.

Advertising Administration: Maria Merkl

Publishers: VCH Verlagsgesellschaft/Verlag I, Postfach 101161, D-69451 Weinheim (Germany)

World Wide Web: http://www.vchgroup.de

Publisher: Dr. E.-E. Wille

Bank connections (Bank, Acc. no., Bank identification code): Dresdner Bank Weinheim, 7511188 0, 670 800 50; Postgiro-Frankfurt, 145314-600, 500 100 60.

Publication twice monthly.

Valid price list for advertisements: No. 30 of October 1, 1996.

Subscription rates for 1997 (including postage and handling charges): Annual institutional subscription (with Chemistry—A European Journal) DM 2481/$ 1830; before January 31, 1997, DM 2356/ $ 1730. Single issue of Angewandte Chemie DM 99. Subscription rates for personal members of national chemical societies DM 392/$ 270 (Angewandte Chemie only). For the prices of Chemistry—A European Journal see masthead therein. Dispatch by airmail is possible; please contact Corinne Wohlgemuth (e-mail: cwohlgem@vchgroup.de) for details.

Orders may be placed through your bookseller or—for members of the GDCh only—directly at the publishers:
Europe: Contact the Subscription Service.

USA and Canada: VCH Publishers Inc., 333 Seventh Avenue, New York 10001. Tel. (212) 629-6200, Fax (212) 629-8140.

Delivery: By direct mail (printed matter) or through booksellers. • **Change of address:** Please notify your bookseller or the publishers immediately. • **Cancellation of subscriptions:** The publishers must be notified not later than three months before the end of the calendar year.

Authors who wish to publish in *Angewandte Chemie International Edition* should consult the current "Notice to Authors", which is printed in the first issue of every year immediately after the Table of Contents, before they draft their manuscript.

Angewandte Chemie International Edition in English is the English version of *Angewandte Chemie*.

Printed in Germany by Konrad Triltsch Druck und Verlagsanstalt Würzburg GmbH.
Printed on acid-free paper, bleached without the use of chlorine.

Note from the Publisher: This issue contains *Chemistry—A European Journal* as a supplement.

For the USA and Canada: ANGEWANDTE CHEMIE International Edition in English (ISSN 0570-0833) is published twice monthly and distributed by VCH Publishers, Inc., 333 Seventh Avenue, New York 10001; fax (800) 367-8247; telephone (800) 683-3695. Annual institutional subscription price (with "Chemistry—A European Journal) US$ 1830 (before January 31, 1997: $ 1730) including postage and handling charges for institutions and $ 270 for individuals who are personal members of a national chemical society, or whose institution already subscribes, or who are retired or self-employed consultants. Periodicals paid at Jamaica, NY 11431. Printed in Germany.

HIGHLIGHTS

In the first carbotetracation, 1, the charged groups are tetrahedrally arranged on an adamantane cage. Carbocations are no longer a domain of physical organic chemistry. They also play a role in organometallic chemistry and biochemistry, as a new samarocene complex containing a norbornadienyl cation fragment and the newly coined term "Olah enzyme" testify.

In the design of peptide-based drugs the β turn has been promoted to a design principle in recent years. In research on antiadhesive RGD mimetics, receptor selectivity has been shown to be encoded in the β-turn type within cyclic peptides of type **1** having an identical lead sequence. Switching the turn type from βII′ to βI inverts the selectivity profile so that a compound originally with antithrombotic activity becomes an antimetastatic agent.

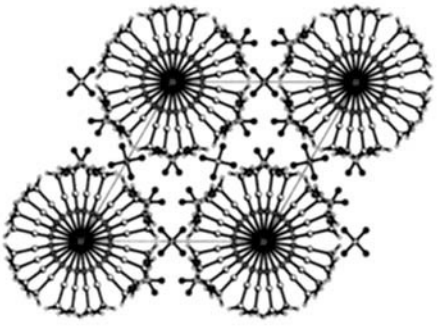
The β Turn as a Selectivity Switch: βI or βII′? That Is the Question

COMMUNICATIONS

One-electron reduction of the rhodium complex **1** has resulted in the first successful conversion of a discrete metal–metal bonded "dimer" into a one-dimensional polymer (**2**). The doped material **2** (depicted on the right) differs significantly from the well-known tetracyanoplatinates in that the metal backbone is cationic. In addition, there is the possibility of fine-tuning the material properties by varying the organic group.



$[Rh_2(MeCN)_{10}](BF_4)_4$ **1**

Unprecedented Conversion of a Compound with Metal–Metal Bonding into a Solvated Molecular Wire

---

Three solid-state techniques—atomic force microscopy, X-ray structure analysis, and diffuse reflectance spectroscopy—were combined to discover why E/Z isomerizations in the crystal, for example **1** → **2**, are possible despite their large spatial demands. These studies revealed, for instance, that on irradiation with wavelengths corresponding to the absorption tail of the crystals, anisotropic surface features appear.

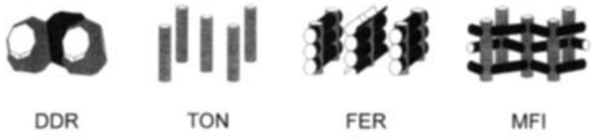
Templates for the arrangement of guest molecules—that is the role played by microporous crystalline SiO_2 modifications in the insertion compounds presented. The electronic interactions between the guest species can be controlled by the dimensionalities of the void systems. When iodine is the guest component, this is directly apparent from the colors of the insertion compounds, which for the host structures shown below range from violet to red-brown.



G. Wirnsberger, H. P. Fritzer, A. Popitsch, G. van de Goor, P. Behrens* 2777–2779

Designed Restructuring of Iodine with Microporous SiO_2

Not interpenetrated, but filled with solvent molecules, the large cavities of the polymer $[Co(NO_3)_2(4,4'\text{-bpy})_{1.5}]_n$ form different structures depending on the solvent system from which it crystallizes. One of the two possible structures (section of structure shown on the right) exhibits hydrophobic cavities about 11 × 11 Å in size. The solvent molecules can be readily removed, but the process has not yet been proven reversible.

A Noninterpenetrated Molecular Ladder with Hydrophobic Cavities

---

Anion complexation drives the self-assembly of appropriately designed macrocycles (sapphyrin and/or calix[4]pyrrole) containing pendant carboxylic arms (black in the schematic representation on the right). The self-assembly process can be disrupted by addition of F^- ions (sapphyrin) or in the case of calix[4]pyrrole, polar solvents.

Anion Binding: Self-Assembly of Polypyrrolic Macrocycles

The total concentrations of reactants and products within a flow-through reactor can be monitored as a function of both position and time by detecting gamma photons arising from the radioactive positron decay of injected ^{11}C nuclei. The method was demonstrated by directly observing catalyst preconditioning and deactivation of a Pt/H-mordenite catalyst bed during the industrially important hexane hydroisomerization reaction.

A high catalytic activity towards alkene epoxidation is shown by titanium-modified MCM41 mesoporous silicas if 2-methyl-1-phenyl-2-propyl hydroperoxide (MPPH) is used as oxidant. This first example in which MPPH has been used as an efficient two-electron oxidizing agent demonstrates that it is a competent replacement for *tert*-butyl hydroperoxide (TBHP) in metal-catalyzed, nonradical hydrocarbon oxidations and that the Ti-MCM41 catalyzed epoxidation of alkenes proceeds by a nonradical mechanism.

An increased stability of duplexes between amide-modified oligonucleotides (depicted on the right) and RNA was achieved by the introduction of 2'-OMe groups. Since the modified oligonucleotides display a very high affinity for their RNA complement and are more stable towards nucleases, they can be considered as promising antisense agents. X = H, OH, OMe; Y = H, OMe.

Synthesis and Enzymatic Degradation of Dendrimers from (*R*)-3-Hydroxybutanoic Acid and Trimesic Acid

In calichearubicin B (1) the aglycon of daunorubicin and the carbohydrate domain of calicheamicin γ_1^1 are linked by a spacer (calichearubicin A lacks this spacer). The aglycone serves as an anthracycline-like intercalator, while the carbohydrate portion binds to the minor groove of DNA. Thus calichearubicin B exhibits properties of both parent compounds.

An audacious macroaldolization is the key step in the first total synthesis of the cytotoxic epothilone A, which starts with the units **1**, **2**, and **3**. This condensation closes the ring to form the macrolide, whose structure was determined and published (also in *Angewandte Chemie*) as recently as July 1996.

Total Synthesis of (−)-Epothilone A

1,2-Addition of the surface silanol groups on SiO_2 to the nitridomolybdenum fragment of the title compound and subsequent α-elimination of neopentane forms the catalytically active surface species **I**. This is the first case in which an alkylated complex is converted into a heterogeneous catalyst in a well-defined way. The immobilized compound is significantly more active in ring-opening metathesis polymerization than the molecular precursor.

A Molecularly Defined, Grafted Olefin Metathesis Catalyst from Tris(neopentyl)nitridomolybdenum(VI)

The *ee* values of the hydrosilylation of acetophenone with the rhodium catalyst **1** are only small; nevertheless, the robustness of the catalyst is impressive: The chiral carbene ligand, which is readily available and can be easily varied, remains bound to the metal in solution to over 100 °C. Thus, no excess of ligand is necessary in the catalytic reactions.

Chiral Heterocylic Carbenes in Asymmetric Homogeneous Catalysis

In a one-pot reaction from 15 components, a tetrahedral host-guest compound forms by self-assembly. Its tripod–iron(II) groups are the corners of a tetrahedron (depicted on the right). The edges of the tetrahedron are bridged by 1,2-dinitrile ligands, and a BF_4^- ion is encapsulated in the tetrahedral cavity.

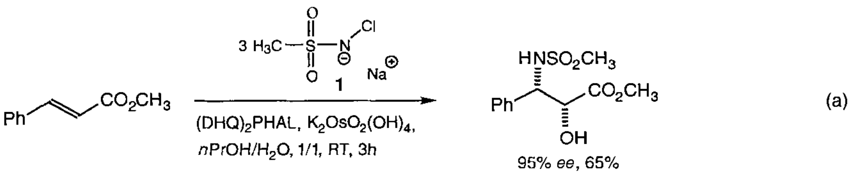
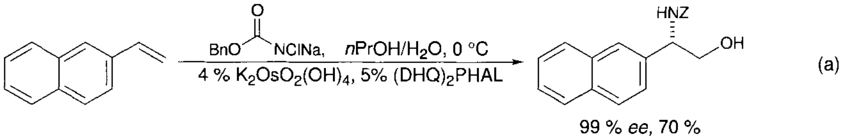
Supramolecular Host–Guest Compounds with Tripod–Metal Templates as Building Blocks at the Corners

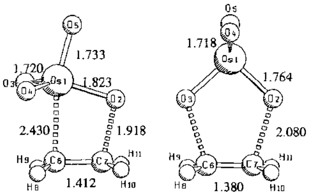
All of the selectivity criteria for catalytic asymmetric aminohydroxylation with sulfonamides [Eq. (a)] are improved when the original nitrogen source, Chloramine-T, is replaced by its methyl analogue, Chloramine-M (**1**). This newly introduced reagent exhibits substantially higher ligand dependence, and for most substrates the desirable phenomenon of ligand-accelerated catalysis was observed. DHQ-H = dihydroquinine, PHAL = 1,3-phthalazinediyl.



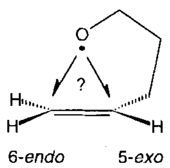
Better enantioselectivities and convenient deprotection make the sodium salts of *N*-chlorocarbamates the oxidant/nitrogen source of choice for the osmium/cinchona alkaloid catalyzed asymmetric aminohydroxylation (AA) of olefins [e.g. Eq. (a)]. This methodology simplifies the synthesis of a vast array of compounds such as unnatural amino acids and other pharmacologically important compounds. DHQ-H = dihydroquinine, PHAL = 1,3-phthalazinediyl, Z = benzyloxycarbonyl.



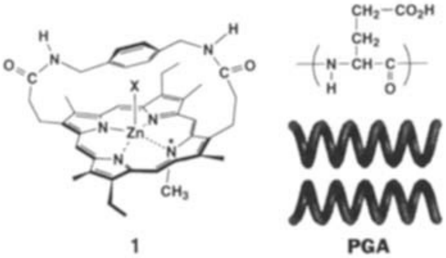
A difference of at least 35 kcal mol^{-1} between the activation barriers results from ab initio calculations for the competing [2+2] and [3+2] additions of OsO_4 to ethylene, clearly favoring the latter pathway (the two transition state structures are pictured on the right). The relative barrier heights for the proposed reaction paths hardly change in the presence of NH_3, used to model the base-catalyzed reaction. These theoretical findings on asymmetric dihydroxylation contradict the conclusions drawn from kinetic studies by Sharpless et al., but support the recent kinetic investigations by Corey et al.



An *exo*:*endo* ratio of 98:2! Thermochemistry would have predicted the opposite, but in the rearrangements of 5-hexenyl radicals the *exo* pathway is preferred due to kinetic reaction control. Selected ab initio methods are able to properly describe cyclizations of the 4-penten-1-oxyl radical (see sketch).

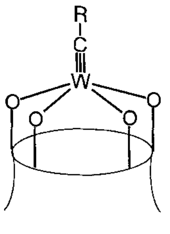


The secondary structure is of primary importance! The D and L forms of α-helical poly(glutamic acid) (PGA) are complexed selectively by the (*R*) and (*S*) isomers, respectively, of the porphyrin-based, chiral receptor **1**, which has a xylylenediamide strap. Helical polypeptides can thus be separated by complexation with enantiomerically pure **1**.

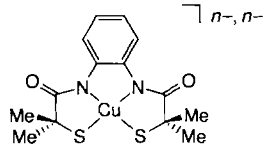


1

Anchoring gives stability. The recently synthesized anionic tungsten alkylidynes fixed over a planar tetraoxo surface of calix[4]arene (see picture) can undergo reversible protonation and metalation by carbophilic metals without disturbing the calixarene ligand. R = Ph, *n*Pr, $SiMe_3$.



Although it was once deemed a nearly impossible task (since Cu^{II} centers are generally readily reduced by thiolates), authentic Cu^{II} and Cu^{III} complexes with aliphatic thiolates in the metal coordination sphere have been synthesized. The unusual pair of square-planar complexes $(NEt_4)_2[Cu(phmi)] \cdot H_2O$ and $(PPh_4)[Cu(phmi)]$ (the anion is depicted on the right) displays the lowest known redox potential ever recorded for a Cu^{III}/Cu^{II} redox couple and has been completely characterized. H_4phmi = *N,N'*-1,2-phenylenebis(2-mercapto-2-methylpropionamide).



$[Cu(phmi)]^{2-,1-}$

Trinuclear gold(I) pyrazolate complexes of type **1** show liquid crystalline phases at room temperature. The molecules are arranged in a hexagonal columnar structure. The mesogenic behavior of these compounds is strongly related to the molecular symmetry, which is determined by the substituents R and R'. R = 3,4-$(H_{21}C_{10}O)_2C_6H_3$, R' = R, 3,4,5-$(H_{21}C_{10}O)_3C_6H_2$.

Substrate-Directed Diastereoselective Hydroformylation of Methallylic Alcohols

---

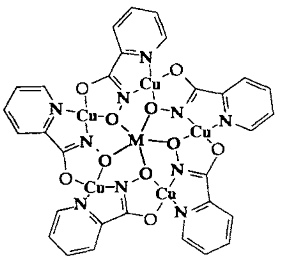
In vitro selection experiments yield unexpected results. An RNA-cleaving DNA enzyme that was selected in the presence of Mg^{2+} ions is much more efficient with Ca^{2+} as the cofactor. The result is even more surprising because of the lower hydrolytic efficiency of Ca^{2+} itself.

D. Faulhammer, M. Famulok* 2837–2841

The Ca^{2+} Ion as a Cofactor for a Novel RNA-Cleaving Deoxyribozyme

---

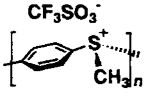
A novel "copper crown" complexes UO_2^{2+} preferentially (see picture), as competition experiments with Ca^{2+} and Cu^{2+} showed. This ligand thus provides an alternative to expanded porphyrins for the complexation of actinides and lanthanides by high denticity, planar ligands.



A. J. Stemmler, J. W. Kampf, V. L. Pecoraro* 2841–2843

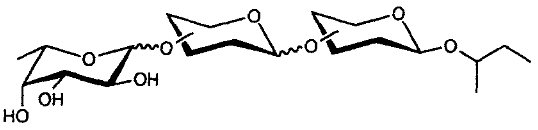
A Planar [15]Metallacrown-5 That Selectively Binds the Uranyl Cation

Alternating phenylene units and methylsulfonium groups make up polymer **1**, which is formed by polymerizing benzene with sodium methanesulfinate. This reaction is conducted in trifluoromethanesulfonate, and xylene and diphenyl ether are also suitable monomers.

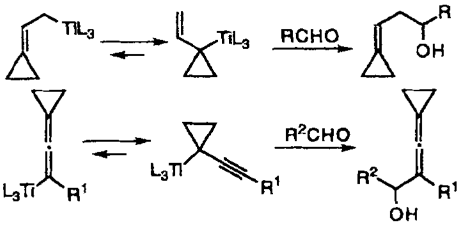


1

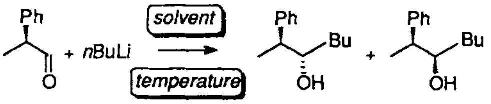
Many different trisaccharides (theoretically 256) can in principle be constructed from only four protected building blocks by following the strategy described for the synthesis of trisaccharide libraries. The method relies on latent-active glycosylation. The formula below gives an idea of the compounds in these libraries.



Steric strain shifts the equilibrium between the two isomeric allyltitanium compounds and isomeric allenyl- and propargyltitanium compounds containing cyclopropane units. This leads to unusual regioselectivity in their additions to electrophilic carbonyl compounds (shown on the right) and thus provides easy access to alkylidenecyclopropane derivatives.

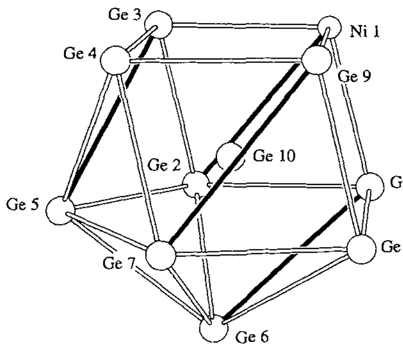


The length of the linear hydrocarbon chain in the solvent is a key factor in the facial diastereoselectivity of the nucleophilic addition of *n*-butyllithium to 2-phenylpropanal [Eq. (a)]. The reaction in these solvents shows inversion temperatures that correlate with the melting point of the solvent.



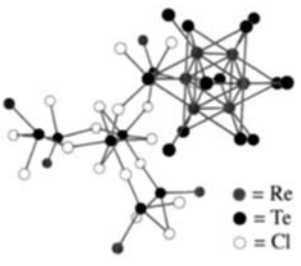
(a)

The first metalated germanide ion and only the second example of a cluster of the rare *nido*-10 (iv + iv) structural type, the anion **1**, was isolated from the reaction of $[Ni(CO)_2(PPh_3)_2]$, K_4Ge_9, and [2.2.2]cryptand in ethylenediamine (en). However, the structure of the $Ge_{10}Ni$ cluster (see picture) is distinctly distorted relative to the ideal *nido*-10 (iv + iv) geometry.



$[K([2.2.2]cryptand)]_2[Ge_9(\mu_{10}\text{-}Ge)Ni(PPh_3)]\cdot en$ **1**

Re_6 octahedra inside Te_8 cubes is a common feature of both title compounds. The picture on the right shows a section of the structure of $Re_6Te_{16}Cl_{18}$, in which the Re_6 octahedron and the binding of the cluster to the $[Te_8Cl_{18}]^{2-}$ ligand are apparent. Different binding to ligands results in a three-dimensional structure for $Re_6Te_{16}Cl_{18}$, and a two-dimensional structure for $Re_6Te_{16}Cl_6$.



Only 10^{12} atoms of an element are required for the determination of its first ionization potential by resonance ionization with laser light in the presence of an electric field and subsequent mass spectrometry. The figure on the right shows the ionization thresholds W_{th} of berkelium and californium and the extrapolation to the external field strength $E = 0$, which yields the ionization potentials I (49989(2) and 50665(2) cm^{-1}, respectively).

Deposition of Data from X-Ray Structure Analyses

In order to make life easier for authors and referees the Cambridge Crystallographic Data Centre (CCDC) and the Fachinformationszentrum Karlsruhe (FIZ) have unified their procedures for the deposition of data from single-crystal X-ray structure analyses.

From now on prior to submitting your manuscripts please deposit the data for your compound(s) **electronically** at the appropriate data base, that is, at the CCDC for organic and organometallic compounds and at the FIZ for inorganic compounds. Both data bases will be pleased to provide help (see our *Notice to Authors* in the first issue of this year). In general, you will receive a depository number from the data base within two working days after electronic deposition; please include this number with the appropriate standard text (see our *Notice to Authors*) in your manuscript. This will enable the referees to retrieve the structure data quickly and efficiently if they need this information to reach their decision.

This is now the uniform procedure for manuscripts submitted to the journals *Angewandte Chemie, Chemische Berichte, Chemistry—A European Journal*, and *Liebigs Annalen*.

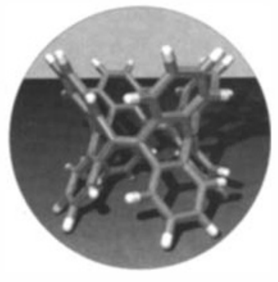
COVER PICTURE

The cover picture shows the first completely conjugated, tubelike hydrocarbon that is constructed by conventional chemical synthesis—a type of "picotube". It is synthesized in one step from tetradehydrodianthracene by photochemically induced metathesis reaction, which makes use of the strain energy as driving force. The highly symmetrical compound is characterized by exceptional stability. Ring-expanding metathesis—a new method for the construction of tubelike molecules—in conjunction with cyclization–dehydrogenation might point the way to interesting tube- and belt-shaped systems. The picture was generated by S. Kammermeier with the program POV-Ray on a Silicon Graphics Workstation. R. Herges et al. report on the synthesis and structure of the picotubes on p. 2669 ff.



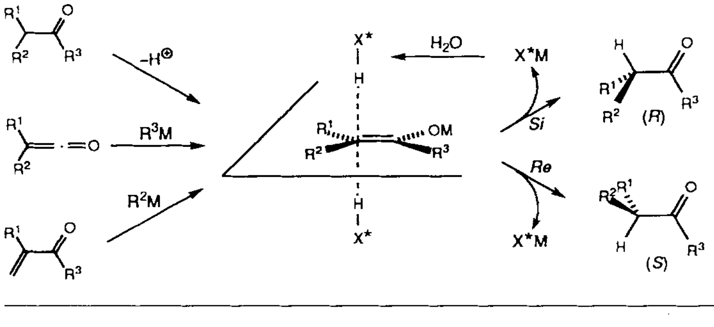
REVIEWS

Contents

The preferential transfer of a proton to one enantiotopic face of an enolate or enol derivative from a chiral proton donor HX* or from an achiral proton source in the presence of a chiral ligand is becoming increasingly important as a synthetic method. By judicious choice of reagents, both ketones and carboxylic acid derivatives can be obtained in almost enantiomerically pure form (see schematic overview below).

C. Fehr* 2566–2587

Enantioselective Protonation of Enolates and Enols



It's a great deal, but we still require additional information—that is the answer to the question in the title. How the knowledge of the three-dimensional structures of protein–ligand complexes and small organic molecules can be exploited for the development of computational tools for predicting binding affinities, molecular conformations, and binding modes is described herein. Evidence is also presented that care is needed—particularly for considerations based purely on structural arguments—since interactions such as hydrogen bonds and lipophilic contacts can lead to unexpected orientations of ligands in a protein pocket.

What Can We Learn from Molecular Recognition in Protein–Ligand Complexes for the Design of New Drugs?

HIGHLIGHTS

Electron transfer from a reducing agent to a fluorocarbon leads to cleavage of the strong and supposedly inert C–F bond. This process can be used to defluorinate perfluoroalkanes to produce perfluoroarenes or -alkenes catalytically under mild conditions. The transfer of two electrons from alkali metal oxalates to chlorofluorocarbons leads to complete degradation at relatively low temperatures [Eq. (a)].

$$C_nF_xCl_y + (x+y)e^- + (x+y)M^+ \longrightarrow nC + xMF + yMCl \qquad (a)$$

G. C. Saunders* 2615–2617

Defluorination of Perfluoroalkanes and Chlorofluorocarbons

In contrast to the antiaromatic and nonelusive mono- and oligophosphetes featuring only two-coordinate phosphorus atoms, unsaturated, four-membered phosphorus heterocycles with at least one η^5,σ^4-phosphorus atom such as triphosphete **1**, which was prepared by Karsch et al., are surprisingly stable compounds. These systems can undergo ring expansion to give five-membered heterocycles such as **2** (according to Bertrand et al.), react to form complexes, or undergo addition and substitution reactions.

Elongated, hexagonal-prismatic seed crystals are the starting point for the hierarchical growth of anisotropic spherical aggregates of fluorapatite in gelatin matrices. Discrete dumbbell-shaped aggregates (scanning electron microscope image shown on the right) are formed by self-similar, branched, needlelike upgrowths at both ends of the seeds. With successive generations, these aggregates close to give spheres with diameters of up to 400 µm. The system makes it possible to monitor the development of an abiotic information pattern into the macroscopic range.

"Almost all possibilities have been exhausted", stated H. Wieland in 1913 in the preface to his monograph *Die Hydrazine* with regard to the synthesis of N,N′-substituted hydrazines. Even today suitable reagents and methods are lacking for the preparation of these compounds, which are important as precursors of pharmaceuticals, agrochemicals, and dyestuffs. The readily available, protected hydrazine **1** is a new reagent that may fill this gap.

Completely unexpectedly, $[ae\text{-}B_{20}H_{17}O(CH_2)_4OR]^{2-}$ **1** is formed and not the expected $[ae\text{-}B_{20}H_{17}OR]^{4-}$ in the reaction of $[n\text{-}B_{20}H_{18}]^{2-}$ with alkoxides NaOR (R = methyl, isopentyl). The products result from the nucleophilic attack by an alkoxide ion on a THF solvent molecule that is associated with $[n\text{-}B_{20}H_{18}]^{2-}$. The anhydrous oxidation of **1** in ethanol produced the $[\mu\text{-}B_{20}H_{17}O(CH_2)_4OR]^{2-}$ ions (**2**), which can be hydrolyzed to produce the $[\mu\text{-}B_{20}H_{17}OH]^{2-}$ anion.

Coelenterands: A New Class of Metal-Encapsulating Ligands

Simply by flipping up, suitable ligand units attached to the calix[4]arene–iron(III) complex represented schematically on the right can bind the "soft" iron(II) ion generated on reduction (X = coordinating buffer molecules). The calixarene bears two sets of ion-binding groups: one for "hard" and one for "soft" metal ions. The metal complex switches between the two states during redox reactions, and this switching process can be followed in real time by UV/Vis spectroscopy.

Deposition of Data from X-ray Structure Analyses

In order to make life easier for authors and referees the Cambridge Crystallographic Data Centre (CCDC) and the Fachinformationszentrum Karlsruhe (FIZ) have unified their procedures for the deposition of data from single-crystal X-ray structure analyses.

From now on prior to submitting your manuscripts please deposit the data for your compound(s) **electronically** at the appropriate data bank, that is, at the CCDC for organic and organometallic compounds and at the FIZ for inorganic compounds. Both data banks will be pleased to provide help (see our *Notice to Authors* in the first issue of this year). In general, you will receive a depository number from the data bank within one working day after electronic deposition; please include this number with the appropriate standard text (see our *Notice to Authors*) in your manuscript. This will enable the referees to retrieve the structure data quickly and efficiently if they need this information to reach their decision.

This is now the uniform procedure for manuscripts submitted to the journals *Angewandte Chemie, Chemische Berichte, Chemistry—A European Journal*, and *Liebigs Annalen.*

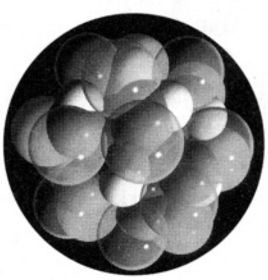
COVER PICTURE

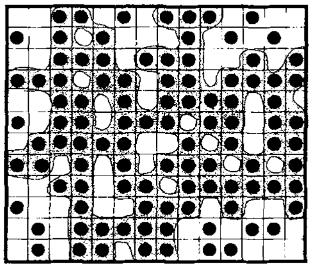


The cover picture shows a computer-generated space-filling representation of the product of photochemical chlorination of decamethyl-1,12-dicarba-*closo*-dodecaborane(12), decakis(dichloromethyl)-1,12-dicarba-*closo*-dodecaborane(12). The semitransparent Cl atoms (yellow) allow the visualization of the underlying and camouflaged icosahedral 1,12-dicarba-*closo*-dodecaborane framework, in which B is red, H is white, and C is gray. The CH vertices are buried in an array of five axially oriented Cl atoms arising from nearby $CHCl_2$ substituents. Apparent hydrocarbons of the type described here by M. F. Hawthorne et al. on p. 2536 ff. constitute a new class of carborane derivatives replete with unique chemistry and applications. The picture was produced by Darren M. Ricciardi, Imperative Images, Aurora, CO, USA, using the program Lightwave 3D by NEWTEK.

REVIEWS

Contents

The addition of diazonaphthoquinones to novolak resins controls the dissolution of solid films of these materials by perturbing their percolation field (shown on the right). This rather unexpected effect is the basis of a photolithographic resist (light-sensitive varnish) used in the manufacture of almost all of today's integrated circuits ("computer chips").



Continuous improvement of the McMurry reaction since its discovery in the 1970s has led to impressive applications in syntheses of natural products and pharmaceuticals. In addition, the exact mode of action of the titanium reagents has been scrutinized. In the latest variant the active titanium species is not generated before but during the reductive coupling of the carbonyl-containing substrate.

HIGHLIGHTS

The subject of an exciting debate—does electron transfer play a role in bimolecular nucleophilic substitution (a)? How would this reaction differ from the classical S_N2 reaction (b)? A number of research groups have employed electrochemical and computational methods to determine if alternatives exist for one of the best known mechanisms in organic chemistry.

$$Nu^- + R\text{-}X \longrightarrow Nu^\bullet + R^\bullet + X^- \longrightarrow R\text{-}Nu + X^- \quad \text{(a)}$$

$$Nu^- + R\text{-}X \longrightarrow [Nu\cdots R\cdots X]^- \longrightarrow R\text{-}Nu + X^- \quad \text{(b)}$$

Remarkable news concerning the long-known and well-investigated reaction system naphthalene/sodium in THF is reported: At room temperature a reversible intermolecular transfer of hydrogen takes place both between naphthalene rings and also with THF molecules. In contrast, the corresponding lithium and potassium systems show no such behavior. In addition, alkanes and cycloalkanes as solvent additives effect a significant increase in the H/D exchange rate in the sodium system. Benzene, toluene, ethene, and even methane (!) also take part in the H/D exchange reactions in the naphthalene/sodium system.

Synthesis, Structure, and Vibrational Spectra of Al_3BC_3, a Carbidecarboborate of Aluminum with Linear $(C{=}B{=}C)^{5-}$ Anions

Desilylations can trigger the intramolecular aldol reaction of alicyclic tricarbonyl compounds. Ester enolates are formed selectively and cyclize to give functionalized hydrindanones [Eq. (a); R^1 = (−)-menthyl, (−)- and (+)-phenylmenthyl; SiR_3 = $SiMe_3$, $SiPh_2Me$]. The cyclization products are extremely important and useful synthetic building blocks for the synthesis of steroids.

Asymmetric Cyclization of α-Silyl Esters to Give Functionalized Hydrindanones

The mechanism of stereodifferentiation was elucidated for the triplet ring-closure reaction of 1,2-dimethyltrimethylene (shown schematically on the right). The combined analysis of potential energy surfaces and spin-orbit coupling surfaces indicated that stereodifferentiation reflects the energetic behavior of the triplet state. This could well be a general feature of triplet photoreactions. ISC = intersystem crossing.

M. Klessinger* 2502–2504

Model Calculations on the Stereoselectivity of the Triplet Photoreaction of 1,2-Dimethyltrimethylene

Pairwise exchange of geminal protons in unsaturated carbonic acid derivatives of the type $H_2C{=}C(R)COOR'$ during the rhodium(I)-catalyzed hydrogenation [Eq. (a)] has been proven conclusively for the first time by using in situ NMR spectroscopy and parahydrogen (PHIP method). The most important conclusion is that the formation of the hydridoalkyl intermediates must be a reversible reaction.

Proof of a Reversible, Pairwise Hydrogen Transfer during the Homogeneously Rhodium(I)-Catalyzed Hydrogenation of α,β-Unsaturated Carbonic Acid Derivatives with In Situ NMR Spectroscopy and Parahydrogen

A considerable extension of the synthetic potential of lithium arsenides is likely through the alanates $[LiAl(AsHR)_4]$ (R = H, triorganosilyl), which can be synthesized from $LiAlH_4$ and H_2AsR. For example, the Zintl compound $[Li(tmeda)]_3As_7$ **1** was obtained by thermal decomposition in the presence of tmeda, and the first As_4Si_4 cubane was prepared by mild arsanylation of $RSiCl_3$ (R = 2,4,6-iPr$_3$C$_6$H$_2$). The novel complex **2** with an adamantane framework was formed from $RAsH_2$ (R = $Me_2C(i\text{Pr})SiMe_2$) and $LiAlH_4$. tmeda = $Me_2NCH_2CH_2NMe_2$, dme = $MeOCH_2CH_2OMe$.

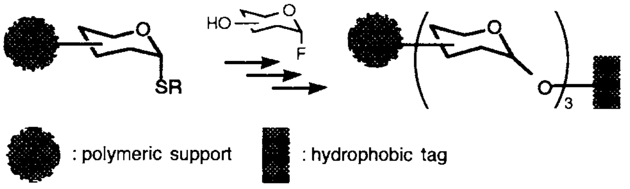
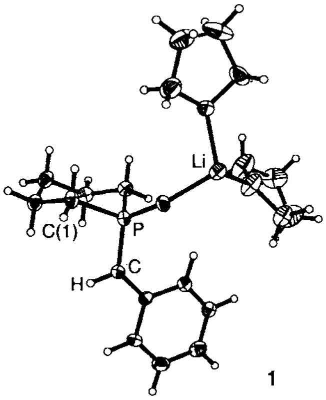
Lithium Arsanylalanates as Arsenide Sources: A Simple Route to the Zintl Anion As_7^{3-} and the Synthesis of a Tetraarsatetrasilacubane

Only a single purification step is required to isolate the glycoconjugate-related oligosaccharides prepared by a new strategy, which is shown schematically below. Prior to purification the support-bound oligosaccharide, which is labeled with a hydrophobic tag, is cleaved from the polymeric support and deprotected.

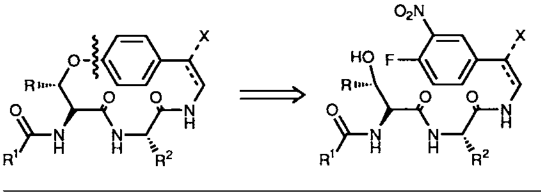


139 rotational lines of the ^{28}Si isotopomer of free silaethene $H_2C{=}SiH_2$ (**1**) have been observed in the gas phase by millimeter wave spectroscopy. The search was guided by ab initio calculations at the MP2, CCSD, and CCSD(T) levels with TZ2Pf basis sets. The rotational constants determined experimentally and by ab initio methods for **1** with a planar C_{2v}-symmetric structure agree within about 0.5%. Compound **1** was best produced by vacuum pyrolysis of 5,6-bis(trifluoromethyl)-2-silabicyclo[2.2.2]octa-5,7-diene in an Ar stream; **1** decomposes exponentially with a $1/e$ lifetime at ambient temperature of 30 ± 2 ms.

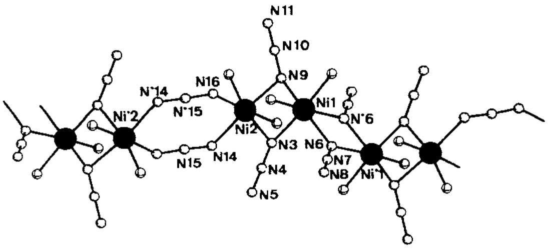
The anionic benzyl carbon atom is sp^2 hybridized in **1**, the first lithiated phosphane oxide that has been characterized by X-ray crystallography. In the solid state as well as in THF solution, **1** is shown to exist as a dimer with no Li–C contacts. Unlike related phosphonamides, **1** prefers an orthogonal conformation of the benzylic group in the solid state.



Macrocyclization by ether formation (retrosynthesis shown below), the key step in a conceptually novel approach to cyclopeptide alkaloids, relies on an intramolecular nucleophilic substitution reaction. This new strategy was demonstrated for the synthesis of model compounds for the 14-membered cyclopeptide alkaloids, an important class of natural products.



A complex sequence of ferro- and antiferromagnetic interactions occurs in the compound [Ni(N,N'-dmen)(μ-N_3)$_2$] (N,N'-dmen = N,N'-dimethylethylenediamine), which exists as a one-dimensional chain in the solid state (shown below; C atoms of the amine ligands are omitted). The magnetic behavior of this unusual spin system has been analyzed in detail.



The simultaneous activation of carbon dioxide and benzene by SiF_3^+ in the gas phase has been investigated by FT-ICR spectrometry. The key step is the formation of a tightly bound $SiF_3^+-(CO_2)$ adduct, which converts the unreactive carbon dioxide into an electrophile able to carbonylate benzene efficiently. At low pressures the benzoyl cation is formed.

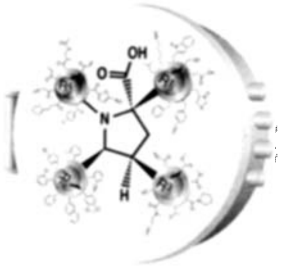
Pages 2273–2412

COVER PICTURE

The cover picture shows an everyday application of the combinatorial principle—the door of a safe! The four knobs of the combination lock are analogous to the four different groups R^1–R^4 attached to a small organic molecule. The illustration underlines the tremendous number of compounds possible by varying relatively few substituents. Combinatorial methods can provide access to every possible combination, and the correct solution provides access to a valuable target.



REVIEW

Contents

A numbers game or serious science? Many investigators are posing this question about the use of combinatorial chemistry in the search for new pharmaceuticals. It is undisputed, however, that this young and very rapidly developing area has attracted widespread international attention within a very short time. The authors give a comprehensive review and comment on current trends.

Combinatorial Synthesis of Small Organic Molecules

CORRESPONDENCE

Contents

A coin with two sides: chemistry has both static and dynamic aspects. Yet in research in solid-state chemistry attention has focused almost exclusively on the former. Thus, the systematic investigation of the dynamic properties of materials such as the mechanisms of solid-state processes can be considered long overdue and essential for the development of strategies for rational synthesis and tailor-made materials.

R. Schöllhorn* 2338

Solid-State Chemistry: Restoring the Balance

HIGHLIGHT

In spite of relatively few examples, two-center catalysis is proving to be a clever and effective means of performing diverse reactions with both high regio- and enantioselectivity. A simple scheme allows classification of the efficient M^1-M^2–binol complexes **1** as well as the enzymes urease and carbon monoxide dehydrogenase. M^1 = La, Al,...; M^2 = Li, Na, K, ...

Unactivated gold powder readily reacts with Me_3EI_2 (E = P, As) in diethyl ether to form the planar complex $[AuI_3(AsMe_3)]$ and, surprisingly, the trigonal-bipyramidal complex $[AuI_3(PMe_3)_2]$ (structure shown on the right); the latter readily hydrolyzes to form $[(Me_3PO)_2H][AuI_2]$. The oxidation of this noble metal to Au^{3+} and the production of complexes of different stoichiometries and structures illustrates the oxidizing power and the subtlety of these Me_3EI_2 reagents.

Pd^{II}/Pd^{IV} or Pd^{II}/Pd^0? The unusual Pd^{II} catalyst **1** was reduced to a Pd^0 complex by reaction with an amine and a base. β-Hydrogen elimination and subsequent C–H bond-forming reductive elmination generate a coordinated tris(o-tolyl)phosphane. The same palladium(II) metallacycle was reduced to Pd^0 in a cross-coupling reaction by C–C bond-forming reductive elimination to form coordinated $P(o\mathrm{Tol})_2(C_6H_4CH_2Ar)$. Thus, these compounds can react by a Pd^{II}/Pd^0-containing catalytic cycle.

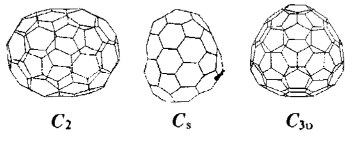
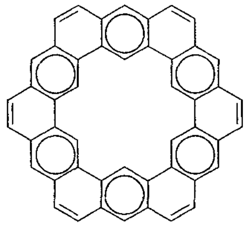
Endohedral fullerene compounds with isomeric carbon frameworks have been identified for the first time. The three stable isomers of $Tm^{2+}@C_{82}^{2-}$ were separated by HPLC, and characterized by cyclic voltammetry and by UV/Vis/NIR and ^{13}C NMR spectroscopy as probably having C_2, C_s, and C_{3v} symmetry (see picture).



U. Kirbach, L. Dunsch* 2380–2383

The Existence of Stable Tm@C_{82}-Isomers

Kekulene is indeed a "normal" aromatic molecule. This conclusion is reached in a theoretical study in which a number of calculated properties of kekulene and reference compounds such as benzene, phenanthrene, and 1,2:7,8-dibenzanthracene were compared. Structure **1** is the most apt description of this molecule, and claims of superaromaticity can finally be laid to rest.



1 (benzenoid, D_{6h})

H. Jiao, P. von R. Schleyer* .. 2383–2386

Is Kekulene Really Superaromatic?

Simple chromatography using SiO_2 impregnated with (*S*)-4-chlorophenylcarbamoyllactic acid ((*S*)-**2**) can be used to separate the enantiomers of receptor **1** (R_f((*R*)-**1**/R_f((*S*)-**1**) = 0.8/0.1). The very large association constant of the more stable complex [(*R*)-**1**·(*S*)-**2**] (5.7×10^5 M^{-1}) was determined in a series of competitive NMR titrations with α-amino acid derivatives, which form less stable complexes with **1**.

COVER PICTURE

The cover picture shows a novel rhodium(II) carbonyl hydrido complex, which is proposed as the active catalyst for regioselective hydroformylation, as well as sections from the 500 MHz ^{1}H NMR and $^{1}H\{^{31}P\}$ NMR spectrum of this compound in situ. The unusually large coupling constant of 164 Hz is not attributed to a *trans*-^{2}J(P,H) coupling, but to a ^{1}J(Rh,H) coupling. More about the behavior of this dinuclear rhodium complex is reported by Stanley et al. on p. 2253ff.

Contents

Vertebrate genes can often be identified based on analogies to *Drosophila* genes. This homology has been important in advancing the understanding of vertebrate development on a genetic level, and indicates that a basic body plan is common to the vertebrates and arthropods. Comparisons of patterning in flies and vertebrates have been successful most recently in studies of zebra fish.

C. Nüsslein-Volhard* 2176–2187

The Identification of Genes Controlling Development in Flies and Fishes (Nobel Lecture)

Establishing inbred lines from single flies carrying mutagenized chromosomes was the strategy behind the mutagenesis experiments conducted by E. Wieschaus and C. Nüsslein-Volhard in Heidelberg. Within two generations, homozygous flies were obtained whose development was compared with that of their heterozygous siblings. The results from 27000 inbred lines led to first indications of the causes of early morphological changes in embryogenesis.

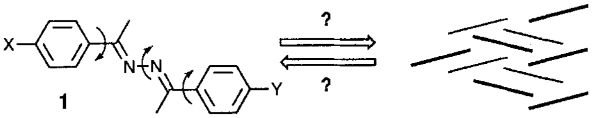
HIGHLIGHTS

Despite recent progress, true crystal engineering remains an elusive goal. Subtle differences in energy, as in the rotamers of **1**, may cause great differences in solid-state structures, and the influence of a crystalline environment on molecular parameters is even less well-understood. Successes and problems in the studies of the structures of molecular crystals are discussed.



J. J. Wolff* 2195–2197

Crystal Packing and Molecular Geometry

The two universally existing ribosomal elongation factors ET-Tu and EF-G are archetypes of the large family of G-proteins, which regulate a plethora of processes in the cell according to a basic scheme. In the past few years the crystal structures elucidated for various conformations of the elongation factors have provided exciting insights into the functions of G-proteins and into the mechanism of protein biosynthesis.

K. H. Nierhaus* 2198–2201

The Tricks of Ribosomal Elongation Factors

COMMUNICATIONS

Infinite channels with a diameter 10.5 Å are formed by the DNA-base hybrid **1** in the solid state. These channels arise because **1** specifically communicates the hydrogen bonding codes of the nucleobases cytosine and guanine ("C" and "G") to unambiguously assemble hexagonal, macrocyclic aggregates $\mathbf{1}_6$, which overlap in the crystal.

Reminiscent of a windmill, the novel triple-helicate $[(Fe^{III})_2Fe^{II}OL_3]$ **1**, a neutral oxo-centered mixed-valence complex, is formed in a one-pot reaction by self-assembly. The pentadentate ligand L acts in a tritopic fashion and connects the three iron ions in a triangular plane. At the center of **1** lies a μ_3-O^{2-} ion. The structural similarity of **1** with trinuclear carboxylatoiron complexes is striking.

Toward the Design of Porous Organic Solids: Modular Honeycomb Grids Sustained by Anions of Trimesic Acid

---

Red crystals of **1** were obtained by treatment of Hg^{II} salts with PhSeSiMe$_3$ in organic solvents. Depending on the starting materials and conditions, **1** crystallizes either in the cubic space group *P*23 or in the trigonal space group *P*3$_2$. The diameter of the cluster that crystallizes in the cubic space group is about 2400 pm (the framework of the $Hg_{32}Se_{50}$ cluster is depicted on the right). In addition, the other title compounds were prepared and isolated in the form of colorless crystals.

[$Hg_{32}Se_{14}(SePh)_{36}$] **1**

Chelation of the *cis*-enediolate form of dihydroxyacetone phosphate (see picture on the right) is the key step in the mechanism of action of Zn^{2+}-dependent aldolases. This proposal is derived from inhibition studies with model compounds for both ground and transition states and from an X-ray structure determination of a protein–ligand complex. The high degree of asymmetric induction occurring at both termini of the newly formed C–C bond can now be explained.

Delight from degradation and decomposition. The aesthetically pleasing $[Ni_{32}C_6(CO)_{36}]^{6-}$ carbide cluster was obtained by the degradation of $[Ni_{38}C_6(CO)_{42}]^{6-}$ under a CO atmosphere and by the thermal decomposition of $[Ni_{10}C_2(CO)_{16}]^{2-}$. Its structure, the metal–carbon core of which is shown on the right, consists of an extended fragment of the $Cr_{23}C_6$ lattice stabilized in a shell of edge-bridging carbonyl ligands.

The surface polarity can be regulated for amorphous, microporous Si/Ti mixed-oxide catalysts during their variable, single-step, preparation procedure (sol–gel). In contrast to zeolites the surface of these catalysts is thus tunable to the polarity of the substrate. Oxidations of various substrates can be catalyzed selectively not only with hydrogen peroxide but also with organic peroxides; the highest conversions are obtained with catalysts that have optimized surface polarity.

Isolation and Characterization of the Dimetallofullerene $Ce_2@C_{80}$

The inherent stabilizing effects of lone pair substituents from the first five rows of the periodic table on carbocations depend primarily on the *group* rather than on the *period*, judging from high-level ab initio computations (QCISD(T)/DZ++PP//MP2(fc)/DZ+P). When planarity is imposed on the pnictogen compounds, the stabilization energies from group 15 substituents are almost constant (ca. 95 kcal mol^{-1} from N to Sb, based on CH_3^+) and exceed the stabilization energies of chalcogens (60–66 kcal mol^{-1}, O<S≈Se<Te) and halogens (18–38 kcal mol^{-1}, F<Cl≈Br<I).

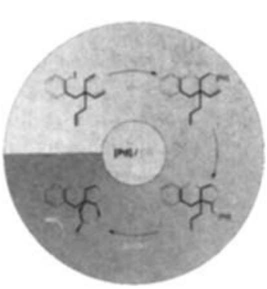
COVER PICTURE

The cover picture shows the palladium-catalyzed cyclization cascade of an iodotriene in the presence of CO in which "living" organopalladium species are formed as intermediates. Remarkably, this reaction succeeds with terminal alkenes that usually undergo β-dehydropalladation in the Heck reaction. E. Negishi et al. report more about this first cascade-type acylpalladation yielding polycycles with an angular mode of fusion on p. 2125ff. In the reaction shown seven C–C bonds are formed in one step.



REVIEWS

Contents

Two and sometimes even three metal ions are essential for the activity of many enzymes that catalyze the hydrolysis of phosphate ester and amide bonds. In addition to many mononuclear metallohydrolases, a number of metalloenzymes have been structurally characterized in which the active sites contain two adjacent metal ions that permit the transfer of phosphoryl and acyl groups. These studies provide detailed insight into the chemistry of two-metal ion catalysis—an important step towards the design of new artificial catalysts.

Two-Metal Ion Catalysis in Enzymatic Acyl- and Phosphoryl-Transfer Reactions

---

The efficiency of a demanding synthesis is often determined by the combination of protecting groups employed. Tried-and-true protecting groups are briefly presented here, including those that can be cleaved with acids, bases, fluoride ions, oxidation, reduction, light, and enzymes. Examples from published syntheses outline general themes and tactics for the development of successful protecting group strategies.

M. Schelhaas,
H. Waldmann* 2056–2083

Protecting Group Strategies in Organic Synthesis

HIGHLIGHTS

A cocktail of imaginative synthetic approaches, unique conformational behavior and analysis, unusual spectroscopic properties, and asymmetric synthesis, all liberally spiced with an assortment of intriguing structures (like **1**), is served up to illustrate recent advances in the diverse field of cyclophane chemistry. Cyclophanes can be auxiliaries in asymmetric synthesis and perhaps also starting materials for fullerenes.

COVER PICTURE

Contents

The cover picture shows a polyhedral representation of the structure of the nitridosilicate $BaYbSi_4N_7$. The overall SiN network structure in this compound consists of star-shaped $[N(SiN_3)_4]$ building blocks (blue). Here for the first time nitrogen atoms (red) that covalently bridge four silicon atoms were discovered. The nitridosilicates thus have significantly more possibilities for forming different structures than the oxosilicates. More about these fascinating results in solid-state chemistry is reported by H. Huppertz and W. Schnick on pages 1983–1984.

REVIEWS

Contents

Improved binding properties for hybridization with RNA and increased stability towards nucleases—DNA and RNA analogues composed of modified nucleic acids must display these key features for application as potential antisense therapeutics. Although much data has been accumulated on the chemical stability of numerous synthetic analogues, as well as on their cell permeation and RNA hybridization properties, the structural origins of the altered selectivity and stability are often only poorly understood. X-ray crystallography can yield insight, and interpretation of the thermodynamic data on the basis of the 3D structures may be helpful in the development of new and improved nucleic acid analogues.

HIGHLIGHTS

Contents

Metal–porphyrin π bonds such as those in 1 and 2 were hitherto unknown modes of coordination in porphyrin complexes. However, arene complexes of this kind were recently synthesized by Rauchfuss et al. (*Angew. Chem. Int. Ed. Engl.* **1996**, *35*, 1833). Metal–porphyrin interactions of this type may also play a role in reactions catalyzed by metalloporphyrins.

Peptide Nucleic Acids (PNAs) Containing Thymine Monomers Derived from Chiral Amino Acids: Hybridization and Solubility Properties of D-Lysine PNA

The initiation step in a deprotonation of CH-acidic compounds could be the formation of a complex between the organic precursor and the metalation reagent. This is the conclusion drawn from the reaction of $Ph_2P(=O)CH_3$ with $(Me_3Si)_2NLi$, which yielded a stable dimeric adduct $[(Me_3Si)_2NLi \cdot O{=}P(CH_3)Ph_2]_2$ with a central Li_2N_2 ring. MO calculations on the model system $H_2LiNLi \cdot O{=}P(CH_3)_2$ support these experimental findings.

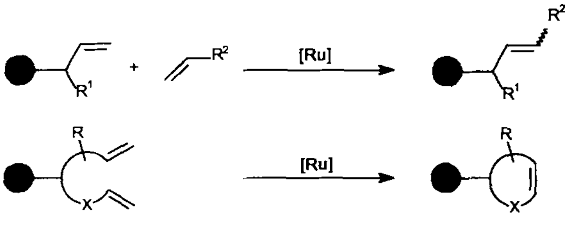
Cationic Iridium(III) Carbonyl Complexes: [Ir(CO)$_6$]$^{3+}$ and [Ir(CO)$_5$Cl]$^{2+}$

Dispersing water in a fluorocarbon seems against nature, since two more antipathetic types of liquids, in terms of intermolecular interactions, just do not exist. Every single characteristic relevant to water-in-fluorocarbon reverse emulsion stability (solubility and diffusivity parameters, interfacial tension and densities) is unfavorable. Yet stable emulsions of this type can be prepared with an appropriate fluorinated surfactant. Such reverse emulsions have potential as a new class of pulmonary drug-delivery system.

V. M. Sadtler, M. P. Krafft,
J. G. Riess* 1976–1978

Achieving Stable, Reverse Water-in-Fluorocarbon Emulsions

Cross metathesis between carrier-bound and dissolved olefins enable the simple construction of disubstituted double bonds on the solid phase (see below). As expected, ring-closing metathesis of immobilized diolefins can also be achieved in good yields by this method. The olefin metathesis can thus also be applied in topical solid-phase syntheses.



M. Schuster, J. Pernerstorfer,
S. Blechert* 1979–1980

Ruthenium-Catalyzed Metathesis of Polymer-Bound Olefins

The formation of a hydroperoxo ligand that bridges two Mn^{II} centers can be discussed as the first step in the reaction of dioxygen with [Mn(salophen)] complexes. This oxygenation leads to the selective oxidation of an imino group to an amido group and thus finally to a hydroxy-bridged Mn^{III}-polymer (see picture on the right). H_2salophen = *N,N-o*-phenylenebis(salicylidenimine).

Dioxygen Activation by a Manganese Complex Containing a Schiff Base: Selective Oxidation of an Imino to an Amido Group within the Salophen Ligand and Formation of a Hydroxy-Bridged Mn^{III}-Polymer

Four silicon atoms have been connected to one central nitrogen atom for the first time in $BaYbSi_4N_7$. These $N^{[4]}$ bridges significantly extend the spectrum of possible linkages in Si–N network structures of nitridosilicates. While oxosilicates are built up by SiO_4 tetrahedra with either terminal oxygen atoms or simply bridging $O^{[2]}$ atoms, the $N^{[2]}$, $N^{[3]}$, and $N^{[4]}$ linkages in nitridosilicates enable novel highly cross-linked Si–N network structures.

LUCY—A Program for Structure Elucidation from NMR Correlation Experiments

Stable in air for weeks as a solid and for days in solution, the blue-green pentaethynylcyclopentadienyl radical **1** is readily formed from ethynylated cyclopentadiene derivatives, which were prepared as potential precursors to decaethynyl metallocenes. The stability of **1** contrasts strikingly with that of previously described pentaaryl- and pentaisopropylcyclopentadienyl radicals, which, although stable at 25 °C, are highly sensitive to oxygen.

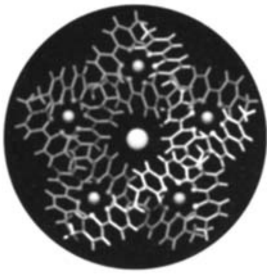
Deutscher Chemiker

International Edition in English

1996
35/16
Pages 1745–1876

COVER PICTURE



The cover picture shows the crystal structure of a unique supramolecular architecture consisting of five tris(bispyridine) ligands (shown in different colors) wrapped around five Fe^{II} ions (purple) in a double-helical fashion and closed to form a torus around a central chloride ion (green). This circular helicate is an analogue of circular DNA. Its formation also points to the possibility of designing self-assembling systems that generate receptors for specific substrates from a collection of suitable ligands and metal ions. More about the circular helicate and the concept of "virtual combinatorial libraries" is reported by J.-M. Lehn et al. on p. 1838ff.

REVIEWS

Contents

The ozone hole, a nuclear winter, and the greenhouse effect are some of the themes that concerned Paul Crutzen in his work, for which he was awarded the Nobel Prize in 1995. Here he reports on his path to his results and his plans for the future.

P. J. Crutzen* 1758–1777

My Life with O_3, NO_x, and Other YZO_x Compounds (Nobel Lecture)

Cause and result can be geographically widely separated. This fact is corroborated by the finding that the annually recurring ozone hole over Antarctica, which has been steadily increasing in size since 1985, is predominantly due to anthropogenic emissions from the Northern Hemisphere. How the realization dawned that it is primarily the chlorine atoms released by photochemical reactions of CFCs in the upper stratosphere that destroy the ozone shield is described by M. J. Molina in his Nobel Lecture.

M. J. Molina* 1778–1785

Polar Ozone Depletion (Nobel Lecture)

Hope for the atmosphere is the cautiously worded resumé of F. S. Rowland based on his knowledge of the developments in recent years about the influence of the CFCs on the ozone budget. Thanks to the restrictions that came into effect in the 1990s, the concentrations of some CFCs in the atmosphere have already reached their maximum value; for others this point will be reached in the near future. Nevertheless, large ozone losses are expected in the Antarctic spring until the middle of the 21st century.

F. S. Rowland* 1786–1798

Stratospheric Ozone Depletion by Chlorofluorocarbons (Nobel Lecture)

The smallest C_n clusters produced to date by [2+2]cycloreversion (*cyclo*-C_{12} and *cyclo*-C_{16}) as well as *cyclo*-C_{20} can be synthesized from propellane-annelated dehydroannulenes (**1**–**3**). Spectroscopic data indicate that the dehydroannulenes have either a planar (**2**) or a puckered (**3**) conformation.

A convenient route to the stanna[*n*]ferrocenophanes **1** and **2** is presented. The series of homologous hetero[2]ferrocenophanes of the type $[Fe(C_5H_4EMe_2)_2]$ (E = C, Si, Sn) is thus supplemented by **1**. A comparison of the molecular structures (for E = C, Si, Sn) reveals that as the E–E bond length increases, the strain in the [2]ferrocenophane molecule decreases.

Synthesis of New Hybrid Materials by Intercalation of a Bifunctional Aminophosphane and Its Tungsten Pentacarbonyl Complex in α-Zirconium Phosphate

---

Displaced intermolecular and intramolecular equilibria, which lead to a nonlinear change in the concentration ratios of intermediates, are possibly the cause for the experimentally long-known nonlinear temperature dependence of logarithmic product ratios in selection processes (isoinversion principle). This interpretation takes into account a change in dominance of differences in the activation enthalpy and entropy for the overall selection process, as well as a change in the rate-determining step with variation of the temperature.

D. Heller,* H. Buschmann, H.-D. Scharf 1852–1854

Nonlinear Temperature Behavior of Product Ratios in Selection Processes

---

Useful intermediates for the synthesis of functionalized, linear alkyl chains by classical Grignard reactions or reactants for the synthesis of biblock copolymers by further reaction with polar monomers—the dialkylmagnesium compounds described herein are accessible in a living transfer polymerization under very mild conditions with [Cp$^*_2$LnCl$_2$Li(OEt$_2$)$_2$] (Ln = Nd, Sm) as catalysts and simple dialkylmagnesium compounds RMgR′ (R = Et, R′ = Bu or R = R′ = n-hexyl) using ethylene as substrate.

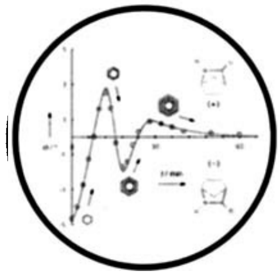
COVER PICTURE

The cover picture shows the time dependence of the optical rotation of a solution of a mixture of the bicyclic lactam 2-azabicyclo[2.2.2]hept-5-en-3-one enantiomers, which depicts oscillations during resolution by the preferential crystallization method. This phenomenon arises because layers of the (–)- and (+)-enantiomers (depicted as red and green hexagons, respectively) crystallize alternately from solution to form each crystal. The results on this apparently bizarre and unprecedented oscillating behavior are described in the communication by A. Collet et al. on p. 1666.



REVIEWS

The incorporation of inorganic elements in the main chain of polymers is an attractive method for accessing processable materials with novel properties. In this article, recent advances in the inorganic polymer field are surveyed, with emphasis on the new polymer systems prepared over the last decade such as **1**–**3**.

Delivery: By direct mail (printed matter) or through booksellers. ● **Change of address:** Please notify your bookseller or the publishers immediately. ● **Cancellation of subscriptions:** The publishers must be notified not later than three months before the end of the calendar year.

Authors who wish to publish in *Angewandte Chemie International Edition* should consult the current "Notice to Authors", which is printed in the first issue of every year immediately after the Table of Contents, before they draft their manuscript.

Angewandte Chemie International Edition in English is the English version of *Angewandte Chemie*.

Printed in Germany by Konrad Triltsch Druck und Verlagsanstalt Würzburg GmbH.
Printed on acid-free paper, bleached without the use of chlorine.

Note from the Publisher: This issue contains *Chemistry—A European Journal* as a supplement.

For the USA and Canada: ANGEWANDTE CHEMIE International Edition in English (ISSN 0570-0833) is published twice monthly except in July and December (22 issues) and distributed by VCH Publishers, Inc., 303 NW 12th Avenue, Deerfield Beach, FL 33442-1788; fax (800) 367-8247; telephone (800) 683-3695. Annual subscription price: US$ 1448/$1498 (airmail) including postage and handling charges for institutions and $ 198/$ 248 (airmail) for individuals who are personal members of a national chemical society, or whose institution already subscribes, or who are retired or self-employed consultants. Periodicals paid at Deerfield Beach, FL 33442-1788. **POSTMASTER:** Send address changes to Angewandte Chemie IE, VCH Publishers, Inc., 333 Seventh Avenue, New York 10001. Telephone (212) 629-6200; fax (212) 629-8140. Printed in Germany.

HIGHLIGHTS

A Darwinistic principle in catalysis? The term for the catalysis of an asymmetric, catalyzed reaction by its product is "asymmetric autocatalysis". The enantiomeric excess of a self-replicating system such as that described by Soai et al. can be amplified enormously in several reaction cycles [Eq. (a)].

A. Seger 1657–1659

Asymmetric Autocatalysis with Amplification of Chirality

Metallic or ferromagnetic properties are displayed by Cu complexes with the dicyanoquinodiimine (DCNQI) anion and a V complex with the tetracyanoethyletylene (TCNE) anion. These exceptional properties arise from pπ–dπ ligand–metal interactions. An entire field based on the coordination chemistry of organocyanides is emerging, aided by the discoveries of unusual molecules such as **1** (M = Fe, Ni, Cu, Zn) that involve coupling of two TCNE ligands on a metal center.

The first catalytic and enantioselective opening of *meso* epoxides with trimethylsilylcyanide (TMSCN) [Eq. (a)] is reported. Combinatorial strategies and solid-phase techniques were used for optimization of asymmetric induction through parallel synthesis and screening of peptide-derived ligands. A dipeptide Schiff base that affords high enantioselectivities was identified through iterative modification of the modular ligand structure.

All's well that ends well! The complete assignment of the structure of the largest known natural product that is not a biopolymer (maitotoxin) has concluded with the determination of the configurations of the stereogenic centers in its two acyclic side chains. The results of NMR studies were confirmed by comparison with synthesized model compounds. The absolute configuration was determined by analysis of a fragment of the natural product and a corresponding synthesized unit by GC with a chiral column. In the contracted structure below, the acyclic side chains are attached to the termini of a polycyclic polyether.

Asymmetric alkylations and kinetically controlled aldol reactions are possible with the planar-chiral η^2-manganese complexes of cyclopent-2-enone that can now be prepared in enantiomerically pure form [Eq. (a); LDA = lithium diisopropylamide; R = Me, allyl, Bn or RX = R'CHO, R' = *i*Pr, Ph]. After mild demetalation the chiral cyclopentenone derivatives, which are difficult to prepare by other means, are obtained with good enantiomeric excesses.

$La_9Br_5(CBC)_3$: A New Superconductor

Sterically hindered triazacyclononane derivatives bearing one alkyl-substituted phenolato group have enabled the synthesis of copper complexes that mimic key intermediates in the postulated catalysis cycle of galactose oxidase. For example, one-electron oxidation of the copper(II) complex pictured on the right yields benzaldehyde, probably with participation of a Cu^{II} complex containing a phenoxyl radical. A similar mechanism has been proposed for the active enzyme.

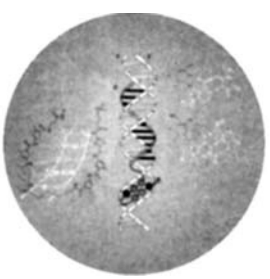
COVER PICTURE



The cover picture shows a ribbon model of a hairpin pyrrole/imidazole polyamide–oligonucleotide simultaneously binding the major and minor grooves of DNA (red circles: *N*-methylimidazole; blue circles: *N*-methylpyrrole rings; diamond: β-alanine). The structural formulas on the right depict the molecular interactions responsible for sequence-specific recognition: T·AT and C+GC base triplets are formed by Hoogstein hydrogen bonding of T to a Watson–Crick AT base pair and protonated ^{Me}C to a Watson–Crick GC base pair. On the left is the complex of the polyamide ImPyPy-γ-ImPyPy-β with the site 5′-TGACA-3′ (circles with dots: lone pairs on N3 of purines and O2 of pyrimidines; circles containing an H: N2 hydrogen on guanine; dashed lines: putative hydrogen bonds). The energetics and specificity of the complex is reported by Szewczyk et. al. on pages 1487ff. The picture was generated with MacDraw Pro software.

REVIEWS

Contents

Open-minded carbohydrate chemists are well advised to consider glycals for oligosaccharide synthesis. Glycal-based methods, which obviate many of the onerous protecting group manipulations that have dominated this field, have led to syntheses of blood group determinants and antigen recognition domains. The artificial glycoprotein at the most advanced stage of preclinical development is the protein conjugate **1** of the human globo H breast tumor antigen.

Poly(phenylenesulfidephenylenamine) (PPSA)—the "Compound" of Polyphenylenesulfide with Polyaniline

The first high-nuclearity uranium complex contains an octahedral array of metal centers that is coordinated by twelve diphenylphosphate as well as eight oxo or hydroxo ligands. Although the degree of protonation of the capping centers could not be determined unambiguously, many of the findings point to OH ligands. The picture on the right shows the U_6O_8 framework of the complex.

Transition metal catalyzed reactions of the diborylacetylene 1 allow access to perborylated C–C multiply bonded systems. Cyclotrimerization of **1** results in the hexaborylbenzene **2**. Diboration of **1** with the diborane **3** provides the tetraborylethene derivative **4**. Compounds **2** and **4** react with LiMe and $AlMe_3$ under cleavage of the boron–oxygen bonds. The dodecamethyl derivative $C_6(BMe_2)_6$ forms the structurally characterized complex $[C_6(BMe_2)_6 \cdot 2Li_2O_2C_6H_4 \cdot 8NC_5H_5]$ with pyridine and $Li_2O_2C_6H_4$.

Reversible Formation of Raftlike Organoimidotetrarhodium Clusters by the Migration of RhL_n^+ Fragments

C–Cl bonds approximately 10 pm longer than those in CH_2Cl_2 are present in $LiCHCl_2 \cdot 3C_5H_5N$ (**1**). This and the sum of the bond angles around C (308° excluding the C–Li bond) confirms the increased p character of the C–Cl bonds and thus the pronounced electrophilicity of carbenoids. Calculations on the solvated and nonsolvated carbenoid and the comparison with experimental data reveal the remarkable influence of solvation on structure, stability, and ^{13}C chemical shift, which is useful for predicting the structures of such molecules in solution.

The remarkable change in the B–N bond lengths of $CH_3CN \cdot BF_3$ and $HCN \cdot BF_3$ between the gas phase and the condensed phase has been attributed to effects of the surrounding medium. Results herein suggest that in BF_3-rich argon matrices, $CH_3CN \cdot BF_3$ and $HCN \cdot BF_3$ are present in the form with a short B–N bond, as is $CH_3CN \cdot BF_3$ in solution in benzene. The two structural alternatives for $HCN \cdot BF_3$ are shown schematically above.

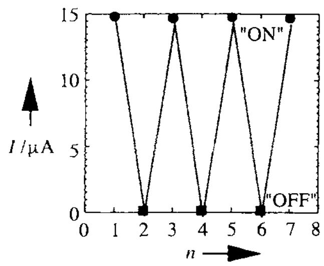
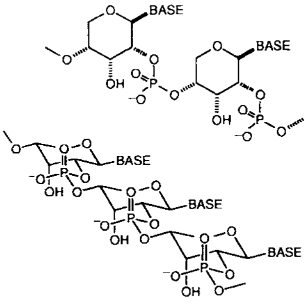
G. Solladié,* P. Hugelé, R. Bartsch,
A. Skoulios 1533–1535

New Family of Enantiomerically Pure Liquid Crystals Containing a Chiral Biphenyl Core

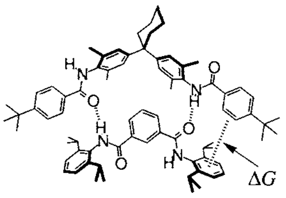
A phenoxynaphthacenequinone forms a densely packed monolayer together with 1-tetradecanethiol on a gold electrode. The assembly can be reversibly switched to enable amperometric transduction of an optical signal. In the diagram on the right the current is switched off by irradiation with UV light.



Pyranosyl-RNA, an isomer of natural RNA (constitution and pairing conformation shown on the right), displays remarkable properties. Homochiral pyranosyl-RNA strands with opposite senses of chirality are found to pair to give quasi-racemic duplexes. Correspondingly altered pairing rules result.

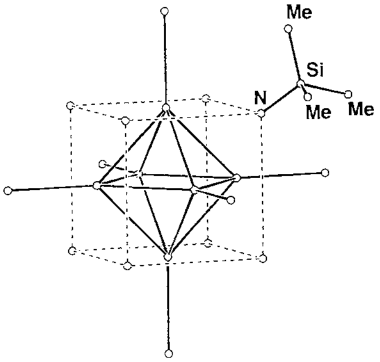


Quantitative descriptions of complex recognition processes rely on the measurement of the magnitude of weak intermolecular interactions such as the π–π interaction between arene units. In one approach thermodynamic cycles of compounds with structural variations (mutations) are constructed. The association energy ΔG for the edge-to-face π–π interaction in complex **1** was determined to be 1.4 ± 0.8 kJ mol^{-1}.

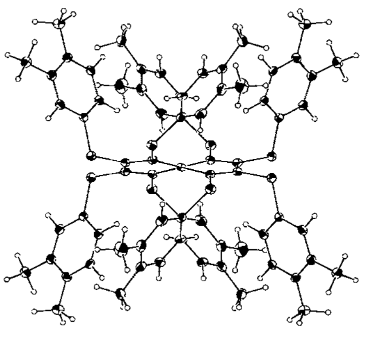


1

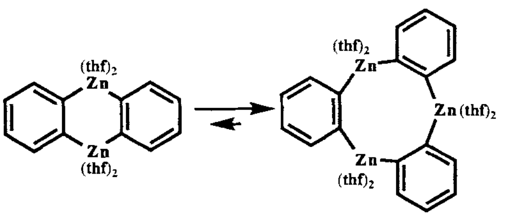
Under extremely mild conditions, $[Re_6Q_5Cl_9]^-$ ions (Q = S, Se) react with bis(trimethylsilyl)amine derivatives to give clusters of the type $[Re_6Q_5(\mu_3\text{-}NSiMe_3)Cl_8]^{2-}$ (shown on the right). These are isostructural and isoelectronic with the Chevrel–Sergent cluster cores $[Mo_6Q_8]^{4-}$. The μ_3-imido-functionalized clusters react with electrophiles and thus offer opportunities to extend the chemistry of genuine inorganic–organic hybrid compounds.



Nanoscale cavities with *T* symmetry capable of accommodating such diverse species as $S{=}CCl_2$, $PbEt_4$, and C_{60} are formed by the designed title compound. The adducts crystallize, uniquely for a purely organic system, in the cubic space group *Pn*$\bar{3}$. The crystal structure of the title compound in its $PbEt_4$ clathrate is shown on the right.



Dimeric in the crystal and trimeric in THF solution—this remarkable phenomenon is shown by *ortho*-phenylenezinc, which can be obtained from the analogous mercury compound and zinc. In solution the equilibrium shown below lies well to the right. The dimer probably crystallizes due to favorable packing effects.



M. Schreuder Goedheijt, T. Nijbacker,
O. S. Akkerman, F. Bickelhaupt,*
N. Veldman, A. L. Spek 1550–1552

Synthesis and Structure of *ortho*-Phenylenezinc

By employing boronato instead of carboxylato bridges in the dication $[\mathrm{Mn}_2^{IV}(\mu\text{-O})(\mu\text{-PhBO}_2)_2\mathrm{L}_2]^{2+}$ (L = 1,4,7-trimethyl-1,4,7-triazacyclononane), a Mn_2^{IV} unit has been stabilized for the first time. Together with the di-μ-carboxylato-μ-oxodimanganese complexes of analogous structure, there is now an "isostructural series" available containing Mn_2^{II}, $\mathrm{Mn}^{II}\mathrm{Mn}^{III}$, Mn_2^{III}, $\mathrm{Mn}^{III}\mathrm{Mn}^{IV}$, Mn_2^{IV} units. The Mn K-edge energy of the corresponding complexes increases linearly with increasing oxidation level. This is of importance for EXAFS investigations of metalloproteins containing manganese.

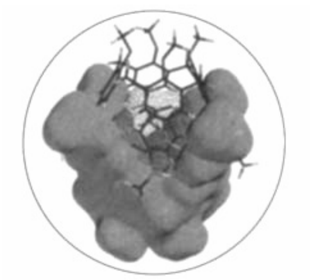
COVER PICTURE

The cover picture shows the van der Waals surface (represented by a grid) and the structure (stick model) of a benzene molecule included in the cavity of a molecular capsule. This host is composed of two calix[4]arenes that are held together by hydrogen bonds. The blue space-filling model at the bottom represents the van der Waals surface of the bottom calixarene, the gray stick model the structure of the upper calixarene. The host–guest complex is obtained within minutes by simply stirring a solution containing the calix[4]arene dimer and benzene. J. Rebek, Jr. et al. report more on p. 1326ff on the affinities of these calixarene capsules to other molecules.



REVIEWS

Contents

Chiral *ansa*-metallocene complexes are excellent catalysts for enantioselective carbomagnesations, hydrogenations, polymerizations, and Diels–Alder reactions. They can also be employed in stoichiometric amounts as chiral mediators in enantioselective reactions; however, recovery of the metallocene is not always possible. The future of chiral metallocene catalysts in preparative organic chemistry depends critically on their cost and ease of preparation.

Predicting structures of solids capable of existence is the first step in planning the syntheses of solid-state compounds. The modular approach presented here determines such structure candidates by using global optimization methods to find metastable minima on the potential energy surface. So far the method has been applied to systems characterized by ionic or van der Waals bonding. The good agreement with experimental findings suggests that predictions for yet unknown compounds, for example alkali metal nitrides such as Na_3N and Ca_3SiBr_2, are also most likely to be correct.

First Step Towards Planning of Syntheses in Solid-State Chemistry: Determination of Promising Structure Candidates by Global Optimization

HIGHLIGHTS

Very selective and under mild conditions. These features characterize the cleavage of C–H bonds in alkenes and arenes by the cationic iridium(III) complex **1** developed recently by Arndtsen and Bergman. The extremely high reactivity of this compound is attributed to the presence of separated ion pairs, evident also in the crystal. The remarkable tolerance of **1** towards functional groups bodes well for possible applications in synthesis.

What is the Structure of the Calmodulin Antagonist Konbamide from *Theonella* sp.? Synthesis of Two Isomers by Direct Biomimetic Introduction of Bromine in Hydroxytryptophan-Containing Cyclic Peptides

---

Exclusive mono-insertion into one of the polar metal–metal bonds is an apt description of the reaction of thermally stable ZrFe$_2$ and ZrRu$_2$ complexes **1** with methyl isocyanide [Eq. (a); M = Fe, Ru]. Thus surprisingly, the second of the two polar Zr–M bonds in **1** as well as the distorted tetrahedral coordination geometry of the Zr atom remain intact. The low degree of steric congestion in **1** is manifest in a rapid rotation about the Zr–M bonds that cannot be frozen out even on cooling to 180 K.

35/11
Pages 1141–1248

EDITORIAL

Science for the future—that is the slogan for the 75th anniversary of the founding of the VCH Verlagsgesellschaft. "Future grows from the past", and the latter is portrayed in this quick overview. The company was founded as "Verlag Chemie" by the Deutsche Chemische Gesellschaft (German Chemical Society), the Verein Deutscher Chemiker (Association of German Chemists) and the Verein zur Wahrung der Interessen der chemischen Industrie (Society for the Protection of the Interests of the Chemical Industry). From the beginning the traditional German chemical journals, *Angewandte Chemie*, *Chemische Berichte*, and *Liebigs Annalen*, have been the most important products of the company, and despite the drive for expansion in the last 15 years, little has changed in this respect.

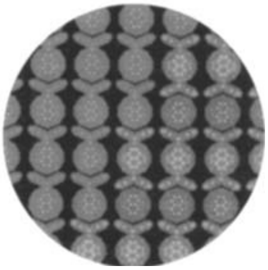
The Gesellschaft Deutscher Chemiker (GDCh) was the successor of two of the learned societies and for about 40 years, until the beginning of the nineties, the main owner of the publishing company. In this time Verlag Chemie, as it was known until the end of 1984, underwent continual expansion. Journals were published for other scientific organizations and societies (as they had been all along) and new ones were founded, an impressive book publishing program was established, and in recent years publishing interests beyond chemistry were nurtured, in particular by subsidiaries such as Ernst & Sohn, Akademie Verlag (both located in Berlin), and the Academy Group (London).

After more than a decade without the term "chemistry" in the company's name, the interests of chemistry are served better than ever: the traditional journals *Chemische Berichte* and *Liebigs Annalen* have been strengthened by a phase of reorientation; the former is now publishing inorganic and organometallic chemistry and the latter all fields of organic chemistry. In the material sciences *Advanced Materials* has secured its place as a top journal; *Angewandte Chemie* has continued its way as a leading international chemistry journal; the start of *Chemistry—A European Journal* could not have been more successful. VCH has become **the** textbook publishers in chemistry in Germany. Furthermore, there has been incredible success on the German-speaking market with books such as the "Chemische Kabinettstücke" by Roesky and Möckel; an English translation of the book ("Chemical Curiosities: Spectacular Experiments and Inspired Quotes") will appear in August, an Italian one is in preparation. Also in the international scene, recent new publications, for example, by Curran/Giese/Porter ("Stereochemistry of Radical Reactions"), Drauz/Waldmann ("Enzyme Catalysis in Organic Synthesis"), Fürstner ("Active Metals. Preparation—Characterization—Applications"), Lehn ("Supramolecular Chemistry. Concepts and Perspectives"), Nicolaou/Sorensen ("Classics in Total Synthesis"), Schmalzried ("Chemical Kinetics of Solids"), and Stang/Diederich ("Modern Acetylene Chemistry") have been extraordinarily well received. Our goal is to continue this path into the future.

With this background, the brand new alliance between VCH and Wiley—this renowned scientific publishing company founded in 1807 acquired a 90% interest in the VCH Publishing Group in early May—offers great opportunities: the GDCh journals (which continue to be owned by the GDCh and published by VCH) will certainly profit from Wiley's excellent worldwide distribution network; the same is true for the English book publishing program. The new partnership will be extremely beneficial also in terms of developments in electronic media. On the other hand, Wiley will profit from VCH's competence in all areas of science, and chemistry in particular, as well as its presence in the German-speaking and continental European market. Professor Dr. E. Winterfeldt, the President of the GDCh, said: "...we have been looking for a suitable partner to strengthen the Society's [international] publishing interests. Wiley has a high reputation in Germany and throughout Europe, and our publishing partnership will help us effect our ambitious plans for cooperation between all European chemical societies and chemists.... In fact, in accordance with an already published concept the GDCh—Wiley have already given their backing—will distribute ownership rights of the new top journal *Chemistry—A European Journal* to chemical societies in Europe. Real steps towards a European **chemistry for the future**".

COVER PICTURE

The cover picture shows schematically the progress of a thermally induced transformation to an ordered solid. This involves a kind of disproportionation of the monoadduct of [60]fullerene and anthracene into the parent [60]fullerene and the antipodal bisadduct as an ordered 1:1 mixture. More about this solid-state reaction, which opens a very efficient access to the bisadduct, is reported by B. Kräutler et al. on page 1204ff.



REVIEWS

Contents

The field of nanochemistry aspires to the synthesis of forms that exist and function at the nanometer scale. The question is, how can this goal be achieved? Self-assembly processes, ubiquitous in Nature, provide remarkably concise and efficient methods for arriving at such compounds and complexes. The burgeoning field of nanochemistry must, therefore, learn lessons from Nature and transfer concepts from biology to chemistry and apply these lessons to the synthesis of unnatural forms.

D. Philip, J. F. Stoddart 1154–1196

Self-Assembly in Natural and Unnatural Systems

HIGHLIGHTS

The potential of bioorganometallic chemistry as a new interdisciplinary research area is illustrated impressively by organoruthenium complexes with peptide ligands. Ruthenium–π-arene fragments are of interest both as markers for peptides that can be readily introduced and as promoters of complex synthetic transformations such as the preparation of cyclic peptide antibiotics and of linear oligopeptides in a one-pot procedure.

Application of π-Arene–Ruthenium Complexes in Peptide Labeling and Peptide Synthesis

---

$[N_6CaBa_{14}]$ clusters separated by a matrix of sodium atoms that can alternatively be considered as stars of octahedra (shown on the right) comprising face-shared $[NCaBa_5]$ octahedra with common Ca vertices are present in $Na_{14}Ba_{14}CaN_6$ recently described by Simon and Steinbrenner (*Angew. Chem. Int. Ed. Engl.* **1996**, *35*, 552). This compound, the first discrete subnitride cluster, is not only a link between Na/Ba subnitrides and the classic Rb/Cs suboxides, but also an important extension of the structural chemistry of this class of compounds—not least because a "real" cation (Ca^{2+}) is present in the saltlike interior of the cluster.

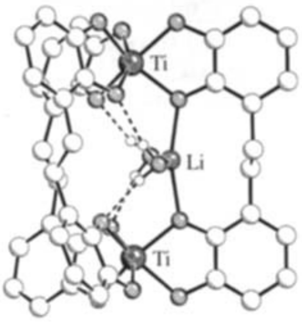
"This is a substance or group of substances about which there has been much discussion" is a statement we read in an older standard textbook of inorganic chemistry with reference to a (usually) amorphous blue material that was first mentioned by C. W. Scheele in 1778 and discussed by J. J. Berzelius in 1826, and that today is known as "molybdenum blue". Now based on the knowledge of compound **1** with an archetypal structure, the more than 200 year old mystery regarding the nature of this multifunctional material with its interesting properties has been partly unveiled.

$(NH_4)_{25\pm5}[Mo_{154}(NO)_{14}O_{420}(OH)_{28}(H_2O)_{70}]\cdot nH_2O$ **1**

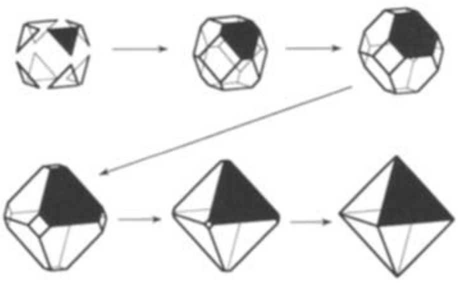
A. Müller,* J. Meyer, E. Krickemeyer,
E. Diemann 1206–1208

Molybdenum Blue: A 200 Year Old Mystery Unveiled

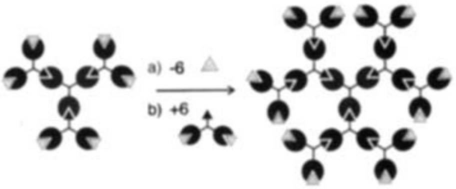
A distorted square-planar coordinated Li^+ ion is located in the pocket of the triple-stranded helicate (structure shown on the right) formed by self-assembly of three ethylene-bridged bis(catecholate) ligands, and two titanium(IV) ions. This unusual coordination geometry is the result of steric effects and stabilizing hydrogen bonds between the two water molecules bound to the Li^+ ion and oxygen atoms of the ligands.



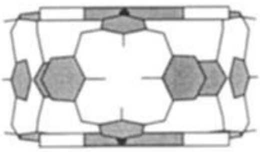
The growth of crystals of the structurally related zeolites FAU and EMT may be characterized by layer upon layer propagation. This previously proposed mechanism has been confirmed by results of an investigation into the crystal growth features in zeolite Y by atomic force microscopy. The intergrowing surfaces of the crystal (see schematic representation on the right) are constructed by the deposition of sodalite-like building units, leading to the formation of terraces.



Up to third-generation metallodendrimers can be constructed by a repetitive sequence of reactions with building blocks that contain two coordinatively unsaturated Pd centers ("pie" shape) and one labile, coordinating cyano group (▲, see representation below). The key steps of assembly are the displacement of the chloro ligands (△) with $AgBF_4$ and the in situ reaction with the cyano groups of the dendrimer building blocks to give the next generation. The resulting dendrimers have molecular masses of up to 25 kDa.



The calix[4]arene skeleton serves both as a spacer and as a molecular platform for preorganization in molecular boxes such as **1** constructed from calixarene-based melamine and isocynanuric acid derivatives, which self-assemble in double-rosette structures (shown schematically on the right). These ensembles were characterized by 2D NOESY experiments, which provide information on intramolecular H–H distances and cross relaxation rates.



The hydrolysis half-life is reduced from 75 years to eight minutes for bis(*p*-nitrophenyl)phosphate (50 °C, pH 7) when binuclear complexes like **1** are added; related complexes lead to similar effects. The cleavage of plasmid DNA is also accelerated dramatically. In these catalyzed reactions the distance between the metal centers plays a critical role.

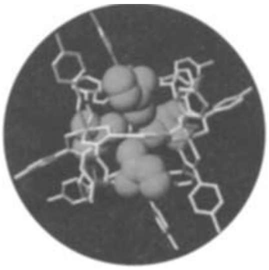
COVER PICTURE

The cover picture shows the ball-and-stick model viewed down the crystallographic S_4 axis of a tetrahedral cluster formed by the self-assembly of four gallium(III) ions (green) and six ligands (gold). The cavity of the supramolecular assembly is penetrated by four dimethylformamide molecules (red; space-filling representation). The cluster formation is driven by symmetry number incommensurate lock-and-key interactions. More about this concept and its application is reported by Raymond et al. on pages 1084ff. The picture was generated from crystal coordinates with CAChe software.



REVIEWS

Contents

Rejuvenation of an almost forgotten reaction! The application of modern free-radical techniques has revealed the significant synthetic potential of free-radical carbonylation, which was long neglected after its discovery in the 1950s. A variety of carbonyl compounds including aldehydes, unsymmetrical ketones, macrolides, and δ-lactones can be prepared efficiently often in a single step.

I. Ryu,* N. Sonoda 1050–1066

Free-Radical Carbonylations: Then and Now

The activation of molecules containing σ bonds in homogeneous and heterogeneous phases is of fundamental importance in particular with regard to conversions of hydrocarbons such CH_4. However, structurally characterized model compounds with σ-coordinated alkanes are unknown to date. The development and the current level of understanding in the field of transition metal coordinated σ bonds is presented here using selected examples. Whether the recently synthesized organometallic silane complexes exhibit model character for isolable σ-alkane complexes is also discussed.

Formation of Fe^{IV} and Ni^{IV} by Electrochemical and Chemical Oxidation of an Iron-Substituted Nickel(II) Hydroxide: The Direct Two-Electron Step $Ni^{II} \rightarrow Ni^{IV} + 2e^-$

Surprisingly stable is the dinuclear complex cation $[1CuCu]^{2+}$ with entwined ligand **1** (shown on the right; ●, ○ = Cu^+) that can be demetalated in a stepwise manner. The singly demetalated complex $[1Cu]^+$ can be converted to give dissymmetrical heterodinuclear complexes $[1CuAg]^{2+}$ and $[1CuZn]^{3+}$ (○ = Ag^+ and Zn^{2+}, respectively). The electrochemical and spectroscopic properties of these molecular knots, in which the coordinating phenanthroline groups are linked through a "conducting" phenylene spacer, differ considerably from the corresponding compounds with "nonconducting" bridges.

Bis(diisopropylamino)carbene

The lattice symmetry chiefly determines the structure of the XeF_7^- ion in $CsXeF_7$. The influence of the lone pair of electrons is here very weak, and the anion has a capped octahedral structure (C_{3v} symmetry). The dinuclear anion $Xe_2F_{13}^-$ in $NO_2Xe_2F_{13}$ can be structurally divided into an XeF_6 molecule and an XeF_7^- ion. In this case the anion XeF_7^- is a capped trigonal prism (C_{2v} symmetry).

2

Highly stereoselective, repetitive Diels–Alder reactions provide a route to novel molecular tweezers, which are excellently preorganized for the formation of complexes and for the self-assembly of side chains. Bond angle deformations, which require little energy, allow the tweezer arms to be expanded or compressed; thus, as receptors they can, to a certain extent, provide a geometrical fit to the structure of a potential substrate. The structure of a tweezer of this kind is shown schematically on the right.

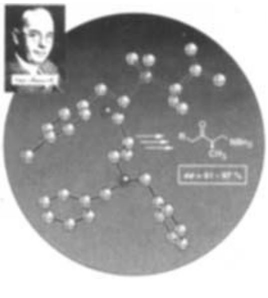
COVER PICTURE



The cover picture shows the ball-and-stick model of an α-silylated β-dibenzylamino ketone (color code: C = gray, O = red, N = blue, Si = green, and Br = claret), which is accessible in a straightforward manner from butanone and from which the corresponding amino ketone can be synthesized readily by racemization-free desilylation. This conversion can be achieved with a whole series of silylated precursors. Thus, roughly 80 years after the discovery of the aminomethylation of aldehydes and ketones by Carl Mannich, this procedure provides the first access to a practical enantioselective Mannich reaction. More about this novel synthetic route to β-amino ketones, which are of great preparative interest, is reported by D. Enders et al. on p. 981 ff.

REVIEWS

How can an enzyme accelerate a pericyclic reaction? The classical effects of solvents and catalysts, which were largely ignored by the chemical community, provide important information about the mechanism of the enzyme, and put the Claisen rearrangement in a new perspective. Nature, it seems, has been paying close attention to the chemical literature!

B. Ganem* 936–945

The Mechanism of the Claisen Rearrangement: Déjà Vu All Over Again

---

Counterintuitive product distribution results can be understood when the reaction mechanism is elucidated by kinetic analysis. Thus, the protonation of alkene complexes gives alkanes at low acid concentration and alkenes at high acid concentration, and this can be explained by pathways involving competitive protonation of the metal or the ligand. Mechanistic studies on the reactions of acids with complexes containing unsaturated hydrocarbon ligands show that the product selectivity need not be attributable to simple regioselective attack of the proton at the hydrocarbon. The ramifications of these mechanistic features on the control of the products of a reaction and their stereochemistry are discussed.

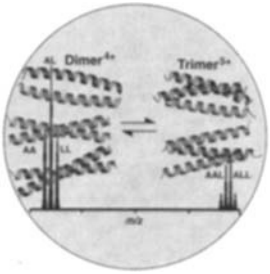
COVER PICTURE

The cover picture shows schematically the structures of dimeric and trimeric complexes of two leucine zipper peptides (designated A and L) and the assigned peaks of the molecular ions in the ESI mass spectrum. The equilibria between the three homo- and heteromeric dimers and the four homo- and heteromeric trimers are recognizable in the spectrum. The development of ESI mass spectrometry and its perspectives for analysis of supramolecular complexes are discussed by M. Przybylski and M. O. Glocker on page 806 ff.



REVIEWS

Contents

Soft ionization methods that yield singly and multiply charged ions of intact complexes containing noncovalent interactions enable the direct mass spectrometric analysis of biomacromolecular complexes such as protein dimers, double-stranded polynucleotides, enzyme–substrate and enzyme–cofactor complexes, and host–guest systems. The method of choice for analysis of supramolecular structures in solution is electrospray mass spectrometry, which is the focus of this review.

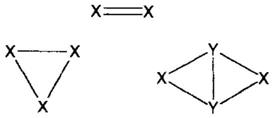
Carbon is an "exotic" element. This is the conclusion drawn following the comparison of the structures and electronic properties of olefins, cyclopropanes, and bicyclo[1.1.0]butanes with related compounds composed of the carbene-analogous elements or fragments X,Y of the heavier Group 13–15 elements (shown schematically on the right). The structures and properties of these inorganic compounds are determined by the intrinsic characteristics of the corresponding carbene analogues X:. The structural distortions in doubly bonded systems can be discussed on the basis of the Carter-Goddard-Malrieu-Trinquier (CGMT) model. Thus, rules with broad application concerning the prediction of structures and electronic character can be better derived by studying the compounds with heavy main group elements.



M. Driess,* H. Grützmacher * 828–856

Main Group Element Analogues of Carbenes, Olefins, and Small Rings

HIGHLIGHTS

The smaller the better! Capillary electrophoresis aims at ever smaller amounts of analyte, as demonstrated by the latest developments described here. Recent results fuel the ultimate dream of the chemist: to find the needle in the haystack and play with it, or to separate and identify by spectroscopy a single component in a complex mixture and subsequently manipulate it, even if it is a single molecule.

A. Paulus * 857–859

Separation, Characterization, and Fraction Collection in the Nanoliter Domain with Capillary Electrophoresis

Modulated thin layer precursor systems provide the basis for a novel rational synthesis strategy for the controlled preparation of complex metastable structures. By sequential deposition of the elements required and subsequent thermal treatment, specific superlattices with alternating composition can be synthesized. The picture shows, as an example, a niobium titanium selenide in which the niobium content increases from top to bottom (intra- and interlayer distances increase; one half of the unit cell of the superlattice is shown).

Chemo- and Diastereoselective Epoxidation of Chiral Allylic Alcohols with the Urea Hydrogen Peroxide Adduct, Catalyzed by Titanium Silicate 1

Nearly equivalent C–C distances in the five-membered ring of the dianion $C_4Me_4Si^{2-}$, which could be isolated in crystalline form as a potassium salt in the presence of [18]crown-6 (structure on the right), suggest a high degree of delocalization. In contrast, ^{29}Si and ^{13}C NMR spectroscopic investigations of the silolyl anions $C_4Me_4SiR^-$ (R = $SiMe_3$, $Si(SiMe_3)C_4Me_4$) show that delocalization in these systems is minimal.

The formation of chiral structures from achiral or racemic components is of great interest because of its implications, for example, for the origin of biological chirality. Monolayers of racemic molecules can form chiral structures, but the precise origin of these structures has been unclear. Images of both enantiomers (that of the (S) enantiomer is shown on the right) and the racemate of a liquid crystal obtained by scanning tunneling microscopy present strong evidence that the racemate forms domains of enantiomerically pure molecules.

COVER PICTURE

The cover picture shows a force microscope image of a MoO_3 nanocrystal resting on the surface of a MoS_2 single crystal. The chemical formula of the nanocrystal was highlighted by writing "MoO_3" on its surface after its components, Mo and O, were identified by atomic resolution imaging. The desired pattern was engraved with a force microscope tip by scanning across the surface with an applied load that exceeded the critical force required to break bonds between atoms as the nanocrystal was plastically deformed. After this "nanomachining", the resulting changes to the MoO_3 nanocrystal were studied nondestructively using the same force microscope tip operating at a much lower load. The ability to manipulate and study the properties of materials on the atomic to nanometer scales is discussed by C. M. Lieber et al. on pp. 686

Contents

HIGHLIGHTS

Over thirty years have passed since the pioneering work of H.-W. Wanzlick on nucleophilic carbenes. A much investigated model is the imidazolidinylidene **1**, which can be generated from dimer **2** and other substrates. The isolation of the stable carbene **3** by A. J. Arduengo III in 1991 sparked incredible developments: addition reactions with increases in the covalency and coordination of the carbene carbon atom dominate the chemistry of such molecules. Recently, Herrmann et al. reported on the use of carbenes as ligands for Pd catalysts.

Nucleophilic Carbenes: An Incredible Renaissance

High economy and simple elegance distinguish the synthesis of functionalized cyclohexadienes by dearomatization of benzene derivatives. Modern processes of this type rely on the activation of arenes in transition metal complexes (Os, Cr, Mn), additions after Lewis acid complexation, and dihydroxylations catalyzed by enzymes. Stereoselective methods [see, for example, Eq. (a)] and C–C bond forming reactions deserve particular attention.

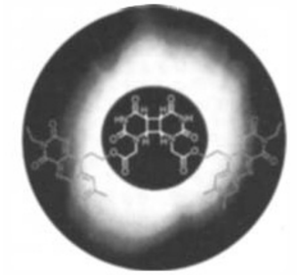
COVER PICTURE

The cover picture shows the structural formula of a uracil dimer (white) substituted with flavin units (yellow) and superimposed on a photograph of a solar eclipse (printed with permission from Eugene Aeppli, Zurich). This dimer was used to model the light-induced DNA repair reaction—the reversion of pyrimidine dimers, which are photoproducts formed on irradiation of DNA with UV light. For cleavage of the uracil dimer with light of longer wavelength (366 nm), the flavin substituents must be in reduced form; this is also a prerequisite for repair with DNA photolyase. T. Carell et al. report more on these model studies on p. 620ff.



REVIEWS

Contents

A rare anniversary gave the impetus for this review: the legendary physicist Friedrich Hund turned 100 years old on February 4, 1996. His significance for chemistry, which does not end with Hund's rules, is acknowledged and honored in this article. Hund and Mulliken cooperated on the development of MO theory, which initially stood in the shadow of VB theory, but eventually took over, becoming generally accepted. The scientific part of this article covers mainly recent insights into Hund's rules, his localization criteria, and coupling cases.

W. Kutzelnigg* 572–586

Friedrich Hund and Chemistry

What is the connection between the total synthesis of brevetoxin and the 1994 Soccer World Cup? Apparently irrelevant factors have extensive ramifications for natural product syntheses. The marine biotoxin brevetoxin B, which is responsible for mass poisoning of humans and marine life during "red tides", was the target of an intense research program in the Nicolaou group. Their perseverance paid off with a wealth of new reactions as dividends. In this "story behind the story" the author describes both the successes and failures along the way.

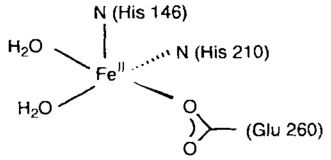
HIGHLIGHTS



Lipid dioxygenases, tyrosine hydroxylase, bleomycin, and isopenicillin N synthase are only a few of the O_2-activating mononuclear non-heme iron-containing biomolecules. In recent years a great deal of effort has been dedicated to the elucidation of the structures and the reaction mechanisms of these systems, as well as to the synthesis of model complexes. In many cases, an iron–peroxo species is proposed as a predominant intermediate. The picture on the right shows the structure of an extradiol catechol dioxygenase recently determined by X-ray structure analysis.

A straightforward synthesis provides surprisingly stable, neutral and anionic μ_3-imidorhodium clusters. The unusual complex $[Rh_4(\mu\text{-}MeC_6H_4N)_2(cod)_4]$, whose structure is shown on the right, contains two bridging imido ligands that cap a triangle of metal atoms. One of these ligands, in addition, coordinates through the *p*-tolyl ring to a [Rh(cod)] moiety in a η^5-cyclohexadienyl-like fashion. cod = 1,5-cyclooctadiene.

In two consecutive one-electron oxidations, oligopyrroles substituted with phenyl capping groups ($PhPy_nPh$, $n = 2-4$) can be oxidized reversibly to give stable cation radicals and dications. Spectroelectrochemical studies give direct evidence that diamagnetic π-dimers of cation radicals are formed in solution. Such dimers may be involved as charge carriers in conducting polypyrrole.

π-Dimers of End-Capped Oligopyrrole Cation Radicals

The number and availability of starting compounds determine the structure diversity possible in a multicomponent reaction. For example, in a set of parallel reactions an amino-functionalized resin (P) was treated with 8 aldehydes, 12 carboxylic acids, and 1 isocyanide to provide 88 of the desired α-acyl amino amides [Eq. (a)]. Additional isocyanides not available commercially can be prepared from α-lithiated benzylisonitrile and used without purification. R^1, R^2 = alkyl, aryl.

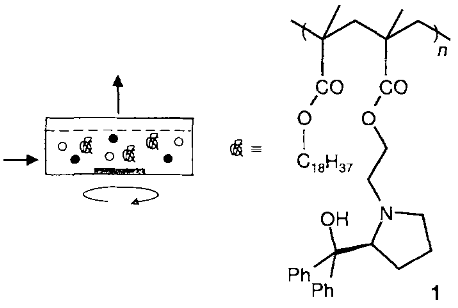
Adapted from biocatalytic reactions the principle of the membrane reactor (represented schematically on the right) is applicable to the continuous asymmetric addition of diethylzinc to benzaldehyde. α,α-Diphenyl-L-prolinol is coupled to a homogeneously soluble polymer (**1**), which enables it to be retained in the reaction vessel by an ultrafiltration membrane. By decoupling the residence time of reactants and the catalyst the total turnover number could be increased by a factor of 10.



U. Kragl,* C. Dreisbach 642–644

Continuous Asymmetric Synthesis in a Membrane Reactor

Ammonium and borate substituents polarize π-electron systems, which then exhibit internal CT bands in the UV/Vis spectrum. These systems (for example **1**) are distinctly more transparent than analogous push–pull-substituted compounds. Since their first-order hyperpolarizabilities are nevertheless similar to push–pull compounds, they are better suited to applications for second harmonic generation.

Gesellschaft
Deutscher Chemiker
International Edition in English
1996
35/5
Pages 465–560

EDITORIAL

Twelve monthly issues make up a volume, and with this first March issue of *Angewandte Chemie* you are receiving the twelfth issue of *Chemistry—A European Journal.* We are actually well into our second volume (nine issues must suffice for the first), but it seems appropriate to give an update on the current status of the two journals. Fraser Stoddart, a strong advocate of *Chemistry – A European Journal*, echoed the reaction of many readers to its inception when he claimed it was "the most significant positive development in the academic publishing business surrounding chemistry as a discipline in a long time." The overwhelmingly positive response is further documented in the following excerpt from a letter we received from K. Wieghardt. Looking ahead he maintains, "The future of this journal depends on how fast the number of printed, first-rate papers can be increased. The volume should quickly be doubled and tripled, but of course not at the expense of quality."

The editorial office has responded to this cry of "we want more" in the first three issues in 1996, and readers will not be disappointed with future contents. In this way we have been able to reduce the rather long publication times that had resulted from the enthusiatic response of authors to first call for papers for the "European Journal". Our goal is to publish manuscripts within three to four months of their final acceptance. Test us with your next top-notch full paper!

Now the interim report on *Angewandte Chemie*: In 1995 the editorial office received 47 reviews, 46 highlights, 1090 communications, and roughly 100 book reviews; 45 reviews, 43 highlights, 533 communications, and around 90 book reviews were published. Most of the reviews, highlights, and book reviews were submitted on invitation; however, we also welcome unsolicited manuscripts for these sections.

Of the 1090 communications received in 1995 (1005 in the previous year, +8 %), 715 (606, +18 %) came from outside of Germany. In mid-February the fate of only about 30 communications submitted in 1995 was still undecided; 566 (52 %) had been rejected. Over the past few years German authors have consistently submitted 300 to 400 communications annually; in 1995 they accounted for 375. The distribution of manuscripts from foreign contributors and its development over the past years are given in Table 1.

Table 1. Origin of manuscripts submitted from outside of Germany.

Country	1995	1994	1989
USA/Canada	225	185	66
Far East [a]	130	87	36
United Kingdom	76	63	28
France	54	57	28
Spain	41	38	19
Italy	37	30	15
Switzerland/Austria	36	43	21
Netherlands	22	22	9
Other	53	47	24

[a] Japan, Korea, China, Hong Kong, and Taiwan.

At the end of every year the Institute of Scientific Information discloses the Impact Factors and Immediacy Indices for the previous year. The trend here is also very positive (Table 2). The Impact Factors of *good* "review journals" are naturally high, and *Angewandte Chemie* profits from this trend. (Impact Factors of the life sciences journals are generally three times higher than those of chemistry journals because many more research groups exist in each specialty.) The Immediacy Index, which is

0570-0833/96/3505-0467 $ 15.00+.25/0

defined as the average number of times a publication is cited in the year in which it is published, is 1.58 for *Angewandte Chemie*, 1.80 for *Chem. Rev.*, 1.61 for *Acc. Chem. Res.*, 0.94 for *J. Am. Chem. Soc.*, 0.53 for *Chem. Commun.*, and 0.46 for *Chem. Soc. Rev.* Put simply, on average *each* publication in *Angewandte Chemie* is cited one to two times in the same year.

Table 2. Impact Factors of a number of important chemistry journals.

Journal	Impact Factors			
	1994	1993	1989	1984
Angew. Chem.	6.327	6.168	5.049	4.007
J. Am. Chem. Soc.	5.039	5.365	4.415	4.43
Chem. Rev.	14.24	15.748	9.656	8.024
Acc. Chem. Res.	9.126	10.879	7.419	7.653
Chem. Soc. Rev.	4.913	6.152	4.406	5.75
Chem. Commun.	2.575	2.54	2.223	2.437

The positive development reflected in all of these numbers led—in complete contrast to trends for most scientific journals—to an increase in the number of personal subscribers in 1995. This growth in individual subscriptions can be ascribed predominantly chemists outside of Germany. The excellent value of *Angewandte Chemie*, which is expressed in hard numbers in Table 3, may be one explanation.

Table 3. Costs of chemistry journals 1993 [a].

Journal	US \$ per 10^6 characters	Cost per unit Impact Factor
Angew. Chem. [b]	43.09	92.97
J. Am. Chem. Soc. [b]	9.51	196.64
Chem. Commun. [b]	66.98	329.13
Chem. Ber. [b]	57.25	549.69
Tetrahedron	145.29	3604.24
Inorg. Chem. Acta	174.08	2141.08

[a] From an article by J. Christman in *Chem. Ind. (London)* **1995**, 2236. [b] Journals published by a scientific society.

What lies ahead? In 1996 *Angewandte Chemie* and *Chemistry—A European Journal* will also make their debut on the World Wide Web. We plan to present our Tables of Contents and several other items, but more on this subject later. A number of journals are now available on CD-ROM. In a survey of readers/users of *Angewandte Chemie* in 1994 we found that interest in this format was not as high as some might have thought. But we continue to make preparations for developments in this direction. VCH is working in cooperation with the German Chemical Society (GDCh) on a project supported by the German Ministry of Education and Science ("The electronic publishing house"). The eventual goal is that every step, from submission of a manuscript (such an antiquated word!) to distribution and reading of the final product, proceeds electronically and without any abrupt change in media. We should not forget, however, that the quality of a journal in whatever format depends on people. A journal is the product of *authors* who write *good* manuscripts, *referees* who frequently contribute to further improving these manuscripts, and finally *editors* who strive for an optimal, reader-friendly presentation. The print medium is far from dead. Scientific journals such as *Angewandte Chemie* are read in the lab, in the office, at home, and during trips...

The editorial office now relies heavily on the most rapid means of communication. The majority of the referee reports are sent in by fax or e-mail. Of course, the rate-determining factors in the publication process remain the writing of the manuscript, the careful refereeing, and the frequently requested revision. The majority of communications last year were published four to five months after *initial submission.* In one extreme case we published a manuscript within four weeks—but that is pushing the referees, editors, and printers to their limits.

The main goal of *Angewandte Chemie* and *Chemistry—A European Journal* in 1996 continues to be rapid publication of excellent papers from all areas of chemistry. But we will not cut corners on our reader-friendly presentation. On the contrary, additional small improvements are planned. We introduced "keywords" this past year, which are intended to direct the reader to articles of interest quickly, and which also facilitate production of the yearly index. Frontispieces (large pictures at the beginning of each review and at the front of the communication section) will soon be in each issue. Chemists are visual people, and often a figure or a formula can convey much more than words can. We are eager to know how you receive this innovation. We encourage authors to give suggestions for these pictures as well as for the cover picture.

"The 20th century is the century of productivity. The 21st century will be the century of quality" was a recent prediction. At *Angewandte Chemie* and *Chemistry—A European Journal* we are prepared! We look forward to receiving your next manuscript!

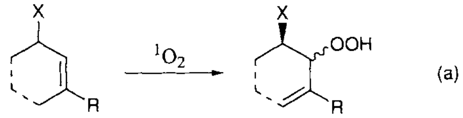
Peter Gölitz

COVER PICTURE

The cover picture shows the structure of the subnitride $Na_{14}Ba_{14}CaN_6$. Ion clusters (blue) of the composition Ba_8CaN_6 with a perowskitelike arrangement of atoms—Ca-centered Ba_8 cubes surrounded by N atoms above all faces—are dispersed in a metallic matrix (red) of sodium and barium. More about this compound, which can be considered a salt dissolved in a metal, is reported by U. Steinbrenner and A. Simon on p. 552 ff.

REVIEWS

The obstinate singlet oxygen can be tamed by a number of factors: steric, stereoelectronic, electronic, and conformational effects of the functional group X play an important role in controlling the direction of the attack of singlet oxygen on alkenes [Eq. (a)]. This unfortunately rarely employed reaction, the Schenck ene reaction, yields diastereoselectively oxyfunctionalized compounds—useful intermediates in organic synthesis. X = hydroxyl, amino, halogen, ether, ester, sulfoxide, sulfone.



M. Prein, W. Adam* 477–494

The Schenck Ene Reaction: Diastereoselective Oxyfunctionalization with Singlet Oxygen in Synthetic Applications

---

Simpler to apply than the original model and supported by the analysis of electron density distributions with the Laplacian operator, the reformulation of the VSEPR model of molecular geometry presented here is based on the concept of electron domains. In this form it is suitable as foundation for a qualitative understanding of the geometry of a large number of molecules, including those of metal compounds. Analyses of the valence and core electron densities with the Laplacian operator often also yield plausible explanations why some molecules do not have the structure predicted by the VSEPR model.

Electron Domains and the VSEPR Model of Molecular Geometry

HIGHLIGHTS

Structural design in the synthesis of solids is now a step closer, at least for mesoporous compounds. Surfactant assemblies are used as templates to structure metal oxides, which are formed from metal alkoxides. By adapting the headgroup of the surfactant to the inorganic component and exploiting the coordination chemistry of the metal atoms in the alkoxides, a wide range of mesoporous metal oxides, including alumina, titania, niobia, and zirconia, becomes available.

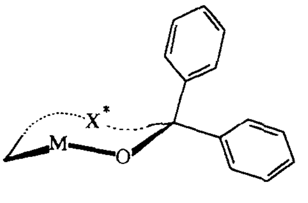
Increasing stereoselectivity in numerous recently developed methods of asymmetric synthesis is possible with the diarylhydroxymethyl group, which is typically employed in deprotonated form as a ligand in metal complexes. In the transition state of these reactions the geminal aryl groups are apparently fixed in a chiral conformation owing to the influence of a permanent stereogenic center X*. A schematic representation of this type of metal catalyst is shown on the right.



M. Braun* 519–522

The "Magic" Diarylhydroxymethyl Group

α,β-Epoxytriflates like epoxytriflate pyranoside **1** undergo rearrangement in a one-pot reaction after treatment with pyridine. The epoxy ring is opened giving N-vinylpyridinium derivatives such as **2**, which can be reduced with NaBH$_4$ and hydrolyzed under acidic conditions to give β-hydroxy ketones. This generally applicable procedure can be used to convert easily accessible epoxypyranoses into deoxyketo sugars like **3** in high yields.

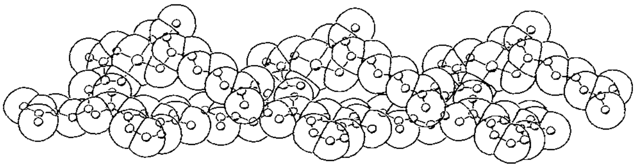
The dianion is the key! Complexes of the type [Cu(Arg)$_2$](L)·nH$_2$0 (L = aromatic dicarboxylate, n = 5,6) formed by self-assembly show double-helical structures in the solid state, which comprise infinite [Cu(Arg)$_2$]$^{2+}$-L^{2-} strands (shown schematically below). In these, the dianions function as bridging ligands, bound through guanidinium–carboxylate pairs, between the complex cations and read the information of handedness coded in the [Cu(Arg)$_2$]$^{2+}$ units.



N. Ohata, H. Masuda, O. Yamauchi* 531–532

Programmed Self-Assembly of Copper(II) -L- and -D-Arginine Complexes with Aromatic Dicarboxylates to Form Chiral Double-Helical Structures

High yields and only traces of side products are possible in the synthesis of epoxides by oxidation of alkenes when the urea/hydrogen peroxide adduct (UHP) is used as the oxygen donor in the methyltrioxorhenium(VII)-catalyzed reaction (see below). Chiral allylic alcohols with 1,3-strain were employed as stereochemical probes; the high *threo* diastereoselectivities obtained allow important mechanistic insights into the oxygen transfer process.

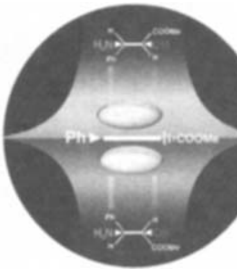
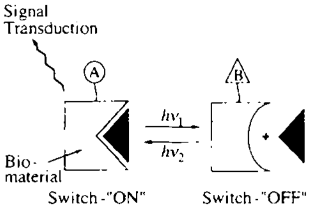
COVER PICTURE



The cover picture shows the catalytic asymmetric aminohydroxylation (AA) of alkenes in action. Methyl cinnamate can be transformed directly into a derivative of the taxol side chain with the catalyst system $K_2OsO_2(OH)_4$ and a phthalazine ligand; Chloramine T serves as the nitrenoid source. Either enantiomer can be produced at will by selection of the appropriate ligand. The asymmetric aminohydroxylation (AA) follows the development of the asymmetric epoxidation (AE) and the asymmetric dihydroxylation (AD)—three reactions whose importance for organic synthesis cannot be overstated. Li, Chang, and Sharpless report more on the new catalytic AA on p. 451 ff. (The cover picture was created by Michael E. Pique, The Scripps Research Institute, La Jolla, CA, USA.)

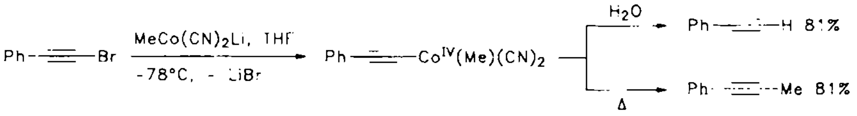
REVIEWS

Contents



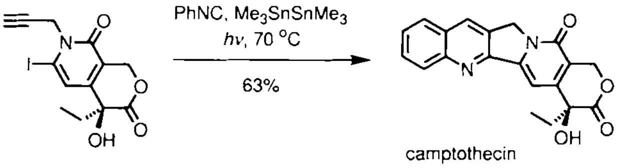
Two methods of making biomaterials photoswitchable are presented here: the covalent linkage of photoisomerizable components (A ⇌ B) to biomolecules and the interaction of the biomaterials with photoswitchable microenvironments. The diagram on the right illustrates the first principle with the formation and dissociation of, for instance, an enzyme–substrate or antibody–antigen assembly. In the isomer state A the bioactive structure of the biomaterial is retained, and formation of the complex with the substrate is activated. In the photoisomer state B the active site is distorted, and dissociation is induced. Such modified compounds form the basis of opto-bioelectronic devices.

The willingness to undergo oxidative addition of electrophiles, the high selectivity, and several unexpected reactions are responsible for making the title compounds, which had been disregarded or unknown for a long time, widely applicable, mild alkylating reagents. For example, (E,Z)-β-fluorostyrene can be converted with Me_4CoLi_2 into (E,Z)-1-phenylproprene in 92% yield. The reaction of bromophenylacetylene with $MeCo(CN)_2Li$ (see below) shows other possibilities.



HIGHLIGHTS

A prime example of applied radical chemistry is the last step of Curran's total synthesis of the antitumor agent camptothecin (below). This and other key sequences demonstrate the importance of radical reactions in natural products chemistry.



U. Koert* 405-407

Radical Reactions as Key Steps in Natural Product Synthesis

Very different ligands have been employed recently for enantioselective hydrogenation. With rhodium phospholane complexes, not only the usual, but also highly substituted enamides such as **1** and acylhydrazones can be hydrogenated. With ruthenium complexes containing chiral amino alcohols, ketones can be converted into the corresponding alcohols with high enantioselectivities.

Novel chain extensions of [{Re*}−C≡C−C≡C−H] ({Re*} = (η^5-C_5Me_5)Re(NO)(PPh_3)) with alkyne or diyne building blocks lead to rhenium-capped oligomers of up to 20 sp carbon atoms (shown on the right, *n* = 6, 8, 10). This methodology allows, for the first time, access to such materials with a homogeneous chain length.

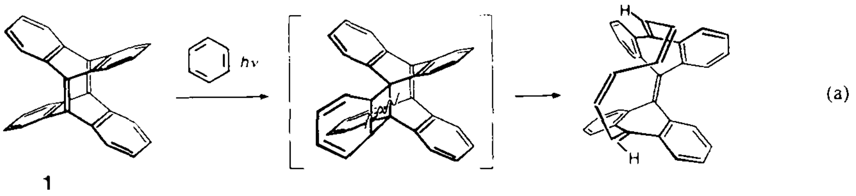
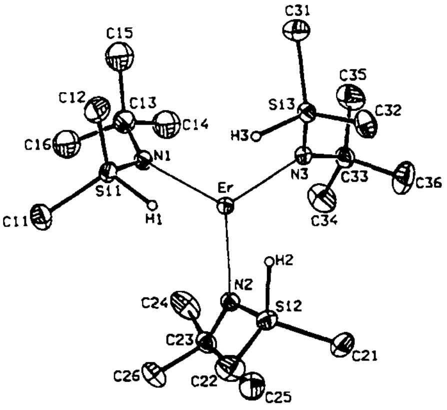
A Step-Growth Approach to Metal-Capped One-Dimensional Carbon Allotropes: Syntheses of C_{12}, C_{16}, and C_{20} μ-Polyynediyl Complexes

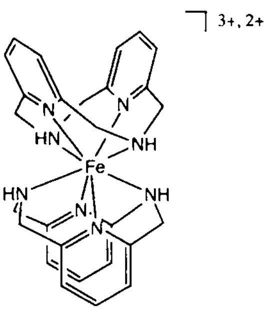
Relief of strain is the driving force for the [2 + 2] cycloaddition and subsequent [2 + 2] cycloreversion of **1** with both open-chain and cyclic alkenes. The metathesis can even be performed with benzene as the olefin component [Eq. (a)]. The product can be roughly described as a ribbon- or beltlike conjugated system.



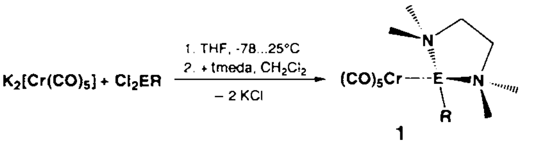
All the *tert*-butyl groups of $[Er\{N(tBu)[Si(CH_3)_2(H)]\}_3]$ (structure shown on the right) reside on the same face of the N_3 plane, whereas all $Si-CH_3$ groups are rotated toward the periphery of the molecule. This results in Er–H interatomic distances of 231.7–236.7 pm for the Si–H moieties folded in toward the metal center.



Eight-coordination and identical ligand environments have been unequivocally established in the pair of stable iron(II) and iron(III) complexes shown on the right. The synthesis, structures and electrochemical properties of these iron complexes are presented here, together with some Mössbauer spectroscopic data on the iron(II) complex.



Redox reactions in the initial products formed from $K_2[Cr(CO)_5]$ and Cl_2ER (E = Al, Ga; R = Cl, alkyl) lead to the formation of aluminum(I) and gallium(I) transition metal complexes of type **1** (shown below) that are surprisingly stable. Stoichiometric CrGa films were prepared from **1** (E = Ga, R = CH_2CH_3) by MOCVD. tmeda = *N,N,N′,N′*-tetramethylethylenediamine.



Since the porous structure is completely retained upon surfactant removal, Nb-TMS1, a hexagonally packed mesoporous transition metal oxide, is an interesting molecular sieve. The synthesis of this material was accomplished by a novel route in which the inorganic precursor **1** and the surfactant **2** were attached by a covalent Nb–N bond; this bond is probably retained throughout the course of the synthesis.

$Nb(OEt)_5$ **1** $C_{14}H_{29}NH_2$ **2**

Enantiomeric excesses of up to 82% are obtained for the α,α-disubstituted products **4** arising from alkylation reactions of borane–amine adducts **2** and **3**, which have a chiral nitrogen atom. The structure of diastereomer **2**, which can be obtained selectively in the boration of **1**, has been established by single-crystal X-ray analysis.

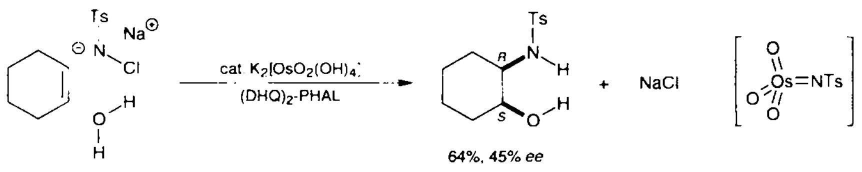
A New Ligand Class for the Asymmetric Dihydroxylation of Olefins

---

The stereospecific *cis* addition of "TsN" and H_2O yields α-hydroxy-*N*-tosylamines (see below). This osmium-catalyzed process, which depends on Chloramine-T as the nitrenoid source, is rendered asymmetric in the presence of cinchona alkaloid ligands. The selectivities for reactions of the six olefins studied range from 33% *ee* (*cis*-stilbene) to 81 % *ee* (*trans*-methylcinnamate). The active agent is presumably the compound $Os(O)_3NTs$ shown in square brackets. $(DHQ)_2$-PHAL = bis(dihydroquininyl)phthalazine (see preceding communication).



G. Li, H.-T. Chang,
K. B. Sharpless* 451–454

Catalytic Asymmetric Aminohydroxylation (AA) of Olefins

Replacing the tosyl with a nosyl (Ns) group—that is the key to an improved method for both allylic amination of olefins and 1,2-diamination of 1,3-dienes. The protecting group recently introduced by Fukuyama et al., the *o*-nitrobenzenesulfonyl (nosyl) group, can be employed with diimidoselenium reagents. The resulting nosylamides can be converted into primary and secondary amines in good to excellent yields. An example of this approach is sketched below in reaction (a) (R = Me, CH_2CHCH_2, CH_2Ph).

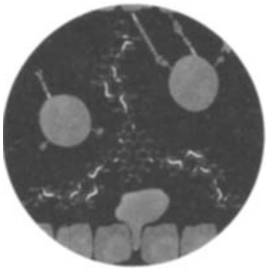
COVER PICTURE



The cover picture shows schematically how leukocytes from the blood stream bind to activated endothelium during inflammation processes and are finally extravasated into the surrounding tissue. The first step is the interaction of glycoproteins on leukocytes with adhesion molecules on the endothelium (P-, E-selectin). The tetrasaccharide sialyl Lewis^X has been identified as the binding epitope in complex glycoproteins, which are bound through carbohydrates to the selectins. Trivalent glycopeptides like that in the middle of the picture, which present three sialyl Lewis^X units, were synthesized by H. Kunz et al. with the goal of achieving improved receptor affinity. The authors describe the results of the adhesion tests and the synthesis of the glycopeptides on pages 321–324.

Still more can be expected from the Horner–Wittig reaction. Not only regioselective but also stereoselective Horner–Wittig additions and eliminations are possible with the bulky, anion-stabilizing Ph_2PO group. For example, alkenes having chiral centers on opposite ends of stereochemically defined double bonds can be constructed. Decisive advantages in these syntheses: Ph_2PO compounds are simple to purify, and diastereomeric β-hydroxy phosphane oxide adducts are easily separated.

A Freely Hinged Macrotricycle with a Molecular Cavity

$[C(OR)_3]^+$ ions are stabilized differently than $[C(XR)_3]^+$ ions (X = S, Se, Te). While the stability of the RO-substituted carbenium ions can be attributed to the high polarity of the $C^{\delta+}-O^{\delta-}$ bond, the polarity of the C–X bond in the homologous S-, Se-, and Te-containing ions is reversed, and the stabilization is achieved by the σ- and π-dative effect of the chalcogen centers. These results were obtained by ab initio calculations on $[C(XH)_3]^+$ ions and by experimental studies on the new compounds $[C(XR)_3][PF_6]$ (X = S, Se, Te; R = 2,4,6-iPr$_3C_6H_2$).

COVER PICTURE

The cover picture shows a methanol molecule interacting with an acid site (AlOH) in the cage of a silicon-rich sodalite (Si = blue, O = red, Al = yellow, C = green, H = white). The spheres representing the alcohol and the acidic site have been enlarged by a factor of two for reasons of clarity, and the methanol molecule is surrounded by an isosurface of its electron density. The dynamic behavior of the alcohol at finite temperature is crucial for the understanding of many catalytic processes. These state-of-the-art computer simulations that provide new insights into the microscopic mechanism of the interaction of methanol with molecular sieves are discussed by E. Nusterer, P. E. Blöchl, and K. Schwarz on p. 175ff.

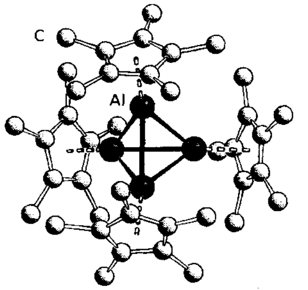
A highlight in the rapidly developing field of Al^I and Ga^I compounds is the synthetic work with high-temperature molecules such as AlCl and GaCl at low temperature. Halides such as $[Al_4Br_4(NEt_3)_4]$ and $[Ga_5Cl_7(OEt_2)_5]$, and organometallic compounds such as [GaCp*] and $[Al_4Cp^*_4]$ (shown on the right) have been prepared, and their structures have been characterized unambiguously.



The atoms shape the properties of the molecules that are constructed from them. This assumption is the fundemantal idea behind the attempt to define electronegativities of atoms, and particularly of atomic (hybrid) orbitals, in a form that enables successful predictions of molecular properties without large theoretical effort. As examples, the comparisons between experimentally determined and theoretically predicted bond energies and force constants of bonds, amongst others, are described.

The search for simple and pharmacologically active enediynes should be considerably facilitated by a new sequence leading to acyclic and also cyclic enediynes, which proceeds via a carbenoid intermediate. The recently reported intramolecular variant yields functionalized enediynes on a multigram scale from readily accessible starting materials in yields of up to 95%.

New, Efficient Routes to Cyclic Enediynes

The first X-ray analysis of a B_{12} protein, the B_{12}-binding domain of the methionine synthase of *Escherichia coli*, led to a surprising finding: there the B_{12} derivative, methylcobalamin, is not bound in the "base-on" form present in solution and in the crystal. Instead a histidine residue coordinates at the cobalt center of the protein-bound cofactor in place of the nucleotide function.

A direct view of a single methanol molecule as it interacts at finite temperatures with the acid site of a zeolite catalyst is obtained from molecular dynamics simulations. The results agree with experimental IR spectra, change the previously held notion of mechanisms of reactions in zeolites, and explain how the silicon-to-aluminum ratio of the framework influences the mode of adsorption for methanol in zeolites. One of the structures calculated is shown schematically on the right.

Single-Chain Polyprenyl Phosphates Form "Primitive" Membranes

Ti- and V-containing amorphous glasses with inner surfaces of several hundred m^2g^{-1} and pore diameters of 0.7 nm can be prepared by a sol–gel process. Like zeolites, these amorphous microporous mixed oxides AMM-M_xSi show catalytic shape-selectivites. The epoxidation of alkenes with *tert*-butylhydroperoxide on Ti-containing glasses is catalyzed size-selectively. In the hydrocracking test of decane, these materials show a product distribution that indicates the presence of Brønstedt centers in a shape-selective environment, as well as tubular pores, the lack of additional cavities, and an effective pore size comparable to those of 10- and 12-ring zeolites.

Ninety chiral centers and a molecular mass of 11354 Da are the outstanding features of the largest C_3-symmetric, chiral dendrimer to date. As general approach to these chiral polyether compounds 1) styrenes or stilbenes are converted into 1,2-diols by asymmetric dihydroxylation; 2) the resulting building blocks are then linked together to form dendrons by a uniquely effective ether-forming reaction, in which the vincinal hydroxyls are alkylated with benzylic bromides by using KOH pellets in refluxing toluene; 3) the dendrons are coupled to a core unit such as 1,3,5-benzenetricarbonyl trichloride.

A lithium-containing intermediate 1 can be isolated in the synthesis of a trigermole from 1,1-dichlorotetraethylgermole. NMR and X-ray diffraction studies reveal that one Li cation is part of a lithocene structure, while the second is in an environment similar to common organolithium compounds. In the solid state, the second lithium center is tetrahedrally coordinated to two nitrogen atoms of TMEDA, the oxygen atom of THF, and the Ge atom of one of the π-complexed germole rings.

COVER PICTURE

The cover picture shows a space-filling model of the anionic cesocene triple-decker complex $[Cp_3Cs_2]^-$. The Cs centers in this strongly bent molecule are highly ionic. The chemistry of anionic metallocenes of main group elements is a rapidly growing field and such metallocenes are structurally as well as theoretically of interest. Mixing cyclopentadienyl alkali metal compounds with cyclopentadienyl anions results in degradation of the CpMCpM polymer chains into smaller units such as $[Cp_2M]^-$ and $[Cp_3M_2]^-$. A structural comparison of these alkali metallocene complexes with the isovalent neutral alkaline earth metallocenes gives additional information on the still not well-understood bonding characteristics. The picture was painted by Peter Brinkmann, Universität Konstanz, using a technique that combines pastels and watercolors. Chemetall GmbH, Frankfurt/Main (Germany), is kindly acknowledged for providing the funding for the color print. Further details on the structure of this complex are reported by S. Harder and M. H. Prosenc on p. 97ff.

REVIEWS

Contents

The advantages of solid-phase synthesis have been recognized by organic chemists, who have adapted numerous well-known reactions for application with immobilized substrates. For example, a polymeric support may act as a protecting group for one functional group of a compound while a second functional group is derivatized. In other applications combinatorial syntheses on supports provide access to libraries of nonpeptides from collections of building blocks. This strategy is essential for supplying new compounds for modern automated screening assays used in the search and optimization of lead structures for drugs.

Organic Chemistry on Solid Supports

Mutual stimulation of ideas in biochemistry, medical practice, and inorganic chemistry has led to the discovery of many molecular details of the biological functions of copper, an essential element in nature. Copper probably became significantly bioavailable only rather late in the evolution of life. This and the unique redox and coordination properties closely link the redox pair Cu^{II}/Cu^{I} with the metabolism of O_2 and with radical ligands.

Copper—A "Modern" Bioelement

HIGHLIGHTS

Even 130 years after its discovery, the pinacol coupling [Eq. (a)] still has plenty of new variants. New reagents have been developed that are suitable not only for the elegant synthesis of 1,2-diols but also for the formation of amino alcohols. This powerful reaction has been used in numerous natural product syntheses.

The reduction of a carbonyl to a methylidyne ligand in the reaction sequence below proceeds readily via the unsaturated hydroxycarbyne complex $[W_2(\mu\text{-COH})(CO)_2(\mu\text{-dppm})Cp_2]^+$, the unexpected protonation product of a neutral carbonyl complex. dppm = $Ph_2PCH_2PPh_2$.

O-Protonation at a Neutral Ditungsten Carbonyl Dimer to Give a Stable Hydroxycarbyne Complex

---

Two types of metal are essential for some reactions! The first efficient catalyst for asymmetric tandem Michael–aldol reactions is the heterobimetallic complex **1**, which is easily prepared from $LiAlH_4$ and (*R*)-2,2′-dihydroxy-1,1′-binaphthyl. The cascade reaction of diethyl methylmalonate, cyclopentenone, and 3-phenylpropanal affords the three-component adduct **2** in 64% yield and 91% *ee*.

A New Multifunctional Heterobimetallic Asymmetric Catalyst for Michael Additions and Tandem Michael–Aldol Reactions

---

Since it can be removed under extremely mild conditions and with complete selectivity by choline esterase, the solubilizing choline ester function is advantageous for high-yielding peptide syntheses. This enzyme-labile protecting group was employed in the synthesis of the S-palmitoylated and S-farnesylated C-terminal lipohexapeptide of the human N-*Ras* protein.
