Back to copper: The Rh-catalyzed reactions of diazocarbonyl compounds with amines, leading to N–H insertion products, have found wide application. However, an enantioselective variant has remained elusive. A return to copper catalysis, first reported for carbene N–H insertions over 50 years ago, in the presence of chiral ligands and a large non-coordinating counterion, has resulted in enantioselective N–H insertion into anilines.

Trifluoromethylboranes and -Borates:
New Synthetic Strategies and
Applications

Sought for weak coordination: The first synthesis of the $[B(CF_3)_4]^-$ ion by fluorination of the $[B(CN)_4]^-$ ion marks the beginning of a new development in the field of B- CF_3 chemistry. In concentrated sulfuric acid one of the CF_3 groups is

transformed into a CO ligand. The borane carbonyl $(CF_3)_3BC\equiv O$ is a reactive species and excellent starting material for the synthesis of various $(CF_3)_3B$ compounds, for example, the pnictogeneethynyl complexes $[(CF_3)_3BC\equiv Pnic]^-$ (Pnic = N, P, As).

Communications

Tri-, bi-, and monoradicals: The reactivity of a σ,σ,σ -triradical, 2,4,6-tridehydropyridinium cation, was compared with that of related mono- and biradicals in a Fourier transform ion cyclotron resonance mass spectrometer. The triradical has a doublet ground state and contains three interacting radical sites. The reactivity of the triradical more closely resembles that of related monoradicals than related biradicals.

Tridehydrobenzenes

Concise Total Synthesis of Cruentaren A

Converging on the target: The highly cytotoxic F-ATPase inhibitor cruentaren A constitutes an interesting lead in the quest for innovative chemotherapeutic agents for the treatment of various diseases, including cancer. Its synthesis was achieved in an overall yield of 3% by an expeditious convergent route involving a ring-closing alkyne metathesis reaction (RCAM) for the formation of the macrocyclic ring (see picture).

Shape-Controlled Nanoparticles

B. Lim, Y. Xiong, Y. Xia* _____ **9279–9282**

A Water-Based Synthesis of Octahedral, Decahedral, and Icosahedral Pd Nanocrystals

Shapes from water: Pd nanocrystals with controllable shapes are synthesized by reducing a Pd salt with citric acid in aqueous solution. Citric acid favors the formation of octahedra, icosahedra, or decahedra (see picture) owing to its strong binding to the {111} facets of Pd. Shape control of these nanocrystals is readily accomplished by adjusting the amounts of Na_2PdCl_4 precursor and citric acid added to the reaction mixture.

Hyperextension: A hydrogen-bonded, dimeric capsule can be expanded with four, eight, or twelve glycoluril spacers (see picture) that increase the cavity's volume by up to 530 Å³ and its length by up to 21 Å. The extended assemblies are

chiral and encapsulate a variety of normal alkanes. The expanded capsules suggest that increasingly complex capsules may emerge from other spacers with hydrogen-bonding capabilities and curved surfaces.

Extended Capsules

D. Ajami, J. Rebek, Jr.* — 9283 – 9286

Longer Guests Drive the Reversible Assembly of Hyperextended Capsules

Chiral assemblies of achiral molecules:

High-resolution STM images of zwitterionic organic dipoles deposited on Si(111)-7×7 show a chiral molecular assembly on this surface (see picture). Density functional calculations demonstrate that a sulfonato group can act as an electrostatic shield that protects the π skeleton of organic molecules from the dangling bonds of semiconductor surfaces, which is a major advance in the deposition of π -conjugated molecules.

Silicon Surface Chemistry

Y. Makoudi, M. Arab, F. Palmino, E. Duverger, C. Ramseyer, F. Picaud, F. Chérioux* — 9287 – 9290

A Stable Room-Temperature Molecular Assembly of Zwitterionic Organic Dipoles Guided by a Si(111)-7×7 Template Effect

Freedom of choice: Both enantiomers of free homoallylic amines with two stereogenic centers (including a quaternary center) can be prepared at will from vinyl copper intermediates derived from either a vinyl iodide or an alkyne (see examples; the sulfinyl group is cleaved readily under mild acidic conditions). In this one-pot strategy, zinc homologation of the vinyl copper species is followed by treatment with a sulfinylimine derivative.

Asymmetric Synthesis

G. Kolodney, G. Sklute, S. Perrone, P. Knochel, I. Marek* — 9291 – 9294

Diastereodivergent Synthesis of Enantiomerically Pure Homoallylic Amine Derivatives Containing Quaternary Carbon Stereocenters

Working together: Synergy between Michael addition and S_N2' displacement allows stabilized carbanions or the nucleophilic carbon atoms of enamines to undergo intramolecular addition to an α,β -unsaturated ester unit bearing an

allylic leaving group to generate unsaturated carbocycles (see scheme). The starting esters are available by a selenium-based alternative to the classical Baylis–Hillman reaction, and complex structures can be assembled.

Synthetic Methods

B. Prabhudas, D. L. J. Clive* — 9295 – 9297

All-Carbon Intramolecular Conjugate Displacement Reactions: An Effective Route to Carbocycles

Solid-Phase Methods

W. Seufert, Z. Q. Beck,

Corrigendum

The authors of this Communication wish to alter the proposed structure of annulene **1**, a system that had previously been reported by Yamaguchi et al.^[1] After one of the authors (F.M.M.) had originally inspected the then available analytical data (¹H and ¹³C NMR spectra, elemental analysis, and ESI-MS data), he affirmed that they were (and still are) consistent with the annulene system. In particular, parent mass spectral signals at *m/z* 531.44353, 587.50648, and 643.56867 for the R = C₁₂H₂₅, C₁₄H₂₉, and C₁₆H₃₃ derivatives, respectively, all correspond to the mass of [1–Cl]⁺. Recently, however, Prof. M. Christl suggested^[2] that the pyridinium salt **2** would be an alternative and more likely possibility. There exists an intriguing ambiguity in this case because **1** and **2** have indistinguishable NMR spectra and elemental analyses and because our [1–2 Cl]²⁺ base peak and the [2–Cl]⁺ parent peak happen to have identical masses. We are now able to differentiate the two structures through weak ¹³C-containing MS signals. These signals have a shift one mass unit higher than the all-¹²C signal (consistent with [2–Cl]⁺) as opposed to 0.5 units higher (consistent with [1–2 Cl]²⁺). In view of these new data, our peaks at *m/z* > 500 must, we surmise, arise from dimers of **2** in the gas phase. Fortunately, the altered identity of the compound in no way affects our high-level calculations on the annulene structure. Moreover, our conclusion based on the NMR data, namely, that the terminal methyl groups of the chains loop within a micelle so as to contact the micelle surface, remains valid, although the micelles are now more classical in nature than we had previously envisioned.

Metal-Free Catalytic Hydrogenation

P. A. Chase, G. C. Welch, T. Jurca,
D. W. Stephan* ————— **8050–8053**

Angew. Chem. Int. Ed. **2007**, 46

DOI 10.1002/anie.200702908

In their Communication the authors stated that “non-transition-metal catalysts for hydrogenation reactions are all but unknown.” However, it should be noted that non-transition-metal systems have been shown to effect hydrogenation under more forcing conditions. For example, DeWitt, Ramp, and Trapasso demonstrated hydrogenation with $i\text{Pr}_3\text{B}$ under 67 atm (1000 psi) H_2 at 220 °C.^[1] Similarly, Haenel and co-workers^[2] among others^[3] showed hydrogenation of coal under almost 148 atm (15 MPa) H_2 and at 280–350 °C using BI_3 or alkyl boranes. As well, superacid systems have also been shown to effect hydrogenation of alkenes at H_2 pressures of at least 35 atm.^[4]
