## A large family ...

... of crystalline uranium, neptunium, and plutonium borates has been prepared to explore how the chemical behavior of these neighboring elements might differ. In their Communication on page 1263 ff., T. E. Albrecht-Schmitt et al. describe highly unusual behavior for neptunium, which forms several layered neptunyl borates with nanoscale features that simultaneously contain Np<sup>IV</sup>, Np<sup>V</sup>, and Np<sup>VI</sup>. The properties of these neptunium compounds contrast sharply with those of uranium and plutonium, which are both present solely as U<sup>VI</sup> or Pu<sup>VI</sup>.
