

## Synthetic Methods

# Palladium-Catalyzed Amidation by Chemoselective C(sp<sup>3</sup>)-H Activation: Concise Route to Oxindoles Using a Carbamoyl Chloride Precursor\*\*

Chihiro Tsukano, Masataka Okuno, and Yoshiji Takemoto\*

As oxindole forms the core of many complex natural products and is an important pharmacophore, its structure has attracted attention for over a century.<sup>[1]</sup> The oxindole structure has been constructed by the formation of a lactam from aniline,<sup>[1a]</sup> Wolff-Kishner-like reduction of isatin,<sup>[1b]</sup> oxidation of indole,<sup>[1c]</sup> transition metal catalyzed intramolecular amidation,<sup>[1d-f]</sup> and the Heck reaction.<sup>[1g,h]</sup> However, a concise method is still required for ready access to the various oxindoles.

Recent research has focused on C-H bond activation after C-C bond formation because the syntheses are straightforward and atom-economical. While catalytic C(sp<sup>2</sup>)-H activation and subsequent C-C bond formation have been studied by many groups, the corresponding C(sp<sup>3</sup>)-H functionalization is less developed.<sup>[2]</sup> With palladium(0)-catalyzed C(sp<sup>3</sup>)-H activation of a methyl group, Baudoin and co-workers reported the synthesis of cyclobutenes,<sup>[3a-d]</sup> and several groups<sup>[3e-6]</sup> described intramolecular cyclization of a five-membered ring. Yu and co-workers also achieved Pd<sup>0</sup>/PR<sub>3</sub>-catalyzed intermolecular arylation of C(sp<sup>3</sup>)-H bonds.<sup>[7]</sup> C(sp<sup>3</sup>)-H bond activation of methyl and methylene groups and subsequent C-C bond formation is challenging.<sup>[8,9]</sup> As discussed by Fagnou and co-workers<sup>[4a]</sup> and Glorius and co-workers,<sup>[9b]</sup> C(sp<sup>2</sup>)-H activation proceeds selectively in the presence of the competitive C(sp<sup>3</sup>)-H bond. Thus, the selectivity for C(sp<sup>3</sup>)-H activation also needs to be addressed for its application to constructing complex molecules.

Oxindole could be readily synthesized using C-H activation chemistry. As shown in Scheme 1, there are three possible synthetic routes: a) palladium(0)-catalyzed C(sp<sup>2</sup>)-H bond activation after C-C bond formation at the *ortho* position of aniline, b) palladium(II)-catalyzed C(sp<sup>2</sup>)-H bond amidation, and c) C(sp<sup>3</sup>)-H bond activation after insertion of carbon monoxide (CO) or C(sp<sup>3</sup>)-H bond amidation. Routes a) and b) have been developed by the groups of Buchwald,<sup>[10]</sup> Yu,<sup>[11]</sup> and Murakami<sup>[12]</sup> independently. Although route c) would be a complementary method, it has not been reported,

**Scheme 1.** Synthetic strategies for oxindole based on C-H activation.

presumably because of the difficulty of C(sp<sup>3</sup>)-H activation compared to C(sp<sup>2</sup>)-H activation.<sup>[13]</sup> In the course of our research, we have used carbamoyl chloride in palladium-catalyzed reactions.<sup>[14]</sup> It is a useful intermediate for preparing lactam moieties, and earlier reports suggest that it could be applied to C-H activation chemistry. Herein we describe a new strategy for the preparation of various oxindoles from a carbamoyl chloride precursor using C-H activation chemistry. Selective C(sp<sup>3</sup>)-H activation in the presence of a C(sp<sup>2</sup>)-H bond is discussed.

On the basis of an earlier report, we first examined the reaction of (2,6-dimethylphenyl)(methyl)carbamoyl chloride **1a**, which was prepared from the corresponding aniline **2a** in 84 % yield, with Pd(OAc)<sub>2</sub> (3 mol %), PCy<sub>3</sub>·HBF<sub>4</sub> (6 mol %), and Cs<sub>2</sub>CO<sub>3</sub> (1.1 equiv) in mesitylene at 135 °C under argon.<sup>[4a]</sup> 1,7-Dimethylindolin-2-one (**3a**) was obtained in an approximately 10 % yield along with a large amount of **2a** (Table 1, entry 1). As Fagnou et al. reported, addition of pivalic acid (PivOH) gave a better yield,<sup>[4a]</sup> but **2a** was still obtained as a major product (entry 2). Interestingly, the reaction without PivOH under a CO atmosphere gave a comparable yield (entry 3). It is noteworthy that addition of PivOH was compatible with the CO atmosphere, and the reaction under these reaction conditions proceeded smoothly to give **3a** in good yield (entry 4). Next, the reaction temperature, and several additives and ligands were examined. The reaction at 120 °C had a comparable yield (entry 5) to that obtained at 135 °C. Although the Ac<sub>2</sub>NH and PivNH<sub>2</sub> additives had little or no effect on the yield, *N*-hydroxypivalamide (PivNHOH)<sup>[15]</sup> was a good additive and the cyclized product **3a** was obtained in 84 % yield (entries 6–8). Addition of a bulky alkyl ligand, such as *t*Bu<sub>3</sub>P·HBF<sub>4</sub><sup>[16]</sup> or *t*Bu<sub>2</sub>PPh, was not effective (entries 9 and 10). The ligand Ad<sub>2</sub>PBu<sup>[17]</sup> (entry 11; optimum reaction conditions) gave better results than PCy<sub>3</sub>·HBF<sub>4</sub>. We also tried to reduce the amount of the palladium catalyst and the reaction with 1 mol % of Pd(OAc)<sub>2</sub> and 2 mol % of Ad<sub>2</sub>PBu gave **3a** in 80 % yield, but additional

[a] The mixture of **1a** was treated with the palladium catalyst (3 mol %), ligand (6 mol %), base (1.1 equiv), and additives in mesitylene at 120 °C.

[b] Yield of isolated product. [c] The reaction was performed at 135 °C.

Ad = adamantyl, Piv = pivaloyl.

reduction in the amount of catalyst and ligand decreased the yield. For example, with 0.3 mol % of Pd(OAc)<sub>2</sub> the yield was 60 % (data not shown).

To investigate the scope of the reaction we applied the optimum reaction conditions to several carbamoyl chlorides, **1b–p**, having various substituents on the aromatic ring and the nitrogen atom. The substrates **1b–p** were obtained from the corresponding anilines **2b–p** in moderate to excellent yield by treatment with triphosgene and pyridine; the exceptions being **1i** and **1n**. These low yields were presumably a result of the instability of the products. Treatment of **1b**, which has no substituent on the aromatic ring (R = H), with Pd(OAc)<sub>2</sub> (3 mol %), Ad<sub>2</sub>PBu (6 mol %), and Cs<sub>2</sub>CO<sub>3</sub> (1.1 equiv) in mesitylene at 120 °C gave the cyclized product **3b** in 62 % yield (Table 2, entry 1). The reactions of **1c** and **1d**, having methyl groups at the C4- and C5-positions gave oxindoles **3c** and **3d**, respectively (entries 2 and 3). These results indicate that the substituent at the C6-position is not essential, and starting materials with substituents at other positions can be used. The reactions of **1e** and **1f** gave oxindoles **3e** and **3f**, respectively, with excellent chemoselectivity (entries 4 and 5). The desired product **3g** was not obtained and degradation to aniline **2g** (81 %) was observed in the case of (2,6-diethylphenyl)(methyl)carbamoyl chloride **1g** (entry 6). Under these reaction conditions, C–H activation of the methyl group only occurred to form a five-membered ring. The reaction of substrate **1h** with an ethyl group on the nitrogen atom proceeded smoothly to give oxindole **3h** in 79 % yield (entry 7). Several functional groups, such as

**Table 2:** Reaction scope and limitations.<sup>[a,b]</sup>

| 1            |       |                        | 6            |       |                        | 11           |       |                        |              |
| 2            |       |                        | 7            |       |                        | 12           |       |                        |              |
| 3            |       |                        | 8            |       |                        | 13           |       |                        |              |
| 4            |       |                        | 9            |       |                        | 14           |       |                        |              |
| 5            |       |                        | 10           |       |                        | 15           |       |                        |              |

[a] A solution of **1** in mesitylene was treated with Pd(OAc)<sub>2</sub> (3 mol %), Ad<sub>2</sub>PBu (6 mol %), Cs<sub>2</sub>CO<sub>3</sub> (1.1 equiv), and PivNHOH (0.3 equiv) under CO at 120 °C. [b] Yield of isolated product indicated within parentheses. [c] Pd(OAc)<sub>2</sub> (5 mol %), and Ad<sub>2</sub>PBu (10 mol %) were used.

methoxy, chlorine, fluorine, ester, and trifluoromethyl, were tolerated under these reaction conditions. The reactions of **1i–n** gave the corresponding oxindoles **3i–n** in moderate to good yield (entries 8–13). In some cases, the corresponding aniline **2** was observed as a by-product. The reaction of carbamoyl chloride **1o** with a nitro group gave the desired oxindoles **3o** along with a large amount of aniline **2o** in approximately 20% yield (entry 14). Surprisingly, the reaction of **1p** gave the oxindole **3p** as the major product and a small amount of by-product (15%) derived from C(sp<sup>2</sup>)–H activation, which is a more favorable process than C(sp<sup>3</sup>)–H activation.<sup>[4a,6]</sup> Our conditions could be applied to substrates with various functional groups to prepare oxindoles.

Because selective C(sp<sup>3</sup>)–H activation was observed, we investigated to see whether or not the selectivity could be controlled by changing the electron density of the aromatic ring. Compounds **4a–c** and **5** were designed and treated under the same reaction conditions (Scheme 2). The reactions of **4a**

**Scheme 2.** Investigation of the reaction conditions.

and **4b** (R = Me and CF<sub>3</sub>) gave oxindoles **6a** and **6b**, respectively, each derived from C(sp<sup>3</sup>)–H activation, and a small amount of the isomers **7a** and **7b** (11–15%), which were derived from C(sp<sup>2</sup>)–H activation. Interestingly, with the methoxy group as a substituent, the reaction of **4c** proceeded smoothly and the competitive C(sp<sup>2</sup>)–H activation was mostly suppressed. The reaction of **5**, having a naphthalene moiety, gave only oxindole **8**. Additionally, when carbamoyl chloride **1p** was treated under the previously reported reaction conditions (Pd(OAc)<sub>2</sub> (3 mol %), Cy<sub>3</sub>P·HBF<sub>4</sub> (6 mol %) and Cs<sub>2</sub>CO<sub>3</sub> (1.1 equiv) in mesitylene at 135 °C),<sup>[4a]</sup> no selectivity was observed and **3p** (24%), **10** (23%), and the corresponding aniline (36%) were obtained (data not shown). These results indicate that C(sp<sup>3</sup>)–H activation is more favorable than C(sp<sup>2</sup>)–H activation under these reaction conditions. To the best of our knowledge, this is a first example of a chemoselective palladium(0)-catalyzed C(sp<sup>3</sup>)–H activation.

The proposed mechanism is shown in Scheme 3. The reaction commences with oxidative addition of Pd<sup>0</sup> to give the intermediate **A**. Under the optimum reaction conditions, CO elimination from **A** was suppressed by performing the reaction under a CO atmosphere. The formation of a six-membered transition state<sup>[3b,c,4]</sup> led to C(sp<sup>3</sup>)–H activation to give the intermediate **B**, which was converted into oxindole

**Scheme 3.** Possible reaction mechanism.

along with the production of Pd<sup>0</sup>. The effect of PivNHOH is not clear, but we assume that it assists in benzylic C(sp<sup>3</sup>)–H activation from **A**.

In summary, a new strategy using C(sp<sup>3</sup>)–H activation was investigated for rapid access to various oxindoles using carbamoyl chloride precursors. The reaction with Ad<sub>2</sub>PBU as a ligand and PivNHOH as an additive under CO was effective. Under the developed reaction conditions, selective C(sp<sup>3</sup>)–H activation occurred in the presence of the competitive C(sp<sup>2</sup>)–H bond. These results will be helpful in synthesis of complex molecules using C(sp<sup>3</sup>)–H activation. Further mechanistic studies and synthetic application are in progress.
