

# Selective Generation of Formamides through Photocatalytic CO<sub>2</sub> Reduction Catalyzed by Ruthenium Carbonyl Compounds\*\*

Katsuaki Kobayashi, Takashi Kikuchi, Susumu Kitagawa, and Koji Tanaka\*

**Abstract:** The selective formation of dialkyl formamides through photochemical CO<sub>2</sub> reduction was developed as a means of utilizing CO<sub>2</sub> as a C<sub>1</sub> building block. Photochemical CO<sub>2</sub> reduction catalyzed by a [Ru(bpy)<sub>2</sub>(CO)]<sup>2+</sup> (bpy: 2,2'-bipyridyl)/[Ru(bpy)<sub>3</sub>]<sup>2+</sup>/Me<sub>2</sub>NH/Me<sub>2</sub>NH<sub>2</sub><sup>+</sup> system in CH<sub>3</sub>CN selectively produced dimethylformamide. In this process a ruthenium carbamoyl complex ([Ru(bpy)<sub>2</sub>(CO)-(CONMe<sub>2</sub>)]<sup>+</sup>) formed by the nucleophilic attack of Me<sub>2</sub>NH on [Ru(bpy)<sub>2</sub>(CO)]<sup>2+</sup> worked as the precursor to DMF. Thus Me<sub>2</sub>NH acted as both the sacrificial electron donor and the substrate, while Me<sub>2</sub>NH<sub>2</sub><sup>+</sup> functioned as the proton source. Similar photochemical CO<sub>2</sub> reductions using R<sub>2</sub>NH and R<sub>2</sub>NH<sub>2</sub><sup>+</sup> (R = Et, nPr, or nBu) also afforded the corresponding dialkyl formamides (R<sub>2</sub>NCHO) together with HCOOH as a by-product. The main product from the CO<sub>2</sub> reduction transitioned from R<sub>2</sub>NCHO to HCOOH with increases in the alkyl chain length of the R<sub>2</sub>NH. The selectivity between R<sub>2</sub>NCHO and HCOOH was found to depend on the rate of [Ru(bpy)<sub>2</sub>(CO)(CONR<sub>2</sub>)]<sup>+</sup> formation.

Increases in the concentration of atmospheric CO<sub>2</sub> are primarily associated with the consumption of fossil fuels. Responses to the associated greenhouse effect have included reductions in the consumption of fossil fuels by some nations as well as the recycling of CO<sub>2</sub> as a C<sub>1</sub> resource under mild reaction conditions. Photo- and electrochemical reactions are the most feasible pathways for the utilization of CO<sub>2</sub> in this respect. However, despite substantial efforts to develop effective electrode materials and solid and molecular catalysts for use in electro- and photochemical CO<sub>2</sub> reductions, with a few exceptions the reduction products remain limited to CO and/or HCOOH.<sup>[1]</sup> Thermal reactions between CO<sub>2</sub> and

electron donating substrates, such as olefins, dienes, and epoxides, have been widely applied during the use of CO<sub>2</sub> as a C<sub>1</sub> building block in organic synthesis.<sup>[2]</sup> In contrast, the catalytic incorporation of CO<sub>2</sub> into organic moieties through the reductive activation of the CO<sub>2</sub> molecule rather than by reaction with a reactive organic functional group has rarely been achieved.

Metal complexes are widely used as molecular catalysts in photo- and electrochemical CO<sub>2</sub> reduction,<sup>[1d,3]</sup> and the reaction mechanisms associated with CO<sub>2</sub> reductions using Ru<sup>[4]</sup> and Re complexes<sup>[5]</sup> have been well-documented. When using Ru, a carbonyl group of the dicationic species [Ru(bpy)<sub>2</sub>(CO)]<sup>2+</sup> (bpy = 2,2'-bipyridyl) successively reacts with OH<sup>-</sup> to give [Ru(bpy)<sub>2</sub>(CO)(COOH)]<sup>+</sup> and [Ru(bpy)<sub>2</sub>(CO)-(CO<sub>2</sub>)]<sup>0</sup>. In aqueous solution, these three complexes exist in equilibrium [Eq. (1)],<sup>[6,7]</sup> and act as precursors to CO and HCOOH production and as CO<sub>2</sub> carriers in electro-<sup>[7,8]</sup> and photochemical<sup>[9]</sup> CO<sub>2</sub> reductions.

Electrochemical CO<sub>2</sub> reduction catalyzed by [Ru(bpy)<sub>2</sub>(CO)]<sup>2+</sup> using Me<sub>2</sub>NH<sub>2</sub><sup>+</sup> in place of H<sub>2</sub>O as a proton source predominantly produces HCOOH in CH<sub>3</sub>CN because the regeneration of [Ru(bpy)<sub>2</sub>(CO)]<sup>2+</sup> is depressed owing to the reduced availability of protons in the catalytic cycle.<sup>[10]</sup> Furthermore, electrochemical CO<sub>2</sub> reduction in the presence of Me<sub>2</sub>NH under otherwise similar reaction conditions generates both HCOOH and DMF in a molar ratio of 3:1.<sup>[11]</sup> One-step conversion from the dialkyl amine into the corresponding dialkyl formamide in this manner during CO<sub>2</sub> reduction represents an attractive utilization of CO<sub>2</sub> as a carbon source [Eq. (2)].

Herein we report the selective generation of either dialkyl formamide or HCOOH during photochemical CO<sub>2</sub> reduction, catalyzed by [Ru(bpy)<sub>2</sub>(CO)]<sup>2+</sup> in the presence of [Ru(bpy)<sub>3</sub>]<sup>2+</sup>, R<sub>2</sub>NH, and R<sub>2</sub>NH<sub>2</sub><sup>+</sup> acting as the photosensitizer, electron source, and proton source, respectively, in dry CH<sub>3</sub>CN.

Photochemical CO<sub>2</sub> reduction catalyzed by [Ru(bpy)<sub>2</sub>(CO)]<sub>2</sub>(PF<sub>6</sub>)<sub>2</sub> (0.5 mM) was performed in CH<sub>3</sub>CN (15 mL) in the presence of [Ru(bpy)<sub>3</sub>](ClO<sub>4</sub>)<sub>2</sub> (5 mM), Et<sub>3</sub>NHPF<sub>6</sub> (0.2 M), Et<sub>3</sub>N (0.5 M), and Na<sub>2</sub>SO<sub>4</sub> (see the Experimental Section). The irradiation of this mixture with visible light (385 nm < λ < 740 nm) for 12 h readily generated H<sub>2</sub> (70 μmol) and HCOOH (75 μmol), accompanied by a small

amount of CO (3.8  $\mu\text{mol}$ ). Thus  $\text{Et}_3\text{NHPF}_6$  was found to work as a good proton source in photochemical  $\text{CO}_2$  reduction. To our surprise, a similar  $\text{CO}_2$  reduction process using  $\text{Me}_2\text{NH}_2\text{Cl}$  in place of  $\text{Et}_3\text{NHPF}_6$  under otherwise the same reaction conditions completely depressed  $\text{H}_2$  evolution, instead generating DMF (165  $\mu\text{mol}$ ) as the main product, together with small amounts of  $\text{HCOOH}$  and  $\text{CO}$  (Table 1). This result

**Table 1:** Photochemical  $\text{CO}_2$  reduction using  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  under various conditions.

Amine	Ammonium	Li salt	Products [ $\mu\text{mol}$ ] <sup>[a]</sup>			
			$\text{H}_2$	$\text{CO}$	$\text{HCOOH}$	DMF
$\text{Et}_3\text{N}$	$\text{Et}_3\text{NHPF}_6$		70	3.8	75	N.D.
$\text{Et}_3\text{N}$	$\text{Me}_2\text{NH}_2\text{Cl}$		N.D.	6.4	14	165
$\text{Me}_2\text{NH}$	$\text{Me}_2\text{NH}_2\text{Cl}$		N.D.	N.D.	trace	131

[a] N.D. = not detected.

clearly indicates that  $\text{Me}_2\text{NH}_2\text{Cl}$  plays the role of the proton source in the photochemical  $\text{CO}_2$  reduction, and the resultant  $\text{Me}_2\text{NH}$  reacts with  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  to produce  $[\text{Ru}(\text{bpy})_2(\text{CO})(\text{CONMe}_2)]^+$  as the precursor to DMF.<sup>[11]</sup> Indeed, DMF was selectively produced as the sole product from photochemical  $\text{CO}_2$  reduction when  $\text{Me}_2\text{NH}$  was used as the electron source in place of  $\text{NEt}_3$  (Table 1).

The participation of  $\text{Et}_3\text{NH}^+$  or  $\text{Me}_2\text{NH}_2^+$  in the equilibrium between  $[\text{Ru}(\text{bpy})_2(\text{CO})(\text{CO}_2)]^0$ ,  $[\text{Ru}(\text{bpy})_2(\text{CO})(\text{COOH})]^+$ , and  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  as the proton source in  $\text{CH}_3\text{CN}$  is the key factor in photochemical  $\text{CO}_2$  reduction. In aqueous solutions, the  $\text{Ru}-\text{CO}_2$  scaffold of  $[\text{Ru}(\text{bpy})_2(\text{CO})(\text{CO}_2)]^0$  undergoes hydrogen bonding with  $\text{H}_2\text{O}$ , whereas the complex is stabilized by an acid–base interaction with Lewis acids in non-protic media. The  $\text{Li}^+$  ion shows especially strong interaction with the oxygen of the  $\text{Ru}-\text{CO}_2$  scaffold.<sup>[12]</sup> As such, photochemical  $\text{CO}_2$  reduction in the presence of  $\text{Li}^+$  ions was conducted to clarify the effects of a Lewis acid on the equilibrium shown in Equation (1) when assisted by  $\text{Me}_2\text{NH}_2^+$  in  $\text{CH}_3\text{CN}$ . The substantial decrease in DMF production observed in the presence of  $\text{Li}^+$  can be explained by the blocking effect of  $\text{Li}^+$  on the interspecies conversions of Equation (1) owing to the stabilization of  $[\text{Ru}(\text{bpy})_2(\text{CO})(\text{CO}_2)]^0$  in  $\text{CH}_3\text{CN}$  (Table 1).

Metal carbamoyl complexes have been isolated following the reactions of  $[(\text{C}_5\text{H}_5)\text{W}(\text{CO})_4]\text{PF}_6$  and  $[(\text{C}_5\text{H}_5)\text{Mo}(\text{CO})_4]\text{PF}_6$  with primary amines.<sup>[13]</sup> In the present study, a colorless  $\text{CH}_3\text{CN}$  solution of  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  turned yellow upon the addition of excess  $\text{Me}_2\text{NH}$ , which is due to the formation of  $[\text{Ru}(\text{bpy})_2(\text{CO})(\text{CONMe}_2)]^+$ . However, concentration of this solution under a  $\text{N}_2$  stream caused the  $\text{Me}_2\text{N}^-$  to dissociate from the carbamoyl group, leading to recovery of the original  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$ . Similarly, a yellow  $\text{CH}_3\text{CN}$  solution containing  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  and an excess of  $\text{Me}_2\text{NH}$  and  $\text{Me}_2\text{NH}_2^+$  did not give any reaction products following concentration of the solution in the dark. Although pure  $[\text{Ru}(\text{bpy})_2(\text{CO})(\text{CONMe}_2)]^+$  has not been successfully isolated,<sup>[11]</sup> cyclic voltammograms (CVs) acquired in this study did show strong interactions between

$[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  and  $\text{Me}_2\text{NH}$  [Eq. (3)]. As has been

reported,  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  in  $\text{CH}_3\text{CN}$  exhibits an irreversible cathodic peak at  $-1.03 \text{ V}$  vs. SCE and anodic peaks at  $-0.45$  and  $-0.14 \text{ V}$  under Ar (Figure 1a).<sup>[9b]</sup> The addition of

**Figure 1.** Cyclic voltammograms of  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  (1.0 mM) in a) the absence and b) the presence of 0.5 M  $\text{Me}_2\text{NH}$  in  $\text{CH}_3\text{CN}$  containing 0.1 M  $n\text{Bu}_4\text{NPF}_6$  under argon. The sweep rate of both voltammograms was  $0.1 \text{ V s}^{-1}$ .

excess  $\text{Me}_2\text{NH}$  to this solution results in the complete disappearance of the original redox peaks of  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$ , and these are replaced by two pseudo reversible redox couples at  $-1.39$  and  $-1.63 \text{ V}$  (Figure 1b). The large negative shift of the redox wave is attributed to bond formation between  $\text{Me}_2\text{N}^-$  and the  $\text{Ru}-\text{CO}$  scaffold, which acts as a strong donor group. Indeed, the ESI-MS spectrum of a  $\text{CH}_3\text{CN}$  solution of  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  containing 0.5 M  $\text{Me}_2\text{NH}$  indicates the generation of  $[\text{Ru}(\text{bpy})_2(\text{CO})(\text{CONMe}_2)]^+$  ( $m/z$  514.11) and also contains small peaks owing to  $[\text{Ru}(\text{bpy})_2(\text{CO})(\text{COOH})]^+$  ( $m/z$  487.11) (Figure 2a). The appearance of  $[\text{Ru}(\text{bpy})_2(\text{CO})-$

**Figure 2.** a) ESI-MS spectrum of  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  (1.0  $\mu\text{M}$ ) in  $\text{CH}_3\text{CN}$  containing 0.5 M  $\text{Me}_2\text{NH}$  and b) the simulated spectrum of  $[\text{Ru}(\text{bpy})_2(\text{CO})(\text{CONMe}_2)]^+$ .

(COOH)]<sup>+</sup> in the ESI-MS spectrum of a mixture of [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> and Me<sub>2</sub>NH suggests another pathway to the formation of a carbamoyl complex through the displacement of the OH group on the Ru-COOH scaffold by Me<sub>2</sub>NH [Eq. (4)] in the present DMF generation reaction. However,

the ESI-MS spectra of [Ru(bpy)<sub>2</sub>(CO)(COOH)]<sup>+</sup> and [Ru(bpy)<sub>2</sub>(CO)(COOMe)]<sup>+</sup> in CH<sub>3</sub>CN exhibited no changes at all following the addition of 0.5 M Me<sub>2</sub>NH to their solutions. This result clearly rules out the occurrence of the reaction in Equation (4). It is therefore concluded that [Ru(bpy)<sub>2</sub>(CO)(CONMe<sub>2</sub>)]<sup>+</sup> is formed through the reaction of Me<sub>2</sub>NH with [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup>, as in Equation (3), rather than with [Ru(bpy)<sub>2</sub>(CO)(COOH)]<sup>+</sup> [Eq. (4)].

Similar to [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup>, [Ru(tpy)(bpy)(CO)]<sup>2+</sup> (tpy = 2,2':2'',6'-terpyridine) also catalyzes electrochemical CO<sub>2</sub> reduction.<sup>[14]</sup> [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> and [Ru(tpy)(bpy)(CO)]<sup>2+</sup> exhibit catalytic abilities for CO<sub>2</sub> reduction under electrolysis at potentials more negative than -1.20 and -1.30 V, respectively, as the former undergoes irreversible two-electron reduction at -1.03 V and the latter exhibits one reversible and one irreversible reduction at -1.03 and -1.37 V in CH<sub>3</sub>CN. However, photochemical CO<sub>2</sub> reduction using [Ru(tpy)(bpy)(CO)]<sup>2+</sup> in place of [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> under otherwise the same reaction conditions produced a relatively small yield of DMF (3.3 μmol), and no other products were detected. The absorption spectrum of [Ru(tpy)(bpy)(CO)]<sup>2+</sup> changed upon the addition of 0.5 M Me<sub>2</sub>NH in CH<sub>3</sub>CN such that a new band emerged at 509 nm, implying the formation of an adduct between [Ru(tpy)(bpy)(CO)]<sup>2+</sup> and Me<sub>2</sub>NH. The ESI-MS spectrum of [Ru(tpy)(bpy)(CO)]<sup>2+</sup> in the presence of 0.5 M Me<sub>2</sub>NH demonstrated the formation of the amine adduct rather than the carbamoyl complex (Supporting Information, Figure S1). In contrast, there was very little change in the (2+/+) and (+/0) redox waves in the CV of [Ru(tpy)(bpy)(CO)]<sup>2+</sup> upon the addition of Me<sub>2</sub>NH in CH<sub>3</sub>CN. These observations indicate that the redox potential of [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> undergoes a substantial negative shift upon the formation of an adduct with Me<sub>2</sub>NH, while the one- and two-electron reduced forms of [Ru(tpy)(bpy)(CO)]<sup>2+</sup> do not interact with Me<sub>2</sub>NH at all. In contrast to the reaction with Equation (3), the amine adduct formation [Eq. (5)] in the

presence of excess amounts of Me<sub>2</sub>NH reflects the weak Lewis acidity of the CO ligand of [Ru(tpy)(bpy)(CO)]<sup>2+</sup> (ν(CO) = 2004 cm<sup>-1</sup>) compared with that of [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> (ν(CO) = 2039, 2091 cm<sup>-1</sup>).<sup>[14,15]</sup>

The coexistence of R<sub>2</sub>NH and R<sub>2</sub>NH<sub>2</sub><sup>+</sup> (R = Et, *n*Pr, and *n*Bu) in the photochemical CO<sub>2</sub> reduction means that these species also work as the electron and proton sources for the formation of R<sub>2</sub>NCHO (Table 2). Each CV of the mixture of

Et <sub>2</sub> NH	Et <sub>2</sub> NH <sub>2</sub> PF <sub>6</sub>	4.6	14	29
<i>n</i> Pr <sub>2</sub> NH	<i>n</i> Pr <sub>2</sub> NH <sub>2</sub> PF <sub>6</sub>	2.6	45	14
<i>i</i> Pr <sub>2</sub> NH	<i>i</i> Pr <sub>2</sub> NH <sub>2</sub> PF <sub>6</sub>	N.D.	21	N.D.
<i>n</i> Bu <sub>2</sub> NH	<i>n</i> Bu <sub>2</sub> NH <sub>2</sub> PF <sub>6</sub>	2.9	73	25

**Table 3:** Redox potentials of [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> in the presence of various amines and the reaction rate constants between [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> (0.5 mM) and various alkyl amines (0.5 M).

Amine	<i>E</i> [V]	<i>k</i> <sub>obs</sub> [s <sup>-1</sup> ]
Me <sub>2</sub> NH	-1.39, -1.63	165
Et <sub>2</sub> NH	-1.43, -1.64	4.4
<i>n</i> Pr <sub>2</sub> NH	-1.40, -1.62	2.7
<i>n</i> Bu <sub>2</sub> NH	-1.42, -1.63	4.2

[Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> and Et<sub>2</sub>NH, *n*Pr<sub>2</sub>NH, or *n*Bu<sub>2</sub>NH in CH<sub>3</sub>CN closely resembles that of [Ru(bpy)<sub>2</sub>(CO)(CONMe<sub>2</sub>)]<sup>+</sup> (Table 3; Supporting Information, Figure S2). Furthermore, the ESI-MS spectra of [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> in the presence of 0.5 M dialkyl amine (Et<sub>2</sub>NH, *n*Pr<sub>2</sub>NH, or *n*Bu<sub>2</sub>NH) in CH<sub>3</sub>CN demonstrate the formation of [Ru(bpy)<sub>2</sub>(CO)(CONR<sub>2</sub>)]<sup>+</sup> (Supporting Information, Figure S3). The tendency of the main product to transition from R<sub>2</sub>NCHO to HCOOH with an increase in the carbon chain length of the *n*-alkyl group is correlated with the increasing difficulty of the nucleophilic attack of the increasingly bulky *n*R<sub>2</sub>NH on the Ru-CO scaffold. Furthermore, photochemical CO<sub>2</sub> reduction in the presence of both *i*Pr<sub>2</sub>NH and *i*Pr<sub>2</sub>NH<sub>2</sub><sup>+</sup> produced only a small amount of HCOOH without any accompanying *i*Pr<sub>2</sub>NCHO. Such a drastic change in the reduction product is associated with the steric hindrance of the two *i*Pr groups of *i*Pr<sub>2</sub>NH on the nucleophilic attack at the carbonyl carbon of [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup>, as neither [Ru(bpy)<sub>2</sub>(CO)(CON(*i*Pr)<sub>2</sub>)]<sup>+</sup> nor [Ru(bpy)<sub>2</sub>(CO)(CONH(*i*Pr)<sub>2</sub>)]<sup>2+</sup> was detected in the ESI-MS spectrum of a mixture of [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> and a large excess of *i*Pr<sub>2</sub>NH in CH<sub>3</sub>CN. Taking into account the *pK*<sub>a</sub> values of *i*Pr<sub>2</sub>NH<sub>2</sub><sup>+</sup> (11.9) and [Ru(bpy)<sub>2</sub>(CO)(COOH)]<sup>+</sup> (9.6), *i*Pr<sub>2</sub>NH will exclusively remove protons from traces of water in the CH<sub>3</sub>CN, and the resulting OH<sup>-</sup> will shift the equilibrium shown in Equation (1) to [Ru(bpy)<sub>2</sub>(CO)(CO<sub>2</sub>)]<sup>0</sup> that is more labile and slowly decomposes in dry CH<sub>3</sub>CN. Indeed, the CV of [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> in the presence of 0.5 M *i*Pr<sub>2</sub>NH did not show any clear redox couples (Supporting Information, Figure S5).

The time-dependent electronic absorption spectra of a CH<sub>3</sub>CN solution of [Ru(bpy)<sub>2</sub>(CO)<sub>2</sub>]<sup>2+</sup> (0.50 mM) upon the addition of excess amounts of R<sub>2</sub>NH (R = Me and Et) were monitored by rapid scanning spectroscopy (Figure 3 a,b). The spectral changes in the presence of Me<sub>2</sub>NH and Et<sub>2</sub>NH exhibited first-order kinetics and ceased within 50 ms and 1 s, respectively, and the final spectra of both solutions were

**Figure 3.** Spectral changes of a  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  solution upon addition of a) 0.5 M  $\text{Me}_2\text{NH}$  and b)  $\text{Et}_2\text{NH}$ , and variations in the absorption at 400 nm over time after the mixing of  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  and c)  $\text{Me}_2\text{NH}$  or d)  $\text{Et}_2\text{NH}$ .

essentially the same. The rate constants,  $k_{\text{obs}}$ , determined by analysis of the time course data at 400 nm were 165 and  $4.4 \text{ s}^{-1}$  for the reactions of  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  with  $\text{Me}_2\text{NH}$  and  $\text{Et}_2\text{NH}$ , respectively (Figure 3c and d). Similarly, the pseudo-first-order rate constants for the reaction of  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  with  $n\text{Pr}_2\text{NH}$  and  $n\text{Bu}_2\text{NH}$  were also determined, and the results are summarized in Table 3. The rate constant of the reaction of  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  with  $\text{Me}_2\text{NH}$  is close to two orders of magnitude larger than those obtained with  $\text{Et}_2\text{NH}$ ,  $n\text{Pr}_2\text{NH}$ , and  $n\text{Bu}_2\text{NH}$ , and comparison of Tables 2 and 3 clearly indicates that the selectivity for dialkyl formamide formation is regulated by the reaction rate of the nucleophilic attack of the dialkyl amine on  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$ .

The most plausible mechanism for photochemical  $\text{CO}_2$  reduction affording dialkyl formamides is presented in Scheme 1. The reaction rate of the adduct formation between  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$  and  $\text{R}_2\text{NH}$  has a crucial effect on the selectivity for dialkyl formamide formation, and selective production of DMF in the presence of  $\text{Me}_2\text{NH}$  and  $\text{Me}_2\text{NH}_2^+$  is ascribed to the rapid formation of  $[\text{Ru}(\text{bpy})_2(\text{CO})_2(\text{CONMe}_2)]^+$ .

In conclusion, we have succeeded in the selective formation of DMF from  $\text{CO}_2$  and  $\text{Me}_2\text{NH}$  by photochemical reduction. The selectivity for the dialkyl formamide has been

**Scheme 1.** Proposed reaction mechanism for dialkyl formamide and  $\text{HCOOH}$  generation by  $\text{CO}_2$  reduction.

shown to increase with an increase in the reaction rate of the nucleophilic attack on the carbonyl ligand of  $[\text{Ru}(\text{bpy})_2(\text{CO})_2]^{2+}$ . Furthermore, it is evident that  $\text{Li}^+$  blocks the formation of  $\text{Ru}-\text{CO}$  due to its stabilization of the  $\text{Ru}-\text{CO}_2$  scaffold, and thus completely inhibits formamide formation.

## Experimental Section

Photochemical formamide generation was conducted in  $\text{CH}_3\text{CN}$  (15 mL) containing  $[\text{Ru}(\text{bpy})_2(\text{CO})_2](\text{PF}_6)_2$  (0.5 mM),  $[\text{Ru}(\text{bpy})_3](\text{ClO}_4)_2$  (5 mM), dialkyl amine (0.5 M), dialkyl ammonium salt (0.2 M), and  $\text{Na}_2\text{SO}_4$  (3.0 g). After bubbling  $\text{CO}_2$  into the  $\text{CH}_3\text{CN}$  solution for several minutes, photoirradiation was carried out using a 300 W Xe lamp filtered by a mirror module (385–740 nm) with stirring. The reaction was continued for 12 h. The concentrations of  $\text{H}_2$  and  $\text{CO}$  in the product gas phase were determined by gas chromatography (GC) and the quantity of  $\text{HCOOH}$  in the solution phase was measured by capillary electrophoresis. The identities of formamide derivatives were assessed by GC–mass spectrometry (GC–MS), and their quantities were determined by GC.
