

**The relationship between chemical structure and protective effect of dithiocarbamate derivatives against experimental hepatic injury induced by carbon tetrachloride administration in rats**

(Received 17 November 1965; accepted 12 January 1966)

A NUMBER of substances having protective effect against experimental hepatic damage induced by  $\text{CCl}_4$  administration have been reported by investigators. Concerning dithiocarbamates, Palma *et al.*<sup>1</sup> have described the antagonistic effect of 2-methylpiperazine dithioformate on various hepatic lesions induced by lipid enriched diet, pyridine and ethionine treatment and X-ray irradiation combined with  $\text{CCl}_4$  administration in mice. Previously we found the protective effect of piperazine  $\text{NN}'$ -biscarbodithioate on liver damage induced by  $\text{CCl}_4$ .<sup>2</sup> This paper describes the relation of chemical structure of dithiocarbamate derivatives with their activity in protecting liver damage caused by  $\text{CCl}_4$  in rat, as judged by plasma transaminase levels.

Male Donryu rats aged 8 weeks weighing 180-200 g were used and maintained on standard laboratory chow (CLEA CE-2). A suspension of  $\text{CCl}_4$  in gum tragacanth was administered intraperitoneally in a dose of 0.1 ml/kg. Tested compounds were administered orally just before the injection of  $\text{CCl}_4$ . For the determination of transaminase activities, blood was collected from heart of rats under pentobarbital anesthesia 24 hr after administration of  $\text{CCl}_4$ . The plasma was obtained by centrifugation. Activities of plasma transaminases, GOT and GPT, were determined by the method of Reitman and Frankels<sup>3</sup> and expressed in Karmen units. Tested compounds were evaluated as being protective against hepatic injury induced by  $\text{CCl}_4$ , when the activities of plasma transaminases were reduced.

The results are summarized in Table 1 and discussed with respect to the relationship between chemical structure and protective effect. Metal salts of dithiocarbamic acid and xanthogenic acid

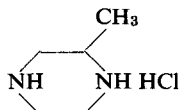

TABLE 1 THE REDUCTION OF PLASMA TRANSAMINASE LEVELS BY DITHIOCARBAMATE DERIVATIVES AND RELATED COMPOUNDS IN RATS INTOXICATED BY  $\text{CCl}_4$ .

	Plasma transaminase levels (Karmen unit)	
	GPT	GOT
H \ NCSSNa	20 $\pm$ 6	93 $\pm$ 15
CH <sub>3</sub> CH <sub>3</sub> \ NCSSNa	13 $\pm$ 1	120 $\pm$ 32

Figures in the tables show mean ± standard deviation.

were protective, whilst their ester and their ring forms, carbodithioate (or carbothioate) including C-CSSH (C-COSH) radical, isothiocyanate and thiourea derivatives did not show any protective effect. The corresponding compounds lacking the -CSSH radical of dithiocarbamates and some thio compounds known as detoxicating agents, namely, sodium thiosulfate, glutathione, BAL and thioctic acid had no efficiency in our experimental conditions. EDTA also had no protective effect, although its effectiveness has been reported by Calvert and Brody<sup>4</sup> and some other workers.<sup>5</sup>

From these results, it is concluded that the compounds having a -CSSH radical on the N or O atom exhibit a considerable, strong protective effect. It is likely that the effectiveness of dithiocarbamates may be attributed to the same mechanism as that of tetraethylthiuram disulfide, for it has been suggested by several workers that the latter compound may be changed into diethyl dithiocarbamate in animal bodies.<sup>6, 7, 8</sup> It has also been reported that CS<sub>2</sub> may be metabolized into dithiocarbamate in animal body.<sup>9</sup> It is probable, therefore, that the effectiveness of CS<sub>2</sub> may be due to the metabolite.
