Effects of incorporation of $\alpha 5$ subunits into $\alpha 4\beta 2$ nicotinic acetylcholine receptors on pharmacological functions of nicotinic ligandsJenny Zhang^{*}, Merouane Bencherif, Terry Hauser

Targacept, Inc., Winston-Salem, NC, USA

To elucidate their role in diseases and disorders such as addiction, pain and attention deficit/hyperactivity disorder, the heteromeric $\alpha 4\beta 2$ nicotinic acetylcholine receptors (NNRs) have been the focus of many studies. Recently, investigations have shown that other members of the NNR family, such as $\alpha 5$ expressed with $\alpha 4\beta 2$ in the brain, may play important roles in these diseases. Receptor functions involving activation and desensitization are influenced by many factors including subunit composition which is likely modified during the course of diseases. In the present study, we co-transfected concatenated $\beta 2$ – $\alpha 4$ dimers with single $\alpha 4$, $\beta 2$ or $\alpha 5$ monomers, to express low sensitivity (LS)- $\alpha 4\beta 2$, high sensitivity (HS)- $\alpha 4\beta 2$ or ($\alpha 4\beta 2$)₂ $\alpha 5$ ($\alpha 4\beta 2\alpha 5$) NNRs respectively in HEK293F cells. Subsequently the effect of $\alpha 5$ incorporation on the pharmacological properties of $\alpha 4\beta 2$ agonists varenicline, cytisine, and sazetidine-A was investigated by a membrane potential method. For varenicline and cytisine, the activation profiles were very similar on all three $\alpha 4\beta 2$ NNRs. They partially activated LS- $\alpha 4\beta 2$ with comparable potencies but had no detectable activities at HS- $\alpha 4\beta 2$ NNRs. At activation of $\alpha 4\beta 2\alpha 5$, similar potency and efficacy were observed as compared to their respective responses at LS- $\alpha 4\beta 2$ NNRs. Sazetidine-A, in contrast, was a potent full agonist at HS- $\alpha 4\beta 2$ with low activity at LS- $\alpha 4\beta 2$. Its partial agonistic activity at $\alpha 4\beta 2\alpha 5$ was similar to that at LS- $\alpha 4\beta 2$. Interestingly, when cells were pretreated with these agonists and then challenged with acetylcholine (ACh), they all displayed similar desensitization efficacy, to a complete degree, at the three $\alpha 4\beta 2$ NNRs, again with comparable potencies for varenicline and cytisine. Additionally, onset of the desensitization was within minutes for all agonists tested and fastest for sazetidine-A. We also characterized the influence of $\alpha 5$ on sensitivities of $\alpha 4\beta 2$ NNRs to the antagonists dihydro-beta-erythroidine (DH β E) and TC-5280. When co-applied with ACh, DH β E and TC-5280 displayed IC₅₀ values of 114 and 177 nM at HS- $\alpha 4\beta 2$, 123 and 364 nM at LS- $\alpha 4\beta 2$, and 85 and 439 nM at $\alpha 4\beta 2\alpha 5$, respectively. Under pre-treatment condition, TC-5280 was more potent and selective to desensitize HS- $\alpha 4\beta 2$ and $\alpha 4\beta 2\alpha 5$ NNRs. In summary, for three agonists tested, incorporation of $\alpha 5$ shifted their activation responses to LS- $\alpha 4\beta 2$ -like and their desensitization responses to HS- $\alpha 4\beta 2$ -like. Understanding the changes in pharmacological functions influenced by receptor subunit composition will help us to understand the physiological role of such receptors and to better design drugs that target the relevant receptor subtypes involved in diseases.

It has been proposed that modulation of the nicotinic acetylcholine receptor $\alpha 6^*$ (where the asterisk indicates additional subunits) subtype may offer therapeutic opportunities in overcoming nicotine addiction and in alleviating motoric dysfunction associated with Parkinson's disease. Progress in the identification of selective $\alpha 6^*$ ligands has previously been hampered by the lack of robust, pharmacologically relevant high-throughput assays. Until recently, the only assay amenable to high throughput *in vitro* screening was the $\alpha 6/4\beta 4$ chimera. Native $\alpha 6^*$ subtypes associated with dopaminergic activity are believed to contain an $\alpha 6$ – $\beta 2$ interface which is missing in the $\alpha 6/4\beta 4$ chimera, calling into question the relevance of this data for predicting *in vivo* activity in animal models of addiction and Parkinson's disease. We have recently identified a number of compounds with moderate to high affinity for $\alpha 6^*$ -containing receptors through screening of previously published nicotinic ligands and Targacept proprietary database libraries in a variety of assay formats. These include novel $\alpha 6\beta 3\beta 4\alpha 5$ construct expressed in mammalian cells, rat native tissue from $\alpha 6$ -rich brain areas, an $\alpha 6/3\beta 2\beta 3$ chimera expressed in mammalian cells, and autoradiography in rat striatum. The affinity and, consequently, selectivity versus other nicotinic receptor subtypes ($\alpha 4\beta 2$, $\alpha 3\beta 4$) varied greatly depending on the assay system. We present here the *in vitro* profiles of these diverse ligands across multiple $\alpha 6^*$ affinity measures and preliminary structure–activity relationships. The relevance of $\alpha 6^*$ binding affinity to $\alpha 6^*$ function, as measured by Calcium flux in the $\alpha 6/3\beta 2\beta 3$ chimera and the α -conotoxin MII-sensitive component of striatal dopamine release, will also be discussed.

Construction of cell line heterologously expressing the $\alpha 6/3\beta 2\beta 3$ nicotinic acetylcholine receptor (nAChR) subtypeP. Whiteaker^{1,*}, L. Lucero¹, R.J. Lukas¹, C. Hepler², J.P. Strachan², S. Letchworth²¹ Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ, USA² Targacept, Inc., Winston-Salem, NC, USA

Natively-expressed $\alpha 6^*$ nAChRs are predominantly expressed in combination with $\beta 2$ and $\beta 3$ subunits ($\alpha 6\beta 2\beta 3^*$ nAChRs; asterisk denotes other possible subunits). Heterologous expression of functional $\alpha 6^*$ nAChRs in mammalian cell lines has historically proved difficult. In order to overcome this problem, we have applied a combination of approaches to increase expression of functional nAChRs, without using a gain-of-function mutation that could alter EC₅₀ and IC₅₀ values or change agonist efficacies. Native $\alpha 6$ subunits were replaced with $\alpha 6/3$ chimeric subunits, which have
