In Figure 9, FRETs in the quadruplex system on 40mer matrix oligo-DNA. The Y-axis of Figure 9 is the same as Figures 8a and 8b. Eo-(blank)-(blank)-TR system (**E10a + 10b + 10c + T10d + m30a'b'c'd'**) showed almost same excitation spectra as TR (**10a + 10b + 10c + T10d + m30a'b'c'd'**). No effective energy transfer from Eo to TR separated 30 residues. Eo-Rho-(blank)-TR system (**E10a + R10b + 10c + T10d + m30a'b'c'd'**) and Eo-(blank)-Rho-TR system (**E10a + 10b + R10c + T10d + m30a'b'c'd'**) showed excitation peak around 560 nm. The intensity was larger in the latter, which had shorter distance (10 residues) between Rho and TR. In Eo-Rho-Rho-TR system, larger excitation peak for Rho was observed because this system two Rhos. In addition to the Rho excitation peak, small peak corresponding with Eo was observed around 520 nm. This suggest some energy transfer from Eo to TR separated 30 residues. Quantitative for all excitation spectra below.

On the basis of the titration fluorescence spectra and excitation spectra, we were able to estimate quenching efficiency ( $Q(\%)$ ) and energy transfer efficiency ( $T(\%)$ ). Quenching efficiency ( $Q(\%)$ ) based on fluorescence quench-

ing of the donor chromophore was calculated using the following equation:

$$Q(\%) = (q - q_0)/(1 - q_0) \times 100$$

where  $q = 1 - I/I_0$ , and represents the quenching with acceptor/oligo-DNA conjugate,  $q_0$  is the quenching with free chromophore and oligo-DNA without chromophore,  $I$  is the fluorescence intensity, and  $I_0$  is the fluorescence intensity of donor/oligo-DNA conjugate.

Energy transfer ( $T(\%)$ ) based on excitation spectra was calculated using the following equation (54):

$$T_{app}(\%) = \frac{A_{(x)}}{A_{(100)}} \times 100 = \left\{ \frac{\phi_D F_D}{\phi_A F_A} (1 - T) + T \right\} \times 100$$

$T_{app}$  is the apparent energy transfer,  $A_{(100)}$  is the emission spectrum,  $A_{(x)}$  is the excitation spectrum of measurement system,  $\phi_D$  and  $\phi_A$  are the quantum yields of donor and acceptor chromophore, and  $F_D$  and  $F_A$  are the fluorescence of donor and acceptor chromophore/area of the emission spectrum.

The  $Q(\%)$ ,  $T_{app}(\%)$ , and  $T(\%)$  obtained for the molecular assemblies of chromophore/oligo-DNA conjugates with matrix oligo-DNAs summarized in Table 2. The efficiencies for one-step FRET from Eo to Rho and from Rho to TR were 32.3% and 36.3%, respectively. Direct energy transfer from Eo to TR in Eo-(blank)-TR system was 0%, because the 20 residue distance and small overlap of absorbance and emission spectra. In contrast, the Eo-Rho-TR system showed effective energy transfer (23.7% efficiency). The effect of Rho as a mediator was clear. The two-step energy transfer efficiency from Eo to TR though Rho was smaller than that of the one-step FRETs, but larger than their product. When comparing the Eo-Rho system and the Eo-(blank)-Rho system, energy transfer efficiency decreased depending the distance. This is not exactly in line with the Förster equation, probably due to the flexibility of the spacer groups and friction of the chromophores. Single Rho mediator systems, Eo-Rho-(blank)-TR system and Eo-(blank)-Rho-TR system, showed 13.8% and 8.5% of energy transfer efficiencies, respectively. On the other hand, the Eo-Rho-Rho-TR system having two Rho mediators showed larger energy transfer efficiency (21.6%), which was similar to that of the Eo-Rho-TR system (23.7%). These results indicate energy migration between two Rho mediators.

Sequential and quantitative duplex formation of chromophore/oligo-DNA conjugates with matrix oligo-DNA was investigated by QCM analysis. The following Sauerbrey equation was for the AT-cut shear mode QCM (55),

$$\Delta F = - \frac{2F_0^2}{A\sqrt{\rho_q \mu_q}} \Delta m$$

where,  $\Delta F$  is the measured frequency change (Hz),  $F_0$  the fundamental frequency of the QCM ( $27 \times 10^6$  Hz),  $\Delta m$  is the mass change (g),  $A$  is the electrode area ( $4.9 \text{ mm}^2$ ),  $\rho_q$  is the density of quartz ( $2.65 \text{ g cm}^{-3}$ ), and  $\mu_q$  is the shear modulus of quartz ( $2.95 \times 10^{11} \text{ dyn cm}^{-2}$ ). Previous calibration for the 27 MHz QCM showed that a frequency decrease of 1 Hz corresponded to a  $0.61 \text{ ng cm}^{-2}$  mass increase (53).

Typical results for the assembly of **E10a**, **R10b**, and **T10d** with **m30a'b'd'** are shown in Figure 10. First, 80 pmol of **m30a'b'd'** was added to **m30a'b'd'** bound to avidin-immobilized QCM sensor tip (total concentration of **E10a**

**Table 2. Quenching and Energy Transfer Efficiencies**

		$Q(\%)^a$	$T_{app}(\%)^b$	$T(\%)^c$
$E0 \rightarrow Rho$		50.2	45.8	32.3
$E0 \rightarrow (blank) \rightarrow TR$		5.4	2.4	0
$Rho \rightarrow TR$		62.5 <sup>d</sup>	46.8	36.3

$E0 \rightarrow (blank) \rightarrow Rho \rightarrow TR$		11.7	11.5	8.5
$E0 \rightarrow Rho \rightarrow Rho \rightarrow TR$		57.5	24.2	21.6

<sup>a</sup> Quenching efficiency of donor. <sup>b</sup> Apparent energy transfer estimated from excitation spectra. <sup>c</sup> Energy transfer efficiency calculated from the following equation:  $T_{app}(\%) = A_{(X)}/A_{(100)} \times 100 = \{\phi_D F_D / \phi_A F_A (1 - T) + T\} \times 100$  where  $A_{(100)}$ , emission spectrum;  $A_{(X)}$ , excitation spectrum of measurement system;  $\phi_{D(A)}$ , quantum yield of donor (acceptor) chromophore;  $F_{D(A)}$ , fluorescence of donor (acceptor) chromophore/area of emission spectrum. <sup>d</sup> Calculated from quenching of Rho.

**Figure 10.** Typical time dependencies of QCM frequency for immobilized **m30a'b'd'** responding to addition of **E10a**, **R10b**, and **T10d** in 0.05 M Tris·HCl–0.5 M NaCl buffer (pH 7.5) at 15 °C.

= 10 nM). A decrease in frequency was observed and a further 160 pmol of **E10a** was added. After this second addition of **E10a**, a larger decrease in frequency was observed (twice the decrease observed with the first addition). Following this, a further 160 pmol of **E10a** was added, and slight decreases in frequency and saturation of frequency change were observed. These results indicate that 400 pmol of **E10a** was an excess for immobilized **m30a'b'd'** and that the **m30a'b'd'** on QCM sensor tip quantitatively bound to **E10a**. The decrease in frequency was 59.5 Hz after total **E10a** addition (400 pmol). Second, 400 pmol of **R10b** was added to the solution, and a similar decrease in frequency (62.2 Hz) as seen with **E10a** (400 pmol) was observed. After confirmation of no further **R10b** binding by addition of excess **R10b** (800 pmol), 400 pmol of **T10d** was added to the solution. A slightly higher but similar decrease in frequency (75.0 Hz) as observed with **E10a** (400 pmol) was observed. No further **T10d** binding was confirmed by addition of excess **T10d** (800 pmol). These results indicate that almost the same amounts of **E10a**, **R10b**, and **T10d** bound to **m30a'b'd'**, and each 10-residue region of **m30a'b'd'** was quantitatively by **E10a**, **R10b** and **T10d**. From these

**Figure 11.** CD Spectrum for equivalent mixture of **m40a'b'c'd'**, **E10a**, **R10b**, **R10c**, and **T10d** (solid line), and equivalent mixture of **m40a'b'c'd'**, **10a**, **10b**, **10c**, and **10d** (dashed line) in 0.05 M Tris·HCl–0.5 M NaCl buffer (pH 7.5) at 15 °C. Concentration of each conjugate and oligo-DNA =  $1.0 \times 10^{-5}$  M.

results, formation of the expected assembly of chromophore/oligo-DNA conjugates with matrix oligo-DNA, as shown in Figure 2, was strongly suggested.

In order to obtain information about the conformation of the assembly, CD spectra were measured for equivalent mixtures of chromophore/oligo-DNA conjugates and matrix oligo-DNA at 15 °C. Figure 11 shows a typical example for equivalent mixtures of **E10a**, **R10b**, **R10c**, **T10d**, and **m40a'b'c'd'**, which were used in the experiment shown in Figure 7. Strong negative and positive cotton effects were observed around 250 and 280 nm, respectively. This pattern displays the typical characteristics of a B-form DNA duplex and is almost the same as that seen for the equivalent mixture of **10a**, **10b**, **10c**, **10d**, and **m40a'b'c'd'**. The assembly system of the four kinds of chromophore/oligo-DNA conjugates with the 40mer matrix oligo-DNA therefore displayed a B-form double helical conformation. Other systems, such as **E10a**, **R10b**, **T10d**, and **m30a'b'd'**, showed similar results. Figure 12 shows geometrical illustrations for assemblies of the three types of chromophore/oligo-DNAs and matrix oligo-DNA (30 or 40mer) assuming B-form double helical conformation. As the B-form DNA duplex has 10 residues per turn (34 Å), the system was believed

**Figure 12.** Schematic illustration geometry of chromophore arrays constructed on oligo-DNA assemblies. (a) 1:1:1 mixture of **E10a**, **R10b**, **T10d**, and **m30a'b'd'**, (b) 1:1:1:1 mixture of **E10a**, **R10b**, **R10c**, **T10d**, and **m40a'b'c'd'**.

to have all chromophores on the same side of the duplex at one-pitch distance (34 Å), as shown in Figure 12.

## CONCLUSIONS

Three chromophores (Eo, Rho, and TR) were attached to the 5'-terminal ends of 10mer oligo-DNAs in order to produce chromophore/oligo-DNA conjugates. Programmed sequential arrangements of chromophores separated by regulated distances of about one pitch of DNA duplex (34 Å) on noncovalent molecular assembly systems in aqueous media were then constructed by mixing conjugates with longer matrix oligo-DNAs. Multistep FRET from Eo to TR through one or two Rho mediators was observed on the molecular assemblies. The results suggested that photon-energy transfer occurred from Eo to TR separated by a long distance (three helical pitches, 104 Å) through Rho mediators via a multistep FRET on the molecular assemblies. The information obtained from these systems will be useful in constructing a photon-collecting antenna for an artificial photosynthetic system, as well as in enhancing our understanding of the mechanisms of energy transfer behavior in noncovalent molecular assembly system, such as natural photosynthetic systems. In subsequent research, details of the FRET behaviors of chromophores on oligo-DNA assemblies should be investigated using measurements of fluorescence lifetime and transition state absorption spectra of the chromophores.

## ACKNOWLEDGMENT

A part of this study was financially supported by a Grant-in-Aid for Scientific Research on Priority Areas from The Ministry of Education, Science, Sports and Culture, Japan. The authors express their thanks to Prof. Yoshio Okahata, Department of Biomolecular Engineering Tokyo Institute of Technology, for his assistance in QCM analysis.

**Supporting Information Available:** Experimental procedures for synthesis of chromophore/oligo-DNA conjugates, spectral data for conjugates, melting curves of assemblies, and illustration of QCM analysis. This material is available free of charge via the Internet at <http://pubs.acs.org/BC>.

# Multivalent Poly(ethylene glycol)-Containing Conjugates for In Vivo Antibody Suppression

David S. Jones,\* Michael J. Branks, Mary-Ann Campbell, Keith A. Cockerill, Jeffrey R. Hammaker, Christina A. Kessler, Eric M. Smith, Anping Tao, Huong-Thu Ton-Nu, and Tong Xu

San Diego, California 92121 Received June 19, 2003; Revised Manuscript Received August 19, 2003

Poly(ethylene glycol) (PEG) was incorporated into multivalent conjugates of the N-terminal domain of  $\beta_2$ GPI (domain 1). PEG was incorporated to reduce the rate of elimination of the conjugates from plasma and to putatively improve their efficacy as toleragens for the suppression of anti- $\beta_2$ GPI antibodies and the treatment of antiphospholipid syndrome (APS). Three structurally distinct types of multivalent platforms were constructed by incorporating PEG into the platform structures in different ways. The amount of PEG incorporated ranged from about 5000 g per mole to about 30000 g per mole. The platforms were functionalized with either four or eight aminooxy groups. The conjugates were prepared by forming oxime linkages between the aminooxy groups and N-terminally glyoxylated domain 1 polypeptide. The plasma half-life of each conjugate, labeled with  $^{125}\text{I}$ , was measured in both mice and rats. The half-lives of the conjugates ranged from less than 10 min to about 1 h in mice, and from less than 3 h to about 19 h in rats. The ability of five tetravalent conjugates to suppress anti-domain 1 antibodies in immunized rats was also measured. Incorporation of PEG in the conjugates significantly reduced the doses required for suppression, and the amount of reduction correlated with the amount of PEG incorporated.

## INTRODUCTION

B cell tolerance is a new approach to the treatment of B cell-mediated autoimmune diseases in which autoantibodies are pathogenic. The approach relies on multivalent presentation of B cell epitopes that are devoid of T cell epitopes to suppress the formation of antibody-producing cells immunospecifically and, therefore, selectively suppress pathogenic antibody formation. More information on the underlying principles of B cell tolerance can be found in recent review articles (1–3). Molecules designed to selectively suppress a pathogenic antibody response are called B cell toleragens. They are composed of multiple B cell receptor epitopes or mimetic epitopes connected to nonimmunogenic multivalent platforms. B cell toleragens have been successfully used to reduce antibody levels in animal models and in humans suffering from autoimmune diseases. Toleragens composed of double-stranded oligonucleotides (dsON) were developed for treating systemic lupus erythematosus (SLE). Those toleragens suppressed anti-dsON antibodies in mice immunized with dsON (4, 5). Human clinical trials have demonstrated suppression of anti-double-stranded DNA antibodies in patients suffering from SLE (6).

Toleragens composed of mimetic epitopes of  $\beta_2$ GPI are under development for treating antiphospholipid syndrome (APS), a condition in which anti- $\beta_2$ GPI antibodies (also referred to as anti-phospholipid antibodies) are believed to cause thrombotic events. Toleragens prepared using peptide mimics of  $\beta_2$ GPI were effective in suppressing anti-peptide antibody formation in an animal model; however, the peptides themselves bound the anti- $\beta_2$ GPI antibodies of only a small subset of patients (7). The

N-terminal domain of  $\beta_2$ GPI (domain 1) was recently discovered to recognize a high percentage of (APS) patient antisera (8). A toleragen composed of domain 1 was effective in suppressing anti-domain 1 antibodies in mice immunized with domain 1 (9). Antibody suppression in mice, using both the peptide toleragens and the domain 1 toleragen, required in vitro treatment of primed spleen cells followed by transfer into immune-ablated hosts. The domain 1 toleragen was, however, effective in vivo in rats immunized with domain 1. The difference in in vivo effectiveness of the toleragens in mice and rats was attributed to differential rates of clearance for the two species, and it became apparent that the effectiveness of toleragens could be improved by decreasing their rate of clearance from circulation.

Rapid clearance is a problem that is often encountered in the development of polypeptide-based therapeutic drugs that are generally administered parenterally. Frequent dosing of such drugs is not desirable, because it increases the cost of drug and is inconvenient for the patient. Continuous infusion is often necessary to maintain an effective drug concentration. In general, proteins of less than approximately 70 kDa, the size of albumin, will clear from blood by passing through the glomerular membrane in a size dependent manner (10).

A solution to rapid kidney clearance of drugs is to increase their physical size. That can be accomplished by attaching the drug to a macromolecule of sufficient size to prevent it from passing through the glomerular membrane (11). There are numerous examples of conjugates of polypeptides and macromolecules that have been prepared to enhance efficacy. Adriamycin and mitomycin C have been attached to 70 kDa dextran to prepare forms of those drugs that are more persistent in the circulation (12, 13). Attachment of poly(ethylene glycol) (PEG) to polypeptides has been widely used to improve their clinical effectiveness (11, 14, 15). In addition to reducing

**Figure 1.** Three distinct types of PEG-containing conjugate structures.

kidney clearance and providing prolonged in vivo circulation half-lives, "PEGylated" proteins may be less susceptible to proteolysis or clearance by receptor-mediated mechanisms, and they may be less immunogenic and antigenic (16). Other advantageous properties of PEG are its water solubility, its amenability to chemical modification at one or both termini, and its availability in a variety of molecular weight ranges with low polydispersity. Some examples of polypeptides that have been attached to PEG to prolong their circulation half-lives include antibody fragments (17), granulocyte colony stimulating factor (18), bovine hemoglobin (19), growth hormones (20), insulin (21), and interferon  $\alpha$ -2a (22). Several PEGylated polypeptides have been approved for treating human diseases. Further examples, of which there are many, may be found in recent review articles (14, 15).

This report describes new anti- $\beta_2$ GPI specific toleragens that were constructed from novel PEG-containing platforms designed to provide longer circulatory half-lives and therefore greater efficacy. Our aim was to incorporate PEG into the platforms before attachment of domain 1 in order to avoid nonselective modification of the polypeptide and to provide a well-defined conjugate. The syntheses of three novel structurally distinct types of PEG-containing platforms are described, as is the use of these platforms to prepare multivalent conjugates of domain 1. The structural varieties of conjugates are shown graphically in Figure 1. Summaries of pharmacokinetic data and in vivo tolerance data are also presented for the new conjugates.

#### EXPERIMENTAL PROCEDURES

**Abbreviations.** DIPEA, diisopropylethylamine; NHS, *N*-hydroxysuccinimide; DCC, 1,3-dicylohexylcarbodiimide; CDI, 1,1'-carbonyldiimidazole; HOBt, 1-hydroxybenzotriazole hydrate; Et<sub>3</sub>N, triethylamine; Boc, *tert*-butoxycarbonyl; TFA, trifluoroacetic acid; PBS, phosphate buffered saline; TA/D1, transaminated domain 1.

**General.** Monomethoxypoly(ethylene glycol) benzo-triazolyl carbonates of molecular weight 11690 g/mol (mPEG<sub>12K</sub>-BTC), 5215 g/mol (mPEG<sub>5K</sub>-BTC), 22334 g/mol (mPEG<sub>20K</sub>-BTC), 32120 g/mol (mPEG<sub>30K</sub>-BTC), poly(ethylene glycol) bis(benzotriazolyl) carbonate of molecular weight 21529 g/mol (PEG<sub>20K</sub>-bis-BTC), and mono-Boc-diaminopoly(ethylene glycol) of molecular weight 5094 g/mol (BocNH-PEG<sub>(5K)</sub>-NH<sub>2</sub>) were obtained from Shearwater Polymers, Huntsville, AL (now Nektar Therapeutics). *N*-(Benzyloxycarbonyloxy)succinimide was obtained from Aldrich Chemical Co., Milwaukee, WI.

Silica gel chromatography was performed on silica gel (230–400 Mesh ASTM) purchased from Baxter. TLC was

performed on silica gel plates (EM Separations cat. no. 5554). PBS was prepared by dissolving 175 g of NaCl, 6.5 g of NaH<sub>2</sub>PO<sub>4</sub>·H<sub>2</sub>O, and 40.9 g of Na<sub>2</sub>HPO<sub>4</sub>·7H<sub>2</sub>O in H<sub>2</sub>O and diluting to a final volume of 20 L. Sodium acetate 100 mM pH 4.6 buffer was prepared by dissolving 0.820 g (10 mmol) of sodium acetate in 95 mL of water, adding acetic acid to obtain a pH of 4.6, and adding water to obtain a volume of 100 mL. Tris acetate 100 mM pH 8.0 buffer was prepared by dissolving 1.21 g of tris-(hydroxymethyl)aminomethane in 95 mL of water, adding acetic acid to obtain a pH of 8.0, and adding water to obtain a volume of 100 mL. NMR spectra were recorded on a Bruker AC-300 spectrometer with a broad band probe. Low resolution mass spectra were recorded on a Finnigan LCQ electrospray mass spectrometer or obtained from the Mass Spectroscopy Lab at the Scripps Research Institute, San Diego, CA. High-resolution MALDI mass spectra were obtained from the Mass Spectroscopy Lab at the Scripps Research Institute, San Diego, CA. High-resolution FAB mass spectra were obtained from the Mass Spectrometry Laboratory at the University of California at Berkeley, Berkeley, CA. Optical densities of plate wells were obtained with a Power Wave 340 Microplate Spectrophotometer from Bio-Tek Instruments, Winooski, VT. Gamma counts were measured with a Cobra gamma counter from Packard Instruments, Downers Grove, IL. Protein concentrations were determined by UV absorbance at 280 nm using a molar extinction coefficient of 9531 L mol<sup>-1</sup> cm<sup>-1</sup> (1.35 mL mg<sup>-1</sup> cm<sup>-1</sup>) for the domain 1 polypeptide. Nunc Maxisorp Immunoplates were obtained from Nalge Nunc International, Rochester, NY. Recombinant human  $\beta_2$ GPI was obtained from Sigma, St. Louis, MO. Nonfat dry milk was produced by Carnation, Solon, OH. Alkaline phosphatase-conjugated goat anti-rat IgG was obtained from Jackson ImmunoResearch, West Grove, PA. Female CD-1 mice were obtained from The Jackson Laboratories, Bar Harbor, ME. Male Sprague–Dawley rats were obtained from Charles River, Hingham, MA.

**S-Acetyl-6-(*N*-*tert*-butyloxycarbonyl)aminoxyhexane-1-thiol, Compound 2.** To a solution of 77 mg (0.67 mmol) of potassium thioacetate in 15 mL of acetone was added 209 mg (0.61 mmol) of 6-(*N*-*tert*-butyloxycarbonyl)aminoxy-1-iodohexane (23), and the mixture was stirred at room temperature for 18 h. The acetone was removed under vacuum, and the residue was partitioned between 50 mL of CH<sub>2</sub>Cl<sub>2</sub> and 3 × 25 mL of 1 N NaOH. The CH<sub>2</sub>Cl<sub>2</sub> layer was dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, and concentrated to a brown oil. Purification by silica gel chromatography (15/85 EtOAc/hexanes) provided 166 mg (94%) of compound 2 as a colorless oil: <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  1.39 (m, 4H), 1.48 (s, 9H), 1.59 (m, 4H), 2.32 (s, 3H), 2.86 (t, 2H), 3.82 (t, 2H), 7.10 (s, 1H); <sup>13</sup>C NMR (CDCl<sub>3</sub>)  $\delta$  25.5, 28.0, 28.4, 28.6, 29.1, 29.5, 30.8, 76.7, 81.6, 157.1, 196.0; HRMS (MALDI) calculated for (M + Na): C<sub>13</sub>H<sub>25</sub>NaO<sub>4</sub>S: 314.1396. Found: 314.1402.

**6-(*N*-*tert*-butyloxycarbonyl)aminoxyhexane-1-thiol, Compound 3.** Compound 2 (50 mg, 172  $\mu$ mol) and 22  $\mu$ L (17.4 mg, 85.8  $\mu$ mol) of tri-*n*-butylphosphine was placed under nitrogen, and 2 mL of a nitrogen sparged 1 M solution of NaOH in MeOH was added to the mixture. The mixture was stirred for 18 h at room temperature, and 172  $\mu$ L (180 mg, 3 mmol) of TFA was added. The mixture was partitioned between 25 mL of EtOAc and 3 × 25 mL of 1 N HCl, and the combined aqueous layers were extracted with 25 mL of EtOAc. The combined EtOAc extracts were dried (Na<sub>2</sub>SO<sub>4</sub>), filtered, and concentrated. The resulting oil was purified by silica gel chromatography (15/85/0.1 EtOAc/hexanes/MeOH) to

provide 28 mg (65%) of **3** as a colorless oil:  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  1.32 (t, 1H), 1.40 (m, 4H), 1.49 (s, 9H), 1.62 (m, 4H), 2.53 (d of t, 2H), 3.84 (t, 2H), 7.09 (s, 1H);  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ )  $\delta$  24.4, 25.3, 27.8, 28.0, 28.2, 33.7, 76.6, 81.5, 156.8; HRMS (MALDI) calculated for ( $\text{M} + \text{Na}$ ):  $\text{C}_{11}\text{H}_{23}\text{NaNO}_3\text{S}$ : 272.1291. Found: 272.1294.

**Preparation of Compound 5 from Compound 2 without Isolation of Compound 3.** Compound **2** (13 mg, 45  $\mu\text{mol}$ ) and 6  $\mu\text{L}$  (4.5 mg, 22.3  $\mu\text{mol}$ ) of tri-*n*-butylphosphine was placed under nitrogen, and 3 mL of a nitrogen sparged solution of 4/1 6 N  $\text{NH}_4\text{OH}/\text{CH}_3\text{CN}$  was added to the mixture. The mixture was stirred for 1 h at room temperature and concentrated under vacuum. The residue was dissolved in 3 mL of a nitrogen-sparged solution of 10/90 water/ $\text{CH}_3\text{CN}$ . The resulting solution of **3** was kept under nitrogen atmosphere, and 10 mg (7.44  $\mu\text{mol}$ ) of compound **4** (prepared as described in ref 5) was added, followed by 8  $\mu\text{L}$  (5.77 mg, 44.6  $\mu\text{mol}$ ) of DIPEA. The mixture was stirred for 18 h and concentrated under vacuum. The residue was purified by silica gel chromatography (multiple step gradient, 1/99 to 5/95 to 7.5/92.5 to 10/90 to 15/85  $\text{MeOH}/\text{CH}_2\text{Cl}_2$ ) to provide 14 mg (93%) of **5** as a colorless oil: TLC (10/90  $\text{MeOH}/\text{CH}_2\text{Cl}_2$ ),  $R_f$  = 0.3;  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  1.51 (m, 92H), 2.22 (t, 8H), 2.54 (t, 8H), 3.19 (m, 24H), 3.38 (brd s, 8H), 3.75 (m, 12H), 3.82 (t, 4H), 4.19 (t, 4H), 7.38 (brd s, 8H), 7.94 (s, 4H);  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ )  $\delta$  12.2, 17.2, 18.3, 25.0, 25.2, 26.2, 27.6, 28.0, 28.2, 28.8, 28.9, 32.6, 35.8, 39.3, 42.5, 54.2, 64.3, 69.0, 70.1, 76.2, 81.0, 156.6, 156.7, 169.2, 173.5; mass spectrum (ES)  $m/z$  calculated for  $\text{C}_{92}\text{H}_{173}\text{N}_{14}\text{O}_{26}\text{S}_4$  ( $\text{M} + \text{H}$ ): 2018. Found: 2018; HRMS (ESI) ( $\text{M} + 2\text{Na}$ ) $^{+2}$  calculated for  $\text{C}_{92}\text{H}_{172}\text{Na}_2\text{N}_{14}\text{O}_{26}\text{S}_4$ : 1031.5617. Found: 1031.5633.

**6-(*N*-*tert*-Butyloxycarbonyl)aminooxyhexanoic Acid, Compound 7.** To a magnetically stirred solution of 7.2 g (26 mmol) of compound **6** (**23**) in 10 mL of EtOH was added 5 mL of 50% w/w NaOH solution in water. The reaction was done in 5 min, as determined by TLC (1/5 EtOAc/hexanes). The reaction mixture was concentrated, and the residue was partitioned between 20 mL of  $\text{CH}_2\text{Cl}_2$  and 20 mL of 1 N HCl solution. The layers were separated, and the aqueous layer was extracted with 6  $\times$  10 mL portions of  $\text{CH}_2\text{Cl}_2$ . The combined  $\text{CH}_2\text{Cl}_2$  layers were dried ( $\text{MgSO}_4$ ), filtered, and concentrated to give 6.5 g (99%) of compound **7** as a colorless oil.  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  1.44 (m, 2H), 1.48 (s, 9H), 1.66 (m, 4H), 2.37 (t, 2H), 3.85 (t, 2H), 7.20 (s, 1H);  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ )  $\delta$  24.6, 25.5, 27.8, 28.4, 34.0, 76.6, 82.0, 157.5, 179.3; HRMS (MALDI) calculated for ( $\text{M} + \text{Na}$ ):  $\text{C}_{11}\text{H}_{21}\text{NaNO}_5$ : 270.1312. Found: 270.1309.

**Synthesis of Compound 8.** To a magnetically stirred solution of 1.00 g (4.04 mmol) of compound **7** in 10 mL of  $\text{CH}_2\text{Cl}_2$  at 0  $^\circ\text{C}$  was added 511 mg (4.44 mmol) of NHS followed by 1.25 g (6.06 mmol) of DCC. The mixture was brought to room temperature within 1 h. The mixture was stirred for 16 h, 750  $\mu\text{L}$  of acetic acid was added, and the mixture was placed in the freezer for 30 min. The solids were removed by filtration, and the filtrate was concentrated to a viscous oil. Purification by silica gel chromatography (15/85 acetone/toluene) provided 1.13 g (81%) of compound **8** as a white amorphous solid:  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  1.48 (s, 9H), 1.51 (m, 2H), 1.68 (m, 2H), 1.79 (m, 2H), 2.63 (t, 2H), 2.84 (br. s, 4H), 3.87 (t, 2H), 7.18 (br. s, 1H);  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ )  $\delta$  24.32, 25.07, 25.53, 27.42, 28.16, 30.77, 76.13, 81.51, 156.89, 168.45, 169.15; HRMS (MALDI) calculated for ( $\text{M} + \text{Na}$ ):  $\text{C}_{15}\text{H}_{24}\text{NaN}_2\text{O}_7$ : 367.1476. Found: 367.1474.

**Synthesis of Compound 9.** A magnetically stirred solution of 1.49 g (11.4 mmol) of 6-aminocaproic acid and

958 mg (11.4 mmol) of  $\text{NaHCO}_3$  in 144 mL of water was cooled to 0  $^\circ\text{C}$ . To the solution was added 27.8 mL of  $\text{CH}_3\text{CN}$  followed by a solution of 1.31 g (3.80 mmol) of compound **8** in 30 mL of  $\text{CH}_3\text{CN}$ . The mixture was brought to room temperature within an hour and stirred for 18 h. The mixture was concentrated, and the residue was partitioned between 70 mL of 1 N HCl and 2  $\times$  70 mL of  $\text{CH}_2\text{Cl}_2$ . The combined  $\text{CH}_2\text{Cl}_2$  layers were washed with brine, dried ( $\text{MgSO}_4$ ), filtered, and concentrated. Purification by silica gel chromatography 45/55/0.5 acetone/toluene/acetic acid provided 1.18 g (86%) of compound **9** as a viscous oil.  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  1.42 (m, 4H), 1.49 (s, 9H), 1.53 (m, 2H), 1.65 (m, 6H), 2.20 (t, 2H), 3.38 (t, 2H), 2.88 (q, 2H), 3.86 (t, 2H), 5.84 (br t, 1H), 7.67 (br s, 1H);  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ )  $\delta$  24.1, 25.3, 25.4, 26.1, 27.5, 28.2, 29.0, 33.7, 36.4, 76.4, 81.7, 157.2, 173.4, 177.6; HRMS (MALDI) calculated for ( $\text{M} + \text{Na}$ ):  $\text{C}_{17}\text{H}_{32}\text{NaN}_2\text{O}_6$ : 383.2152. Found: 383.2141.

**Synthesis of Dimer Cassette, Compound 10.** To a magnetically stirred solution of 1.09 g (3.04 mmol) of compound **9** in 11 mL of EtOAc was added 493 mg (3.04 mmol) of CDI. The reaction was stirred under  $\text{N}_2$  for 1 h, and 160  $\mu\text{L}$  (152 mg, 1.48 mmol) of diethylenetriamine was added followed by 423  $\mu\text{L}$  (307 mg, 3.03 mmol) of  $\text{Et}_3\text{N}$  at which time a precipitate formed. The mixture was stirred for 3 h and partitioned between 25 mL of  $\text{H}_2\text{O}$  and 200 mL of  $\text{CH}_2\text{Cl}_2$ . The  $\text{CH}_2\text{Cl}_2$  layer was washed with 25 mL of  $\text{H}_2\text{O}$  and 25 mL of brine, dried ( $\text{MgSO}_4$ ), filtered, and concentrated. Purification by silica gel chromatography (step gradient 17/83/0.5  $\text{MeOH}/\text{CH}_2\text{Cl}_2$ /concd  $\text{NH}_4\text{OH}$  to 20/80/0.5  $\text{MeOH}/\text{CH}_2\text{Cl}_2$ /concd  $\text{NH}_4\text{OH}$ ) provided 851 mg (73%) of compound **10** as a light yellow, glassy solid.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ )  $\delta$  1.38 (m, 8H), 1.46 (s, 9H), 1.49 (m, 4H), 1.62 (m, 12 H), 2.18 (t, 4H), 2.20 (t, 4H), 2.75 (t, 4H), 3.16 (t, 4H), 3.30 (t, 4H), 3.77 (t, 4H);  $^{13}\text{C}$  NMR ( $\text{CD}_3\text{OD}$ )  $\delta$  26.5, 26.6, 26.8, 27.6, 28.6, 28.8, 30.2, 37.0 (36.98), 37.0 (37.02), 39.7, 40.2, 49.4, 77.2, 81.9, 159.1, 176.0, 176.5; HRMS (MALDI) calculated for ( $\text{M} + \text{H}$ ):  $\text{C}_{38}\text{H}_{74}\text{N}_7\text{O}_{10}$ : 788.5491. Found: 788.5488.

**Compound 12.** To a solution of 1.50 g (7.76 mmol) of compound **11** (prepared as described in ref 24) and 1.30 g (15.52 mmol) of  $\text{NaHCO}_3$  in 20 mL of  $\text{H}_2\text{O}$  at 0  $^\circ\text{C}$  was added a solution of 2.32 g (9.31 mmol) of *N*-(benzyloxycarbonyloxy)succinimide dissolved in 20 mL of dioxane. Cooling was discontinued, and the mixture was stirred for 4 h at room temperature. The mixture was acidified to approximately pH 1 with 1 N HCl and partitioned between 20 mL of 1 N HCl and 100 mL of  $\text{CH}_2\text{Cl}_2$ . The aqueous layer was extracted with four additional 50 mL portions of  $\text{CH}_2\text{Cl}_2$ . All of the  $\text{CH}_2\text{Cl}_2$  extracts were combined, dried ( $\text{MgSO}_4$ ), filtered, and concentrated. The residue was dissolved in 30 mL of  $\text{CH}_2\text{Cl}_2$  and cooled to 0  $^\circ\text{C}$ . To the solution was added 6.26 g (31.0 mmol) of 4-nitrophenylchloroformate followed by addition of 5 mL (4.91 g, 62.1 mmol) of pyridine dropwise over approximately 2 min during which time a precipitate formed. Cooling was discontinued, and the mixture was allowed to stir for 3 h at room temperature. The precipitate was removed by filtration and washed with approximately 20 mL of  $\text{CH}_2\text{Cl}_2$ . Approximately 1 mL of water was added to the filtrate, and the mixture was stirred for 5 min and shaken with 50 mL of 1 N HCl. The organic layer was collected, and the aqueous layer was extracted with 50 mL of  $\text{CH}_2\text{Cl}_2$ . The combined organic layers were washed successively with four 25 mL portions of saturated  $\text{NaHCO}_3$  solution, 25 mL of 1 N HCl, and 25 mL of brine, dried ( $\text{MgSO}_4$ ), filtered, and concentrated. Purification by silica gel chromatography (loaded in  $\text{CH}_2\text{Cl}_2$  and eluted with 50/50 EtOAc/hexanes) provided 3.81 g (75%) of

compound **12** as a viscous oil:  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  3.48–3.82 (m, 12H), 4.39 (m, 4H), 5.12 (s, 2H), 7.34 (m, 7H), 8.23 (d, 2H);  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ )  $\delta$  47.8, 48.2, 67.2, 68.0, 68.1, 68.2, 68.3, 69.6, 69.9, 121.7, 125.2, 127.8, 128.0, 128.5, 136.6, 145.4, 152.4, 155.4, 156.1; HRMS mass spectrum (MALDI) ( $\text{M} + \text{Na}$ ) calculated for  $\text{C}_{30}\text{H}_{31}\text{N}_3\text{O}_{14}$ : 680.1698. Found 680.1697.

**Compound 13.** A solution of 294 mg (0.45 mmol) of compound **12** in 30 mL of pyridine was added to a flask containing 775 mg (0.98 mmol) of compound **10**. Triethylamine (249  $\mu\text{L}$ , 1.81 mmol, 1.79 mmol) was added, and the mixture was stirred at room temperature under nitrogen atmosphere for 18 h. Most of the pyridine was removed under reduced pressure, and the residue was partitioned between 100 mL of  $\text{CH}_2\text{Cl}_2$  and  $3 \times 20$  mL of 1 N HCl. The  $\text{CH}_2\text{Cl}_2$  extract was washed with 20 mL of brine, dried ( $\text{MgSO}_4$ ), filtered, and concentrated to a yellow oil. Purification by silica gel chromatography (step gradient: 5/95/0.1 to 10/90/0.1 to 15/85/0.1 MeOH/ $\text{CH}_2\text{Cl}_2$ /HOAc) provided 633 mg (72%) of compound **13** as a viscous oil:  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ )  $\delta$  1.20–1.52 (m, 24H), 1.43 (s, 36H), 1.60 (m, 24H), 2.16 (m, 16H), 3.12 (m, 8H), 3.33 (m, 20H), 3.50–3.70 (m, 16H), 3.76 (t, 8H), 4.16 (m, 4H), 5.12 (s, 2H), 7.36 (brd s, 5H), 7.93 (m, 4H);  $^{13}\text{C}$  NMR ( $\text{CD}_3\text{OD}$ )  $\delta$  26.6, 26.8, 27.6, 28.7, 28.8, 30.2, 37.0, 38.7, 39.0, 40.2, 40.3, 65.8, 68.3, 70.1, 70.3, 70.5, 77.2, 81.9, 128.8, 129.2, 129.7, 138.1, 158.0, 158.1, 159.1, 176.0, 176.2; HRMS mass spectrum (MALDI) ( $\text{M} + \text{Na}$ ) calculated for  $\text{C}_{94}\text{H}_{167}\text{N}_3\text{O}_{28}$ : 1977.1997. Found 1977.1899.

**Compound 14.** A solution of 300 mg (0.15 mmol) of compound **13** and 8.8  $\mu\text{L}$  (9.2 mg, 0.13 mmol) of acetic acid in 20 mL of MeOH was purged with  $\text{H}_2$ . To the solution was added 75 mg of 10% palladium on carbon. A hydrogen-filled balloon was attached, and the mixture was stirred for 2 h. The flask was purged with nitrogen, the catalyst was removed by filtration, and the mixture was concentrated to provide 282 mg (quantitative yield) of compound **14** as a gummy solid:  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ )  $\delta$  1.38 (m, 16H), 1.48 (m, 44H), 1.65 (m, 24H), 2.20 (t, 16H), 2.83 (t, 4H), 3.17 (t, 8H), 3.38 (m, 16H), 3.63 (t, 4H), 3.69 (t, 4H), 3.78 (t, 4H), 4.21 (m, 4H);  $^{13}\text{C}$  NMR ( $\text{CD}_3\text{OD}$ )  $\delta$  26.7, 27.0, 27.8, 28.8, 28.9, 30.3, 37.1, 38.8, 39.1, 40.3, 49.9, 66.0, 70.4, 70.9, 77.3, 82.0, 158.2, 159.2, 176.1, 176.3; mass spectrum (ESI) ( $\text{M} + \text{H}$ ) $^+$  calculated for  $\text{C}_{86}\text{H}_{162}\text{N}_{15}\text{O}_{26}$ : 1821. Found 1821; HRMS (MALDI) ( $\text{M} + \text{Na}$ ) calculated for  $\text{C}_{86}\text{H}_{162}\text{N}_{15}\text{O}_{26}$ : 1821.1809. Found 1821.1803.

**Compound 16b.** To a solution of 20 mg (11.0  $\mu\text{mol}$ ) of compound **14** in 5 mL of DMF was added 103 mg (8.8  $\mu\text{mol}$ ) of compound **15b** (mPEG<sub>12K</sub>-BTC) followed by 5  $\mu\text{L}$  (3.6 mg, 35.9  $\mu\text{mol}$ ) of  $\text{Et}_3\text{N}$ . The mixture was stirred at room temperature for 18 h and concentrated. The residue was purified by silica gel chromatography (multistep gradient: 5/95 to 15/85 to 20/80 MeOH/ $\text{CH}_2\text{Cl}_2$ ) to provide 109 mg (92%) of compound **16b** as a waxy solid:  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  1.37 (m, 16H), 1.49 (m, 44H), 1.65 (m, 24H), 2.20 (t, 16H), 3.20 (q, 8H), 3.36 (m, 16H), 3.61 (m, 4H), 3.68 (m, approximately 1056H), 3.84 (t, 8H), 3.91 (m, 4H), 4.23 (m, 4H); mass spectrum (MALDI) average  $m/z$  calculated for  $\text{C}_{610}\text{H}_{1208}\text{N}_{15}\text{O}_{289}$ : 13370. Found: 13711.

**Compound 16a.** This compound was prepared in 69% yield using essentially the same procedure used for the preparation of compound **16b**; however, compound **15a** (mPEG<sub>5K</sub>-BTC) was used:  $^1\text{H}$  NMR (4:1  $\text{CDCl}_3/\text{CD}_3\text{OD}$ )  $\delta$  1.37 (m, 16H), 1.49 (m, 44H), 1.65 (m, 24H), 2.20 (t, 16H), 3.20 (q, 8H), 3.36 (m, 16H), 3.61 (m, 4H), 3.68 (m, approximately 468H), 3.84 (t, 8H), 3.91 (m, 4H), 4.23 (m, 4H); mass spectrum (MALDI) average  $m/z$  calculated for  $\text{C}_{316}\text{H}_{619}\text{N}_{15}\text{O}_{142}$ : 6898. Found: 6800.

**Compound 16c.** This compound was prepared in 92% yield using essentially the same procedure used for the preparation of compound **16b**; however, compound **15c** (mPEG<sub>20K</sub>-BTC) was used:  $^1\text{H}$  NMR (5:1  $\text{CDCl}_3/\text{CD}_3\text{OD}$ )  $\delta$  1.37 (m, 16H), 1.49 (m, 44H), 1.65 (m, 24H), 2.20 (t, 16H), 3.20 (q, 8H), 3.36 (m, 16H), 3.61 (m, 4H), 3.68 (m, approximately 2024H), 3.84 (t, 8H), 3.91 (m, 4H), 4.23 (m, 4H); mass spectrum (MALDI) average  $m/z$  calculated for  $\text{C}_{1094}\text{H}_{2175}\text{N}_{15}\text{O}_{531}$ : 24023. Found: 23400.

**Compound 16d.** This compound was prepared in 54% yield using essentially the same procedure used for the preparation of compound **16b**; however, compound **15d** (mPEG<sub>30K</sub>-BTC) was used:  $^1\text{H}$  NMR (5:1  $\text{CDCl}_3/\text{CD}_3\text{OD}$ )  $\delta$  1.37 (m, 16H), 1.49 (m, 44H), 1.65 (m, 24H), 2.20 (t, 16H), 3.20 (q, 8H), 3.36 (m, 16H), 3.61 (m, 4H), 3.68 (m, approximately 2,900H), 3.84 (t, 8H), 3.91 (m, 4H), 4.23 (m, 4H); mass spectrum (MALDI) average  $m/z$  calculated for  $\text{C}_{1538}\text{H}_{3663}\text{N}_{15}\text{O}_{753}$ : 33818. Found: 33775.

**Compound 17.** To a solution of 54 mg (29.6  $\mu\text{mol}$ ) of compound **14**, 9 mg (13.5  $\mu\text{mol}$ ) of compound **12**, and 8 mg (53.9  $\mu\text{mol}$ ) of HOBT in 5 mL of anhydrous pyridine was added 15  $\mu\text{L}$  (10.9 mg, 107.8  $\mu\text{mol}$ ) of  $\text{Et}_3\text{N}$ . The mixture was stirred for 18 h and concentrated to a viscous oil. The residue was purified by HPLC using a 24 mm  $\times$  30 cm  $\text{C}_{18}$  column (gradient 30% to 60% B over 60 min; A =  $\text{H}_2\text{O}/0.1\%$  TFA, B =  $\text{CH}_3\text{CN}/0.1\%$  TFA) to provide 17 mg (31%) of compound **17** as a waxy white solid:  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ )  $\delta$  1.20–1.51 (m, 48H), 1.43 (s, 72H), 1.60 (m, 48H), 2.19 (t, 32H), 3.14 (t, 16H), 3.32 (m, 32H), 3.50 (m, 12H), 3.59 (m, 12H), 3.64 (m, 12H), 3.78 (t, 16H), 4.18 (m, 12H), 5.12 (s, 2H), 7.32 (m, 5H);  $^{13}\text{C}$  NMR ( $\text{CD}_3\text{OD}$ )  $\delta$  26.6, 26.8, 27.6, 28.6, 28.8, 30.2, 37.0, 38.7, 39.0, 40.2, 65.8, 68.3, 70.2, 70.6, 77.2, 81.9, 128.8, 129.2, 129.3, 129.7, 129.9, 138.2, 157.8, 157.9, 158.0, 159.1, 176.0, 176.2; HRMS (ESI) ( $\text{M} + 3\text{Na}$ ) $^{+3}$  calculated for  $\text{C}_{190}\text{H}_{343}\text{N}_3\text{O}_{60}$ : 1362.8134. Found: 1362.8224.

**Compound 18.** A solution of 9 mg (2.24  $\mu\text{mol}$ ) of compound **17** in 10 mL of MeOH was placed under an  $\text{H}_2$  atmosphere by applying partial vacuum and filling with  $\text{H}_2$ . To the solution was added 10 mg of 10% palladium on carbon, a  $\text{H}_2$ -filled balloon was attached, and the mixture was stirred at room temperature for 2 h. The flask was purged with  $\text{N}_2$ , the catalyst was removed by filtration, and the filtrate was concentrated to provide 6 mg (69%) of compound **18** as a colorless gum:  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ )  $\delta$  1.23–1.50 (m, 48H), 1.48 (s, 72H), 1.61 (m, 48H), 2.19 (t, 32H), 3.08 (brd t, 4H), 3.17 (t, 16H), 3.38 (m, 36H), 3.52 (m, 8H), 3.63 (t, 8H), 3.70 (m, 12H), 3.78 (t, 16H), 4.21 (m, 12H);  $^{13}\text{C}$  NMR ( $\text{CD}_3\text{OD}$ )  $\delta$  26.7, 26.9, 27.7, 28.7, 28.9, 30.2, 37.1, 38.8, 39.1, 40.3, 65.9, 70.3, 77.2, 81.9, 158.0, 158.1, 159.1, 176.0, 176.2; mass spectrum (ESI) ( $\text{M} + \text{H}$ ) $^+$  calculated for  $\text{C}_{182}\text{H}_{338}\text{N}_{31}\text{O}_{58}$ : 3887. Found 3887. HRMS (ESI) ( $\text{M} + 3\text{Na}$ ) $^{+3}$  calculated for  $\text{C}_{182}\text{H}_{337}\text{N}_{31}\text{O}_{58}$ : 1318.1350. Found: 1318.1419.

**Compound 19.** To a solution of 13 mg (3.34  $\mu\text{mol}$ ) of compound **18** in 5 mL of pyridine was added 60 mg (2.68  $\mu\text{mol}$ ) of compound **15c** (mPEG<sub>20K</sub>-BTC) followed by 5  $\mu\text{L}$  (3.6 mg, 35.9  $\mu\text{mol}$ ) of  $\text{Et}_3\text{N}$ . The mixture was stirred at room temperature for 18 h and concentrated. The residue was purified by silica gel chromatography (multistep gradient: 10/90 to 15/85 to 20/80 MeOH/ $\text{CH}_2\text{Cl}_2$ ) to provide 45 mg (68%) of compound **19** as a waxy solid:  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  1.30 (m, 32H), 1.50 (m overlapping s at 1.48, 88H), 1.67 (m, 48H), 2.24 (t, 32H), 3.23 (m, 16H), 3.41 (m, 32H), 3.65 (m, approximately 2024H), 3.70 (t, 24H), 3.89 (m, 16H), 4.21 (m, 12H); mass spectrum (MALDI) average  $m/z$  calculated for  $\text{C}_{1127}\text{H}_{2227}\text{N}_{31}\text{O}_{531}$ : 24696. Found: 23270.

**Compound 21.** To a solution of 22 mg (27.3  $\mu\text{mol}$ ) of compound **10** in 5 mL of pyridine was added 236 mg (10.9  $\mu\text{mol}$ ) of compound **20** (PEG<sub>20K</sub>-bis-BTC) followed by 8  $\mu\text{L}$  (5.8 mg, 57.4  $\mu\text{mol}$ ) of Et<sub>3</sub>N. The mixture was stirred at room temperature for 18 h and concentrated. The residue was purified by silica gel chromatography (multistep gradient; 5/95 to 10/90 to 15/85 to 20/80 MeOH/CH<sub>2</sub>Cl<sub>2</sub>) to provide 242 mg (96%) of compound **21** as a white solid: <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  1.35 (m, 16H), 1.48 (m, 44H), 1.61 (m, 24H), 2.20 (m, 16H), 3.22 (m, 8H), 3.52–3.96 (m, approximately 2000H), 4.23 (m, 4H); mass spectrum (MALDI) average  $m/z$  calculated for C<sub>1040</sub>H<sub>2068</sub>N<sub>14</sub>O<sub>504</sub>: 22836. Found: 23246.

**Compound 24.** To a solution of 3.87 mg (4.85  $\mu\text{mol}$ ) of compound **22** (25) in 5 mL of pyridine was added 124 mg (24.2  $\mu\text{mol}$ ) of compound **23** (BocNH-PEG<sub>(5K)</sub>-NH<sub>2</sub>) and 5  $\mu\text{L}$  (3.63 mg, 35.9  $\mu\text{mol}$ ) of Et<sub>3</sub>N, and the mixture was stirred for 18 h and concentrated under vacuum. The residue was purified by silica gel chromatography (step gradient; 5/95 to 15/85 MeOH/CH<sub>2</sub>Cl<sub>2</sub>) to provide 77 mg (77%) of compound **24** as a white solid: <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  1.48 (s, 36H), 3.32 (m, 16H), 3.52–3.96 (m, approximately 1818H), 4.10 (m, 8H); mass spectrum (MALDI) average  $m/z$  calculated for C<sub>933</sub>H<sub>1860</sub>N<sub>8</sub>O<sub>464</sub>: 20604. Found: 21340.

**Compound 25.** Compound **24** (77 mg, 3.73  $\mu\text{mol}$ ) was dissolved in 5 mL of TFA, and the mixture was allowed to stand for 3 h. The TFA was removed under a stream of N<sub>2</sub>, and the residue was dissolved in 5 mL of CH<sub>2</sub>Cl<sub>2</sub>. To the resulting solution was added a solution of 7.72 mg (22.4  $\mu\text{mol}$ ) of compound **8** in 5 mL of CH<sub>2</sub>Cl<sub>2</sub> followed by 35  $\mu\text{L}$  (25.4 mg, 251  $\mu\text{mol}$ ) of Et<sub>3</sub>N. (Note: The pH of the mixture should be checked and adjusted accordingly with Et<sub>3</sub>N to make sure it is basic.) The mixture was stirred under nitrogen for 18 h and partitioned between 50 mL of CH<sub>2</sub>Cl<sub>2</sub> and three 25 mL portions of 1 N HCl. The CH<sub>2</sub>Cl<sub>2</sub> layer was washed with brine, dried (MgSO<sub>4</sub>), filtered, and concentrated. Purification by silica gel chromatography (step gradient; 5/95 to 10/90 MeOH/CH<sub>2</sub>Cl<sub>2</sub>) provided 42 mg (53%) of compound **25** as waxy solid: <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  1.40 (m, 8H), 1.48 (s, 36H), 1.66 (m, 16H), 2.18 (t, 8H), 3.32 (m, 16H), 3.38–3.89 (m, approximately 1818H), 4.10 (m, 8H), 4.97 (t, 4H), 6.43 (t, 4H), 7.47 (s, 4H); mass spectrum (MALDI) average  $m/z$  calculated for C<sub>957</sub>H<sub>1904</sub>N<sub>12</sub>O<sub>472</sub>: 21122. Found: 21796.

**Synthesis of Compound 1a (LJP 1027).** Compound **5** (4.1 mg,  $2.05 \times 10^{-6}$  mol) was treated with 3 mL of a solution of 1/9 TFA/CH<sub>2</sub>Cl<sub>2</sub> for 2 h at room temperature. The mixture was concentrated to an oil under vacuum, and immediately 200  $\mu\text{L}$  of 0.1 M pH 8.0 tris acetate buffer was added followed by 200  $\mu\text{L}$  of CH<sub>3</sub>CN. The resulting solution was added to a helium sparged solution of 87 mg ( $12.1 \times 10^{-6}$  mol) of TA/D1 in 10.9 mL of 0.1 M pH 4.6 sodium acetate buffer using approximately 0.5 mL of CH<sub>3</sub>CN to rinse residual material into the reaction mixture. The mixture was allowed to stand for 16 h at room temperature, and the resulting mixture was purified by preparative HPLC (1 in.  $\times$  30 cm diphenyl column (Vydak), 12 mL/min, gradient 27% to 45% B over 40 min; A = H<sub>2</sub>O/0.1% TFA, B = CH<sub>3</sub>CN/0.1% TFA). The fractions containing product were lyophilized to provide 34 mg (55%) of compound **1a** as a white powder: mass spectrum (ESI)  $m/z$  calculated for C<sub>1352</sub>H<sub>2104</sub>N<sub>338</sub>O<sub>370</sub>S<sub>24</sub>: 29783. Found: 29783.

**Synthesis of Compound 1g (LJP 1082).** Compound **21** (318 mg,  $13.9 \times 10^{-6}$  mol) was treated with 16 mL of a solution of 1/1 TFA/CH<sub>2</sub>Cl<sub>2</sub> for 30 min at room temperature. The mixture was concentrated to an oil under vacuum, and immediately 3 mL of 0.1 M pH 8.5 Tris

acetate buffer was added followed by 3 mL of CH<sub>3</sub>CN. The resulting solution was added to a helium-sparged solution of 532 mg ( $7.53 \times 10^{-5}$  mol) of TA/D1 in 35 mL of 0.1 M pH 4.6 sodium acetate buffer using 2 mL of CH<sub>3</sub>CN to rinse residual material into the reaction mixture. The pH was adjusted to between 4.4 and 4.6 by addition of approximately 2.4 mL of 5 N NaOH solution, and the mixture was allowed to stand for 16 h. The pH was adjusted to 7 by addition of 5 N NaOH solution, and the mixture was dialyzed against water followed by 10 mM pH 7 sodium phosphate solution for approximately 16 h until a conductivity of 1.0 mmho was obtained. The resulting solution was purified in three portions by cation exchange chromatography (2 cm  $\times$  17 cm column packed with Toyopearl CM650M (TosoHass); flow rate 8 mL/minute; gradient 2–13% B 0–120 min; A = 9/1 10 mM pH 7 sodium phosphate/CH<sub>3</sub>CN, B = A + 1 M NaCl). The fractions containing product were partially lyophilized to reduce the volume and dialyzed against water. The desalted solution was lyophilized to provide 413 mg (59%) of compound **1g** as a white powdery solid: mass spectrum (MALDI) average  $m/z$  calculated for C<sub>2300</sub>H<sub>4000</sub>N<sub>338</sub>O<sub>848</sub>S<sub>20</sub>: 50600. Found: 51620.

**Compound 1b (LJP 1078).** Compound **1b** was prepared in a manner essentially similar to that described for compound **1g**. A mole ratio of 6.0/1.0 of TA/D1/compound **16a** was used resulting in an overall yield of 55% of compound **1b**: mass spectrum (MALDI) average  $m/z$  calculated for C<sub>1576</sub>H<sub>2551</sub>N<sub>339</sub>O<sub>486</sub>S<sub>20</sub>: 34666. Found: 35025.

**Compound 1c (LJP 1081).** Compound **1c** was prepared in a manner essentially similar to that described for compound **1g**. A mole ratio of 8.0/1.0 of TA/D1/compound **16b** was used resulting in an overall yield of 35% of compound **1c**: mass spectrum (MALDI) average  $m/z$  calculated for C<sub>1870</sub>H<sub>3140</sub>N<sub>339</sub>O<sub>633</sub>S<sub>20</sub>: 41143. Found: 41922.

**Compound 1d (LJP 1077).** Compound **1d** was prepared in a manner essentially similar to that described for compound **1g**. A mole ratio of 6.0/1.0 of TA/D1/compound **16c** was used resulting in an overall yield of 59% of compound **1d**: mass spectrum (MALDI) average  $m/z$  calculated for C<sub>2354</sub>H<sub>4107</sub>N<sub>339</sub>O<sub>875</sub>S<sub>20</sub>: 51802. Found: 51636.

**Compound 1e (LJP 1086).** Compound **1e** was prepared in a manner essentially similar to that described for compound **1g**. A mole ratio of 6.6/1.0 of TA/D1/compound **16d** was used resulting in an overall yield of 31% of compound **1e**: mass spectrum (MALDI) average  $m/z$  calculated for C<sub>2808</sub>H<sub>5015</sub>N<sub>339</sub>O<sub>1102</sub>S<sub>20</sub>: 61803. Found: 61739.

**Compound 1f (LJP 1084).** Compound **1f** was prepared in a manner essentially similar to that described for compound **1g**. A mole ratio of 12.0/1.0 of TA/D1/compound **19** was used resulting in an overall yield of 11% of compound **1f**: mass spectrum (MALDI) average  $m/z$  calculated for C<sub>3710</sub>H<sub>6219</sub>N<sub>579</sub>O<sub>1251</sub>S<sub>40</sub>: 81638. Found: 81893.

**Compound 1h (LJP 1083).** Compound **1h** was prepared in a manner essentially similar to that described for compound **1g**. A mole ratio of 5.4/1.0 of TA/D1/compound **25** was used resulting in an overall yield of 61% of compound **1h**: mass spectrum (MALDI) average  $m/z$  calculated for C<sub>2217</sub>H<sub>3836</sub>N<sub>336</sub>O<sub>816</sub>S<sub>20</sub>: 48898. Found: 49390.

**Measurement of Anti-domain 1 Antibodies in Rats.** Nunc Maxisorp Immunoplates were coated overnight with 50  $\mu\text{L}$  of 5  $\mu\text{g/mL}$  of recombinant human  $\beta$ -2-GPI in pH 9.6 carbonate buffer at 4 °C. Subsequent steps were carried out at room temperature. Plates were washed 3 $\times$  with PBS and then blocked by treating with 250  $\mu\text{L}$  of a 2% solution of nonfat dry milk for 1 h in PBS. Plates were washed 3 $\times$  with PBS, and then wells were treated for 1 h with 50  $\mu\text{L}$  of serial dilutions of each serum sample in PBS in triplicate. Plates were washed 3 $\times$  with

**Scheme 1<sup>a</sup>**

<sup>a</sup> Reagents and conditions: (a) pH 4.6 sodium acetate buffer;  $R$  = multivalent platform,  $x = 4$  or  $8$ ,  $D1$  = domain 1 polypeptide of  $\beta_2$ GPI (amino acid sequence RTCPK PDDL P FSTV V PLKTF YEPGE EITYS CKPGY VSRGG MRKFI CPLTG LWPIN TLKCT PR).

PBS, and then the wells were treated for 1 h with 50  $\mu$ L of alkaline phosphatase-conjugated goat anti-rat IgG diluted 1:2000 in PBS/0.1% BSA. Plates were washed 3 $\times$  with H<sub>2</sub>O and developed for 20 min with chromogenic substrate solution consisting of 10 gm of phenolphthalein monophosphate, 97.4 mL of 2-amino-2-methyl-1-propanol, 9.62 mL of H<sub>2</sub>O, and 21 mL HCl of concd HCl solution. Color development was stopped by adding 50  $\mu$ L of 0.2 M Na<sub>2</sub>HPO<sub>4</sub> to each well, and optical absorbance at 550 nm was measured. Nominal antibody units were assigned to the standard pool, and the concentrations of anti-domain 1 antibody (units/mL) in test sera were derived from the standard curve. Serum from nonimmunized animals was used as a control, and a pool of sera from immunized animals was used to generate a standard curve of antibody levels at various dilutions. Percent suppression of anti-domain 1 antibody by the various multivalent domain 1 conjugates was calculated by comparison to PBS-treated controls.

**Measurement of Plasma Half-Life of Conjugates in Rats and Mice.** The compounds were radiolabeled with <sup>125</sup>I by the iodine monochloride method (26) and injected iv into female CD-1 mice or male Sprague-Dawley rats. Mouse plasma samples were collected periodically for 1 h, and rat plasma samples were collected for 24 h. The amount of radiolabeled drug was detected using a gamma counter. Pharmacokinetic parameters were calculated using WinNonLin software (Pharsight, Mountain View, CA). Plasma half-lives were calculated from the areas under the time-concentration curves using the formula  $t_{1/2} = \ln 2(AUC/C_0)$  assuming a single component first-order elimination at  $t = t_{1/2}$ .

**RESULTS AND DISCUSSION**

Three types of novel PEG-containing platforms were designed and synthesized, and they were used to prepare multivalent conjugates of domain 1. The types of platform differ in the way PEG was incorporated. In one type of platform monomethoxy PEG, which has only one end available for attachment chemistry, was attached to a platform intermediate with a free secondary amine. A second type of platform was prepared in which bivalent PEG is incorporated as an integral part of the platform by branching at each end of the PEG chain. The third type of platform was prepared with PEG incorporated into each of four branching arms of the platform. A non-PEG-containing platform was also prepared. All of the platforms contained either four or eight Boc-protected aminoxy groups. Each of the platforms was converted to a multivalent domain 1 conjugate by a two step process involving removal of the Boc-protecting groups and subsequent reaction of the free aminoxy groups with transaminated domain 1 (TA/D1) as described in Scheme 1. TA/D1 is a derivative of domain 1 that has been N-terminally glyoxylated by a transamination reaction as previously described (9).

The non-PEG containing conjugate, compound **1a**, was prepared to serve as a non-PEG control. The synthesis began with the preparation of a thiol-containing Boc-

protected aminoxy linker, compound **3**, as described in Scheme 2. The linker was prepared from 6-iodo-*N*-Boc-1-aminoxyhexane (**2**) by reaction with potassium thioacetate to provide compound **2**. Hydrolysis of **2** with ammonium hydroxide provided compound **3**. The ammonium hydroxide and solvent were removed, and the crude thiol was used directly in the next step.

Reaction of **3** with compound **4** provided the tetravalent Boc-protected aminoxy platform, compound **5**, as described in Scheme 3. The Boc protecting groups were removed by treating with trifluoroacetic acid, and TA/D1 was attached to the resulting free aminoxy groups to provide conjugate **1a** (LJP 1027).

A series of domain 1 toleragens were prepared with attached monomethoxy PEG of different molecular weights. The synthesis of these molecules began by preparing a bivalent Boc-protected aminoxy linker, compound **10**, with a free secondary amine as diagrammed in Scheme 4. Compound **6** was prepared as described previously (23), and it was saponified to provide compound **7**. Compound **7** was converted to the *N*-hydroxy-succinimidyl ester, compound **8**, which was used to acylate 6-aminocaproic acid to provide compound **9**. Treatment of compound **9** with carbonyldiimidazole followed by diethylenetriamine provided the key intermediate, compound **10**, also referred to as the dimer cassette.

A tetravalent Boc-protected aminoxy scaffold with a free secondary amine attachment site was prepared as

Scheme 5<sup>a</sup>

<sup>a</sup> Reagents and conditions: (a) *N*-(benzyloxycarbonyloxy)succinimide, NaHCO<sub>3</sub>, H<sub>2</sub>O, dioxane; (b) 4-nitrophenylchloroformate, pyridine; (c) compound **10**, pyridine, Et<sub>3</sub>N; (d) H<sub>2</sub>, Pd/C, acetic acid, MeOH; (e) Et<sub>3</sub>N, DMF; (f) TFA/CH<sub>2</sub>Cl<sub>2</sub>; (g) transaminated domain 1 polypeptide, 100 mM pH 4.6 sodium acetate, CH<sub>3</sub>CN.

described in Scheme 5. Compound **12** was prepared in two steps from bis(2-(2-hydroxyethoxy)ethyl)amine, compound **11**, which was prepared as previously described (24). Compound **11** was first treated with *N*-(benzyloxycarbonyloxy)succinimide to place a Cbz protecting group on the secondary nitrogen atom. The hydroxyl groups were subsequently converted to 4-nitrophenyl carbonate esters using 4-nitrophenyl chloroformate. Compound **12** was reacted with compound **10** to provide compound **13**, and the Cbz protecting group was removed by hydrogenolysis to provide compound **14**. Compound **14**, also referred to as a tetramer cassette, was connected to monomethoxy-PEG of various average molecular weights. Thus reaction of compound **14** with hydroxybenzotriazole esters of methoxy-PEG with average molecular weights of approximately 5000 g/mol, 12000 g/mol, 20000 g/mol, and 30000 g/mol, compounds **15a–d**, gave rise to PEG-containing Boc-protected tetraivalent platforms **16a–d**. The Boc protecting groups were removed by treating with trifluoroacetic acid, and TA/D1 was attached to the free aminoxy groups to provide conjugates **1b–e**.

An octavalent analogue was prepared as described in Scheme 6. Condensation of the tetramer cassette, compound **14**, with compound **12** provided the Cbz-protected octamer cassette, compound **17**. The Cbz protecting group was removed by hydrogenolysis to provide the octamer

cassette, compound **18**. The octamer cassette was connected to methoxy-PEG with an average molecular weight of approximately 20000 g/mol using essentially the same chemistry described above for the tetraivalent analogues, and the resulting platform was similarly deprotected and conjugated with TA/D1 to provide compound **1f**.

The second type of PEG containing domain 1 conjugate was prepared as described in Scheme 7. The synthesis began by attaching a dimer cassette to each end of PEG. Thus, the bis(hydroxybenzotriazolyl) carbonate ester of PEG with a molecular weight of approximately 20000 g/mol, compound **20**, was treated with 2 equiv of compound **10** to provide compound **21**. Compound **21** was deprotected and treated with TA/D1 under standard conditions to provide compound **1g**.

The third class of PEG-containing conjugates was prepared by incorporation of PEG into each of the linking arms of the platform as described in Scheme 8. This example incorporates a total of approximately 20000 g/mol of PEG with 5000 g/mol of PEG in each arm. Thus, tetraivalent 4-nitrophenyl carbonate ester **22** was reacted with mono-Boc-diamino-PEG of approximately 5000 g/mol, compound **23**, to provide the branched Boc-protected tetraamine **24**. The protecting groups were removed, and the resulting tetraamine was condensed with compound

**8** to give the tetravalent aminoxy platform, compound **25**. The platform was deprotected and treated with TA/D1 under standard conditions to provide compound **1h**.

The pharmacokinetics of several radiolabeled domain 1 conjugates was studied, as was their ability to suppress anti-domain 1 antibodies and the relevant antibody producing cells in vivo. Pharmacokinetics and antibody suppression data is summarized for the tetravalent conjugates presented in this report. The potency of five tetravalent conjugates as toleragens was evaluated for their ability to suppress antibody levels in rats immunized with domain 1. Rats were primed with a conjugate of domain 1 and KLH (**9**) and adjuvant, treated with toleragen, and boosted.<sup>1</sup> Serum samples were col-

lected, and anti-domain 1 antibody levels were measured using an ELISA. Table 1 summarizes the results of the antibody suppression experiments. It is clear that the three 20 kDa PEG conjugates (**1d**, **1g**, and **1h**) are required in lower doses to achieve significant antibody

<sup>1</sup> Lewis rats (Harlan, Indianapolis, IN) weighing approximately 200 g were immunized ip with 10  $\mu$ g of domain 1-KLH conjugate in alum with pertussis as adjuvant. Three weeks after the primary immunization, groups of four animals were treated iv with toleragen (0.88, 8.8, or 88 nmol/kg; 2.5, 0.25, and 0.025 mg of polypeptide per kilogram of body weight) or PBS control. Five days after treatment, animals were boosted ip with 10  $\mu$ g of domain 1-KLH conjugate, and sera samples were collected 7 days after boost.)

suppression. The 5 kDa PEG conjugate **1b** appears to be marginally more effective than **1a**, which contains no PEG.

The rates of elimination of all of the conjugates were measured in mice and in rats. The conjugates were radiolabeled with  $^{125}\text{I}$  using the iodine monochloride method (26), and the plasma concentrations of the compounds were measured in female CD-1 mice and in male Sprague–Dawley rats dosed at 1 mg/kg.<sup>2</sup> The shapes of the time vs concentration curves were quite different in mice than in rats. In mice most of the conjugate cleared from plasma during the initial phase, whereas in rats most of the clearance took place during the second phase. The half-lives of the conjugates in both species are reported in Table 2. It is evident that, among the tetravalent conjugates, increases in the amount of PEG correlate with reduction in clearance rates. Increasing the molecular weight by increasing the number of

copies of domain 1 polypeptide from four to eight, however, resulted in a possible increase in clearance. Compound **1f**, having 20 kDa PEG, has eight polypeptide domains and appears to clear marginally faster than the other conjugates with 20 kDa PEG.

## CONCLUSION

We have described the preparation of three novel types of multivalent PEG-containing platforms. The platforms were used to prepare well-defined conjugates of the first domain of  $\beta_2\text{GPI}$ , and the conjugates were studied for efficacy as B cell toleragens. It is clear that incorporation of PEG into the conjugates improved their effectiveness in suppressing the formation of anti-domain 1 antibodies in rats that were immunized with domain 1. In general as the molecular weight contribution from PEG increased, lower doses of toleragen were required. As the amount of PEG incorporated into the molecules was increased, the amount of suppression at all doses increased. The trend is most noticeable at the medium and low doses (8.8 and 0.88 nmol/kg). The improved efficacy of these conjugates is most likely a result of their persistence in circulation.

It is likely that in addition to size-dependent kidney filtration, clearance of the conjugates can take place by other mechanisms such as uptake by various tissues, and incorporation of PEG may also affect the rates of clearance by those mechanisms. Conversely, glomerular filtration rates can depend on properties other than size. Comparison of the clearance rate of compound **1d** with that of compound **1f** shows that increasing the number of polypeptide epitopes actually appears to result in faster clearance; whereas, one might expect the opposite if size were the only factor affecting clearance. The domain 1 polypeptide is positively charged due to an excess of positively charged amino acids, and it is well-known that charge can affect clearance from circulation. The glomerular filtration rate of anionic IgG has been shown to be slower than that of cationic IgG (28). Similarly, it has been demonstrated that the kidney filtration rate of dextran depends on charge, with positively charged molecules clearing faster than negatively charged molecules (29).

It is noteworthy that the spacing of the epitopes does not seem to significantly affect the ability of the conjugates to suppress antibody formation in the immunized rat model in which they were tested. The results with the three tetravalent conjugates (**1d**, **1g**, and **1h**), which contain 20000 MW PEG and are quite different in structure, show that they are remarkably similar in both their pharmacokinetic profiles and their ability to suppress antibody formation. Information on the relative abilities of the three structurally distinct tetravalent conjugates (**1d**, **1g**, and **1h**) to cluster B cell surface receptors would provide additional insight into the mechanism of B cell tolerance. Future studies will be aimed at further probing the structure activity relationships of

<sup>2</sup> Equivalent pharmacokinetics was demonstrated between the Lewis rats used in the present efficacy studies and the Sprague–Dawley rats.)

B cell toleragens with the goal of developing improved therapies for autoimmune diseases.

Received March 19, 2003; Revised Manuscript Received August 26, 2003

Peptide nucleic acids (PNA's) have shown to hold potential as antisense drugs. In this study we have designed PNA drugs for the microsomal triglyceride transfer protein (MTP), which is known to play a critical role in the assembly of atherogenic lipoproteins, and have converted the most potent drug into a liver-targeted prodrug. First, we have synthesized three PNA sequences targeting domains on the mouse MTP mRNA, which were not involved in intrastrand base-pairing interactions as judged from its secondary structure. Only one of the PNA's, PNA569, showed dose-dependent inhibition of MTP expression in a cell-free system for coupled transcription/translation of MTP. Second, to improve the cellular uptake of this PNA drug, we have conjugated PNA569 to a high affinity ligand for the asialoglycoprotein receptor, K(GalNAc)<sub>2</sub>. As compared to the parent PNA, the prodrug PNA-K(GalNAc)<sub>2</sub> was found to display to a markedly improved capacity to inhibit MTP mRNA expression in parenchymal liver cells. A glycoconjugated nonsense control appeared to be ineffective. In conclusion, the design of a targeted PNA is described to reduce MTP expression in parenchymal liver cells by 70%. The presented approach for targeted tissue-specific down-regulation of genes by PNA's may be valid for other genes as well.

## INTRODUCTION

Peptide nucleic acids (PNA's) are DNA analogues, in which the phosphate backbone has been replaced by an *N*-(2-aminoethyl)glycine pseudopeptide backbone. The achiral, uncharged, and rather flexible peptide backbone permits a more stable hybridization to DNA and RNA oligomers and thus a higher sequence specificity (1, 2). PNA's have been used to block protein expression both at a transcriptional and at a translational level (3). As compared to other more commonly used nucleotide analogues, cellular uptake of PNA's tends to be even lower, which has hampered the application of PNA oligomers in an in vivo setting (4, 5). Accordingly, therapeutic PNA activity has been demonstrated in cell-free translation/transcription systems (6) and after microinjection in individual cells (7). Cutrona et al. (8) have recently described that PNA uptake by Burkitt's lymphoma cells was considerably enhanced after conjugation to a so-called nuclear location signal (NLS), leading to a significant down-regulation of the target gene, *c-myc*. Likewise, several other groups have reported an improved PNA uptake after conjugation to an NLS (9, 10) and to intracellular translocation peptides (11). Another strategy was pursued by Chiarantini et al. (12) who successfully applied opsonized erythrocytes to selectively deliver entrapped PNA to monocytes/macrophages. Although

these approaches appear to be effective in vitro, reports showing effective transfection in vivo are scarce (13, 14).

In this study we have explored to the potential of targeted PNA delivery. PNA drugs have been designed against the murine microsomal triglyceride protein (MTP), which is a rate-limiting key enzyme in the assembly of atherogenic apoB100-containing lipoproteins by parenchymal liver cells (15, 16). MTP activity was found to correlate with the blood levels of these lipoproteins (17), making MTP an excellent target for therapeutic intervention in hyperlipidemia. From the secondary structure of murine MTP mRNA, we selected three regions that were not involved in base-pairing reactions and synthesized PNA sequences targeting these domains. The most potent PNA drug was subsequently conjugated to a high affinity tag for the asialoglycoprotein receptor (ASGPr), K(GalNAc)<sub>2</sub>, which was previously shown effective in redirecting (oligo)nucleotides and peptides to this receptor (18, 19). We demonstrate that the activity of antisense PNA's can be considerably improved through K(GalNAc)<sub>2</sub>-aided targeting to the asialoglycoprotein receptor.

## EXPERIMENTAL PROCEDURES

**Materials.** Tris-saturated biophenol, pH 8, was purchased from Biosolve Ltd. (Valkenswaard, The Netherlands). Ribogreen was from Molecular Probes (Eugene, OR). Superscript II reverse transcriptase and RNaseH were obtained from Life Technologies (Frederick, MD). Oligonucleotides and Goldstar DNA polymerase were from Eurogentec (Seraing, Belgium). The TnT in vitro transcription/translation assay was from Promega (Leiden, The Netherlands). All other chemicals were of analytical grade.

<sup>†</sup> Leiden/Amsterdam Center for Drug Research, Division of Biopharmaceutics.

<sup>‡</sup> Leiden Institute of Chemistry.

**Synthesis.** Synthesis of the PNA025, PNA341, PNA569, control PNA, and the PNA glycoconjugates were performed as previously described (20). PNA's were routinely checked for purity (RP-HPLC, high-resolution mass spectroscopy) and chemical identity (mass spectroscopy) as described (20).

**Cell-Free Assay for Coupled Transcription/Translation (TnT).** MuMTP cDNA was cloned in an T7 polymerase promote driven transcription vector for use in the transcription/translation assay (TnT). The TnT assay was performed as follows. TnT mixtures were prepared containing 5  $\mu$ L of rabbit reticulocyte lysate (RRL), 0.4  $\mu$ L of reaction buffer, 0.2  $\mu$ L of T7-polymerase, 0.2  $\mu$ L of amino acid mixture (1 mM) without methionine, 0.4  $\mu$ L of  $^{35}$ S-methionine (2  $\mu$ Ci), and 0.4  $\mu$ L of muMTP plasmid (0.5  $\mu$ g/ $\mu$ L) with or without PNA025, PNA341, PNA569, or nonsense PNA (500 nM; total volume 10  $\mu$ L) and subsequently incubated for 60 min at 30 °C. Next, 25  $\mu$ L of protein sample buffer (62 mM Tris, 12.5% glycerol (v/v), 1.25% SDS (w/v), 2.5% (v/v)  $\beta$ -mercaptoethanol, and 0.25% (w/v) bromophenol blue pH 6.8) were added, and the mixture was denatured for 3 min at 95 °C. Samples were applied to a 15% denaturing SDS-polyacrylamide gel, and the gel was run for 30 min at 100 V and subsequently for 1 h at 200 V in 0.02 M Tris, 0.16 M glycine, and 0.1% SDS (w/v). Gels were fixed in a solution of 45% methanol (v/v) and 0.5 M acetic acid and autoradiographed by exposure to a phosphor-imager screen for 2 days. As a measure of muMTP synthesis, we have quantified the amount of incorporated  $^{35}$ S-methionine using ImageQuant software (Molecular Dynamics, Sunnyvale, CA).

**Isolation of Mouse Parenchymal Liver Cells.** Parenchymal liver cells were isolated from anaesthetized mice (10–12 weeks old male C57bl/6KH mice; 22–27 g; Broekman Institute BV, Someren, The Netherlands) by perfusion of the liver for 10 min at 37 °C with collagenase (type IV, 0.05%, w/v) according to the method of Seglen (21). Cells were >99% pure as judged by light microscopy. Nonviable cells were removed by density gradient centrifugation (10 min; 100g) after diluting the cell suspension 1:1 with Percoll, and the viable cells (>98%) were subsequently washed and dissolved in the incubation medium.

**Down-Regulation of MTP mRNA in Mouse PC Cells.** Mouse parenchymal liver cells were incubated 3 h after seeding ( $2 \times 10^5$  cells/well) with PNA's. Cells were incubated for 4 h at 37 °C in the absence or the presence of PNA569, PNA569-K(GalNAc)<sub>2</sub>, or nonsense PNA-K(GalNAc)<sub>2</sub> (200nM). After incubation, medium was removed, 1 mL medium was added, and cells were incubated for 24 h at 37 °C. Cells were lysed, total RNA was isolated, and the muMTP-to-muGAPDH amplicon ratio was determined by quantitative radioactive RT-PCR as described below.

**Quantitative Radioactive RT-PCR of Murine MTP.** The relative abundance of murine MTP mRNA was monitored through quantitative RT-PCR with glyceraldehyde-3-phosphate dehydrogenase (GAPDH) as an internal standard. Total RNA was isolated from mA3/F2 or parenchymal liver cells by lysis in GTC solution (4 M guanidinium isothiocyanate; 25 mM sodium citrate buffer, pH 7.0; 0.5% *N*-lauroyl sarcosine; and 0.1 M  $\beta$ -mercaptoethanol) according to Chomczynski and Sacchi (22). After phenol–chloroform extraction, the total RNA was precipitated by adding 2.5 volumes of ice-cold ethanol. The mixture was placed at –20 °C for at least 1 h and centrifuged for 45 min at 10000g. Pellets were washed twice with 70% ethanol in DEPC-treated water and were

dissolved in 20  $\mu$ L of DEPC-treated Tris/EDTA buffer (10 mM Tris-HCl, 1 mM EDTA, pH 8.0). The RNA concentration in the samples was determined with the RNA-specific fluorescent dye Ribogreen according to the procedure of Jones et al. and using yeast tRNA as calibration standard (yield: 6–18  $\mu$ g/ $6 \times 10^5$  cells) (23). Total RNA (2  $\mu$ g) was reverse transcribed using 100 Units Superscript II reverse transcriptase (Life Technologies, Gaithersburg, MD) and subsequently amplified in the presence of [ $^{32}$ P]- $\alpha$ -dCTP (0.8  $\mu$ Ci) and Taq polymerase (0.4 Units, Eurogentec, Brussels, Belgium) using muMTP primers (forward: 5'-gga.aaa.ccg.caa.gac.agc; reversed: 5'-ctt.gt-t.ggg.ctc.ggt.agg; 100 ng). cDNA was amplified for 22 rounds using the following cycling parameters: denaturing step 30 min at 95 °C, annealing step: 60 min at 54 °C; elongation step 2 min at 72 °C. Unless otherwise stated, muGAPDH primers (forward: 5'-gag.cga.gac-.ccc.act.aac; reversed: 5'-atg.agc.cct.tcc.aca.atg; 100 ng) were added after four cycles, and the mixture was amplified according to the above protocol for another 18 cycles. Aliquots of 20  $\mu$ L were mixed with 2.5  $\mu$ L of loading buffer (40% (w/v) sucrose, 0.25% (w/v) bromophenol blue, 0.25% (w/v) xylene cyanol) and subjected to electrophoresis on 10% polyacrylamide gel (1.5 mm thickness) under nondenaturing conditions in 1  $\times$  TBE buffer (0.1 M Tris, 0.1 M boric acid, 2.5 mM EDTA, pH 8.0). The gels were fixed with 7% acetic acid, washed five times with water, and exposed overnight to a phosphor-imager screen. The intensity of the muMTP and muGAPDH amplicons was quantified using ImageQuant software (Molecular Dynamics, Sunnyvale, CA). To minimize RT reaction variability, all RNA samples were reverse transcribed simultaneously by using a RT "master mix". Formation of muMTP amplicons in the presence or the absence of muGAPDH primers was identical. Intraexperimental variation in the muMTP-to-muGAPDH amplicon ratio amounted to 13% and 18% starting from a single batch of cDNA and mRNA, respectively ( $n = 5$ ). The RT-PCR signal was completely linear under the conditions used in this study, and the PCR efficiency per cycle was close to the theoretical maximum.

**Data Processing.** Saturation binding data and substrate curves of initial uptake were analyzed according to a single site binding model using nonlinear regression (Prism, GraphPAD Software, Inc., San Diego, CA). Values are expressed as means  $\pm$  SEM. Data variance was analyzed statistically by means of one-way ANOVA with Dunnet's Post testing.

## RESULTS

**Antisense Sequences.** In search of effective antisense drugs for muMTP, we have selected a set of potentially active sequences targeting different regions on the muMTP. On the basis of secondary structure analysis (Mfold vs 3.1; 24), we have identified sites which are not likely involved in base pairing reactions (i.e. hairpins and pseudoknots) and might thus be accessible to antisense drug hybridization (Figure 1). Three sequences were selected from the single strand frequency plot (plotting the chance that a single nucleotide is involved in base-pairing; obtained from the 25 energetically most favorable secondary RNA structures). Two domains (341 and 569), corresponding with the highest peaks from the plot, were selected as PNA target, while PNA025 was designed as it appeared to be the most accessible site near the translation initiation codon. These PNA sequences were synthesized, purified, and subsequently tested for their ability to inhibit muMTP synthesis (Table 1).

**Figure 1.** Identification of potential antisense sites. Mapping of the secondary structure of muMTP mRNA using the Mfold algorithm (24). Arrows indicate the specific mRNA regions targeted by the PNA antisense drugs.

**Table 1.** Sequences of PNA Drugs Used in This Study

nonsense	TTT CCA TGA CTT CTT TGT
nonsense cluster	CAT ATA CAT TGA TC-K(GalNAc) <sub>2</sub>

**Effect of PNA on muMTP Synthesis in a Cell-Free System.** To evaluate the antisense activity of the selected sequences, a cell-free assay for coupled transcription/translation (TnT) was developed. Basically, muMTP mRNA was transcribed from a T7 polymerase promoter-flanked muMTP cDNA construct and translated in situ under the agency of rabbit reticulocyte lysate (RLL) and <sup>35</sup>S-methionine. Synthesis of full length <sup>35</sup>S-labeled muMTP (96 kD) was established by PAGE electrophoresis and subsequent autoradiography.

The selected PNA sequences were first tested for their capacity to inhibit muMTP transcription or translation in the TnT assay at a concentration of 500 nM. From Figure 2 only PNA569 appeared to be capable of inhibiting muMTP synthesis. PNA025, PNA341, and the nonsense PNA control did not show any inhibition of muMTP. Since PNA569 seemed to display antisense activity, we investigated the concentration dependency of its effect. PNA569 appeared to inhibit muMTP expression in a concentration-dependent fashion (Figure 3a). Maximal inhibition of <sup>35</sup>S-muMTP synthesis was attained at 500 nM, while the EC<sub>50</sub> was calculated to be 357 nM. PNA569 also affected luciferase synthesis from a T7 polymerase promoter driven luciferase vector, albeit at a much lower potency (EC<sub>50</sub> = 15 μM) (Figure 3b). Apparently, a rather narrow concentration window exists, in which PNA569 is able to specifically down-regulate muMTP synthesis.

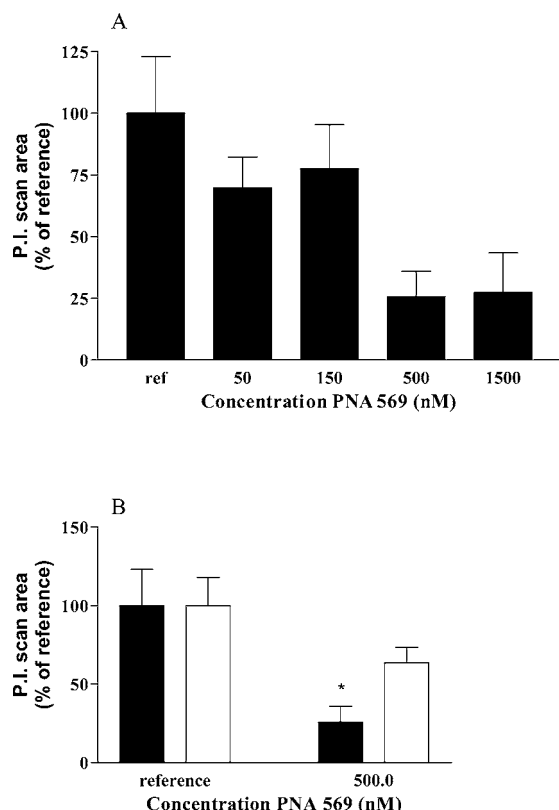

**In Vitro Binding Studies.** We and others have previously shown that conjugation of drugs oligonucleotides and proteins to a cell-specific ligand is a powerful strategy to improve their uptake by the target tissue (25, 20). In analogy this strategy may also prove effective for PNA's and will result in higher antisense activity. Hence

**Figure 2.** Potency of PNA's to inhibit muMTP expression in a cell-free system for coupled transcription/translation. The expression of <sup>35</sup>S-met muMTP was measured by a rabbit reticulocyte lysate-containing in vitro assay for coupled transcription/translation in the presence of PNA025, PNA341, PNA569, or nonsense PNA (500 nM). The results are expressed as percentage of the amount of full length <sup>35</sup>S-met muMTP synthesized in the absence of PNA's. Statistical significant difference relative to control is indicated by \* ( $P < 0.05$ ). Data are means  $\pm$  SEM of three determinations in triplicate.

we have prepared a glycoconjugated PNA prodrug to target parenchymal liver cells, by coupling PNA to K(GalNAc)<sub>2</sub>, a high affinity ligand for the asialoglycoprotein receptor on this cell type (20). The affinity of PNA-K(GalNAc)<sub>2</sub> for the asialoglycoprotein receptor (ASGPr) was monitored in an in vitro competition assay of <sup>125</sup>I-ASOR binding to mouse parenchymal liver cells. PNA-K(GalNAc)<sub>2</sub> gave complete and monophasic inhibition of <sup>125</sup>I-ASOR binding with an affinity that was similar to that of the glycoside ligand itself ( $K_d$  = 77 nM; data not shown) (19, 20). This indicates that attachment of the PNA to the K(GalNAc)<sub>2</sub> did not dramatically affect the affinity for the ASGPr.

**Antisense Effect of PNA and PNA-K(GalNAc)<sub>2</sub> in Vitro.** A quantitative radioactive RT-PCR-based assay was set up to measure muMTP mRNA levels in parenchymal liver cells. We have evaluated the effect of the most potent PNA and its glycoconjugate on muMTP expression in freshly isolated parenchymal liver cells. Cells were incubated for 4 h with 200 nM of PNA569, PNA569-K(GalNAc)<sub>2</sub>, or nonsense PNA-K(GalNAc)<sub>2</sub>. After 24 h, cells were harvested, and their muMTP content was measured relative to that of the GAPDH

**Figure 3.** (A) Dose dependency of inhibitory effect of PNA569 on muMTP expression in the TnT assay. (B) Inhibitory effect of PNA569 (500 nM) on muMTP expression and luciferase in the TnT assay. The expression of  $^{35}\text{S}$ -Met muMTP and  $^{35}\text{S}$ -Met luciferase was measured in the TnT assay in the presence of 50–1500 nM of PNA569. The results are expressed as percentage of the amount of  $^{35}\text{S}$ -Met muMTP formed in the absence of PNA. Statistical significant difference relative to luciferase down-regulation is indicated by \* ( $P < 0.05$ ). Data are means  $\pm$  SEM of three determinations in triplicate.

housekeeping gene. Figure 4 shows that the muMTP-to-GAPDH ratio was significantly reduced after incubation with PNA569-K(GalNAc)<sub>2</sub> ( $p < 0.05$ ), while the parent PNA569 and a nonsense glycoconjugate (nonsense PNA-K(GalNAc)<sub>2</sub>) gave only a minor nonsignificant reduction of mRNA MTP levels.

## DISCUSSION

Over the past few years, PNA have emerged as one of the most promising antisense or anti-gene drugs (26, 27). In this study we selected a set of potentially active PNA sequences against muMTP. MTP is essential for the assembly and secretion of apoB-containing lipoproteins and as such an interesting target for the therapeutic intervention in hyperlipidemia. Potential PNA target sequences were identified by secondary structure analysis of muMTP mRNA using a computerized Mfold algorithm, which was previously shown to generate accurate predictions of the RNA folding pattern (24). Three sequences were subsequently synthesized and tested for their activity in a cell-free assay for coupled transcription/translation (TnT). This assay has already been successfully used for the initial validation of phosphodiester and phosphorothioate nucleotides targeting the glutathione S-transferase Mu1/2 gene (28). As shown in this study, the TnT assay is also appropriate for testing PNA drugs. Our results show that, of the antisense drugs tested, only PNA569 was able to induce a specific inhibition of muMTP synthesis. The activity of PNA569 was less than

**Figure 4.** Down-regulation of MTP mRNA in mouse parenchymal liver cells by PNA and PNA-K(GalNAc)<sub>2</sub>. The expression of muMTP mRNA was measured after incubation of parenchymal liver cells with PNA569, PNA-K(GalNAc)<sub>2</sub>, or nonsense PNA-K(GalNAc)<sub>2</sub> (200 nM). The results are expressed as the ratio between MTP and GAPDH. Statistical significant difference relative to control is indicated by \*\* ( $P < 0.01$ ). Data are means  $\pm$  SEM of three determinations in triplicate.

that of a phosphodiester analogue targeting the same site ( $\text{EC}_{50} = 18$  nM). PNA025 and PNA341 appeared to be ineffective, which concurs with the poor activity of phosphodiester drugs targeting the same sites (ODN025 and ODN341 gave only 29% and 81% inhibition at 150 nM, respectively) [Vrins et al., manuscript in preparation]. Nevertheless this apparent similarity may not necessarily reflect a corresponding mode of action, as the phosphodiester probably act inhibitory via RNaseH-mediated target strand degradation, whereas the antisense activity of PNA's was reported not to involve RNaseH-mediated degradation (29–31). From the in vitro assay it can also be concluded that at higher concentrations (>500 nM), PNA569 inhibits luciferase synthesis as well. This inhibition may be attributed to a nonspecific aptameric effect rather than by specific hybridization of the PNA to the luciferase cDNA, since no homology was observed between the MTP and luciferase cDNA.

Second, we have demonstrated in this study the inhibition of muMTP mRNA levels by mouse parenchymal liver cells after conjugation of the PNA569 with a high affinity ligand for the asialoglycoprotein receptor. Although recently a number of potent MTP inhibitors have been developed (32), this PNA569 conjugate offers the advantage of only inhibiting liver MTP, leaving MTP expression in the intestine unaffected. Previous studies in our lab confirmed that, upon injection into mice, K(GalNAc)<sub>2</sub>-derivatized PNA mainly accumulated in the liver, while intestinal uptake was only marginal (20). This PNA was directed against human MTP and did not cross-hybridize to murine MTP cDNA, thus hampering in vivo evaluation in a mouse model for hyperlipidemia. Here we present a targeted PNA prodrug that upon incubation with parenchymal liver cells effected a significant reduction of mouse MTP expression by 70%. This reduction was neither observed for a glycoconjugated control PNA, establishing that the PNA inhibited muMTP expression in a sequence dependent fashion, nor for the parental PNA569 drug. The actual mode of action of the glycoconjugated PNA remains to be solved. It has been reported that PNA-RNA heteroduplexes are not degraded by RNase H (33), suggesting that the antisense effect of PNA569 is attributable to steric interference with translation or to RNA destabilization. PNA was reported to promote a sequence-specific lowering of mRNA levels (34). Aldrian-Herrada et al. (35) proposed that hybridization of antisense PNA to the target may interdict mRNA translation by shuttling the PNA/RNA hybrids into the proteasome compartment leading to its

degradation. Theoretically mRNA down-regulation might reflect an RT-PCR artifact. PNA-RNA hybrids are known to be resistant to phenol extraction and urea treatment (36). Reverse transcription of the PNA/MTP might be less efficient, which will translate in a seemingly reduced mRNA level. Unpublished studies within our lab showed that RT-PCR interference may occur at PNA concentrations > 100–500 nM. However, as PNA569 was also a potent inhibitor in the TnT assay, the latter is not a very plausible explanation. In either case, the observed PNA-induced reduction in muMTP mRNA levels clearly demonstrates that the antisense PNA was able to enter parenchymal liver cells and to hybridize to the corresponding intracellular target. The fact that PNA-RNA heteroduplexes do not induce cleavage of the mRNA target by Rnase H can be considered an advantage as nonspecific effects due to the interaction of the antisense or nonsense PNA with other mRNA molecules are less likely to result in a temporary arrest of translation (9).

In conclusion, we demonstrate a marked inhibition of muMTP expression in freshly isolated parenchymal liver cells by a glycoconjugated PNA drug. This glycoconjugated PNA will provide an excellent tool for therapeutic evaluation of MTP down-regulation in a mouse model for hyperlipidemia.

Received May 16, 2003; Revised Manuscript Received September 18, 2003

The B-cell lymphoma/leukemia-2 (*bcl-2*) proto-oncogene has been associated with the transformation of benign lesions to malignancy, disease progression, poor prognosis, reduced survival, and development of resistance to radiation and chemotherapy in many types of cancer. The objective of this work was to synthesize an antisense peptide nucleic acid (PNA) complementary to the first six codons of the *bcl-2* open reading frame, conjugated to a membrane-permeating peptide for intracellular delivery, and modified with a bifunctional chelating agent for targeting imaging and therapeutic radiometals to tumors overexpressing *bcl-2*. Four peptide–PNA constructs were synthesized by a combination of manual and automated stepwise elongation techniques, including *bcl-2* antisense conjugates and nonsense conjugates with no complementarity to any known mammalian gene or DNA sequence. The PNA sequences were synthesized manually by solid-phase 9-fluorenylmethoxycarbonyl (Fmoc) techniques. Then a fully protected lysine monomer, modified with 1,4,7,10-tetraazacyclododecane-*N,N,N',N''*-tetraacetic acid (DOTA) for radiometal chelation, was coupled manually to each PNA sequence. Synthesis of the DOTA–PNA conjugates was followed by automated elongation with a peptide sequence (PTD-4-glycine, PTD-4-G), known to mediate cellular internalization of impermeable effector molecules, or its retro-inverso analogue (*ri*-PTD-4-G). Preparation of the four conjugates required an innovative synthetic strategy, using mild acid conditions to generate hydrophobic, partially deprotected intermediates. These intermediates were purified by semipreparative reversed-phase HPLC and completely deprotected to yield pure peptide–PNA conjugates in 6% to 9% overall yield. Using modifications of this synthetic strategy, the *ri*-PTD-4-G conjugate of *bcl-2* antisense PNA was prepared using a lysine derivative of tetramethylrhodamine (TMR) for fluorescence microscopy. Plasma stability studies showed that <sup>111</sup>In-DOTA-labeled *ri*-PTD-4-G–anti-*bcl-2* PNA was stable for 168 h at 37 °C, unlike the conjugate containing the parent peptide sequence. Scanning confocal fluorescence microscopy of TMR-labeled *ri*-PTD-4-G–anti-*bcl-2* PNA in Raji lymphoma cells demonstrated that the retro-inverso peptide was active in membrane permeation and mediated cellular internalization of the antisense PNA into the cytoplasm, where high concentrations of *bcl-2* mRNA are expected to be present.

## INTRODUCTION

Apoptosis, or programmed cell death, is a major pathway by which both chemotherapeutic drugs and ionizing radiation kill tumor cells (1). The B-cell lymphoma/leukemia-2 (*bcl-2*)<sup>1</sup> gene is a member of a relatively new category of proto-oncogenes involved in cell survival, by blocking apoptosis (2). The *bcl-2* gene product is an inner mitochondrial membrane protein that heterodimerizes with and inhibits a conserved homolog, bax, which accelerates cell death in response to apoptotic

stimuli (3). Overexpression of *bcl-2* in stably transfected cell lines has been implicated in the development of both drug (4–6) and radiation (7–9) resistance.

The *bcl-2* cellular oncogene was discovered by Croce and co-workers, after cloning the chromosome 18 breakpoint region in non-Hodgkin's lymphoma (NHL) (10). Over 85% of follicular lymphomas and approximately 20% of large cell lymphomas carry a t(14;18) translocation (11–13), juxtaposing the *bcl-2* gene with the IgH promoter and deregulating *bcl-2* expression. However, mechanisms other than translocation may deregulate *bcl-2* expression (14, 15) in lymphoma. In addition, 84% of acute myeloid leukemias (16), 80–100% of malignant cells in multiple myeloma (17), and 60–90% of many nonlymphoid malignancies, including breast (18), lung (19, 20), colon (21, 22), prostate (23, 24), neuroendocrine cancers (25), and malignant melanomas (26) overexpress *bcl-2*. In these cancers *bcl-2* expression is often associated with transformation of benign lesions to malignancy, disease progression, and poor prognosis.

Clinical understanding of the role of *bcl-2* in disease progression and treatment response or failure will be-

come increasingly important as drugs that act to down-regulate *bcl-2* mRNA and protein are developed. While the majority of NHL patients respond well initially to conventional chemotherapy, *bcl-2* overexpression has been identified as an independent predictor of increased relapse, shorter disease-free intervals, and poor cause-specific survival (27, 28). The most important recent advances in the treatment of NHL have been the development of targeted immunotherapy and radioimmunotherapy (RIT). The pan-B cell, anti-CD20 monoclonal antibody rituximab down-regulates *bcl-2* through a STAT3- and IL-10-mediated pathway (29, 30), sensitizing lymphoma cells in vitro to apoptotic killing by cytotoxic drugs (31). Data emerging from ongoing Phase III clinical trials suggest that addition of rituximab to combination chemotherapy may improve survival in patients with aggressive lymphoma. Yttrium-90-ibritumomab (Zevalin), the radiolabeled analogue of rituximab, has shown considerable efficacy for RIT of relapsed NHL (32). Zevalin RIT showed a significantly greater response rate than rituximab in a randomized Phase III trial and has effected responses in rituximab-refractory patients. Recent findings that tumor *bcl-2* mRNA and protein levels decrease in response to RIT (33) suggest that down-regulation of *bcl-2* may play a significant role in response to low dose-rate radiation.

Another alternative therapy involves the use of an antisense oligonucleotide, which is complementary to the first six codons of *bcl-2* mRNA and is able to reduce *bcl-2* gene expression. G3139, a DNA phosphorothioate oligonucleotide, has shown efficacy against B-cell lymphoma in tumor-bearing SCID mice (34) and is currently in clinical trials for antisense therapy of *bcl-2*-positive NHL (35). Preliminary results indicated that two of nine patients experienced a reduction in tumor burden. However, more encouraging was the fact that six of eight patients who went on to receive further chemotherapy achieved responses. Similarly, six of 14 patients with *bcl-2*-positive metastatic melanoma in a Phase I/II trial of G3139 and dacarbazine achieved objective responses (36). Thus, *bcl-2* antisense treatment may overcome drug resistance.

Peptide nucleic acid (PNA) (37) is a DNA-like molecule in which the deoxyribose phosphodiester backbone of DNA has been replaced by (2-aminoethyl)glycine units, to which the nucleobases are attached by methylenecar-

bonyl linkers. Compared to DNA oligonucleotides, the superior biological stability and greater affinity and specificity of PNA for complementary mRNA sequences (38) make it extremely attractive for antisense applications. However, poor cellular uptake of unmodified PNAs has limited their utility in vitro and in vivo. Several groups have demonstrated that PNA uptake in target cells can be increased substantially by conjugation to cell membrane-permeating peptides (39–43), such as *Drosophila* Antennapedia (43–58) (pAntp) (44) or an uncleaved peptide from the HIV Tat protein transduction domain (45). Using alanine residue substitution to identify the basic residues critical for cell membrane transduction, Dowdy and co-workers prepared a synthetic protein transduction domain, YARAAARQARA (PTD-4) (46), that was 33-fold more active than the Tat sequence.

The results of these studies suggest that tumor proto-oncogenes such as *bcl-2* might be targeted by radiolabeled, cell-permeating peptide–PNA constructs for in vivo imaging and targeted radiotherapy of cancer. Previously we demonstrated that a radiometal-labeled PTD-4–anti-*bcl-2* PNA conjugate bound to *bcl-2* mRNA with high specificity and thermodynamic stability in cell-free systems (47). We report here the solid-phase synthesis of antisense peptide–PNA conjugates for targeting imaging and therapeutic radiometals to tumor cells expressing high levels of *bcl-2* mRNA. The antisense PNA was based on the 18-residue sequence of G3139, while an 18-mer nonsense PNA did not correspond to any known mammalian gene or DNA sequence in a BLAST database search. The *bcl-2* antisense and nonsense PNAs were conjugated with a new derivative of 1,4,7,10-tetraazacyclododecane-*N,N,N',N''*-tetraacetic acid (DOTA), designed for chelation of radiometals and fully protected for solid-phase peptide and PNA synthesis. The DOTA–PNA conjugates were then coupled by solid-phase techniques to glycine, a small amino acid spacer, followed by PTD-4 or its retro-inverso analogue (*ri*-PTD-4).

Preparation of these DOTA conjugates required the development of an innovative solid-phase synthetic strategy, involving cleavage from the resin and partial deprotection of the peptide–PNA conjugates under mildly acidic conditions. This strategy allowed hydrophobic intermediates to be separated from unreacted PNA by semipreparative reversed-phase HPLC (RP-HPLC). In contrast, tetramethylrhodamine (TMR)-labeled PNA conjugates could be prepared in a straightforward manner by standard solid-phase synthesis, cleavage, deprotection, and purification techniques. Plasma stability studies demonstrated that *ri*-PTD-4 was much more stable to proteolytic degradation than the parent sequence, and scanning confocal fluorescence microscopy studies of the TMR conjugates showed that *ri*-PTD-4-mediated cellular internalization of the antisense PNA in NHL cells known to express high levels of *bcl-2* mRNA.

## EXPERIMENTAL PROCEDURES

**General.** All reagents were HPLC or peptide synthesis grade.  $\text{CDCl}_3$ , phenol, and EDT were obtained from Aldrich Chemical Co. (Milwaukee, WI). Anhydrous *N*-methylpyrrolidinone (NMP), *N,N*-dimethylformamide (DMF), dichloromethane (DCM), acetonitrile, and methanol were obtained from Fisher Scientific, Inc. (Pittsburgh, PA). Trifluoroacetic acid (TFA) was obtained from VWR Scientific Products (St. Louis, MO). All standard, protected Fmoc amino acid derivatives, 2-(1*H*-benzotriazol-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate (HBTU), and 1-hydroxybenzotriazole (HOBt) were ob-

tained from Novabiochem (San Diego, CA). *N*- $\alpha$ -(9-Fluorenylmethoxycarbonyl)-*N*- $\epsilon$ -[tetramethylrhodamine-(5-carbonyl)]-L-lysine (FKT) was purchased from Molecular Probes, Inc. (Eugene, OR). 2-(1*H*-7-Azabenzotriazol-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate (HATU), 1-hydroxy-7-azabenzotriazole (HOAt), all Fmoc/Bhoc protected monomers for PNA synthesis, and Fmoc-XAL PEG PS resin were obtained from PerSeptive Biosystems (Framingham, MA). DOTA tris(*tert*-butyl) ester (DOTA-(OtBu)<sub>3</sub>) was procured from Macrocyclics (Dallas, TX), and *N*- $\alpha$ -Fmoc-L-lysine was purchased from Advanced ChemTech (Louisville, KY). Piperidine, *m*-cresol, *N,N*-diisopropylethylamine (DIEA), thioanisole (TA), triisopropylsilane (TIS), and 2,4,6-trinitrobenzenesulfonic acid (TNBS) were purchased from Fluka (Milwaukee, WI). <sup>111</sup>InCl<sub>3</sub> was obtained from Mallinckrodt, Inc. (St. Louis, MO). Ultrapure water (18 M $\Omega$ -cm resistivity) was used for all procedures. All laboratory glassware was washed with a mixed acid solution (48) and thoroughly rinsed with ultrapure water. Manual reaction vessels were obtained from Chemglass, Inc. (Vineland, NJ). Normal phase TLC plates (Silica Gel 60 F254, plastic-backed) were purchased from EM Science (Gibbstown, NJ).

An Advanced ChemTech ACT Model 396 Omega Multiple Biomolecular Synthesizer was used for automated solid-phase synthesis. <sup>1</sup>H NMR analysis of purified *N*- $\alpha$ -(9-fluorenylmethoxycarbonyl)-*N*- $\epsilon$ -[tris(*tert*-butyl)DOTA]-L-lysine was performed using a Bruker DRX 300 MHz spectrometer (Bruker BioSpin, Westmont, IL), and elemental analysis of the compound was performed by Atlantic Microlab (Norcross, GA). ESI-MS analyses were performed on a Finnigan TSQ7000 mass spectrometer (Thermo Finnigan, San Jose, CA). A Waters (Milford, MA) NovaPak C18 column (3.9  $\times$  300 mm) was used for the LC-MS analysis.

Analytical and semipreparative RP-HPLC were performed on a Beckman Coulter System Gold chromatograph equipped with a 168 diode array detector, a 507e auto-injector, and the 32 KARAT software package (Beckman Coulter, Fullerton, CA). A Keystone Scientific, Inc. (San Jose, CA) C-18 Kromosil column (4.6  $\times$  150 mm, 5  $\mu$ m, 100 Å) was used for analytical HPLC. For semipreparative HPLC, a Waters Prep NovaPak, HR-C18 column (7.8  $\times$  300 mm, 6  $\mu$ m, 60 Å) was used. The flow rate was maintained at 1.0 mL/min for analytical runs and at 4.0 mL/min for semipreparative purification. The wavelengths used for UV detection were 214 and 260 nm for analytical RP-HPLC and 235 and 245 nm for semipreparative RP-HPLC, respectively. Eluents used in all runs consisted of solvent A (0.1% TFA/H<sub>2</sub>O) and solvent B (0.1% TFA/CH<sub>3</sub>CN). Three different gradients were used: (1) "Full Gradient": linear from 5% to 95% solvent B in 45 min, (2) "FKD Gradient" (optimized for semipreparative purification of *N*- $\alpha$ -(9-fluorenylmethoxycarbonyl)-*N*- $\epsilon$ -[tris(*tert*-butyl)DOTA]-L-lysine): linear from 45% to 50% solvent B in 20 min, and (3) "Semiprep Gradient" (optimized for semipreparative purification of hydrophobic, partially deprotected peptide-PNA conjugate precursors): sequential linear from 10% to 20% solvent B in 20 min (step 1), 20% to 30% solvent B in 10 min (step 2), 30% to 50% solvent B in 5 min (step 3), and 50% to 60% solvent B in 20 min (step 4). Isocratic conditions were applied after steps 1 and 2 to permit all hydrophilic species and *m*-cresol to elute, prior to application of steps 3 and 4.

Size exclusion HPLC was performed on a Waters Delta 600 chromatograph equipped with a manual Rheodyne injector, a 2487 dual wavelength UV detector, a Packard (Downers Grove, IL) 500TR Flow Scintillation Analyzer

with a GAMMA-C flow cell for <sup>111</sup>In, a Waters busSAT/IN analog-digital interface, and the Millennium 32 software package. A Phenomenex (Torrance, CA) BioSep-SEC-S 3000 column (7.8  $\times$  300 mm, 5  $\mu$ m, 290 Å), an isocratic mobile phase of 100 mM NaH<sub>2</sub>PO<sub>4</sub>/0.05% NaN<sub>3</sub>, pH 6.8, and a flow rate of 1.0 mL/min were used. Molecular weights estimated by size exclusion HPLC were calculated from a calibration curve generated using a Bio-Rad (Hercules, CA) molecular weight standard.

Raji Burkitt's lymphoma cells were obtained from the American Type Culture Collection (Manassas, VA). Suspension cultures of cells were maintained in exponential growth phase in RPMI 1640 medium (Mediatech, Inc., Herndon, VA), supplemented with 10% fetal bovine serum, 2 mM L-glutamine, and 48  $\mu$ g/mL gentamycin, at 37 °C and 5% CO<sub>2</sub>. Cell viability was determined to be >98% by trypan blue exclusion and hemacytometry.

**PNA Synthesis.** Syntheses of anti-*bcl-2* PNA (tctc-cagcgtgcgcat) and nonsense PNA (tgtgtgtgcacaccttg) were performed in a manual reaction vessel. Fmoc/Bhoc chemistry was used with the following PNA monomers: Fmoc-A(Bhoc)-OH, Fmoc-C(Bhoc)-OH, Fmoc-G(Bhoc)-OH, and Fmoc-T-OH. Fmoc-XAL PEG PS resin was used as a solid support at a substitution level of 0.18 mmol/g. Each cycle of elongation consisted of (1) Fmoc deprotection with 25% piperidine in DMF for 2 cycles of 1 min at room temperature, (2) washing with DMF, DCM, and twice with NMP for 1 min each at room temperature, (3) coupling using a molar ratio of resin:monomer:HATU:DIEA:2,6-lutidine = 1.0:3.0:2.7:3.0:4.5; 5 min of preactivation followed by a 25-min coupling at room temperature, after which the process was repeated, (4) capping with 2 mL of 5% acetic anhydride/6% 2,6-lutidine in DMF for 5 min at room temperature, and (5) washing with NMP, DCM, and twice with DMF for 1 min each at room temperature. All chemical steps were followed by a TNBS test on the resin, and the resulting colorimetric reaction indicated the presence of free primary amines after Fmoc deprotection and the absence of primary amino groups after the coupling and capping steps. After 6, 12, and 18 cycles, aliquots of the resin-bound PNAs were cleaved and Bhoc-deprotected with *m*-cresol:TFA (1:19) for 30 min, and LC-MS analysis was performed to confirm that the observed masses were consistent with the calculated molecular weights of the Fmoc-protected intermediates.

***N*- $\alpha$ -(9-Fluorenylmethoxycarbonyl)-*N*- $\epsilon$ -[tris(*tert*-butyl)DOTA]-L-lysine (FKD, 1).** To 1 mL of anhydrous NMP was added sequentially 218 mg (0.381 mmol) of DOTA(OtBu)<sub>3</sub>, 134 mg (0.352 mmol) of HATU, and 5.1 mg (0.038 mmol) of HOAt with continuous stirring. The reaction mixture was stirred at room temperature for 1.5 h, after which normal phase TLC, using acetone as the mobile phase, showed that formation of the DOTA-(OtBu)<sub>3</sub>-OAt active ester was complete (*R*<sub>f</sub> = 0.66). Then 133 mg (0.360 mmol) of *N*- $\alpha$ -Fmoc-L-lysine was added, and the reaction mixture was stirred at room temperature for 10 min. After quenching the reaction with H<sub>2</sub>O, the reaction mixture was taken into ethyl acetate and extracted with H<sub>2</sub>O, while maintaining the pH at 6.0 with 5% NaHCO<sub>3</sub>. The organic phase was acidified with TFA and washed with water, after which the solvent was removed in vacuo. The residue was dissolved in 1 mL of ethyl acetate and added to 25 mL of diethyl ether with vigorous stirring and cooling to -20 °C. The thick oily precipitate was washed with cold diethyl ether and dried in vacuo, after which it was dissolved in acetonitrile. Unreacted *N*- $\alpha$ -Fmoc-L-lysine was precipitated by dropwise addition of 0.2% TFA, and this process was repeated four to five times. The supernatant was concentrated to

a minimum volume, and the pH of the remaining aqueous solution was adjusted to 6.0 with 5%  $\text{NaHCO}_3$ . The desired product was extracted into ethyl acetate, which was washed with  $\text{H}_2\text{O}$  and evaporated to dryness in vacuo. The resulting oil was dissolved in 1 mL of ethyl acetate, to which was added 15 mL of diethyl ether with vigorous stirring to precipitate the product. After discarding the supernatant, the product was dried in vacuo to yield 308 mg (92.7%) of **1** as a white, microcrystalline solid. Normal phase TLC ( $\text{CHCl}_3:\text{CH}_3\text{OH}:\text{conc'd NH}_4\text{OH}$ , 13:3:1)  $R_f = 0.45$ ; RP-HPLC, Full Gradient,  $t_R = 31.2$  min (98.6% purity); ESI-MS  $m/z$  calcd for  $\text{C}_{49}\text{H}_{74}\text{N}_6\text{O}_{11}$  ( $\text{M} + \text{H}^+$ ) = 924.2, found 923.9 ( $\text{M} + \text{H}^+$ ), 462.5 ( $\text{M} + 2\text{H}^{2+}$ ).

Alternatively, DOTA(OtBu)<sub>3</sub> (658 mg, 1.15 mmol), HATU (427 mg, 1.12 mmol), and HOAt (67.0 mg, 0.492 mmol) were dissolved in 2 mL of NMP at room temperature. The resulting pale yellow solution was stirred for 1.5 h. To this solution of the active ester was added 410 mg (1.11 mmol) of *N*- $\alpha$ -Fmoc-L-lysine. After dissolution, stirring was continued for an additional 2 h. The reaction was quenched by the addition of 1 mL of  $\text{H}_2\text{O}$  and diluted with 40 mL of ethyl acetate. The organic phase was washed with  $3 \times 20$  mL of  $\text{H}_2\text{O}$ . The organic phase was then acidified with the addition of 100  $\mu\text{L}$  of TFA. The organic layer was washed again with  $2 \times 20$  mL of  $\text{H}_2\text{O}$  and concentrated in vacuo, leaving a pale yellow, viscous oil (820 mg, 80.0%). Analytical RP-HPLC under Full Gradient conditions indicated the purity of the crude product to be >89%. The crude product was dissolved in 10 mL of  $\text{CH}_3\text{CN}:\text{H}_2\text{O}$  (1:1). The product was purified by semipreparative RP-HPLC, using the optimized FGD Gradient. The collected fractions, eluting at  $t_R = 26.5$  min, were pooled and lyophilized, yielding 416 mg (40.6%) of **1** as a white solid.  $^1\text{H}$  NMR (300 MHz,  $\text{CDCl}_3$ )  $\delta$  1.4 (s, 27 H), 1.5 (s, 6 H), 2.7 (s, 2 H), 2.7–3.8 (br complex m, 28 H), 4.0 (br s, 1H), 4.2 (t, 2H), 7.3 (dt, 4H), 7.5 (d, 2H), 7.6 (d, 2H); ESI-MS  $m/z$  calcd for  $\text{C}_{49}\text{H}_{74}\text{N}_6\text{O}_{11}$  ( $\text{M} + \text{H}^+$ ) = 924.2, found 923.7 ( $\text{M} + \text{H}^+$ ), 462.4 ( $\text{M} + 2\text{H}^{2+}$ ). Anal. ( $\text{C}_{49}\text{H}_{74}\text{N}_6\text{O}_{11} \cdot 4\text{TFA} \cdot 2\text{H}_2\text{O}$ ): C, H, N: calcd 5.94; found 6.52.<sup>2</sup>

**PTD-4-G-KD-anti-*bcl-2* PNA (2).** Fmoc-anti-*bcl-2* PNA on XAL PEG PS resin was deprotected at the *N*-terminus with 25% piperidine in DMF for two cycles of 1 min at room temperature, followed by washing with DMF, DCM, and twice with NMP for 1 min each at room temperature. A solution containing 40  $\mu\text{mol}$  of **1**, 40  $\mu\text{mol}$  of HOAt, 32  $\mu\text{mol}$  of HATU, and 100  $\mu\text{mol}$  of DIPEA in NMP was stirred for 15 min at room temperature. The resulting mixture was added to 9  $\mu\text{mol}$  of anti-*bcl-2* PNA on 100 mg of XAL PEG PS resin and mixed by nitrogen bubbling for 45 min in a reaction vessel for manual peptide synthesis. This process was repeated twice, after which the resin was reacted for 5 min with 5% acetic anhydride and 6% 2,6-lutidine in DMF at room temperature.

After removal of the *N*-terminal Fmoc group with 25% piperidine in DMF for two cycles of 25 min at room temperature, KD-anti-*bcl-2* PNA resin was then sequentially elongated with PTD-4-G, using the multiple automated synthesizer and standard Fmoc coupling chemistry. The peptide chain was assembled by sequential acylation with protected amino acids, which were activated in situ with HBTU/HOBt. Recoupling at each cycle with a minimal 15-fold molar excess of activated amino

acid derivative was performed, to minimize the production of truncated species. Each cycle of elongation involved the following steps: (1) Fmoc deprotection with 25% piperidine in DMF/NMP for one cycle of 1 min and three cycles of 10 min at room temperature, (2) washing with NMP for four cycles of 1 min at room temperature, (3) coupling with in situ activated amino acid (amino acid: HBTU:HOBt:DIEA molar ratio = 1:0.9:1:2) in NMP for two cycles of 25 min at room temperature, and (4) washing with NMP for two cycles of 1 min at room temperature.

To detach hydrophobic, partially deprotected intermediate products from the resin, two sequential procedures were evaluated in a reaction vessel: (1) reaction with 1% TFA/5% *m*-cresol in DCM for eight cycles of 15 min at room temperature, followed by filtration; and (2) reaction with 50% TFA/5% *m*-cresol in DCM for one cycle of 30 min at room temperature, followed by filtration. The partially deprotected intermediates were isolated by precipitation with cold diethyl ether and evaporation to dryness under a stream of nitrogen. Crude intermediates from both procedures were analyzed by RP-HPLC, using Full Gradient conditions, and then purified by semipreparative RP-HPLC, using Semiprep Gradient conditions. The purified intermediates, eluting from 37 to 41 min retention time for procedure 1 and from 33 to 38 min for procedure 2, were pooled, lyophilized, and then fully deprotected with 87.5% TFA containing 2.5% each of  $\text{H}_2\text{O}$ , phenol, TA, EDT, and TIS for 4 h at room temperature. After this treatment, 4.5 mg (7.7%) of **2** was isolated by precipitation with cold diethyl ether and lyophilized to a white solid. ESI-MS:  $m/z$  2190.0 ( $\text{M} + 3\text{H}^{3+}$ ), 1642.5 ( $\text{M} + 4\text{H}^{4+}$ ), 1314.2 ( $\text{M} + 5\text{H}^{5+}$ ), 1095.1 ( $\text{M} + 6\text{H}^{6+}$ ), 938.9 ( $\text{M} + 7\text{H}^{7+}$ ). The observed molecular ions were consistent with the theoretical molecular weight of **2**, calcd ( $\text{M} + \text{H}^+$ ) = 6569.1.

**PTD-4-G-KD-nonsense PNA (3).** Fmoc-nonsense PNA on XAL PEG PS resin was deprotected at the *N*-terminus with 25% piperidine in DMF for two cycles of 1 min at room temperature, followed by washing with DMF, DCM, and twice with NMP for 1 min each at room temperature. A solution containing 20  $\mu\text{mol}$  of **1**, 20  $\mu\text{mol}$  of HOAt, 18  $\mu\text{mol}$  of HATU, and 60  $\mu\text{mol}$  of DIPEA in NMP was stirred for 15 min at room temperature. The resulting mixture was added to 5  $\mu\text{mol}$  of nonsense PNA on 45 mg of XAL PEG PS resin and mixed by nitrogen bubbling for 45 min in a reaction vessel for manual peptide synthesis. This process was repeated twice, after which the resin was reacted for 5 min with a large excess of acetic anhydride (5% v/v) and 2,6-lutidine (6% v/v) in DMF at room temperature. After Fmoc removal with 25% piperidine in DMF for two cycles of 25 min, KD-nonsense-PNA resin was then sequentially elongated with PTD-4-G on the multiple automated synthesizer, as described for **2**.

To cleave hydrophobic, partially deprotected intermediates from the resin, the following three procedures were performed in sequence of increasing acidity: (1) reaction with 5% TFA, containing 5% each of  $\text{H}_2\text{O}$ , *m*-cresol, and TIS in DCM, for four cycles of 15 min at room temperature, followed by filtration; (2) reaction with 25% TFA, containing 5% each of  $\text{H}_2\text{O}$ , *m*-cresol, and TIS in DCM, for two cycles of 15 min at room temperature, followed by filtration; and (3) reaction with 50% TFA, containing 5% *m*-cresol and 2.5% each of  $\text{H}_2\text{O}$ , TIS, TA, and phenol in DCM, for one cycle of 40 min at room temperature, followed by filtration. The partially deprotected intermediates were isolated by precipitation with cold diethyl ether and evaporation to dryness under nitrogen. These

<sup>2</sup> Elemental analysis for *N*- $\alpha$ -(9-fluorenylmethoxycarbonyl)-*N*- $\epsilon$ -[tris(*tert*-butyl)DOTA]-L-lysine (FKD): Theoretical ( $\text{C}_{49}\text{H}_{74}\text{N}_6\text{O}_{11} \cdot 4\text{TFA} \cdot 2\text{H}_2\text{O}$ ): calcd C, 48.37%; H, 5.84%; N, 5.94%; found C, 48.52%; H, 6.14%; N, 6.52%.

intermediates were analyzed by RP-HPLC, using Full Gradient conditions, and intermediates from procedures 1 and 2 were purified by semipreparative RP-HPLC, using the Semiprep Gradient. The purified intermediates, eluting from 43 to 49 min retention time, were pooled and lyophilized, after which the resulting mixture was treated for 4 h at room temperature with 87.5% TFA containing 2.5% of each of H<sub>2</sub>O, phenol, TA, EDT, and TIS, to afford the completely deprotected product. After precipitation with cold diethyl ether and lyophilization, 3.0 mg (9.1%) of **3** was isolated as a white solid. ESI-MS: *m/z* 2211.1 (M + 3H)<sup>3+</sup>, 1658.0 (M + 4H)<sup>4+</sup>, 1326.9 (M + 5H)<sup>5+</sup>, 1106.1 (M + 6H)<sup>6+</sup>, 948.1 (M + 7H)<sup>7+</sup>. The observed molecular ions were consistent with the theoretical molecular weight of **3**, calcd (M + H)<sup>+</sup> = 6629.2.

***ri*-PTD-4-G-KD-anti-*bcl-2* PNA (4).** *ri*-PTD-4-G-KD-anti-*bcl-2* PNA was prepared from 4  $\mu$ mol of anti-*bcl-2* PNA on 45 mg of XAL PEG PS resin. The synthetic procedure was identical to that employed for **2**, except that after coupling of glycine, all D-amino acid analogues of the PTD-4 residues were added in the reverse sequence. Hydrophobic, partially deprotected crude intermediates were obtained from the three sequential cleavage procedures with increasing TFA concentrations, identical to those utilized for **3**. The partially deprotected intermediates were isolated by precipitation with cold diethyl ether and evaporation to dryness under nitrogen. Crude intermediate products from procedures 1 and 2 were analyzed and purified by RP-HPLC, as described for **2**, and the fraction eluting at 45 to 52 min retention time was collected. After full deprotection and isolation of the final product, using the procedures employed for **2**, 1.7 mg (6.5%) of **4** was obtained as a white solid. ESI-MS: *m/z* 2188.5 (M + 3H)<sup>3+</sup>, 1642.1 (M + 4H)<sup>4+</sup>, 1313.6 (M + 5H)<sup>5+</sup>, 1094.8 (M + 6H)<sup>6+</sup>, 938.7 (M + 7H)<sup>7+</sup>, 821.3 (M + 8H)<sup>8+</sup>, 730.4 (M + 9H)<sup>9+</sup>. The observed molecular ions were consistent with the theoretical molecular weight of **4**, calcd (M + H)<sup>+</sup> = 6569.1.

***ri*-PTD-4-G-KD-nonsense PNA (5).** *ri*-PTD-4-G-KD-nonsense-PNA was synthesized from 9  $\mu$ mol of nonsense PNA on 104 mg of XAL PEG PS resin, using a procedure identical to that employed for **3**, except that the *ri*-PTD-4 sequence was elongated after coupling of glycine. Hydrophobic, partially deprotected crude intermediates were obtained from the three sequential cleavage procedures using increasing TFA concentrations, identical to those employed for **3**. The partially deprotected intermediates were isolated by precipitation with cold diethyl ether and evaporation to dryness under nitrogen. Crude intermediate products from procedures 1 and 2 were analyzed and purified by RP-HPLC, as described for **3**, and the fraction eluting at 42 to 52 min retention time was collected. After full deprotection and isolation of the final product, using the procedures employed for **3**, 3.6 mg (6.1%) of **5** was obtained as a white solid. ESI-MS: *m/z* 2209.8 (M + 3H)<sup>3+</sup>, 1657.9 (M + 4H)<sup>4+</sup>, 1326.4 (M + 5H)<sup>5+</sup>, 1104.8 (M + 6H)<sup>6+</sup>, and 947.6 (M + 7H)<sup>7+</sup>. The observed molecular ions were consistent with the theoretical molecular weight of **5**, calcd (M + H)<sup>+</sup> = 6629.2.

**KT-anti-*bcl-2* PNA (6).** Fmoc-anti-*bcl-2* PNA on XAL PEG PS resin was deprotected at the N-terminus using a procedure identical to that employed for **2**. A solution containing 20  $\mu$ mol of FKT, 20  $\mu$ mol of HOAt, 18  $\mu$ mol of HATU, and 60  $\mu$ mol of DIPEA in NMP was stirred for 15 min at room temperature. The resulting mixture was added to 8  $\mu$ mol of anti-*bcl-2* PNA on 90 mg of XAL PEG PS resin and mixed by nitrogen bubbling for 45 min in a reaction vessel for manual peptide synthesis. This process

was repeated twice, after which the resin was reacted for 5 min with 5% acetic anhydride and 6% 2,6-lutidine in DMF at room temperature. The crude product was cleaved from 45 mg (4  $\mu$ mol) of the resin and deprotected with 87.5% TFA containing 2.5% H<sub>2</sub>O, phenol, TA, EDT, and TIS each for 2 h at room temperature, after which it was purified by semipreparative RP-HPLC, using Semiprep Gradient conditions. The peak eluting at *t<sub>R</sub>* = 34.0 min was collected, and 1.3 mg (6.1%) of **6** was isolated as a magenta solid, after precipitation with cold diethyl ether and lyophilization. RP-HPLC, Full Gradient, *t<sub>R</sub>* = 16.5 min (>99.5% purity); ESI-MS *m/z* 1784.0 (M + 3H)<sup>3+</sup>, 1338.2 (M + 4H)<sup>4+</sup>, 1070.8 (M + 5H)<sup>5+</sup>. The observed molecular ions were consistent with the theoretical molecular weight of **6**, calcd (M + H)<sup>+</sup> = 5333.1.

***ri*-PTD-4-G-KT-anti-*bcl-2* PNA (7).** *ri*-PTD-4-G-KT-anti-*bcl-2* PNA was synthesized from 4  $\mu$ mol of Fmoc-deprotected KT-anti-*bcl-2* PNA on 45 mg of XAL PEG PS resin, using a procedure for elongation of the *ri*-PTD-4-G sequence identical to that employed for **4**. The crude product was cleaved from the resin, deprotected, and purified by semipreparative RP-HPLC using the procedures employed for **6**. The peak eluting at *t<sub>R</sub>* = 35.5 min was collected, and 1.8 mg (6.8%) of **7** was obtained as a magenta solid, after precipitation with cold diethyl ether and lyophilization. RP-HPLC, Full Gradient, *t<sub>R</sub>* = 16.1 min (>99.5% purity); ESI-MS *m/z* 2197.3 (M + 3H)<sup>3+</sup>, 1648.4 (M + 4H)<sup>4+</sup>, 1319.4 (M + 5H)<sup>5+</sup>, 1099.1 (M + 6H)<sup>6+</sup>, 942.2 (M + 7H)<sup>7+</sup>, 824.6 (M + 8H)<sup>8+</sup>, 733.3 (M + 9H)<sup>9+</sup>. The observed molecular ions were consistent with the molecular weight of **7**, calcd (M + H)<sup>+</sup> = 6593.5.

**Plasma Stability Studies.** Compounds **2** and **4** were labeled with <sup>111</sup>In as described previously (47). An aliquot of 948  $\mu$ Ci of <sup>111</sup>In-labeled **2** (4.89  $\mu$ g) or 915  $\mu$ Ci of <sup>111</sup>In-labeled **4** (4.47  $\mu$ g) was added to 1 mL of mouse plasma. The resulting mixtures were incubated at 37 °C for 168 h. Aliquots of 100  $\mu$ L of the mixtures were analyzed by size exclusion HPLC at 0, 0.25, 1, 4, 24, 48, 96, and 168 h of incubation, to determine conjugate and chelate stability.

**Scanning Confocal Fluorescence Microscopy Studies.** An aliquot of **6** (0.18 mg/mL, 34  $\mu$ M) or **7** (0.72 mg/mL, 109  $\mu$ M) in 0.2 M ammonium acetate, pH 5.0, was added to a final concentration of 2.5  $\mu$ M in a suspension of Raji cells (1  $\times$  10<sup>7</sup> cells/mL) in 2.0 mL of RPMI 1640 medium at 37 °C and 5% CO<sub>2</sub>. Cells and supernatants from 100  $\mu$ L of the suspension were separated by centrifugation at 1, 5, and 30 min and at 2 h of incubation. After removal of the supernatant, the cells were fixed by addition of 100  $\mu$ L of 4% formaldehyde and washed with 1% formaldehyde to remove any fluorescent probe in solution. Formaldehyde was not added for fluorescence microscopy of live Raji cells. Live Raji cells were incubated with **6** or **7** as described above and immediately analyzed by fluorescence microscopy. Digital microscopy was performed with an Olympus IX70 microscope/Bio-Rad Radiance 2000 scanning confocal fluorescence system, interfaced to a photomultiplier tube array and computer workstation. Excitation of TMR was accomplished at 568 nm, followed by image acquisition using a 580 nm long path emission filter. All fluorescence microscopy studies were performed using identical microscope settings, and all images were acquired in the medial plane.

## RESULTS AND DISCUSSION

The optimized procedure for the preparation of cell-permeating peptide-PNA conjugates (Figure 1) for

**Figure 1.** Structures of DOTA- and TMR-conjugated PTD-4-G and *ri*-PTD-4-G *bcl-2* antisense and nonsense PNA conjugates. PNA residues are indicated in lower case letters, and peptide residues are indicated in upper case letters.

radiometal targeting of the *bcl-2* proto-oncogene consisted of a combination of manual solid-phase synthesis of PNA sequences and automated solid-phase synthesis of peptide sequences, using standard Fmoc chemistry. Manual syntheses of PNAs were undertaken in order to perform sequential Fmoc deprotection of the growing PNA oligomers under carefully controlled conditions. Unlike peptides, upon Fmoc deprotection, PNA can undergo an alkaline pH-dependent *N*-acyl transfer rearrangement that converts the primary *N*-terminus into an unreactive amide (49). When the automated multiple biomolecular synthesizer was used for PNA synthesis, truncated PNA species or degraded products were often obtained. This problem was likely mechanical in nature and probably resulted from exposure of the PNA to piperidine for periods longer than 1 min during Fmoc deprotection. When PNAs were synthesized manually, piperidine reactions were carried out in precise 1-min cycles, and no evidence of *N*-acyl transfer rearrangement was observed. Using manual solid-phase synthesis techniques, the desired sequences could be prepared in their entirety.

To incorporate a macrocyclic chelating agent into any sequence position of a peptide-PNA conjugate, a new

#### Scheme 1

derivative of DOTA, *N*- $\alpha$ -(9-fluorenylmethoxycarbonyl)-*N*- $\epsilon$ -[tris(*tert*-butyl)DOTA]-L-lysine (FKD, **1**), was prepared as a fully protected building block for solid-phase Fmoc chemistry. DOTA chelates a wide variety of radiometals for diagnostic imaging and targeted radiotherapy, including  $^{111}\text{In}$  ( $T_{1/2}$  = 67.4 h; EC 849 keV (100%);  $\gamma$  173 keV (89%), 247 keV (94%)) and  $^{90}\text{Y}$  ( $T_{1/2}$  = 64.0 h;  $\beta^-$  2.27 MeV (100%)), respectively, with extremely high in vivo stability (50). The synthesis of **1** is shown in Scheme 1. Compound **1** was prepared in a one-pot, two-step process, by activating commercially available DOTA tris(*tert*-butyl) ester with HATU and HOAt and reacting the resulting active ester with commercially available *N*- $\alpha$ -Fmoc-L-lysine. An extensive solvent extraction workup under carefully controlled pH conditions afforded **1** in high yield and 98.6% purity. The only impurity detected by analytical RP-HPLC was the dilysine adduct of DOTA tris(*tert*-butyl) ester (1.4%). Alternatively, compound **1** was obtained in somewhat lower yield using a simplified solvent extraction procedure, followed by semipreparative RP-HPLC. Using a mobile phase gradient optimized for purification of **1**, the bifunctional DOTA derivative was obtained in analytically pure form. Furthermore, this procedure greatly simplified scale-up of the reaction and purification of the desired product. To date, over 1.7 g of **1** have been prepared using these two procedures.

Coupling of **1** to *bcl-2* antisense and nonsense PNAs was followed by sequential automated elongation of the PNA conjugate with the cell-permeating PTD-4-G peptide sequence. Cleavage of the constructs from the resin, with concomitant deprotection, was followed by attempts to purify the crude products by semipreparative RP-HPLC and characterize them by LC-MS. It was discovered that neither the final products nor the unmodified PNA oligomers were retained on RP-HPLC, and both unmodified PNA and DOTA-derivatized PTD-4-G-PNA conjugates coeluted at the solvent front. Therefore, direct separation of the fully deprotected peptide-PNA conjugates from unmodified PNA byproducts was not possible.

To solve this problem, an innovative strategy was devised to detach each conjugate from the resin under mildly acidic conditions, using dilute TFA and a partial cocktail of radical scavengers, to leave most of the protecting groups on the peptide residues. While it was predicted that the crude intermediates obtained by this process would consist of a mixture of different compounds, corresponding to various protecting groups remaining on the peptide, it was hypothesized that these partially protected conjugates would be very hydrophobic and retained on RP-HPLC. This strategy offered the possibility of separating the hydrophobic, partially deprotected intermediates from the very hydrophilic unreacted PNA. By collecting the hydrophobic components and subsequently treating them with a high concentration of TFA in full radical scavenger cocktail, the fully deprotected final products could be obtained.

**Figure 2.** (Top) Semipreparative RP-HPLC chromatogram, using Semiprep Gradient conditions, of intermediate products obtained after cleavage of **2** with 1% TFA containing 5% *m*-cresol. (Bottom) Analytical RP-HPLC chromatogram, using Full Gradient conditions, of hydrophobic, partially deprotected species purified after cleavage of **2** with 1% TFA containing 5% *m*-cresol.

This strategy was ultimately successful for the preparation of PTD-4-G-KD-anti-*bcl-2* PNA (**2**), after developing procedures for cleavage and partial deprotection. Initially two sets of conditions were evaluated, where the concentration of TFA was varied. It was surmised that 1% TFA would be sufficiently acidic to detach the conjugate from the resin without any risk of removing protecting groups, as is the case for the similarly labile 2-chlorotrityl chloride resin. However, after eight cycles of reaction with 1% TFA containing 5% *m*-cresol, only a small amount of crude intermediate product was obtained. After diethyl ether precipitation, the partially deprotected peptide-PNA was purified by semipreparative RP-HPLC, eluting at 37 to 41 min retention time (Figure 2, top). Analytical RP-HPLC (Figure 2, bottom) of the main fraction collected showed that it consisted of a relatively pure hydrophobic species.

The resin was then treated with 50% TFA containing 5% *m*-cresol to ensure full detachment of the conjugate from the resin. Under these conditions, it was anticipated that most of the protecting groups would probably be removed, possibly complicating the subsequent HPLC purification. A much larger quantity of crude intermediate product was obtained and purified by semipreparative RP-HPLC (Figure 3, top). The chromatogram showed that this mixture contained a large amount of hydrophilic species, which had to be discarded because this fraction, eluting at 21 to 29 min retention time, was contaminated with unmodified PNA. The major hydrophobic fraction, eluting at 33 to 38 min retention time, was collected, subjected to analytical RP-HPLC (Figure 3, bottom), and lyophilized. To remove the protecting groups still present, the lyophilized samples obtained by cleavage with 1% and 50% TFA were treated with concentrated TFA and a full cocktail of radical scavengers, in each case yielding a single product, for which ESI-MS analysis showed a pattern of multiply charged molecular ions consistent with the calculated molecular weight of **2**.

**Figure 3.** (Top) Semipreparative RP-HPLC chromatogram, using Semiprep Gradient conditions, of intermediate products obtained after cleavage of **2** with 50% TFA containing 5% *m*-cresol. (Bottom) Analytical RP-HPLC chromatogram, using Full Gradient conditions, of hydrophobic, partially deprotected species purified after cleavage of **2** with 50% TFA containing 5% *m*-cresol.

As observed previously during the synthesis of **2**, the final deprotected *bcl-2* antisense peptide-PNA conjugate was not retained upon subsequent RP-HPLC analysis and eluted with the solvent front. This result confirmed that the procedure for purification of the partially protected precursor was necessary to separate the PTD-4 conjugate from unreacted PNA and obtain the desired product in pure form. In addition, it was concluded that neither 1% TFA nor 50% TFA was an optimal treatment for generating a relatively small number of hydrophobic, partially deprotected precursors in the highest possible yield. Cleavage with 1% TFA gave a relatively pure hydrophobic product, but in low yield, while cleavage with 50% TFA afforded an excessive amount of fully deprotected conjugate, which could not be isolated in pure form by semipreparative RP-HPLC. Therefore, intermediate acid concentrations were then evaluated to optimize the cleavage, deprotection, and purification conditions.

In the synthesis of PTD-4-G-KD-nonsense PNA (**3**), once the protected conjugate had been assembled, the resin was reacted with increasing concentrations of TFA in partial radical scavenger cocktail, until detachment of the partially deprotected intermediates occurred. First, cleavage with four cycles of 5% TFA containing 5% H<sub>2</sub>O, *m*-cresol, and TIS each was attempted, followed by reaction with two cycles of 25% TFA containing 5% H<sub>2</sub>O, *m*-cresol, and TIS each, and finally reaction with one cycle of 50% TFA containing 5% *m*-cresol and 2.5% H<sub>2</sub>O, TIS, TA, and phenol each. Using 5% TFA, a modest amount of product was obtained, but the conjugate was not completely cleaved from the resin. When 25% TFA was employed, a substantially larger quantity of crude intermediate was obtained. Semipreparative RP-HPLC purification (Figure 4, top) afforded mainly very hydrophobic species, eluting at 43 to 49 min retention time, and a relatively small hydrophilic fraction, eluting at 17 to 24 min retention time. Analytical RP-HPLC of the hydrophobic fraction collected revealed that it was com-

**Figure 4.** (Top) Semipreparative RP-HPLC chromatogram, using Semiprep Gradient conditions, of intermediate products obtained after cleavage of **3** with 25% TFA containing 5% H<sub>2</sub>O, *m*-cresol, and TIS each. (Bottom) Analytical RP-HPLC chromatogram, using Full Gradient conditions, of hydrophobic, partially deprotected species purified after cleavage of **3** with 25% TFA containing 5% H<sub>2</sub>O, *m*-cresol, and TIS each.

posed of two major intermediates (Figure 4, bottom). No additional product was recovered from reaction with 50% TFA. The purified hydrophobic species generated by cleavage and slight deprotection with 5% and 25% TFA were pooled and lyophilized, after which they were completely deprotected with concentrated TFA and full radical scavenger cocktail. A single product was isolated, and ESI-MS analysis revealed a pattern of multiply charged molecular ions consistent with the calculated molecular weight of **3**.

Conjugates **2** and **3** were previously labeled to high specific activities with <sup>111</sup>In and <sup>90</sup>Y, and the specificity and stability of hybridization of <sup>90</sup>Y-labeled **2** with *bcl-2* mRNA in cell-free systems was compared to that of the corresponding <sup>32</sup>P-labeled anti-*bcl-2*-DNA (47). While <sup>90</sup>Y-labeled **2** showed equivalent specificity and superior thermodynamic stability in *bcl-2* mRNA binding, the plasma stability of <sup>111</sup>In-labeled **2** was suboptimal, as proteolytic degradation of the PTD-4 sequence was evident after 24 h at 37 °C. Therefore, the *ri*-PTD-4 analogues of **2** and **3** were synthesized in order to improve plasma stability. The retro-inverso peptide, which consists of all D-amino acids in the reverse sequence, places the basic residues of PTD-4 critical for cell permeation in approximately the same three-dimensional spatial configuration as the parent peptide. Thus, *ri*-PTD-4 should retain biological activity mediating cellular internalization of the PNA conjugates and show greater proteolytic stability than the parent peptide. Aldrian-Herrada et al. (39) demonstrated that the retro-inverso counterpart of pAntp was active in causing PNA conjugates to permeate target cells and presumed that it was much more stable to proteolysis. However, before now *ri*-PTD-4 had not been synthesized and evaluated for biological activity and stability.

DOTA-conjugated *ri*-PTD-4 constructs of *bcl-2* antisense (**4**) and nonsense (**5**) PNAs were prepared based on the methods developed for the syntheses of the parent PTD-4 conjugates **2** and **3**. As in the case of conjugate **3**, optimized sequential cleavage and slight deprotection using 5% TFA, followed by 25% TFA, in partial radical scavenger cocktail, was employed. These reaction conditions readily afforded hydrophobic precursors. These precursors were purified by semipreparative RP-HPLC,

completely deprotected in concentrated TFA and full radical scavenger cocktail, precipitated with diethyl ether, and lyophilized to yield **4** and **5**. ESI-MS analysis of **4** and **5** were consistent with the calculated molecular weights of the desired products.

Conjugates **2** and **4** were labeled with <sup>111</sup>In at specific activities of 1298 Ci/mmol and 1370 Ci/mmol, respectively, using a previously published procedure (47). The radiolabeled conjugates were incubated in mouse plasma for 168 h at 37 °C (Figure 5). The retention time of <sup>111</sup>In-labeled **2** shifted reproducibly from 11.4 min immediately upon mixing to 11.5 min at 168 h. In addition, the radiolabeled conjugate peak, initially sharp, showed considerable tailing by 168 h of incubation in plasma. After 168 h at 37 °C, an aliquot of the plasma mixture was spiked with pure <sup>111</sup>In-KD-anti-*bcl-2* PNA and analyzed by size exclusion HPLC. The species corresponding to 11.5 min retention time coeluted with the radiolabeled PNA lacking the PTD-4 sequence, with no observed changes in the chromatographic profile. These results suggested that considerable degradation of PTD-4 by plasma proteases and peptidases had occurred. In contrast, the peak corresponding to <sup>111</sup>In-labeled **4** remained sharp during the 168-h incubation in plasma at 37 °C, its retention time changed by less than 0.02 min, and the lack of lower molecular weight species indicated that *ri*-PTD-4 was stable to plasma proteases and peptidases. During the course of these experiments, the protein-bound fraction of <sup>111</sup>In-labeled **2** changed relatively little, from 28.8% at 0 h to 34.5% at 168 h. By comparison, the protein-bound fraction of <sup>111</sup>In-labeled **4** increased over 4-fold, from 13.7% to 60.2%, during the 168-h incubation in plasma. In the case of conjugate **4**, the major component of protein-associated <sup>111</sup>In (41.7%) eluted at 9.24 min, consistent with the molecular weight of immunoglobulin G (158 kDa). Since transferrin (80 kDa) is the main indium-binding protein in plasma, this result suggested that little, if any, dissociation of <sup>111</sup>In from the DOTA chelate occurred. Instead the protein-associated fractions of <sup>111</sup>In likely resulted from non-specific binding of the radiolabeled peptide-PNA conjugate. Under the size exclusion HPLC conditions employed, transferrin could not be separated from albumin (69 kDa). However, the peak eluting in this molecular weight range, at 10.5 min retention time, corresponded to approximately 6% of the total radioactivity. In addition, no low molecular species corresponding to <sup>111</sup>In transchelated by EDTA in the plasma was observed, a further indication of the kinetic stability of the DOTA chelate.

The superior proteolytic stability of <sup>111</sup>In-labeled **4** rendered it the more suitable peptide-antisense-PNA conjugate to evaluate for tumor *bcl-2* targeting in NHL cells in culture and lymphoma-bearing SCID-hu mouse models. However, prior to initiating these studies, the ability of *ri*-PTD-4 to mediate cellular internalization of anti-*bcl-2* PNA required validation. Therefore, anti-*bcl-2* PNA was conjugated to a lysine derivative of the red fluorescent dye tetramethylrhodamine (TMR) in the same sequence position as DOTA, after which the *ri*-PTD-4-G sequence was added.

KT-anti-*bcl-2* PNA (**6**) was synthesized manually using modifications of the procedures for synthesizing the DOTA-conjugated PNAs. Unlike the DOTA conjugates, the hydrophobic nature of the tetramethylrhodamine residue allowed for isolation of **6** by standard peptide and PNA cleavage, deprotection, and purification conditions. Following assembly, the crude product was cleaved from the resin and completely deprotected, using concentrated

**Figure 5.** (Left) Size exclusion HPLC chromatograms of  $^{111}\text{In}$ -labeled **2** after 0 h (top) and 168 h (bottom) of incubation in mouse plasma at 37 °C. (Right) Size exclusion HPLC chromatograms of  $^{111}\text{In}$ -labeled **4** after 0 h (top) and 168 h (bottom) of incubation in mouse plasma at 37 °C.

TFA and full radical scavenger cocktail, and then purified by semipreparative RP-HPLC. The 33.5 min retention time of **6** allowed for easy separation from the unreacted PNA byproduct. Compound **6** was also conjugated to *ri*-PTD-4-G by automated, stepwise elongation with the peptide sequence using standard Fmoc chemistry. The *ri*-PTD-4-G-KT-anti-*bcl-2* PNA conjugate (**7**) had a retention time of 35.5 min on semipreparative RP-HPLC, also affording easy separation from unmodified PNA. Following RP-HPLC purification, conjugates **6** and **7** were isolated by diethyl ether precipitation and lyophilization. ESI-MS analyses showed patterns of molecular ions that were consistent with the calculated molecular weights of the conjugates. Analytical RP-HPLC analysis of **6** and **7** indicated that the purity of both TMR conjugates was >99.5%.

To determine whether *ri*-PTD-4 was active in cell permeation and mediated cellular internalization of anti-*bcl-2* PNA, scanning confocal microscopy studies were performed with conjugates **6** and **7** in Raji Burkitt's lymphoma cells, after fixation with 4% formaldehyde at various incubation times. Raji cells express high levels of homogeneous 6.5-kb *bcl-2* mRNA (51). During the course of these studies, fluorescence in Raji cells was much more intense with **7** than with **6** at all time points from 0 to 2 h of incubation, but the fluorescence intensity from each conjugate was normalized to the value at 5 min, to show qualitative differences between the two compounds. As shown in Figure 6, at 1 to 5 min, fluorescence from both conjugates was confined largely to the plasma membrane, and a small amount of cytoplasmic staining observed with **7**. By 30 min, cell-associated fluorescence from **7** had decreased considerably, and that from **6** had nearly disappeared. However, after 2 h of incubation, widespread, intense fluorescence was seen in the cytoplasm of essentially all cells exposed to **7**, while little to no fluorescence was observed from **6** at the same time point. The fluorescence microscopy studies demonstrated that *ri*-PTD-4 was active in permeation of the plasma membrane and mediated cellular internalization of the *bcl-2* antisense PNA. Furthermore,

internalization of the *ri*-PTD-4 conjugate **7** in Raji cells delivered the antisense PNA predominantly into the cytoplasm, where concentrations of mRNA, including *bcl-2*, are highest.

Recently, Richard et al. (52) demonstrated that cell fixation with 3.7% formaldehyde caused subcellular redistribution artifacts during fluorescence microscopy studies of cell-penetrating peptides. In that report, fixation of HeLa and CHO cells led to redistribution of fluorescein- and Alexa 488-conjugated Tat peptide into the nucleus, whereas no nuclear uptake was observed in live cells. When Dowdy and co-workers (46) examined the uptake of fluorescein-conjugated PTD-4 in fixed Jurkat cells, both nuclear and cytoplasmic localization were visualized by fluorescence microscopy. To test whether cell fixation led to redistribution artifacts in the present studies, scanning confocal fluorescence microscopy of conjugates **6** and **7** in live Raji cells was performed. Association of **6** and **7** with live cells from 0 to 2 h of incubation was qualitatively similar to the results obtained with fixed cells (data not shown). At 2 h, very little membrane-bound fluorescence from **6** was observed in live Raji cells (Figure 7, left), and essentially all cells incubated with **7** showed internalization of the compound and widespread, intense cytoplasmic staining (Figure 7, right). Surprisingly, though, approximately 50% of live Raji cells incubated with the *ri*-PTD-4 conjugate **7** exhibited nuclear uptake after 2 h of incubation. This result was contrary to the findings of Richard et al. (52), but they studied different cell-permeating peptides in cells of epithelial origin.

The nuclear localization of **7** in live lymphoma cells, but not in fixed cells, suggests that the uptake mechanisms of cell-permeating peptide conjugates are complex and remain poorly understood. As reviewed by Moulton and Moulton (53) and Vives et al. (54), most publications on cell-permeating peptides highlighted energy-independent processes that occurred at low temperatures and in the presence of drugs that inhibit active transport. However, these reviews pointed to recent reports strongly suggesting that arginine-rich peptide

**Figure 6.** Scanning confocal fluorescence microscopy images of Raji cells incubated with **7** (top) or **6** (bottom) at 37 °C and 5% CO<sub>2</sub>, then fixed with 4% formaldehyde. Transmission images of cells with little or no fluorescence are shown in the lower right corner of some panels.

**Figure 7.** Scanning confocal fluorescence microscopy images of live Raji cells incubated with **6** (left) or **7** (right) at 37 °C and 5% CO<sub>2</sub> for 2 h. Arrows indicate cells with nuclear accumulation of **7**. Transmission images of the cells are shown in the lower right corner insets.

conjugates are internalized by an energy-dependent endocytotic pathway. Furthermore, early assay techniques produced artifacts leading to widespread acceptance of the nonendocytotic, membrane-permeating model as the mechanism of uptake.

Using fluorescein conjugates and live COS7 cells, Dom et al. (55) demonstrated that cellular uptake of pAntp is a two-step process. The first step is phase transfer from a hydrophilic to a hydrophobic environment, which is probably mediated by charge neutralization in the presence of negatively charged lipids. Phase transfer of pAntp is then followed by further translocation across the membrane bilayer, a process dependent on a critical tryptophan residue at position 6.

Thorén and colleagues (56) showed that pAntp was internalized by PC-12 and V79 cells via an endocytotic mechanism that could be abrogated at 4 °C or by depleting ATP. In contrast, they observed only an energy-independent, nonendocytotic pathway for R<sub>7</sub>W in the

same cell lines. Behavior of the Tat peptide in those studies was more complex. It showed substantial endocytosis in PC-12 cells, as well as energy-independent uptake. However, in V79 cells, Tat peptide internalization was exclusively energy-independent and led to uniform uptake in the cytoplasm and nuclear accumulation, similar to the subcellular distribution of conjugate **7** in the present studies.

Piwnicka-Worms and co-workers (57) found evidence for a membrane permeability barrier to Tat uptake in well-differentiated epithelial cells that form tight junctions in monolayer culture. They observed a complete lack of internalization of fluorescein-conjugated Tat peptide in monolayers of MDCK and CaCo-2 cells, but treatment with membrane permeabilizing agents resulted in immediate translocation. In contrast, epithelial cells that do not form tight junctions in monolayer culture, such as HeLa and KB 3-1, showed facile cytoplasmic and nucleolar accumulation of the fluorescent Tat conjugate.

However, it should be noted that these fluorescence microscopy studies were performed on paraformaldehyde-fixed cells. Piwnicka-Worms's group have also examined the effects of sequence and chirality on cell permeation activity (58). Screening a library of 42 <sup>99m</sup>Tc-labeled basic domain peptides in live Jurkat cells, Piwnicka-Worms and colleagues found that D-peptides were more active in cell permeation, a result not attributable to decreased proteolytic stability of the corresponding L-sequences. Furthermore, peptide uptake was dependent on length, sequence, and the type of radiometal chelate, with D-Tat-Orn<sup>6</sup> and (D-Arg)<sub>9</sub> having the greatest activity. Taken together, the results of these and the present studies indicate that further investigation of the uptake mechanisms of cell-permeating peptides is clearly warranted.

## CONCLUSION

In the present work, an innovative solid-phase synthesis strategy was developed to prepare, purify, and characterize a variety of cell-permeating peptide-PNA conjugates for targeting imaging and therapeutic radiometals to the *bcl-2* cellular oncogene. The strategy was based on cleavage and partial deprotection of resin-bound DOTA-conjugated peptide-PNA constructs, followed by RP-HPLC separation of the hydrophobic precursors from the hydrophilic unreacted PNA. Using this approach, *bcl-2* antisense and nonsense PNA sequences were conjugated to a new bifunctional derivative of DOTA, which can be incorporated into any position of a peptide-PNA conjugate, and to peptides that mediate cell permeation and internalization of the PNA. Peptide-PNA conjugates for both radiometal and fluorophore labeling were obtained in high purity and 6% to 9% overall yield by this synthetic strategy and modifications of the procedure. The <sup>111</sup>In-labeled retro-inverso PTD-4-G-KD-anti-*bcl-2* PNA conjugate showed superior plasma stability to the parent PTD-4-G construct. Moreover, scanning confocal fluorescence microscopy studies with the analogous tetramethylrhodamine conjugate demonstrated that retro-inverso PTD-4 was active in mediating internalization of anti-*bcl-2* PNA in Raji NHL cells, which are known to express high basal levels of *bcl-2* mRNA. Retro-inverso PTD-4-G-KT-anti-*bcl-2* PNA showed nuclear accumulation in approximately 50% of live cells, but formaldehyde fixation resulted in artifactual redistribution into the cytoplasm only. Further optimization of the design and synthesis of internalizing peptide-PNA conjugates for in vivo tumor uptake could generate powerful oncogene-targeting tools for both diagnostic imaging and targeted radiotherapy of cancer.

## ACKNOWLEDGMENT

This work was supported by NIH Grant CA86290 (W.A. Volkert, PI) and a grant from the University of Missouri Research Reactor Research Partnerships Initiative (to M.R.L.). The authors would like to thank Dr. Mayandi Sivaguru of the University of Missouri-Columbia Molecular Cytology Core, for valuable assistance in performing the fluorescence microscopy studies. We also acknowledge the Department of Veterans Affairs, for providing resources and the use of facilities at the Harry S Truman Memorial Veterans' Hospital in Columbia, MO, and the University of Missouri Research Reactor, for purchasing the Advanced ChemTech ACT Model 396 Omega Multiple Biomolecular Synthesizer used in this research.

**Supporting Information Available:** ESI mass spectra of all peptide-PNA conjugates. This material is available free of charge via the Internet at <http://pubs.acs.org>.

# Polyacetal–Doxorubicin Conjugates Designed for pH-Dependent Degradation

Ryan Tomlinson,<sup>†,‡</sup> Jorge Heller,<sup>§</sup> Steve Brocchini,<sup>\*,‡</sup> and Ruth Duncan<sup>\*,†</sup>

Centre for Polymer Therapeutics, Welsh School of Pharmacy, Cardiff University, King Edward VII Avenue, Cardiff, CF10 3XF, UK, Biomedical Polymers Group, Department of Pharmaceutics, The School of Pharmacy, University of London, 29–39 Brunswick Square, London, WC1N 1AX, UK, and A. P. Pharma, 123 Saginaw Drive, Redwood City, California, California 94063. Received May 22, 2003; Revised Manuscript Received August 1, 2003

Terpolymerization of poly(ethylene glycol) (PEG), divinyl ethers, and serinol can be used to synthesize water soluble, hydrolytically labile, amino-pendent polyacetals (APEGs) suitable for drug conjugation. As these polyacetals display pH-dependent degradation (with faster rates of hydrolysis at acidic pH) and they are not inherently hepatotropic after intravenous (iv) injection, they have potential for development as biodegradable carriers to facilitate improved tumor targeting of anticancer agents. The aim of this study was to synthesize a polyacetal–doxorubicin (APEG–DOX) conjugate, determine its cytotoxicity in vitro and evaluate its potential for improved tumor targeting in vivo compared to an HPMA copolymer–DOX conjugate in clinical development. Amino-pendent polyacetals were prepared, and following succinylation (APEG–succ), the polymeric intermediate conjugated to DOX via one of three methods using carbodiimide mediated coupling (1-ethyl-3-(3-dimethylaminopropyl)-carbodiimide (EDC) in aqueous solution was the most successful). The resultant APEG–DOX conjugates had a DOX content of 3.0–8.5 wt %, contained <1.2% free DOX (relative to total DOX content) and had a  $M_w = 60000$ – $100000$  g/mol and  $M_w/M_n = 1.7$ – $2.6$ . In vitro cytotoxicity studies showed APEG–DOX to be 10-fold less toxic toward B16F10 cells than free DOX ( $IC_{50} = 6$   $\mu$ g/mL and 0.6  $\mu$ g/mL respectively), but confirmed the serinol-succinoyl-DOX liberated during main-chain degradation to be biologically active. When administered iv to C57 black mice bearing subcutaneous (sc) B16F10 melanoma, APEG–DOX of  $M_w = 86000$  g/mol, and 5.0 wt % DOX content exhibited significantly ( $p < 0.05$ ) prolonged blood half-life and enhanced tumor accumulation compared to an HPMA copolymer–GFLG–DOX conjugate of  $M_w = 30000$  g/mol and 6.2 wt % DOX content. Moreover, APEG–DOX exhibited lower uptake by liver and spleen. These observations suggest that APEG anticancer conjugates warrant further development as novel polymer therapeutics for improved tumor targeting.

## INTRODUCTION

Of the many polymer–anticancer drug conjugates that have been proposed (1), 11 have now entered Phase I/II clinical trials (2). These first polymer therapeutics have predominantly used *N*-(2-hydroxypropyl)methacrylamide (HPMA) copolymers (3–8), poly(ethylene glycol) (PEG) (9, 10), or polyglutamate (PGA) (11, 12) as the carrier combined with established drugs such as doxorubicin, paclitaxel, camptothecin, and platinates (2). Clinical studies confirmed the safety of HPMA copolymers, PEG and PGA, and they are now being used as a platform to generate second generation polymer therapeutics containing experimental drugs, that have new therapeutic targets or that are delivered as drug combinations. For example, the antiangiogenic conjugate HPMA copolymer–TNP470 (13), HPMA copolymer conjugates containing natural products (14–17), and the HPMA copolymer-based drug combinations PDEPT (18), PELT (19), and those using catalytic antibodies (20).

Tumor targeting of long circulating polymer conjugates occurs as a result of the enhanced permeability and retention (EPR) effect (21, 22). This passive phenomenon arises because of tumor vasculature hyperpermeability (allowing polymer extravasation) and the lack of tumor tissue lymphatic drainage which subsequently promotes polymer retention. The magnitude of EPR-mediated targeting is directly proportional to the plasma concentration of circulating conjugate (23, 24). So far those conjugates tested clinically all have a  $M_w$  of  $\leq 40000$  g/mol. In the case of HPMA copolymer and PEG conjugates, which are non-biodegradable in the polymer main chain, this ensures polymer is not retained in the body therefore minimizing the danger of cumulative storage. However, this relatively low molecular weight brings the disadvantage of less than optimal EPR-mediated tumor targeting.

To improve further tumor targeting, we have been searching for novel water-soluble biodegradable polymeric carriers that are 'biocompatible', contain a pendent functionality for drug attachment, and have plasma pharmacokinetics that will maximize tumor targeting while minimizing normal tissue exposure. Several degradable polymer families have been investigated including PEG–polyester carbonates (25), dextrans (26), *cis*-aconityl polymers (27), and amino-PEG (APEG) polyacetals

**1** (28). The amino-pendent polyacetals **1** are particularly attractive as novel water-soluble carriers as they are designed to display pH-dependent hydrolytic degradation to liberate monomeric components once internalized into endosomal and lysosomal compartments of the cell. At pH 7.4 they lose 10% of their molecular weight over 72 h, whereas 40% of the molecular weight is lost over 24 h at pH 5.5 (28). Additionally these polyacetals are not inherently hepatotropic following intravenous (iv) injection, and no toxicity in vitro has yet been observed for either the intact polymer or its degradation products (28).

The aims of this study were to further optimize the synthesis of polyacetals **1** (structure **1**) to produce a weight average molecular weight ( $M_w$ ) greater than the renal threshold and to prepare the first APEG antitumor conjugates **2** using doxorubicin (DOX) as a model. The in vitro cytotoxicity of the conjugate **2** and its degradation products were studied. Finally, the pharmacokinetics of APEG–DOX **2** were determined after iv injection and compared with HPMa copolymer–GFLG–DOX to assess whether the polyacetal conjugate **2** has potential for improved tumor targeting.

## MATERIALS AND METHODS

**Materials.** Tri(ethylene glycol) divinyl ether, PEG and *p*-toluenesulfonic acid monohydrate (*p*-TSA) were from Aldrich (Dorset, UK). Fisher supplied the succinic anhydride, 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC) *N*-hydroxysuccinimide (NHS), and *N,N*-dicyclohexylcarbodiimide (DCC). Dichloromethane (DCM), tetrahydrofuran (THF), and toluene were from BDH (Dorset, UK). Before use, THF was distilled from sodium–benzophenone, and DCM was distilled from CaH. Medical grade O<sub>2</sub>, N<sub>2</sub> and CO<sub>2</sub> (all 95% v/v) and liquid nitrogen were supplied by BOC (Surrey, UK). All other reagents were of general laboratory grade and were from Aldrich. Sephadex LH20 was from Pharmacia LKB Biotechnology.

Murine melanoma cells (B16F10) were kindly donated by Prof. I. Hart (St. Thomas's Hospital, London, UK). Tissue culture grade dimethyl sulfoxide (DMSO), 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT), trypan blue, and optical grade DMSO were from Sigma (Dorset, UK). Trypsin, foetal calf serum (FCS), and RPMI 1640 were from Gibco BRL Life Technologies (Paisley, UK).

**Synthesis of Amino-Pendent Polyacetals 1.** Amino-pendent polyacetals **1** were prepared essentially as previously described (28) but with an additional drying step involving Fmoc-serinol. Two molecular weights of PEG were used in this study, 3400 and 2900 g/mol. Briefly, PEG<sub>3400</sub> (5.0052 g, 1.5 mmol) and *p*-TSA (12 mg, 0.05 mmol) were weighed into a 100 mL double-necked round-bottomed flask equipped with a magnetic stirrer bar. The compounds were dried in this flask at 80 °C in a vacuum (0.1 mmHg) for 3 h to remove water. After cooling, the vacuum pump was turned off as the reaction vessel was purged with nitrogen. A solution of the Fmoc serinol diol **4** (0.4616 g, 1.5 mmol) in freshly distilled THF (10 mL) was added by syringe. The THF was evaporated in a vacuum at 80 °C, for 30 min with continuous stirring. After cooling, the reaction vessel was purged with

nitrogen, and freshly distilled THF (20 mL) was added by syringe. A solution of tri(ethylene glycol) divinyl ether **6** (0.601 mL, 3 mmol) in freshly distilled THF (10 mL) was then added by syringe, and the reaction mixture was stirred for 3 h at ambient temperature (Scheme 1). Additional THF was added if the reaction mixture became too viscous to stir. Triethylamine (0.3 mL) was added to complex *p*-TSA and the mixture poured into a stirred solution of hexane (100 mL) to precipitate a white solid. After 10 min, the precipitate was filtered, stirred again in hexane, and isolated. Residual solvent was removed in a vacuum to give the polymer as a white solid. A typical Fmoc-protected amino-polyacetal **7** had a  $M_w$  of 65000 g/mol ( $M_w/M_n = 2.0$ ) as determined by aqueous GPC calibrated with PEG standards. NMR (<sup>1</sup>H, 500 MHz, CDCl<sub>3</sub>):  $\delta = 1.23$ – $1.30$  (3H, m, acetal CH<sub>3</sub>),  $4.75$ – $4.78$  (1H, m, acetal CH),  $7.27$ – $7.73$  (8H, m, Ar).

The Fmoc group was removed by adding (2.0509 g) of the protected polymer **7** to a stirred solution of 20% piperidine in acetonitrile (10 mL) at ambient temperature. TLC (ethyl acetate, UV detection) was used to monitor the reaction which was complete after 0.5 h. The mixture was washed with hexane (30 mL) and the CH<sub>3</sub>CN evaporated in vacuo. The resulting oil was poured into stirred hexane (30 mL) to yield the desired amino-pendent polyacetal **1** as a white solid in quantitative yield. NMR (1H, 500 MHz, CDCl<sub>3</sub>) indicated complete removal of the Fmoc-protection by the absence of characteristic peaks at 7.3–7.8, 4.6, and 4.3. The molecular weight characteristics of the final amino-pendent polyacetal **1** was  $M_w$  65100 g/mol ( $M_w/M_n$  1.89) as determined by aqueous GPC (PEG calibrants) was the same as seen for the Fmoc-protected polyacetal **7**.

**Polyacetal Succinylation. Preparation of Succinoylated APEG 9.** Succinic anhydride (0.0853 g,  $8.5 \times 10^{-4}$  mol) and (dimethylamino)pyridine (DMAP) (0.1014 g,  $8.3 \times 10^{-4}$  mol) were added to a solution of APEG **1** (0.716 g,  $2.1 \times 10^{-4}$  mol NH<sub>2</sub> equiv) and triethylamine (100  $\mu$ L) in anhydrous THF (13 mL) with stirring at ambient temperature under a nitrogen atmosphere. The reaction mixture was stirred for 24 h, and the solution was poured into a solution of diethyl ether (50 mL) to precipitate the succinoylated APEG **9** as a white solid. After filtration, the polymer was dissolved in distilled H<sub>2</sub>O (~15 mL), dialyzed (Spectra Por membrane,  $M_w$  cutoff 2000 g/mol) at 4 °C against distilled H<sub>2</sub>O (2  $\times$  5 l) for 24 h, and lyophilized to yield succinoylated APEG **9** (0.693 g, yield > 95%). GPC (PBS, 1.0 mL/min, PEG calibrants) indicated no change in molecular weight characteristics (64800 g/mol,  $M_w/M_n = 2.0$ ). NMR (<sup>1</sup>H, 500 MHz, CD<sub>3</sub>OD):  $\delta = 2.4$ – $2.5$  (4H, s, NHCOCH<sub>2</sub>CH<sub>2</sub>COOH).

**Conjugation of Doxorubicin To Give APEG–DOX 2.** Three methods were examined for the conjugation of DOX to APEG **1** (Scheme 2).

(A) *Conjugation Mediated by N,N*-Dicyclohexylcarbodiimide (DCC). To a 25 mL flask equipped with a magnetic stirrer bar were added the HCl salt of DOX (9.8 mg,  $1.7 \times 10^{-5}$  mol) and triethylamine (7.1  $\mu$ L,  $5.1 \times 10^{-5}$  mol) in anhydrous methanol (3 mL) to a solution of succinoylated APEG **9** (57.7 mg,  $1.7 \times 10^{-5}$  mol COOH equiv) and DCC (7.0 mg,  $3.4 \times 10^{-5}$  mol) in anhydrous

**Scheme 1. Terpolymerization Gave the Fmoc-Protected Amino-Pendent Polyacetal 7 That Was Deprotected To Give APEG 1**

THF (10 mL). The reaction was stirred under  $N_2$  at ambient temperature for 72 h. Monitoring the disappearance of the free DOX ( $R_f = 0.33$ ) by TLC (butan-1-ol:acetic acid:water, 4:1:5 (29)) indicated that the reaction proceeded slowly and not to completion. Evaporation of the reaction mixture gave a residue that was dissolved in methanol (2–3 mL), and the APEG–DOX **2** was purified twice by LH20 Sephadex column separation ( $2.5 \times 40$  cm). The conjugate fractions were pooled, methanol was evaporated, and the residue was dissolved in water and lyophilized to yield the red conjugate **2** (54.0 mg, yield > 85%).

(B) *Conjugation Mediated by N-Hydroxysuccinimide (NHS) and DCC.* To a stirred solution of succinylated APEG **9** (47.0 mg,  $1.4 \times 10^{-5}$  mol) in anhydrous THF (10 mL) under  $N_2$  were added NHS (5.0 mg,  $4.2 \times 10^{-5}$  mol) and DCC (5.8 mg,  $2.8 \times 10^{-5}$  mol). The reaction mixture was stirred for 2 h at ambient temperature. A solution of DOX·HCl (8.0 mg,  $1.4 \times 10^{-5}$  mol) and triethylamine (5.8  $\mu$ L,  $4.2 \times 10^{-5}$  mol) in anhydrous methanol (3 mL) was then added and the reaction continued for a further 48 h. TLC (butan-1-ol:acetic acid:water, 4:1:5) was used to monitor the reaction. The conjugate was isolated and purified as described in (A) above to yield APEG–DOX **2** (42.3 mg; yield 85%).

(C) *Conjugation Mediated by NHS and 1-Ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC).* To an aqueous solution (distilled  $H_2O$ , 5 mL) of succinylated APEG **9** (52.2 mg,  $1.5 \times 10^{-5}$  mol COOH equiv) was added EDC (12.2 mg,  $6 \times 10^{-5}$  mol) followed by NHS (4.2 mg,  $3 \times 10^{-5}$  mol). The reaction mixture was stirred for 30 min and then DOX·HCl (8.8 mg,  $1.5 \times 10^{-5}$  mol) in distilled  $H_2O$  (4 mL) was added followed by the dropwise addition of triethylamine (4.3  $\mu$ L,  $3 \times 10^{-5}$  mol) over 2 min with rapid stirring. The reaction was stirred a further 24 h. Progress was monitored by TLC (butan-1-ol:acetic acid:water, 4:1:5) for the disappearance of free DOX. The crude reaction mixture was lyophilized and redissolved in methanol and purified using LH20 Sephadex column chromatography ( $2.5 \times 40$  cm) as described in method A above. APEG–DOX **2** was isolated as a red solid following

evaporation of methanol, dissolution in distilled  $H_2O$  and subsequent lyophilization (52.2 mg; yield 90.5%).

**Characterization of Polyacetals and Polyacetal–DOX Conjugates.** *Molecular Weight Determination.* Aqueous gel permeation chromatography (GPC). Method 1: Waters Ultrahydrogel 1000 and 250 columns (7.8 mm ID  $\times$  30 cm) eluted using phosphate-buffered saline (0.7–1.0 mL/min) and UV and RI detectors in series were used with PEG calibrants. Method 2: Triple detection GPC (triSEC–Viscotek) using RI, viscosimetry, and light scattering (90°) detectors. Waters Ultrahydrogel 1000 and 250 columns (7.8 mm ID  $\times$  30 cm) and eluted using 0.2 M  $NaNO_3$  diluted with  $CH_3CN$  (10 v/v%) (0.7 mL/min); the narrow calibrant was PEG and broad calibrant was dextran.

*Determination of Free Doxorubicin in the APEG–DOX Conjugate.* APEG–DOX (1 mg) was dissolved in methanol (900  $\mu$ L). HCl (0.1 M; 100  $\mu$ L) was added and the solution left for 30 min. Aliquots (100  $\mu$ L) were then subjected to HPLC (C-18 reverse phase  $\mu$ Bondapak column eluted at 0.4 mL/min with 29% propan-2-ol in distilled water adjusted to pH 3.2 using *o*-phosphoric acid as mobile phase; detection by UV at 485 nm; data analysis using a PowerChrom system). Free DOX (500 ng/100  $\mu$ L) was used as standard, both with and without the addition of HCl, to confirm that under these conditions that no degradation of DOX or formation of the aglycone had taken place.

*Determination of Total Doxorubicin Content.* APEG–DOX (1 mg) was dissolved in methanol (1 mL), HCl (2 M; 1 mL) was added, and the solution was heated at 50  $^{\circ}C$  for 1.5 h to generate the aglycone (30). A standard curve was generated using free DOX aglycone (1 mg/mL methanol) exposed to the same conditions followed by serial dilutions to the range of 20–400 ng/100  $\mu$ L. Aliquots (100  $\mu$ L) of the degraded samples were then subjected to HPLC analysis as described above. All samples were kept in the dark and stored in polypropylene tubes at 4  $^{\circ}C$ .

*Determination of APEG–DOX and HPMA Copolymer DOX in Tissue Samples.* This method was adopted from

**Scheme 2. Reaction Routes Utilized for the Conjugation of Doxorubicin to APEG 1**

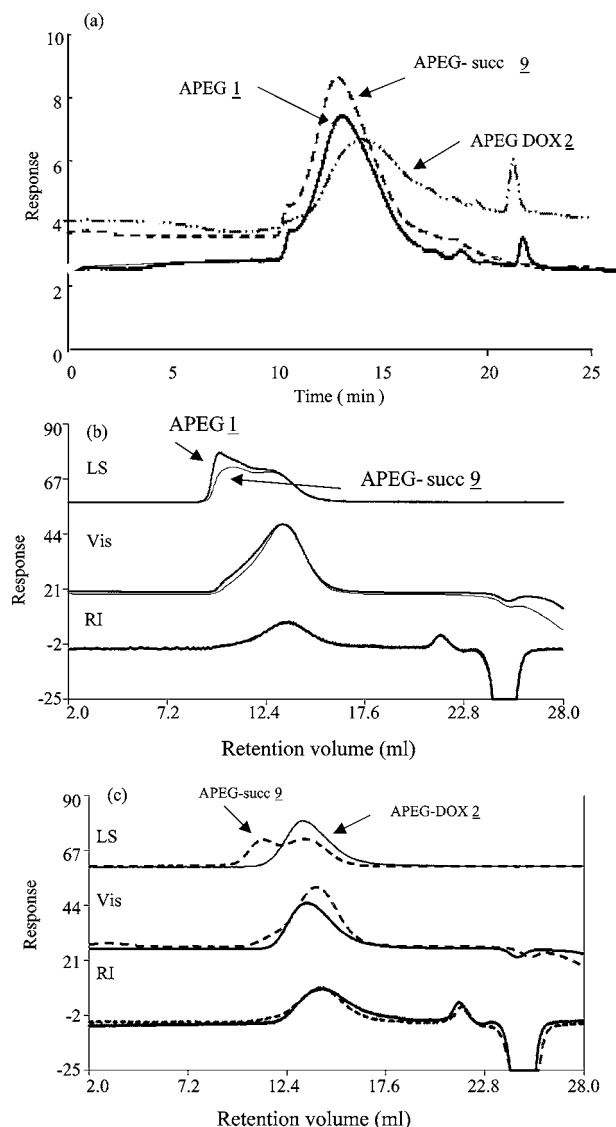

Wedge (*31*) and used to examine the total DOX content of tumor, plasma, and major organs in the body distribution studies. Organs were homogenized in water to a known volume (2–4 mL). Homogenate (975  $\mu$ L;  $n = 2$ ) was pipetted into a 15 mL polypropylene tube, and for plasma, 50  $\mu$ L was diluted with 925  $\mu$ L of distilled water. To each tube was added 25  $\mu$ L of a daunomycin solution (10  $\mu$ g/mL dissolved in distilled water). The tubes were vortexed, and HCl (2 M; 1 mL) was added. Samples were then heated to 50  $^{\circ}$ C for 25 min. Ammonium formate (1 M; approximately 1.5 mL) was added to adjust the pH to 8.5. The samples were revortexed, and NaOH (2 M; 1.0 mL) was added to neutralize the acid. Next chloroform:propan-2-ol (4:1; 5.0 mL) was added and the thoroughly mixed before centrifugation at 1000*g* for 30 min at 4  $^{\circ}$ C. The organic layer was carefully removed and evaporated under flowing N<sub>2</sub> to leave a residue that was redissolved in methanol (100  $\mu$ L) that was then analyzed by HPLC (as described but using fluorescence for detection; excitation at 480 nm and emission at 560 nm). Calibration curves were generated by extraction of DOX, APEG–DOX, or HPMA copolymer DOX from rat liver homogenate or distilled water for plasma samples.

#### Cytotoxicity of APEG–DOX Conjugates in Vitro.

In vitro cytotoxicity was determined using the MTT assay (*32*). B16F10 cells were seeded into 96-well microtiter plates at a density of  $1 \times 10^4$  cells/well. After 24 h, when

the cells had adhered, media was removed, the sample polymers (0.0–1.0 mg/mL media) were added, and free DOX was used as a reference standard. The cells were returned to the incubator for a further 67 h. After this time, MTT solution (20  $\mu$ L; 5 mg/mL in sterile-filtered PBS) was added to each well, and the plates were reincubated for a further 5 h. The formazan crystals were dissolved in DMSO, and the concentration was read at 550 nm using a microtiter plate reader. Cells grown in media alone were used as a reference for 100% viability. The results were expressed as viability (%) relative to a control containing no polymer.

**Body Distribution of APEG–DOX in Mice Bearing a Subcutaneous B16F10 Tumor.** All experiments were conducted according to UKCCCR Guidelines governing experiments with neoplasia (*33*). B16F10 cells ( $1 \times 10^5$ ) were injected sc into C57/B black mice and the tumor allowed to establish to a palpable size (25–50 mm<sup>2</sup>). Polymer conjugates, APEG–DOX or HPMA copolymer DOX, were then injected iv (5 mg/kg DOX-equiv) via the tail vein and the animals killed at the specified time points ( $n = 3$ ). A blood sample was taken and immediately centrifuged (1000*g* at 4  $^{\circ}$ C) to isolate the plasma. The tumor, liver, heart, spleen, kidneys, and lungs were removed, washed in PBS, and stored at –20  $^{\circ}$ C. Total blood volume of the mouse was calculated assuming 5.77 mL per 100 g body weight (*34*). The

**Figure 1.** Comparison of the GPC profiles of APEG, APEG-succ, and APEG-DOX. (a) Traces for APEG 1, APEG-succ 9, and APEG-DOX 2 obtained using aqueous GPC with RI detection only (method 1). (b) Traces obtained using a triple detection aqueous GPC (method 2) of APEG 1 and APEG-Succ 9. (c) Traces obtained using the triple detection system for APEG-DOX 2 (5 wt % loading) and APEG-Succ 9 from which the DOX conjugate was derived.

concentration of DOX in each organ was determined by HPLC as described above and was expressed as a percentage of the injected dose per gram of organ.

**Statistics.** Statistical significance was calculated using the students' *t*-test (two tailed). Statistical significance was defined as  $p < 0.05$ .

## RESULTS AND DISCUSSION

Polymer therapeutics have already demonstrated their ability to provide new, improved medicines, particularly in the treatment of cancer and infectious diseases (35). Design of biocompatible, biodegradable polymers does, however, remain a significant challenge if this concept is to be more widely applied. This was our motivation for preparation of amine-pendent polyacetals **1** (28). It was considered particularly important to design a polymeric carrier that would be stable in the circulation, but show triggered pH-dependent degradation after cellular internalization into the acidic vesicles (endosomes and lysosomes) of the endocytic pathway.

**Figure 2.** A typical HPLC chromatogram APEG-DOX 2 after acid hydrolysis (0.1 N HCl, 30 min at room temperature). The elution of free DOX, serinol-succ-DOX, and DOX aglycone is shown.

The terpolymerization process utilized to make the first amine-pendent polyacetals **1** (APEG) (Scheme 1) (28) has been improved here to ensure that polymers of molecular weight greater than the renal threshold ( $M_w > 40000$  g/mol) could be reproducibly prepared. Adventitious water in the starting reagents, especially PEG, gives polyacetals of variable and sometimes moderate molecular weight ( $M_w$  25000–78000 g/mol;  $M_w/M_n = 1.8$ –2.0). Here considerable care was taken to ensure that glassware, reagents and solvents were dry. The resultant Fmoc-polyacetals **7** were readily deprotected to give the desired APEG **1** that later gave APEG-DOX conjugates of  $M_w$  60000–100000 g/mol and  $M_w/M_n = 1.7$ –2.6. No evidence of degradation in the polymer main-chain was observed during the deprotection step. For the polymerization two molecular weights of PEG were used (2900 and 3400 g/mol). The proportion of Fmoc-serinol **4** to PEG **5** dictated the relative amount of amino pendent functionality in APEG **1**. A 1:1 ratio of these diol monomers was used throughout this study, and incorporation of this ratio of monomers in the polymer main-chain was confirmed by <sup>1</sup>H NMR. There was little difference in the characteristics of polymers (and their conjugates) synthesized using different molecular weight PEGs so PEG<sub>3400</sub> was used to prepare all APEG-DOX batches used for biological evaluation.

### Synthesis and Characterization of APEG-Succ 9.

To synthesize APEG-succ **9** as a precursor polymer for DOX conjugation, APEG **1** was succinoylated with an excess of succinic anhydride (Scheme 2). Complete succinoylation is essential to avoid polymer cross-linking during DOX conjugation. <sup>1</sup>H NMR analysis of APEG-Succ **9** indicated the succinoyl methylene (CH<sub>2</sub>) protons were at 2.4–2.5 ppm. The relative integrals of these protons

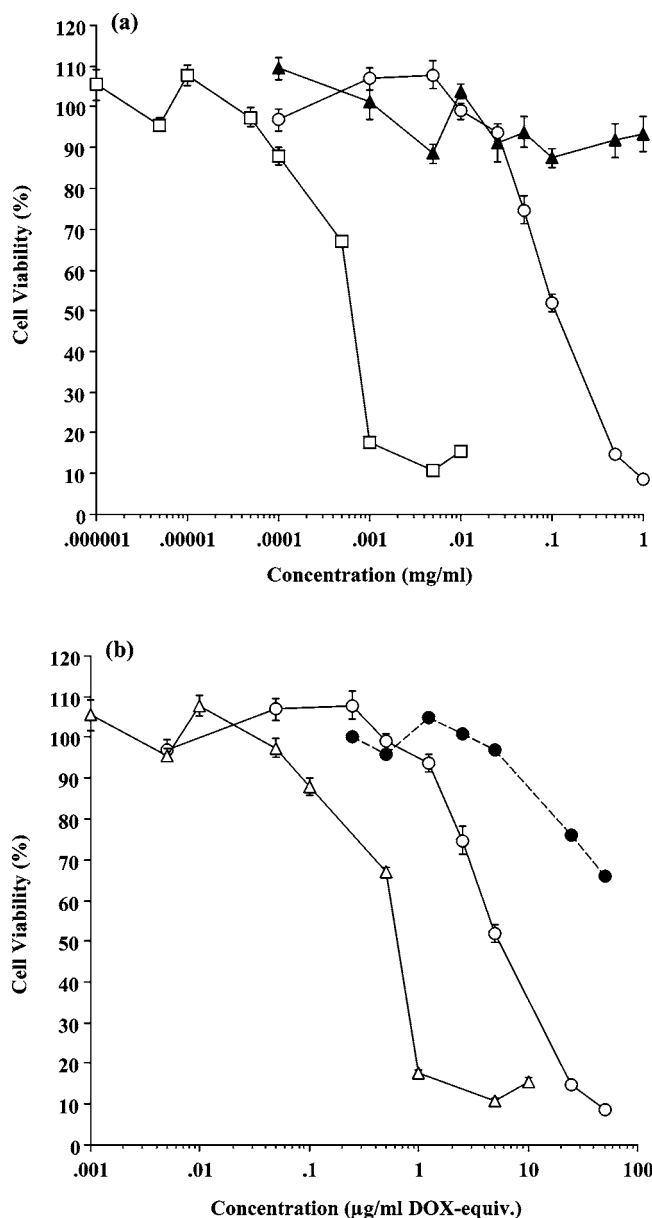

**Figure 3.** Degradation of APEG-DOX at acid pH followed by GPC. APEG-DOX was incubated at pH 3.2 for 22 h at room temperature. The data show superimposed GPC traces (obtained using method 1) indicating main-chain polyacetal hydrolysis with time leading to decreasing molecular weight of the polymer and generation of PEG<sub>3400</sub>.

and the acetal methyl proton at 1.2 ppm could be used to estimate the degree of succinylation. This was always in the range 85–100%. Since the ratio of Fmoc serinol **4** to PEG **5** was 1:1, the number of pendent chains equaled the degree of polymerization. Also, since the molecular weight of the PEG monomer was either 2900 or 3400 g/mol, the degree of polymerization was always ~14–20.

Polymers susceptible to main-chain degradation must be evaluated carefully after each reaction and purification step to determine whether there has been any inadvertent loss in molecular mass. Analysis of APEG-Succ **9** by aqueous GPC (method 1; Figure 1a) showed no significant change in molecular weight during succinylation (Scheme 2; **1**→**9**). To gain further insight into the molecular weight characteristics of these polymers in solution, APEG **1** and the succinylated APEG **9** derivative were also analyzed by triple detection aqueous GPC (RI, viscosimetry and 90° light scattering detectors) (Figure 1b). Light scattering indicated the presence of some higher molecular weight species, but their concentration was low since these species were not detectable by RI. They probably represent polymer aggregates, a phenomena that might be expected due to the high PEG content of the precursors **1** and **9**. Polymer aggregation in aqueous solution has been frequently reported and related to polymer-drug loading, polymer hydrophobicity, temperature, and/or the concentration of the polymer in the eluant (36–38).

#### Synthesis and Characterization of APEG-DOX.

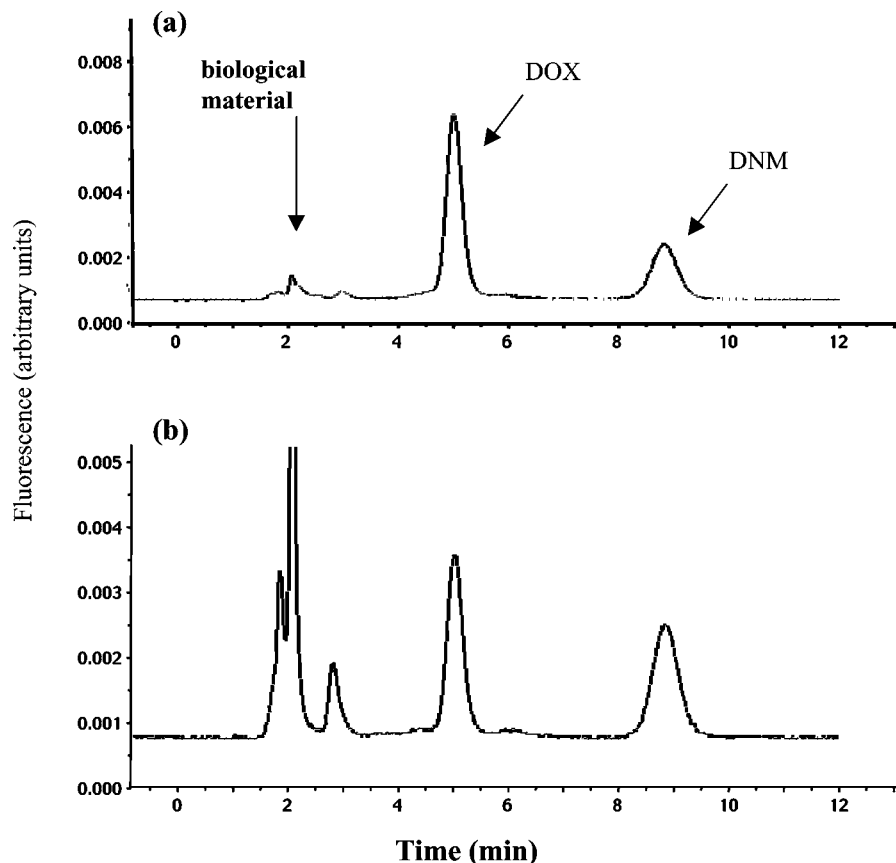

Three synthetic approaches were explored as a means of DOX conjugation to APEG-succ **9** (Scheme 2, reactions A, B, and C). DCC-mediated conjugation (reaction A) produced APEG-DOX conjugates with a DOX content of 3.0–5.0 wt %. This is a low yield since the theoretical maximum for DOX loading is 11.1 wt %, and it is probably due to competitive esterification with methanol. Formation of the NHS ester by DCC in THF prior to the addition of DOX (reaction B) gave no better yield (DOX content 5.4 wt %). These two approaches were therefore abandoned in favor of DOX conjugation using EDC in aqueous solution (reaction C), as this route gave conjugates with a much better yield (8.5 wt % DOX content).

**Figure 4.** In vitro cytotoxicity of APEG-DOX assessed using B16F10 cells. (a) Cytotoxicity of free DOX (□), APEG-DOX **2** (○) and APEG-succ **9** (▲) expressed as compound concentration. (b) Data for free DOX (△) and APEG-DOX **2** (○) in this case expressed as relative DOX concentration. Knowing that this APEG-DOX conjugate contains 1% free DOX the cytotoxicity attributable to this contamination is also shown (●). Data represent mean ± SE ( $n = 6$ ).

The DOX content of all APEG-DOX batches synthesized are given in Table 1. Total DOX content was determined either by UV spectroscopy or HPLC analysis after acidic hydrolysis of the conjugate at 50 °C to liberate DOX aglycone **10**. Use of the UV extinction coefficient to estimate total drug content is easy and routinely used by many. However, reliance on these values is not advisable, as the extinction coefficient often changes after drug conjugation, and any resultant inaccuracy would give a dangerous measure of clinical dose (2). For this reason, validated techniques had to be developed to determine the total and free DOX content of HPMA copolymer-DOX conjugates (39). In this case it is noteworthy that the DOX content of APEG-DOX measured by HPLC was consistently 20–40% higher than that measured by UV (Table 1). Also important to note is the DOX loading capacity (8.5 wt %) of APEG **1** conjugates

**Figure 5.** Typical HPLC traces used to determine total DOX content of biological samples in the biodistribution studies. (a) Plasma; (b) tumor. Elution of DOX-aglycone and DNM-aglycone is shown. In both cases a small amount of sample residue is present, but this elutes close to the solvent peak and is well resolved from the peaks of interest.

compares favorably with other polymer–DOX conjugates tested clinically (HPMA copolymer-gly phe-leu-gly–DOX 8.5 wt % (4), or proposed as potential clinical candidates (PEG–DOX, 2.5–5 wt % (40) and poly(glutamic acid)–DOX, 5–16 wt % (41).

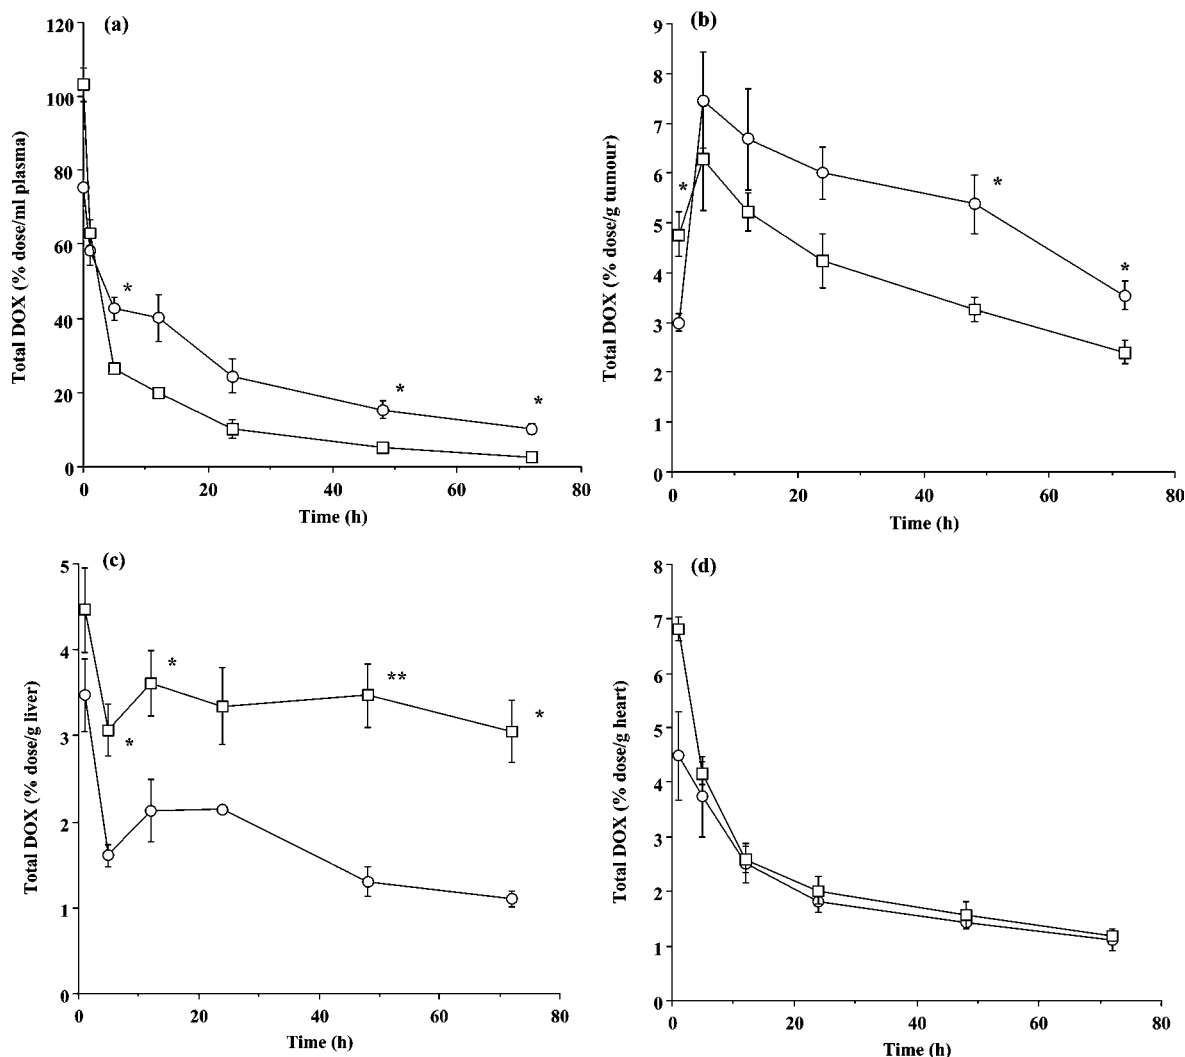

In all cases the free DOX content of APEG–DOX conjugates was  $\leq 1.2\%$  of the total DOX content (Table 1). Determination of free DOX levels required development of a new analytical method, as the extraction techniques previously employed for isolation of DOX from HPMA copolymer–DOX conjugates (30, 31, 40) led to partitioning of APEG–DOX into both organic and aqueous phases (chloroform:propan-2-ol (4:1)/water). Gradient HPLC (40) was also impossible due to retention of the APEG–DOX conjugates on the C-18  $\mu$ bondapak columns used. The method developed used mild degradation of the polyacetal polymer backbone using 0.1 M HCl at room temperature for 30 min to generate serinol-succ–DOX **11** (structure 2) without causing generation of DOX-aglycone **10** from free DOX in the sample. This allowed HPLC separation and quantitation of both serinol-succ–DOX **11** and free DOX. A typical HPLC chromatogram of the hydrolyzed APEG–DOX **2** is shown in Figure 2. DOX is known to be stable in the pH range 3.0–6.5 (29), and indeed free DOX exposed to the conditions used here for 4 h did not produce any DOX-aglycone **10**. Therefore it was concluded that the DOX aglycone present in these samples arose from subsequent degradation of the isolated serinol-succ–DOX **10**. The standard curve was generated for free DOX exposed to these analytical conditions was used to calculate the free drug content in each APEG–DOX sample (Table 1).

APEG–DOX **2** conjugates showed a decrease in the polymer aggregation behavior compared to that of the

### 10

APEG-succ **9** precursor on GPC (Figure 1c). There was no evidence of polymer cross-linking during DOX conjugation, and in fact some batches of APEG–DOX **2** had an apparently lower molecular weight than the precursor from which they were generated (Figure 1a). This was likely due to DOX conjugation causing a diminution of polymer hydrodynamic radius (14). Degradation of the polymer did not occur during DOX conjugation, as the viscosimetry and RI signals showed neither an increase in heterodispersity nor appearance of lower molecular weight degradation products (e.g. PEG). Importantly, dual channel GPC using RI and UV detectors in series also indicated that the DOX had bound homogeneously across the polymer molecular weight range (results not shown).

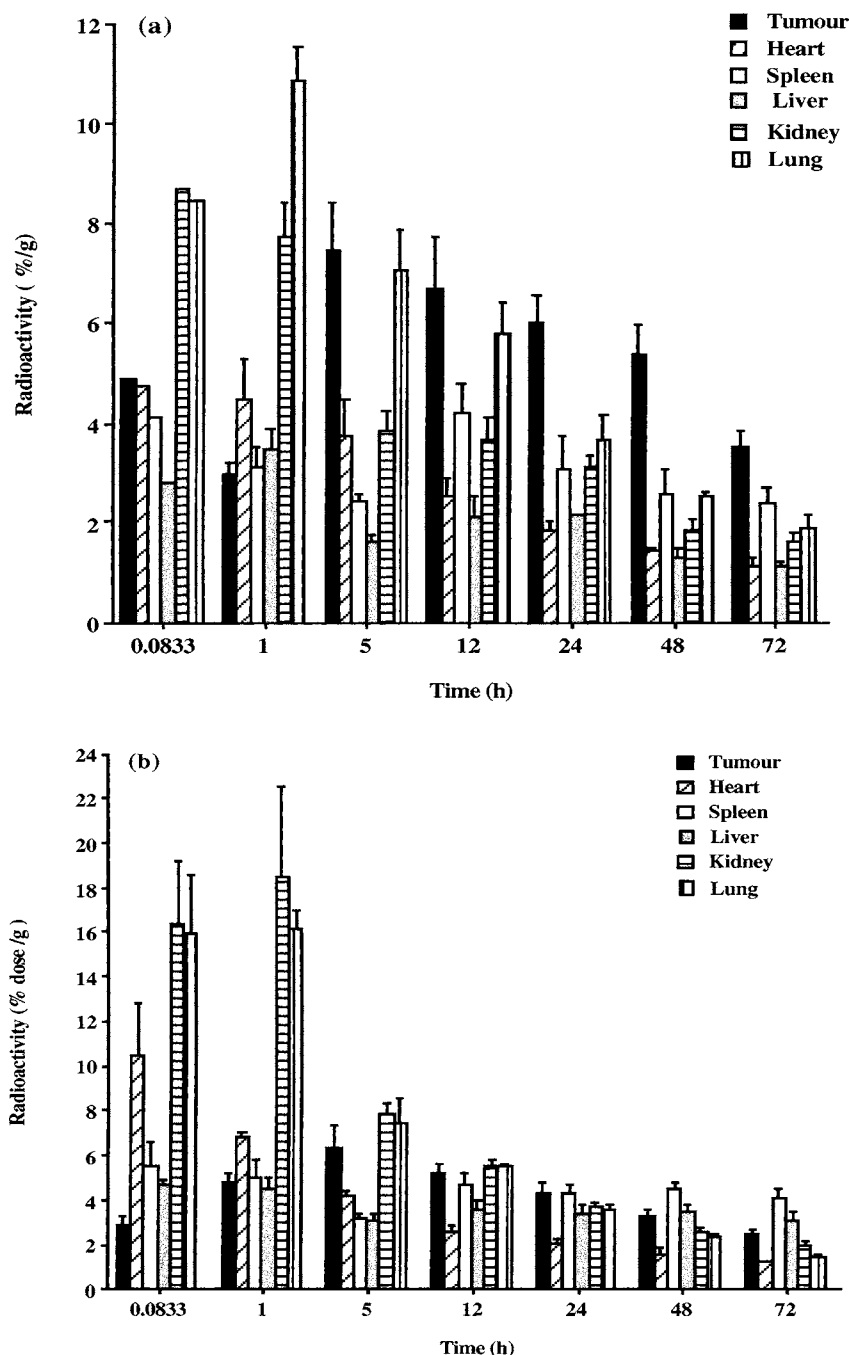

**Figure 6.** The biodistribution of APEG-DOX and for comparison HPMA copolymer-DOX administered iv (5 mg/kg DOX-equivalent) to mice bearing sc B16F10 melanoma tumors. In all cases total DOX content is shown after injection of APEG-DOX (○) or HPMA copolymer-DOX (□). (a) Plasma (expressed as percent dose per mL of plasma); (b) tumor; (c) liver; (d) heart. Organ data are expressed as % dose/g tissue. In all cases the data represent mean values  $\pm$  SEM ( $n = 3$ ) and statistical significance is indicated by \*  $p < 0.05$  and \*\*  $p \leq 0.01$ .

**pH-Dependent Degradation of APEG-DOX.** Incubation of APEG-DOX conjugates at pH 3.2 (Figure 3) led to a reduction in polymer molecular weight and appearance of degradation products with time. Complete degradation of the polymer backbone occurred over 24–48 h. This observation was consistent with the earlier studies which showed that APEG 1 and APEG-succ 9 rapidly degraded at pH 6.5 and 5.5, but not at pH 7.4 (28), and confirmed that DOX conjugation to the APEG main-chain did not impair backbone degradation. Moreover, these observations suggested that serinol-succ-DOX would be efficiently liberated intracellularly following conjugate internalization.

**In Vitro Cytotoxicity of APEG-DOX.** Before in vivo valuation, it was important to verify the potential antitumor activity of the APEG-DOX conjugate. Whereas APEG-succ was not cytotoxic against B16F10 cells up to concentrations of 1 mg/mL, the APEG-DOX 2 conjugate had an  $IC_{50}$  value of 6  $\mu$ g/mL (DOX-equivalent) (Figure 4). This was 10-fold lower than observed for free DOX ( $IC_{50} = 0.6 \mu$ g/mL). Activity of APEG-DOX is not simply attributable to the small amount of free DOX in the sample (~1% of total DOX) (Figure 4b). It is well-known that polymer conjugates display lower  $IC_{50}$  values in vitro than those for the parent compound due to their changed

cellular pharmacokinetics (slower endocytic captured compared with rapid transmembrane passage of free drug) (3). The relatively 'high'  $IC_{50}$  value observed for APEG-DOX compared with HPMA copolymer-DOX conjugates suggests that serinol-succinoyl-DOX 10 is, like other anthracycline prodrugs (42), a potent antitumor agent.

**In Vivo Pharmacokinetics of APEG-DOX.** The rationale for development of an APEG-DOX conjugate was the desire to produce improved EPR-mediated tumor targeting. Thus it was essential to establish that APEG-DOX would be long circulating (and not hepatotropic) and demonstrate improved tumor targeting compared to the HPMA copolymer-DOX, a conjugate currently undergoing clinical development (4). The biodistribution of APEG-DOX 2 ( $M_w = 86000$  g/mol,  $M_w/M_n = 2.6$ ; DOX content 5.0 wt %) and HPMA copolymer-gly phe-leu-gly-DOX ( $M_w = 30000$  g/mol,  $M_w/M_n = 1.3$ –1.5; 6.2 wt % DOX) in C57 mice bearing a sc B16F10 tumor was investigated after iv administration of both conjugates at a dose of 5 mg/kg DOX-equivalent. An HPLC assay was used to quantitate the total DOX content of plasma and tissues, and in this case daunomycin was used as an internal reference standard (Figure 5). The results obtained are summarized in Figures 6 and 7.

**Figure 7.** Comparison of the body distribution of APEG-DOX (panel a) and HPMA copolymer-gly phe-leu-gly-DOX (panel b) in all tissues after iv administration to C57 mice bearing sc B16F10 melanoma. The results are expressed as % dose/g for all tissues. (mean  $\pm$  SE and  $n = 3$ ).

Both APEG-DOX and HPMA copolymer-DOX displayed a biphasic pattern of plasma clearance with a  $t_{1/2\alpha}$  of  $\sim 1$  h (Figure 6a). The similarity in this early phase clearance can be attributed to the polydispersity of APEG-DOX which contained a significant proportion of the injected sample of  $M_w$  lower than the renal threshold ( $< 40000$  g/mol), i.e., of similar  $M_w$  to HPMA copolymer-DOX. Plasma levels of APEG-DOX were, however, significantly higher ( $p < 0.05$ ) than seen for HPMA copolymer-DOX after 5, 48, and 72 h (Figure 6a). The  $t_{1/2\beta}$  for HPMA copolymer-DOX and APEG-DOX were 3.5 and 19 h, respectively, and after 24 and 72 h, the administered dose remaining in the circulation was 20% and 8% for APEG-DOX compared with 8% and 2% for HPMA copolymer-DOX. During the second phase of elimination the higher molecular weight polyacetal-DOX

fraction circulated longer leading to a 2-fold increase in the plasma area under the curve ( $AUC_{1-72h}$ ).

Although tumor accumulation of HPMA copolymer-DOX was significantly higher at 1 h ( $p < 0.05$ ) (Figures 6b and 7b), APEG-DOX displayed elevated tumor levels at 48 and 72 h ( $p < 0.05$ ). The peak tumor levels attained by both polymers was seen after 5 h and were 7.5 and 6.3% dose/g for APEG-DOX and HPMA copolymer-DOX, respectively. The tumor  $AUC_{1-72h}$  of APEG-DOX was 1.4-fold higher than observed for the HPMA copolymer conjugate.

Prolonged plasma circulation is the driving force for increased tumor targeting (23, 24); however, this phenomenon can potentially also lead to increased normal tissue exposure to the anthracycline. This would obviously be disadvantageous as it might lead to nonspecific

toxicity. Interestingly, liver accumulation ( $AUC_{1-72h}$ ) for HPMA copolymer-DOX was 2-fold higher than APEG-DOX (Figures 6c and 7). Similarly, HPMA copolymer-DOX showed a spleen  $AUC_{1-72h}$  that was 1.5-fold higher than that of APEG-DOX (Figure 7). PEG is an extremely hydrophilic polymer, and it has been widely used to prolong the plasma circulation of proteins and liposomal drug carriers (43, 44). It is probable that the high PEG content within the APEG backbone is responsible for this lower APEG-DOX uptake by the reticuloendothelial system.

The two conjugates showed similar (no significant difference) uptake by heart and lung (Figures 6d and 7). DOX conjugation to HPMA copolymers was shown to abrogate cardiotoxicity commonly associated with DOX therapy during Phase I trials (4). Thus the low heart levels of DOX seen here after administration of APEG-DOX bodes well for reduced cardiotoxicity of this conjugate. The relatively high kidney levels seen at 1 h after administration of both polymers results from their ongoing renal elimination (Figure 7). Significantly higher kidney levels of HPMA copolymer-DOX were seen after 5 and 12 h ( $p < 0.05$ ) probably due to its continued excretion over this time. No progressive accumulation was seen for either HPMA copolymer-DOX or the longer circulating APEG-DOX in any organ (Figure 7).

## CONCLUSIONS

High molecular weight APEGs were used to synthesize APEG-DOX conjugates ( $M_w = 60000-100000$  g/mol;  $M_w/M_n = 1.7-2.6$ ) via a succinoylated intermediate. Conjugates had a DOX content of up to 8.5 wt % and a free DOX of <1.2% total DOX. APEG-DOX maintains the ability to display pH-dependent polymer main-chain degradation, and the serinol-succ-DOX liberated displays antitumor activity in vitro. In vivo biodistribution studies in animals bearing a sc B16F10 tumor confirmed that APEG-DOX had prolonged plasma circulation (2-fold) compared to HPMA copolymer-DOX. This led to a 1.4-fold increase in DOX tumor targeting, but moreover, administration of APEG-DOX led to significantly less deposition of DOX in liver and the spleen. This is the first conjugate designed for pH-triggered intracellular main-chain degradation. The data presented here suggest that further in vivo studies are warranted to define the therapeutic index of APEG-DOX, and synthesis APEG-DOX conjugates with narrower polydispersity, moreover with all polymer chains of  $M_w$  > than the renal threshold, would maximize the tumor targeting potential of this novel polymeric carrier.

# Diphtheria Toxin–Epidermal Growth Factor Fusion Protein and Pseudomonas Exotoxin–Interleukin 13 Fusion Protein Exert Synergistic Toxicity against Human Glioblastoma Multiforme Cells

Tie Fu Liu, Mark C. Willingham, Stephen B. Tatter, Kimberley A. Cohen, A. Corinne Lowe, Andrew Thorburn, and Arthur E. Frankel\*

Departments of Cancer Biology, Surgery, Pathology and Comparative Medicine, Wake Forest University School of Medicine, Winston-Salem, North Carolina 27157. Received July 1, 2003; Revised Manuscript Received October 7, 2003

The cytotoxicity of combinations of a diphtheria toxin–human epidermal growth factor fusion protein (DAB<sub>389</sub>EGF) and a Pseudomonas exotoxin–human interleukin 13 fusion protein (IL13PE38QQR) was tested against 14 human glioma cell lines. After cells were cultured for 48 h with various concentrations of the fusion proteins, the percentage reductions in thymidine incorporation were determined. Seven of fourteen cell lines were highly sensitive to DAB<sub>389</sub>EGF alone, and six cell lines were highly sensitive to IL13PE38QQR alone with IC<sub>90</sub>'s < 100 pM. When combined, synergistic cell killing was observed for seven of the cell lines based upon concave isobolograms and combination indices (CI's) of 0.2 to 0.7. Supraadditive cytotoxicity was confirmed by measurements of induction of apoptosis. Receptor expression was assessed by flow cytometry and confocal microscopy. Marked heterogeneity of expression of EGFR and IL13R $\alpha$ 2 was seen on all the glioma cell lines. This heterogeneity may contribute to incomplete cell killing with the individual fusion proteins and synergistic cell kill with the combination. These results suggest that both fusion proteins may yield antitumor effects in patients with recurrent gliomas and that combination fusion protein intracranial therapy of malignant gliomas may yield an improved therapeutic index.

## INTRODUCTION

There are 17 000 cases of primary brain tumors per year in the United States (1). Over 80% of these tumors are infiltrative astrocytomas/GBM<sup>1</sup> which arises from malignant transformation of astrocytes (2). In most cases, treatment is unsatisfactory with a median survival of one year for newly diagnosed patients and six months for patients with recurrent disease (3). The two-year survival rate for GBM patients is less than 20%. Both local spread of tumor cells beyond sites of surgery and radiation and chemotherapy- and radiation-resistant tumor cells contribute to the development of refractory disease (4, 5). Novel agents with different mechanisms of action are needed.

One such class of therapeutics is fusion proteins consisting of protein synthesis-inactivating peptide toxins fused to brain tumor-selective ligands. The ligand directs the molecule to the glioma cell surface; after internalization and translocation to the cytosol, the peptide toxin moiety catalytically inactivates protein synthesis leading to cell death. Fusion proteins targeting brain tumor Tf receptors, IL13 receptors, IL4 receptors, and EGFR have been prepared and administered by CED directly into the brain tumor interstitium of patients with refractory GBM (6–9). CED creates a bulk flow that supplements diffusion and leads to achievement of drug concentrations

hundreds-fold greater than by systemic infusion for large areas of the brain parenchyma (10). Fusion protein CED therapy has yielded remissions lasting years in a significant fraction of patients. However, not every patient responds and toxicities to normal brain have occurred. Thus, there is a need to improve the technology.

Since most brain tumors are heterogeneous in their expression of receptors and even glioma cell lines display cell-to-cell variations in receptor density, we reasoned that combinations of fusion proteins targeting different receptors would enhance glioma cell kill and permit lower doses of each fusion protein to be used—reducing normal brain toxicity. In this paper, we tested the cytotoxicity of combinations of DAB<sub>389</sub>EGF and IL13PE38QQR fusion proteins targeting the EGFR and IL13R. Fourteen human glioma cell lines were evaluated. Combination indices and isobolograms were used to assess the presence and degree of synergy (11). In addition, we measured the expression of each of the receptors and estimated the level of receptor heterogeneity.

## MATERIALS AND METHODS

**Fusion Proteins and Antibodies.** DAB<sub>389</sub>EGF was a gift of Ligand Pharmaceuticals (San Diego, CA). The fusion protein was synthesized and partially purified as previously described (12). Vials contained sterile filtered and lyophilized 500  $\mu$ g of DAB<sub>389</sub>EGF, phosphate-buffered saline pH 7.2, 1% mannitol, and 50  $\mu$ M EDTA. Vials were stored at –80 °C. Fusion protein was prepared for experiments by adding 2 mL of sterile water and gently agitating. Dissolved fusion protein was stored at 4 °C. Lot number was 3E13EB2.

IL13PE38QQR was a gift of NeoPharm (Lake Forest, IL). The fusion protein was synthesized and partially

<sup>1</sup> Abbreviations: GBM, glioblastoma multiforme; IL, interleukin; Tf, transferring; CED, convection-enhanced delivery; EGFR, epidermal growth factor receptor; PE, Pseudomonas exotoxin; DT, diphtheria toxin; MTD, maximum tolerated dose; DLT, dose-limiting toxicity.

purified as described (13). Vials contained sterile filtered IL13PE38QQR at 200  $\mu\text{g/mL}$  in normal saline with 0.2% human serum albumin. Material was stored in aliquots at  $-80^\circ\text{C}$  until used.

Murine monoclonal antibody anti-IL13R $\alpha$ 2 and R-phycoerythrin (PE)-conjugated murine monoclonal antibody anti-IL13R $\alpha$ 2 was purchased from Diaclone SAS (Besancon, France). Mouse anti-EGFR antibody conjugated to fluorescein isothiocyanate (FITC), mouse isotype control antibody IgG2b $\kappa$  conjugated to FITC, and PE-conjugated mouse isotype control antibody IgG1 were obtained from BD Biosciences (Mountain View, CA). Mouse IgG and rhodamine-conjugated goat anti-mouse IgG were purchased from Jackson ImmunoResearch (West Grove, PA).

**Cell Lines.** Cell lines U373MG and U138MG were obtained from the Wake Forest University Tissue Culture Core Laboratory. Cell lines A172, DBTRG05MG, T98G, U87MG, and U118MG were purchased from the American Type Culture Collection (Rockville, MD). Cell lines LN405, GAMG, DKMG, GMS10, 42MGBA, SNB19, and 8MGBA were purchased from the Deutsche Sammlung von Mikroorganismen und Zellkulturen GmbH (braunschweig, Germany). Cells were cultured at  $37^\circ\text{C}$  in a humidified atmosphere containing 5%  $\text{CO}_2$  in air and maintained as described previously (14).

**Cell Cytotoxicity Assays.** Aliquots of 5000 cells were incubated in triplicate in 100  $\mu\text{L}$  of medium (same as that used to grow the cells) in Costar 96-well flat-bottomed plates. After 24 h, DAB<sub>389</sub>EGF, IL13PEQQR, or both in medium were added to each well to yield concentrations ranging from 0 to 1000 pM, and the cells were incubated at  $37^\circ\text{C}$  in 5%  $\text{CO}_2$  for another 48 h. After the incubation, 0.5  $\mu\text{Ci}$  of [ $^3\text{H}$ ]thymidine (NEN DuPont, Boston, MA) in 50  $\mu\text{L}$  of medium was added to each well, and incubation was continued for an additional 16 h at  $37^\circ\text{C}$  in 5%  $\text{CO}_2$ . Plates were frozen at  $-80^\circ\text{C}$  and thawed; cell lysates were harvested using a Skatron Cell Harvester (Skatron Instruments, Lier, Norway) on to glass fiber mats; and the cpm of incorporated radiolabel were counted using an LKB liquid scintillation counter gated for  $^3\text{H}$ . The  $\text{IC}_{90}$  was defined as the concentration of toxin that inhibited thymidine incorporation by 90% compared to control wells. The percentage of maximum [ $^3\text{H}$ ]thymidine incorporation was plotted versus the log of the toxin concentration, and nonlinear regression with a variable-slope sigmoidal dose-response curve was generated along with  $\text{IC}_{90}$  with use of GraphPad Prism software (GraphPad Software, San Diego, CA). All assays were performed in triplicate. Multiple drug-effect analysis was done using CalcuSyn software (BioSoft, Ferguson, MO). Both the  $\text{IC}_{90}$  isobologram and the  $\text{IC}_{90}$  combination index (CI) were derived using the software and the equation of T. C. Chou (11). The  $\text{CI} = A/A_0 + B/B_0$ .  $A_0$  and  $B_0$  are individual drug concentrations producing the effect;  $A$  and  $B$  are the drug concentrations in the combination yielding the same effect. Isobolograms are graphs of  $A$  versus  $B$  with individual points ( $A$ ,  $B$ ) noted yielding the desired effect. The graphs of ( $A$ ,  $B$ ) points for a given effect yield concave, straight lines or convex curves for synergistic, additive or antagonistic interactions, respectively.

For analysis of nuclear morphology, cells were treated with the drugs for 48 h then stained with Hoescht 3258 as previously described (15). Cells were deposited onto slides using a cytospinner and scored for apoptotic nuclei by fluorescence microscopy.

**Flow Cytometry.** Aliquots of 1 000 000 cells were pelleted at 600g and resuspended in 80  $\mu\text{L}$  of phosphate

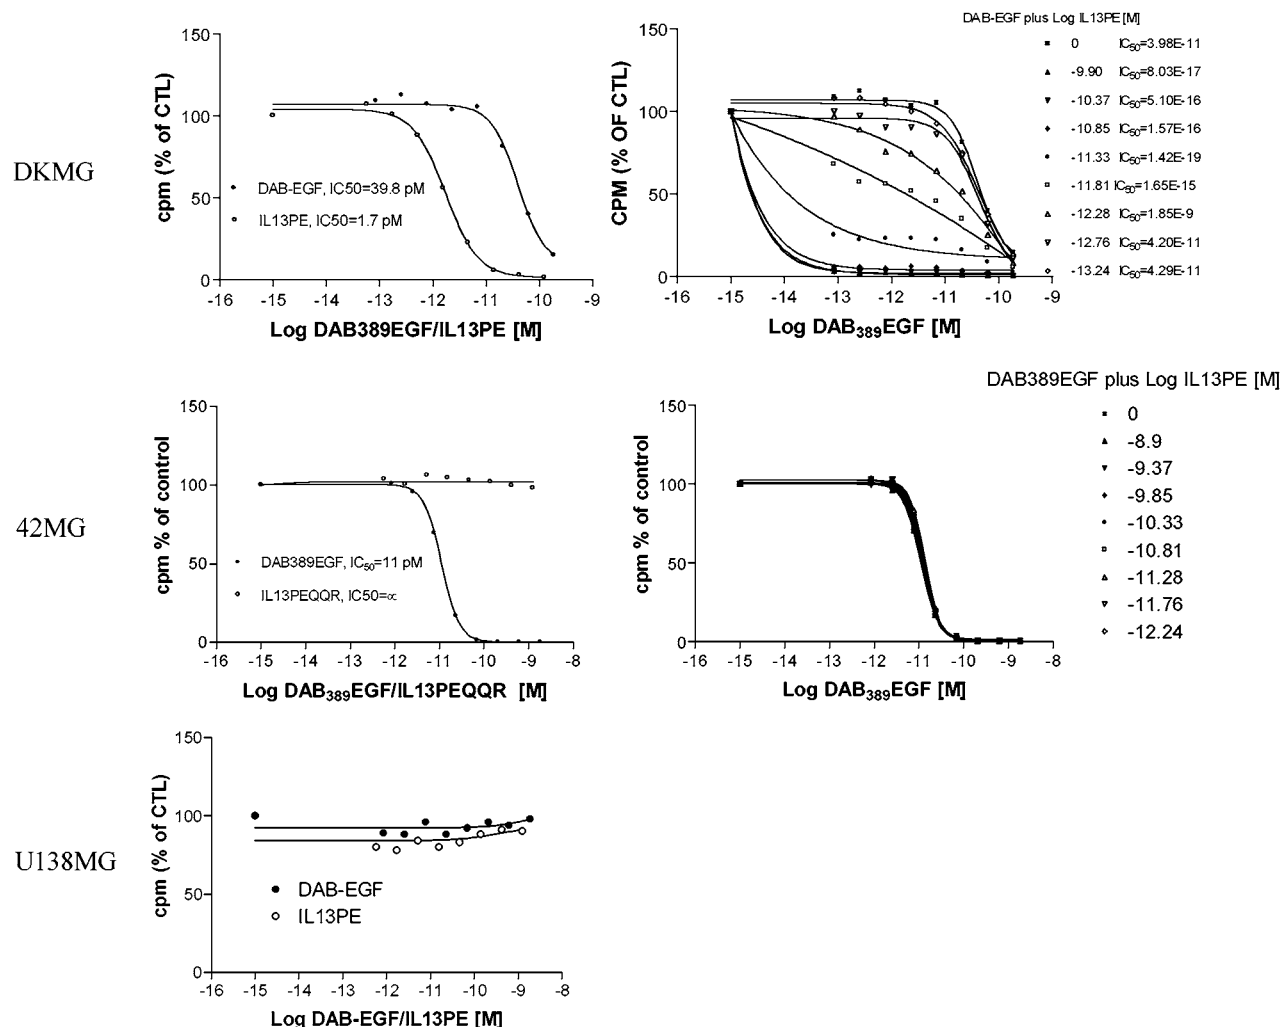

buffered saline (PBS) with 1% bovine serum albumin (BSA). Different aliquots were incubated with 10  $\mu\text{L}$  of PE-conjugated mouse IgG1 anti-IL13R $\alpha$ 2 antibody or PE-conjugated mouse IgG1 isotype control antibody. After 45 min on ice, cells were washed with PBS/BSA and incubated with 10  $\mu\text{L}$  of FITC conjugated mouse anti-EGFR antibody or FITC conjugated mouse IgG2b $\kappa$  isotype control antibody. After 30 min on ice, cells were washed with PBS/BSA and resuspended in 1 mL of PBS/BSA. A volume of 250  $\mu\text{L}$  of 3.7% formaldehyde was added to each tube, and the cells were assayed on an EPICS-XL flow cytometer (Coulter, Hialeah, FL) with filters set for simultaneous PE and FITC fluorescence detection. Gates were based on isotype control antibody staining such that there were  $<2\%$  positive cells with isotype control PE- and FITC-conjugated antibodies. Ten thousand cells were evaluated for PE and/or FITC positivity. Receptor heterogeneity was estimated by the ratio of the sum of single (PE or FITC) stained cells to doubly PE- and FITC-stained cells. Flow cytometric analysis was performed on cells on two separate occasions.

**Confocal Microscopy.** Number 1 coverslips were precoated with 0.1 mg/mL poly-L-lysine (Sigma) for 5 min at room temperature and rinsed three times with PBS. Ten thousand cells were grown on the precoated coverslips in six-well culture plates overnight at  $37^\circ\text{C}/5\% \text{CO}_2$ . The coverslips were then rinsed with cold PBS/0.1% sodium azide and blocked with 10% normal goat serum in PBS/0.1% sodium azide (blocking buffer) for 30 min. Cells were then incubated with 10  $\mu\text{g/mL}$  mouse anti-human IL13R $\alpha$ 2 monoclonal antibody or IgG1 mouse control antibody for 1 h in blocking buffer followed by incubation for another 1 h with 15  $\mu\text{g/mL}$  goat anti-mouse IgG conjugated to rhodamine at  $4^\circ\text{C}$  in blocking buffer. Cells were then incubated with 10  $\mu\text{g/mL}$  mouse IgG in PBS/0.1% sodium azide (second blocking buffer) for 30 min and 1 h with a 1:10 dilution of FITC-conjugated anti-EGFR or FITC-mouse IgG2b $\kappa$  control antibody at  $4^\circ\text{C}$  also in second blocking buffer. After all incubations with antibodies, slides were washed three times with cold PBS/0.1% sodium azide. Slides were postfixed with 3.7% formaldehyde in PBS and mounted in mounting medium (Victor Labs, Burlingame, CA). The staining was analyzed in a LSM 510 microscope (Zeiss) with the LSM 510 image browser software.

**Statistical Analysis.** Linear regression analysis was used to correlate  $\text{IC}_{90}$ 's and CI's with mean fluorescence intensity and percent single positive and doubly positive cells using GraphPad software.

## RESULTS

**Glioma Cell Lines Are Sensitive to Fusion Proteins.** Thirteen of fourteen glioma cell lines were killed by DAB<sub>389</sub>EGF alone, and seven cell lines were highly sensitive with mean  $\text{IC}_{90}$ s of 4 to 58 pM (Table 1). Similarly, seven of the glioma cell lines were killed by IL13PE38QQR and six were highly sensitive with  $\text{IC}_{90}$ 's of 6 to 85 pM (Table 1). Interestingly, the cell lines most sensitive to DAB<sub>389</sub>EGF were not the same as those most sensitive to IL13PE38QQR. Only three cell lines (U373MG, SNB19, and GMS10) were highly sensitive ( $\text{IC}_{90} < 100 \text{ pM}$ ) to both fusion proteins. When cells were exposed to a mixture of both fusion proteins, synergistic cell killing was observed for seven of the cell lines with combination indices (CI's) of 0.3 to 0.7 (Figure 1 and Table 1). Isobolographic analyses confirmed concave isoboles for these cell lines (Figure 2). For analysis of

**Figure 1.** Glioma cell cytotoxicity by DAB<sub>389</sub>EGF and IL13PE38QQR. Ten thousand cells were incubated 48 h with the indicated concentrations of fusion proteins and then pulsed with 1  $\mu$ Ci of <sup>3</sup>H-thymidine and harvested onto glass fiber mats using a cell harvester and counted on a Betaplate scintillation counter. Cell lines noted in the left margin. The left panels show single agent treatments; the right panels show the effect of the combinations. Among the three displayed cell lines, only DKMG shows synergistic drug interaction. The other two cell lines lack sensitivity to IL13PE38QQR or both DAB<sub>389</sub>EGF and IL13PE38QQR.

supraadditivesensitivity of the fusion protein mixture, the cells had to show at least partial sensitivity to each fusion protein alone (IC<sub>90</sub> ≤ 1000 pM). U373MG cell apoptosis was greater with combination of DAB<sub>389</sub>EGF and IL13PE38QQR than with either agent alone at the same protein concentrations (Figure 3).

**Figure 2.** Isobologram showing 90% inhibition of thymidine incorporation of LN405 cells with exposure to combinations of DAB<sub>389</sub>EGF and IL13PEQQR. The mean combination index was 0.29 determined by CalcuSyn software. CI values of 0.1–0.4 demonstrate strong synergism. The points were fitted by nonlinear regression using GraphPad software (solid line;  $R^2 = 0.99$ ). The dotted line exhibits the theoretical combinations with additive effect; points below the dotted line are associated with a synergistic effect; points above the dotted line are associated with an antagonistic effect. The DAB<sub>389</sub>EGF/IL13PEQQR shows synergism at different concentrations.

**Glioma Cell Lines Show Heterogeneous Expression of EGFR and IL13R $\alpha$ 2.** By two color immuno-

**Figure 3.** Supraadditive fusion protein-induced U373MG cell nuclear fragmentation. A. Phase and fluorescence micrograph at  $32\times$  of DAB<sub>389</sub>EGF, IL13PE38QQR, or combination DAB<sub>389</sub>EGF plus IL13PE38QQR-treated U373MG Hoechst 33258-stained cells. B. Histogram with percent apoptosis (fragmented nuclei) versus drug. DAB<sub>389</sub>EGF yielded 20% apoptosis at 21 pM for 48 h; IL13PE38QQR yielded 17% apoptosis at 14 pM for 48 h; the combination of the two fusion proteins at the same concentrations yielded 54% apoptosis at 48 h.

fluorescence and flow cytometry, all of the glioma cell lines displayed cell-to-cell variations in expression of both EGFR and IL13R $\alpha$ 2 (Figure 4 and Table 2). EGFR was expressed on a greater percentage of cells and at higher density than IL13R $\alpha$ 2 on each of the cell lines. The cell line U138MG was the only cell line with very low levels of both individual receptors. The fraction of cells expressing both receptors varied from 1% to 40% among the cell lines. The DAB<sub>389</sub>EGF fusion protein potency (IC<sub>90</sub>) correlated with the percent total EGFR positive cells ( $p < 0.0001$ ) but not the mean EGFR density measured by flow cytometry ( $p = 0.11$ ). Most of the correlation between percent positive cells and potency was secondary to the influence of two low potency cell lines (A172 and U138MG) which each had low percent EGFR positive cells. There was no correlation between IL13PE38QQR potency (IC<sub>90</sub>) and either IL13R $\alpha$ 2 density ( $p = 0.33$ ) or percent IL13R $\alpha$ 2-positive cells ( $p = 0.33$ ). Synergy (CI) did not correlate with either the percent receptor doubly positive cells ( $p = 0.70$ ) or the ratio of single positive to doubly positive cells ( $p = 0.95$ ). Immunofluorescence confocal microscopy confirmed the results from flow cytometry (Figure 5).

## DISCUSSION

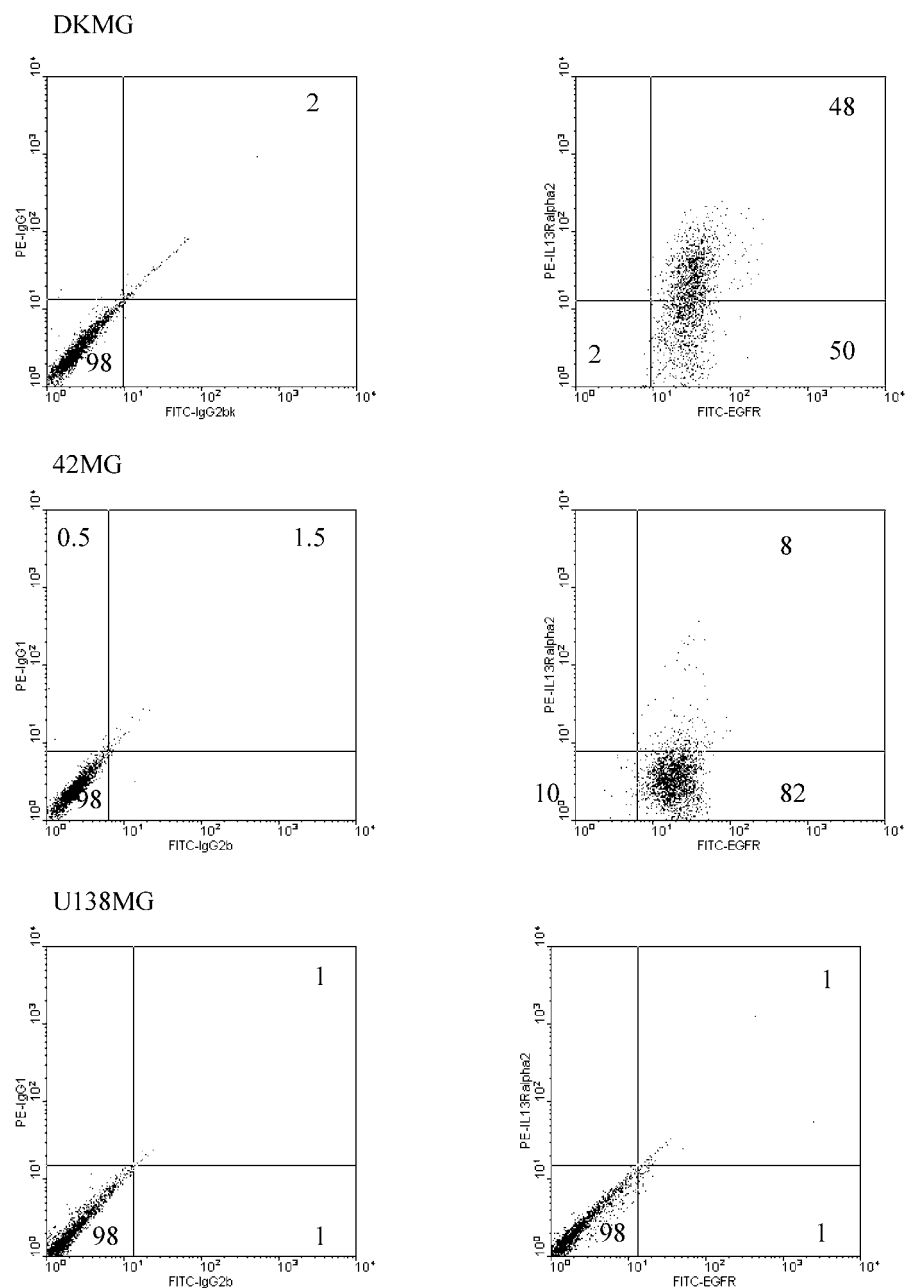

Both DAB<sub>389</sub>EGF and IL13PE38QQR were potently cytotoxic to a number of human glioma cell lines. This confirms and extends previous observations with DAB<sub>389</sub>EGF and IL13PE38QQR (13, 16, 17). Since both these fusion proteins require receptor expression on the tumor cells for binding and intoxication and there is minimal or absent expression of the receptors in normal brain, they should be excellent single agents for CED therapy

of brain tumors. In preliminary phase I/II studies, fusion proteins targeted to each of these receptors showed antitumor efficacy (8, 9).

Our study is the first demonstration that some gliomas may not respond equally to EGFR and IL13R $\alpha$ 2-directed fusion proteins. We found six out of fourteen glioma cell lines that displayed marked differences in sensitivity to DAB<sub>389</sub>EGF and IL13PE38QQR with IC<sub>90</sub> ratios of approximately 10-fold or more. This suggests that although responses may be seen in refractory glioma patients to each fusion protein, they may be different for different fusion proteins in different patients. We recently completed an immunohistochemical survey of 39 patients with high-grade gliomas and found markedly different receptor expression for EGFR and IL13R $\alpha$ 2 for nine of the patients (18). In contrast, only two of the patient samples lacked both EGFR and IL13R $\alpha$ 2. Thus, inclusion of immunohistochemical reactivity in fusion protein CED clinical trials may improve remission rates. Alternatively, combinations of EGFR- and IL13R $\alpha$ 2-directed fusion proteins may also yield improved response rates. This is consistent with the clinical results to date (8, 9). Not every patient responded to individual EGFR- or IL13R $\alpha$ 2-directed fusion proteins, and many of the responses were transient. Neurotoxicities were observed at higher doses. In an effort to widen the therapeutic index with these agents, we examined the anti-glioma activity in vitro of a combination of fusion proteins targeting the two receptors.

Combinations of agents for treatment of cancer patients have been sought for a long time. The hypothesis has been that individual agents could be used at lower doses to achieve the same antitumor effect and that the

**Figure 4.** Flow cytometry of glioma cell lines stained with FITC- and PE-labeled antibodies. Dot-plots showing glioma cells as individual points. The left panels show the isotype control IgG2b–FITC fluorescence on the *x*-axis and isotype control IgG1–PE fluorescence on the *y*-axis. The right panels show the anti-EGFR–FITC fluorescence on the *x*-axis and anti-IL13Rα2–PE fluorescence on the *y*-axis. Note DKMG has doubly stained cells whereas 42MG has only EGFR and U138MG lacks EGFR and IL13Rα2.

**Figure 5.** Confocal immunofluorescence microscopy. EGFR and IL13R $\alpha$ 2 were detected as described in text. Left hand photomicrographs are IL13R $\alpha$ 2 staining (red); middle photomicrographs shows EGFR staining (green); and right-hand photomicrographs show combined EGFR and IL13R $\alpha$ 2 staining (yellow). Bar equals 20  $\mu$ m. Cell lines are listed as follows: A: U87MG, B: GAMG, C: 8MGBA, D: U373MG, E: SNB-19, F: GMS10, G: 42MGBA, H: LN405, I: DKMG, J: T98G, K: DBTRG05MG, L: A172, M: U118MG, and N: U138MG.

individual agent toxicities would be consequently reduced. Efficacy would be maintained. Recent dramatic successes with combinations of rituximab, cyclophosphamide, vincristine, doxorubicin, and prednisone for lymphomas and trastuzumab with taxanes for breast cancer support the hypothesis. However, clinical evidence of additive or supraadditive efficacy of combinations for brain tumors is not available. Since protein synthesis inactivating toxins kill cells by a different mechanism than DNA or proliferation damaging drugs and have nonoverlapping side effects (minimal myelosuppression or mucositis), immunotoxin/cytotoxic drug combinations have been tested for a number of malignancies. Fewer

studies have been done with immunotoxin combinations since rarely have there been two agents available for a given cancer. Again, the hypothesis is that differentially targeted toxins will yield less damage to normal tissues when used in combination. Lower doses of each may be used, and fewer normal tissues should have both receptors. The combination of DAB<sub>389</sub>EGF and IL13PE38QQR yielded synergistic toxicity to seven of the fourteen cell lines. The combination indices of 0.2 to 0.7 suggested excellent supraadditive toxicity. The results confirm and extend our previous observation of synergistic cell kill on a single glioma cell line (16). While no similar studies have been done in brain tumors, there are two studies

in breast carcinoma (19, 20), two studies in lymphoma (21, 22), and three studies in leukemias (23–25) demonstrating supraadditive toxicity with mixtures of antibody–toxin conjugates. Quantitative isobolographic analyses were only performed in the breast cancer studies where combination indices of 0.1 to 0.4 were observed. Single mixture studies suggested synergistic toxicities in the lymphoma and leukemia studies. These findings in different tumor types lead to the hypothesis that, when several different cell surface receptors are present on a tumor, mixtures of fusion proteins targeting the different receptors may yield an improved therapeutic index.

The molecular mechanism for the synergistic toxicity is undefined. We examined the possible role of receptor heterogeneity. EGFR and IL13R $\alpha$ 2 were measured on individual cells by flow cytometry and epifluorescence microscopy. Populations of cells with only EGFR or IL13R $\alpha$ 2 were found in all seven cell lines. We hypothesize that only mixtures of fusion proteins can efficiently kill such mixed populations. We were not able to correlate CI with the degree of heterogeneity because of the narrow range in CIs. Comparisons using transfected cells with defined numbers of each receptor will help confirm or negate this hypothesis. Other groups have correlated immunotoxin synergy with receptor heterogeneity (19, 20, 26). Other factors may also play a role in the observed synergy such as total cell surface-bound fusion protein or modulation of internalization. Increased antibody binding to EGFR and IL13R $\alpha$ 2 was observed over the amount for each receptor alone for all seven glioma cell lines showing synergistic cell kill. Increased cell surface-bound toxin conjugate was reported with mixtures of the different conjugates in one of the leukemia studies (24). While we did not study rates of receptor internalization, such increased internalization was reported with cocktails of immunotoxins in a breast carcinoma and a lymphoma study (20, 22).

IL13R $\alpha$ 2 expression was lower than EGFR expression. The different physiology of the two receptors likely accounts for the difference. Cell line culture conditions and the choice of monoclonal antibodies may have also influenced the difference in measured cell surface receptor densities.

Regardless of mechanism, the synergistic toxicity of DAB<sub>389</sub>EGF and IL13PE38QQR will permit use of lower doses of each fusion protein in brain tumor CED therapy to achieve the same degree of cell kill. This should reduce toxicities to normal brain tissues which may express low levels of individual receptors. Testing of the combinations in animal models should help test whether the mixture provides a wider therapeutic index. Both these agents show promise for efficacy in clinical trials of patients with radiotherapy and chemotherapy refractory recurrent high-grade gliomas and should undergo further development both as single and combination agents.

#### ACKNOWLEDGMENT

The work was supported in part by the National Institutes of Health grants R01CA76178 (A.F.), R21CA090550 (A.F.), and R01CA090263 (A.F.). We thank Ligand Pharmaceuticals and NeoPharm for gifts of fusion proteins, and the WFU Tissue Culture Core Laboratory for storage and maintenance of the glioma cell lines. We thank Raj K. Puri for guidance and critical review of the manuscript.

Received July 16, 2003

The ability to use magnetic nanoparticles for cell tracking, or for the delivery of nanoparticle-based therapeutic agents, requires a detailed understanding of probe metabolism and transport. Here we report on the development and metabolism of a dual fluorochrome version of our tat-CLIO nanoparticle termed Tat(FITC)-Cy3.5-CLIO. The nanoparticle features an FITC label on the tat peptide and a Cy3.5 dye directly attached to the cross-linked coating of dextran. This nanoparticle was rapidly internalized by HeLa cells, labeling 100% of cells in 45 min, with the amount of label per cell increasing linearly with time up to 3 h. Cells loaded with nanoparticles for 1 h retained 40–60% of their FITC and Cy3.5 labels over a period of 72 h in label-free media. Over a period of 144 h, or approximately 3.5 cell divisions, the T2 spin-spin relaxation time of cells was not significantly changed, indicating retention of the iron oxide among the dividing cell population. Using confocal microscopy and unfixed cells, both dyes were nuclear and perinuclear (broadly cytoplasmic) after Tat(FITC)-Cy3.5-CLIO labeling. Implications of the rapid labeling and slow excretion of the Tat(FITC)-Cy3.5-CLIO nanoparticle are discussed for cell tracking and drug delivery applications.

## INTRODUCTION

The ability of membrane-translocating peptides to move materials through the plasma membrane or even cell layers and tissues has the potential to lead to the development of new types of pharmaceuticals, which can overcome cellular barriers for the delivery of current compounds. The membrane-translocating sequence of the tat protein of HIV (tat-peptide) has been used to ferry diagnostic and therapeutic agents across membranes and has led to new forms of cyclosporine (1), improved radiotherapies (2), and new methods for intracellular delivery of DNA and enzymes (3–5). However, the development of tat peptide-based pharmaceuticals would be furthered, not merely by studies on the efficacy of such compounds, but by a thorough understanding of the transport and degradation of tat-like probes.

The relationship between probe utility on one hand and probe metabolism and transport on the other can be illustrated with tat-CLIO (tat-cross-linked iron oxide), a magnetic nanoparticle to which tat peptides have been attached (6, 7). Tat-CLIO-loaded cells have been used to study cell movement in vivo in a variety of medically important applications including stem cell engraftment (7) and T cell infiltration in adoptive immunotherapy (8). In magnetic resonance (MR) cell tracking applications, excretion of the nanoparticle after internalization, if it occurs, limits the observation time of labeled cells. On the other hand, for the tat-mediated delivery of therapeutic agents, particularly for delivery of agents across epithelial or endothelial barriers, internalization without externalization would not permit tat-drug conjugates to

pass through cell layers and achieve tissue penetration. In the liver tat-CLIO crosses endothelial barriers in the vasculature and is found in the parenchyma (9). The tat-mediated delivery of a diverse type of molecules including fluorochromes, peptides, and enzymes through tissues in vivo has been reported (10, 11).

With the interrelated, long-term objectives of understanding the fate of Tat-CLIO-loaded cells followed by magnetic resonance (MR) tracking in vivo, and determining the ability of Tat-CLIO to undergo transepithelial or transendothelial transport, we examined the uptake and excretion of dual fluorochrome, multimodal (fluorescent and magnetic) tat-nanoparticles. Here we describe a Tat-CLIO that is detectable by its effects on MR with one fluorochrome, fluorescein isothiocyanate (FITC), attached to each tat peptide, Tat(FITC), and a second fluorochrome, Cy3.5, is attached to the coating of nanoparticle (cross-linked iron oxide, CLIO). We term this form of tat-CLIO Tat(FITC)-Cy3.5-CLIO, to denote its dual fluorochrome labels. On the basis of fluorescent activated cell sorter (FACS) analysis, Tat(FITC)-Cy3.5-CLIO was rapidly internalized and slowly excreted by HeLa cells. On the basis of effects on the cellular T2 (spin-spin relaxation time), the superparamagnetic iron oxide nanoparticle cores were not eliminated during the 7-day observation period. Implications of this pharmacokinetic pattern are described for cell tracking and pharmaceutical targeting applications.

## MATERIALS AND METHODS

**Nanoparticle Synthesis.** To synthesize dual fluorochrome-labeled magnetic nanoparticles, the dye Cy3.5 was first attached to the amines of a cross-linked dextran-coated nanoparticle termed amino-CLIO, to yield Cy3.5-CLIO. The tat peptide, denoted Tat(FITC), was attached to the nanoparticle using the bifunctional reagent, suc-

**Figure 1.** Synthesis and features of Tat(FITC)-3.5-CLIO. (A) Synthetic scheme. (B) Schematic diagram showing features of Tat(FITC)-3.5-CLIO. Tat(FITC) is the peptide GRKKRRQRRRGYK(FITC)C-NH<sub>2</sub>. Succinimidyl iodoacetate (SIA) gives a thioether (S-C) linkage between the peptide and the nanoparticle.

**Table 1.** Physical Properties of Tat(FITC)-Cy3.5-CLIO

nanoparticle	Cy3.5/nanoparticle	Tat(FITC)/nanoparticle	size (nm)
Tat(FITC)-Cy3.5-CLIO	1.4	24	49.1

cinimidyl iodoacetate (SIA), as shown in Figure 1A. A schematic representation of the structure of Tat(FITC)-Cy3.5-CLIO is shown in Figure 1B.

A tat peptide, termed Tat(FITC), with the sequence GRKKRRQRRRGYK(FITC)C-NH<sub>2</sub> was synthesized and purified as described (9). The amino-CLIO nanoparticle was prepared as described (6, 12).

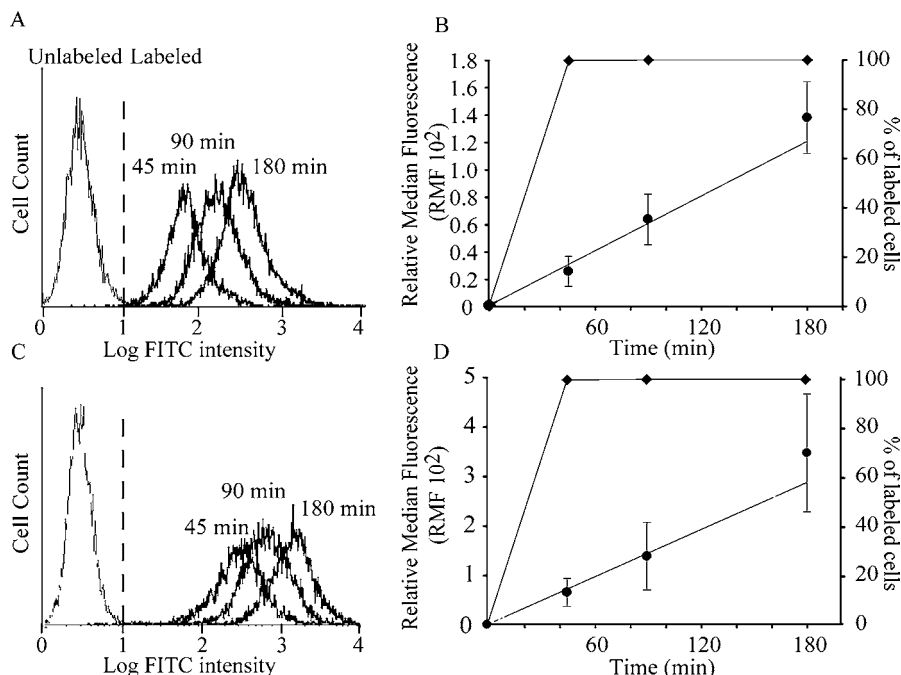

Cy 3.5-CLIO was prepared by adding 175  $\mu$ L of amino-CLIO (2 mg Fe) to one tube of monofunctional Cy3.5 dye as supplied by the manufacturer (Amersham Biosciences, Little Chalfont, UK). The mixture was vortexed and allowed to sit for a minimum of 2 h. Reaction with Cy3.5 consumes 1.4 amino groups per nanoparticle, out of a total of 40–60 amino groups per nanoparticle. Cy 3.5-CLIO was added to *N*-succinimidyl iodoacetate (SIA, 4 mg, 14  $\mu$ mol, Molecular Bioscience, Boulder, CO) in 100  $\mu$ L of DMSO. The mixture was vortexed, allowed to sit for 1 h, and purified with a PD-10 desalting column (Sigma) in 0.02 M citrate, 0.15 M NaCl, pH 8. A single separation step was used to remove unreacted Cy3.5 and SIA.

Tat(FITC)-Cy3.5-CLIO was prepared by adding Tat(FITC) (60  $\mu$ L, 5 mM) in 0.1% v/v trifluoroacetic acid to SIA activated Cy3.5-CLIO (2 mg Fe). The mixture was vortexed and allowed to react for 1–2 h, and unreacted

peptide was removed by ultrafiltration (Minicon YM-30, Millipore, Bedford, MA). The number of attached Cy3.5 and FITC dyes was determined spectrophotometrically, for fluorescein ( $\epsilon_{494} = 73000$ ) and for Cy3.5 ( $\epsilon_{581} = 150000$ ). Iron was determined spectrophotometrically (8), and the ratios of Cy3.5 or Tat(FITC) per nanoparticle were calculated assuming 2064 iron atoms per CLIO particle (13). Properties of the nanoparticle are summarized in Table 1. We previously demonstrated that the ability of cells to internalize tat peptide magnetic nanoparticles increases with increasing numbers of peptides per nanoparticle (14). The Tat(FITC)-Cy3.5-CLIO nanoparticle we employed is similar to that of Zhao et al. but differs in the use of two chemically distinct fluorochromes and in the use of a thioether rather than a disulfide linkage. The thioether-linked Tat(FITC)-Cy3.5-CLIO had improved stability between the peptide and nanoparticle when incubated in cell culture media compared to the disulfide-linked nanoparticle (Koch and Josephson, unpublished observations).

**Cell Culture.** HeLa cells were cultured in MEM (minimum essential medium) containing 10% FBS, supplemented with penicillin (100 units/mL)/streptomycin (100  $\mu$ g/mL), sodium pyruvate (1 mM), and nonessential amino acids (0.1 mM) at 37  $^{\circ}$ C in a humidified atmosphere

**Figure 2.** Uptake of Tat(FITC)-Cy3.5-CLIO nanoparticle or Tat(FITC) peptide. (A) Progressive increase in cell associated fluorescence with Tat(FITC)-Cy3.5-CLIO as shown in the FACS profile (frequency distribution of labeled cells). Dotted line is the demarcation between labeled and unlabeled cells. (B) Data from A are plotted as the median fluorescence of labeled cells divided by median unlabeled cells (relative median fluorescence, RMF). (C and D) Increase in cell fluorescence with Tat(FITC) peptide obtained as in A and B, respectively.

containing 5% CO<sub>2</sub>. Media, balanced salt solutions, and supplements were from Cellgro (Mediatech Inc, Herndon, VA). HeLa cells were cultured as exponentially growing subconfluent monolayers, except when used in experiments lasting 72 h and more, where cells were allowed to reach confluency.

**FACS Analysis. Uptake Studies.** Exponentially growing HeLa cells were trypsinized and seeded at a density of  $10^5$  cells/well in 12 well plates (Becton Dickinson, Bedford, MA). About 18 h later, cells were labeled for 1 h with Tat(FITC)-Cy3.5-CLIO (50  $\mu$ g Fe/mL), or Tat(FITC) peptide (5  $\mu$ M) added in complete cell culture medium. Medium was sterile-filtered (0.2  $\mu$ m, low protein binding, Gelman, Ann Arbor, MI) before addition to cells. After 45, 90, or 180 min, cells were washed 4 $\times$  with HBSS, trypsinized for 7 min, counted, fixed in 2% paraformaldehyde (Fisher Scientific, reagent grade), and analyzed by flow cytometry on a FACS Calibur (Becton Dickinson, Franklin Lakes, NJ) within 2 h after trypsinization. A total of 10 000 cells per sample was analyzed. The numbers of cells with a fluorescence intensity higher than unlabeled cells was used to calculate percent of labeled cells. The baseline was determined by analyzing unlabeled control cells. RMF (relative median fluorescence) was calculated by dividing the median of the labeled cells by the median of an unlabeled cell population.

**Retention in Cells.** HeLa cells were labeled with Tat(FITC)-Cy3.5-CLIO (50  $\mu$ g Fe/mL which corresponds to 7.5  $\mu$ M Tat(FITC) peptide), or Tat(FITC) peptide (5  $\mu$ M) as described for the uptake studies. After 1 h of labeling, cells were washed 4 $\times$  with HBSS, and then not immediately trypsinized and analyzed, but incubated in fresh cell culture medium for 3, 24, 48, or 72 h. At respective time points, cells were trypsinized and analyzed as described for uptake studies.

**Confocal Fluorescence Microscopy.** HeLa cells were cultured on Lab-Tek Chambered Coverglass (Nalge Nunc, Naperville, IL) with a density of  $3 \times 10^4$  cells/cm<sup>2</sup>. Cells were labeled as described for FACS analysis with

either Tat(FITC)-Cy3.5-CLIO (50  $\mu$ g/mL Fe) or free Tat(FITC) peptide (5  $\mu$ M). Cells were observed immediately after labeling, after 24 h and after 72 h. Brightfield and fluorescence images were obtained with a Zeiss Plan-Neofluar 40 $\times$  objective using a Zeiss Axiovert 200 confocal microscope (Zeiss, Jena, Germany) equipped with Argon (488 nm) and HeNe (543 nm) lasers for fluorescence. Exposure time for fluorescence was adjusted at each time point to localize fluorochromes. Background fluorescence was determined by analyzing unlabeled cells. Image acquisition and analysis was done using LSM 5 PASCAL Software.

**MR Imaging.** HeLa cells were seeded in cell culture flasks (175 cm<sup>2</sup>) at a density of  $5 \times 10^4$  cells/cm<sup>2</sup> and allowed to adhere overnight. Cells were washed with fresh cell culture medium and then incubated for 4 h with sterile filtered Tat(FITC)-Cy3.5-CLIO (200  $\mu$ g Fe/mL). Cells were trypsinized (5 min) and divided into new cell culture flasks (175 cm<sup>2</sup>), with each flask containing  $2 \times 10^6$  cells. Two flasks were harvested immediately, cells of another eight flasks were allowed to adhere and kept in culture for different time points up to 96 h. At each time point, adherent cells were washed 4 $\times$  with HBSS, trypsinized, transferred to a conical cell culture tube, centrifuged down, and washed three times with HBSS. Finally, cells were resuspended in warm 0.5% agarose to yield a volume of 100  $\mu$ L and put on ice. The number of cells ranged from  $2.5 \times 10^6$  cells at start of the experiment to  $31 \times 10^6$  cells after 7 days, with a doubling time of 24 h at the beginning and then decreasing to 48 h at the end of the experiment. Immobilized cells were then imaged with a 7T MR Scanner (Siemens, Massachusetts General Hospital, Boston, MA). T2 values were from signal intensity data obtained at six echo times (20, 40, 60, 80, 120 ms), with a repetition time of 2 s. Data were fit to the standard exponential transverse relaxation model used previously (15).

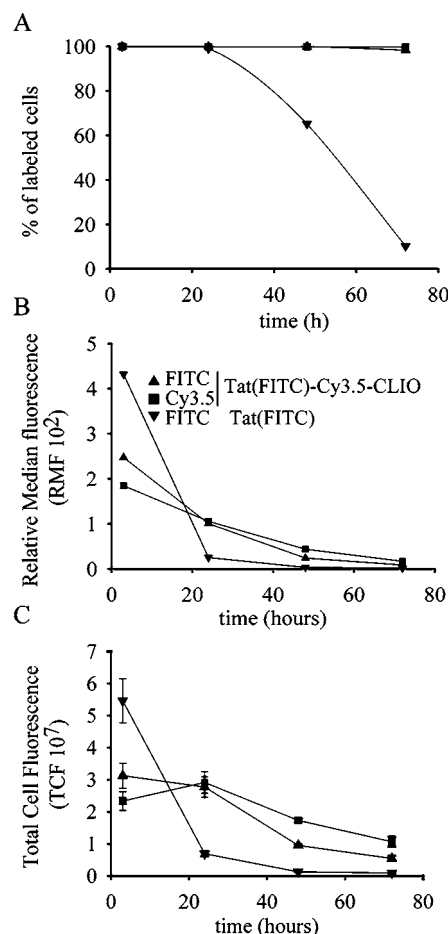

**Figure 3.** Retention of the Tat(FITC)-Cy3.5-CLIO nanoparticle and Tat(FITC) peptide in HeLa cells. HeLa cells were labeled for 1 h with Tat(FITC)-Cy3.5-CLIO (A and B) or Tat(FITC) peptide (C) and washed. Cells were incubated in fresh cell culture medium for 3, 24, 48, or 72 h, trypsinized, and analyzed by flow cytometry. A relative median fluorescence (RMF) is calculated (median labeled/median unlabeled) and, together with additional time points, shown in Figure 4.

## RESULTS

**Uptake of Tat(FITC)-Cy3.5-CLIO.** The uptake of Tat(FITC)-Cy3.5-CLIO was monitored by FACS analysis based on FITC as shown in Figure 2. Figure 2A demonstrates that exposing cells to Tat(FITC)-Cy3.5-CLIO results in a uniform labeling of cells and that the amount of cell-associated nanoparticle increases with the time of incubation. Cell labeling was expressed using two parameters, the percent labeled cells and the relative median fluorescence or RMF, obtained by dividing the median fluorescence of labeled cells by the median fluorescence of unlabeled cells. The dotted line indicates a clear division between labeled and unlabeled cells that occurred at the short incubation time of 45 min. RMF and percent of labeled cells are plotted in Figure 2B, which demonstrates that nanoparticle accumulation (RMF) increased at a constant rate over the 180 min incubation period. Also shown are comparable data for the uptake of the tat(FITC), the peptide of the Tat(FITC)-Cy3.5-CLIO nanoparticle, see Figures 2C and 2D. Again labeling was rapid and highly uniform, and cell-associated fluorescence increased over the 180 min incubation period.

**The Retention of Tat(FITC)-Cy3.5-CLIO in Cells by Fluorescence.** We next examined the retention of both FITC fluorescence and Cy3.5 fluorescence of Tat(FITC)-Cy3.5-CLIO in cells, when cells were loaded for 1 h with Tat(FITC)-Cy3.5-CLIO nanoparticle or Tat(FITC) peptide and were then incubated in media for up to 72 h. Representative FACS histograms after cells have been in media for 3 and 72 h are shown in Figures 3A–C. Data from the 3 and 72 h time points, together with additional time points, are presented in Figure 4. As shown in Figure 4A, after 72 h cells loaded with Tat(FITC)-Cy3.5-CLIO were still labeled, that is had higher fluorescence than a population of unlabeled cells, by either FITC or Cy3.5 fluorescence. On the other hand, after 72 h, more than 80% of cells labeled with Tat(FITC) peptide at the beginning of the experiment were unlabeled. Figures 4B and 4C show the fluorescence of Tat-

**Figure 4.** Retention of fluorescence of cells loaded with the Tat(FITC)-Cy3.5-CLIO nanoparticle or the Tat(FITC) peptide. Cells were loaded for 1 h and analyzed by flow cytometry. For all graphs, (▼) is the FITC fluorescence from the Tat(FITC) peptide, (▲) is the FITC fluorescence from Tat(FITC)-Cy3.5 CLIO, and (■) is the Cy3.5 fluorescence from Tat(FITC)-Cy3.5 CLIO. (A) Percent of labeled cells versus time. (B) Fluorescence per cell as RMF versus time. (C) Total cellular fluorescence (TCF) versus time, where TCF equals RMF times cell number. Experiment is representative for two similar experiments: each data point (A, B) is the median fluorescence intensity of 10 000 cells per sample. Errors bars in (C) represent variations in cell number.

(FITC)-Cy3.5-CLIO or Tat(FITC) peptide loaded cells uncorrected for cell division (B) or corrected for cell division (C). As shown in Figure 4B, the RMF of peptide-loaded cells decreased rapidly, while the FITC and Cy3.5 fluorescence from Tat(FITC)-Cy3.5-CLIO-loaded cells decreased similarly and more slowly than peptide-loaded cells. For Figure 4C, total cell fluorescence (TCF) was obtained by multiplying cell number times the RMF. For Tat(FITC)-Cy3.5-CLIO-loaded cells, the loss of TCF was less than the loss of fluorescence per cell (RMF), indicating that a major source of fluorescence loss was the distribution of the labels to daughter cells.

A second way of ascertaining the retention of the Tat(FITC)-Cy3.5-CLIO is by determining the T2 spin-spin relaxation times of cells. Cells were loaded with nanoparticle and allowed to proliferate in nanoparticle-free media for up to 144 h, and T2 was determined periodically. With this method, nanoparticles can be distributed between dividing cells, but the entire population of cells is retained and analyzed. As shown in Figure 5, the T2 of cells decreases from  $105 \pm 10$  ms to  $50 \pm 5$  ms, indicating the internalization of superparamagnetic iron oxide, and did not increase during the 144 h incubation

**Figure 5.** T<sub>2</sub> relaxation times of cells labeled with the Tat(FITC)-Cy3.5-CLIO. Cells were labeled (4 h), washed, and incubated in fresh cell culture medium for up to 7 days.

period, indicating retention of the superparamagnetic iron oxide core of the Tat(FITC)-Cy3.5-CLIO nanoparticle.

We next examined the intracellular distribution of Tat(FITC)-Cy3.5-CLIO and Tat(FITC) by confocal microscopy as a function of time after loading (Figure 6). Cells were unfixed, to prevent shifts in distribution due to fixation (16), and exposure time was adjusted to correct for the loss of fluorescence (Figure 4B). Nanoparticle-loaded cells showed fluorescence in the nucleus and cytoplasm with either FITC or Cy3.5 immediately after labeling or 24 h after labeling. By 72 h after loading, nuclear fluorescence was not observed. Tat(FITC) also showed a broad intracellular distribution after labeling and after 24 h, whereas after 72 h, fluorescence was similar to unlabeled cells. Overlays of FITC and Cy3.5 fluorescence (yellow in Figures 6C, F, and I) showed a similar distribution of FITC and Cy3.5 fluorescence.

## DISCUSSION

The general design we employed for dual fluorochrome labeled nanoparticles features one fluorochrome directly attached to the cross-linked dextran, Cy3.5, with a second supplied by a FITC-labeled peptide (Figure 1). This allows different peptides to be attached to the same parent nanoparticle with different linkages and valences, and the fate of peptide and nanoparticle can be tracked by fluorescence. Here we use a dual fluorochrome-labeled nanoparticle, Tat(FITC)-Cy3.5-CLIO, with 24 copies of Tat(FITC) attached through a thioether linkage per nanoparticle, and used this nanoparticle to monitor the fate of the Tat(FITC) peptide and nanoparticle (Cy3.5-CLIO) after administration to cells. Tat(FITC)-Cy3.5-CLIO-loaded cells lost fluorescence from FITC and Cy3.5 with a similar time course (Figure 4), and patterns of intracellular distribution of both fluorochromes (Figure 6) were similar. This suggests that Cy3.5 and FITC remain attached to the nanoparticle coating of cross-linked, polymeric dextran and that this coating was poorly excreted over the time course of our experiments. This result was in contrast to a disulfide-linked Tat(FITC)-Cy3.5-CLIO, made as described (14), where FITC fluorescence was far more rapidly lost than Cy3.5 fluorescence (data not shown). Nanoparticles with disulfide linkage between Tat(FITC) and the Cy3.5-CLIO undergo an intracellular separation of Tat(FITC) and Cy3.5-CLIO, with rapid elimination of the Tat(FITC) peptide and retention of Cy3.5-CLIO. High concentrations of glutathione are believed to create a reducing

environment in cells, which can break disulfide bonds (17). Similar results with disulfide-linked conjugates have been obtained by others; see for example, ref 18.

**Tat(FITC) Peptide versus Tat(FITC)-Cy3.5-CLIO Nanoparticle Metabolism.** Both Tat(FITC) and Tat(FITC)-CLIO were rapidly internalized, labeling the population of HeLa cells uniformly, with increasing levels of intracellular fluorescence per cell over the 180 min incubation period (Figure 2). While the internalization of the Tat(FITC) and Tat(FITC)-Cy3.5-CLIO were similar, the fates of the peptide and nanoparticle after internalization were quite different. Tat(FITC)-loaded cells showed a sharp decrease in RMF and TCF after 24 h in peptide-free media (Figures 4B and 4C), and by 72 h more than 80% of cells were unlabeled (Figure 4A). With Tat(FITC)-Cy3.5 CLIO, when a correction was made for cell division, cells retained their fluorescence after 24 h in media and lost only about 50% of their FITC or Cy3.5 over the next 48 h. When cells were loaded with Tat(FITC)-Cy3.5-CLIO and incubated in nanoparticle-free media, T<sub>2</sub> dropped and did not change over a 144 h incubation period, indicating a general lack of excretion of the superparamagnetic iron oxide core of the nanoparticle. Hence the Tat(FITC) peptide rapidly labeled cells, but fluorescence was rapidly lost, presumably due to the excretion of the peptide or a fragment. The Tat(FITC)-Cy3.5-CLIO also rapidly labeled cells, but the excretion was either slow, based on the retention of fluorescence, or not detectable based on relaxation time measurements. The dominant pathway for nanoparticle elimination was distribution to daughter cells after cell division.

The Tat(FITC)-Cy3.5-CLIO nanoparticle is a highly stable nanoparticle because dextran is tightly bound to the surface of the iron oxide by cross-linking, and a reduction-insensitive thioether bond is used to attach the peptide to the nanoparticle. Separation of Cy3.5 and FITC is unlikely, based on the nanoparticle design (Figure 1) that requires a proteolytic cleavage between two highly modified amino acids, the C-terminal cysteine attached to the CLIO nanoparticle, and the penultimate lysine, attached to FITC. Degradation of a major part of the tat peptide may occur without severing the bonds between FITC or Cy3.5 and the coating of cross-linked dextran. The similar retention of the Cy3.5 and FITC fluorescence by cells (Figures 3 and 4) is consistent with this high chemical stability and suggests that both fluorochromes remain attached to the cross-linked coating of dextran after internalization by cells.

HeLa cells loaded with Tat(FITC)-Cy3.5-CLIO were unable to digest the superparamagnetic iron oxide sufficiently to cause T<sub>2</sub> to increase during our 144 h observation period. When injected intravenously, superparamagnetic iron oxides are phagocytosed, with a drop in the T<sub>2</sub> of the liver and spleen (19, 20). Over a period of days, T<sub>2</sub> increases back to normal values, due to dissolution of the iron oxide crystal, with the iron joining normal body pools. Our studies suggest that lifetime of superparamagnetic iron oxide in HeLa cells is considerably longer than in phagocytic cells. The retention of T<sub>2</sub> depression is a desirable feature that can allow cells to be tracked by MRI in vivo for long periods of time.

The ability of tat peptide to deliver a variety of agents of varying sizes and chemical compositions into cells in vitro and in vivo has been explored (1, 21). Particularly intriguing is the potential of the tat peptide to deliver macromolecules such as proteins or enzymes (10, 22, 23) and nanoparticles (9) both into cells and across endo-

**Figure 6.** Localization of Tat(FITC)-Cy3.5-CLIO or Tat(FITC) peptide as a function of time by confocal microscopy of unfixed cells. Cells were labeled with Tat(FITC)-Cy3.5-CLIO (A–I) or Tat(FITC) peptide (K–M). FITC fluorescence is shown in green and Cy3.5 fluorescence in red. The two are superimposed in yellow (C, F, I). Cells were labeled (1 h) analyzed immediately (A–C, K), after 24 h (D–F, L) or after 72 h (G–I, M). Exposure time was adjusted to give similar overall fluorescence intensities at all time points. Arrows indicate perinuclear distribution. Arrowheads indicate nuclear distribution.

thelial and epithelial barriers in vivo. However, a recent study examining radiolabeled tat peptide transport across bladder as an epithelial layer did not find evidence of such transport (24). The loss of cellular fluorescence of Tat(FITC)-Cy3.5-CLIO suggests that the transcellular passage of the nanoparticle, if it occurs, will be a slow and inefficient process compared to internalization. Attempts to study tat-mediated transcellular nanoparticle transport should use analytical methods of very high sensitivity that can detect very stable features of the tat macromolecule or nanoparticle. In the current study we followed the fate of cellular fluorescence for 72 h and internalized superparamagnetic iron oxide over 144 h, a time period during which the fate of a technetium 99m-labeled tat peptide-magnetic nanoparticle would be difficult to observe due to radiochemical decay ( $t_{1/2} = 6$  h) (24). On the other hand, a recently developed enzyme immunoassay method for detecting immunoreactive fluorescein, a method that is nonisotopic and which measures difficult to metabolize fluorescein, might provide an accurate view of the magnitude of the transcellular passage of tat-nanoparticles (25). Using the FITC immunoassay the transcellular transport of Tat(FITC)-Cy3.5-CLIO using CaCo-2 cell monolayers has been observed to have a lag period time course (Koch et al., manuscript in preparation). Studies of metabolism of Tat(FITC) peptide and Tat(FITC)-Cy3.5-CLIO, such as the current one, can lead to insights regarding the likely rates of tat-mediated, transcellular transport in and through cell layers, and guide the selection of analytical tools to measure such transport.

# Transferrin-Containing, Cyclodextrin Polymer-Based Particles for Tumor-Targeted Gene Delivery

Nathalie C. Bellocq,<sup>†</sup> Suzie H. Pun,<sup>†,§</sup> Gregory S. Jensen,<sup>†</sup> and Mark E. Davis<sup>\*,‡</sup>

Insert Therapeutics, Inc., Pasadena, California and California Institute of Technology, Pasadena, California  
Received July 17, 2003

Transferrin is a well-studied ligand for tumor targeting due to upregulation of transferrin receptors in numerous cancer cell types. Here, we report the development of a transferrin-modified, cyclodextrin polymer-based gene delivery system. The delivery system is comprised of a nanoparticle (formed by condensation of a cyclodextrin polycation with nucleic acid) that is surface-modified to display poly(ethylene glycol) (PEG) for increasing stability in biological fluids and transferrin for targeting of cancer cells that express transferrin receptor. A transferrin-PEG-adamantane conjugate is synthesized for nanoparticle modification. The transferrin conjugate retains high receptor binding and self-assembles with the nanoparticles by adamantane (host) and particle surface cyclodextrin (guest) inclusion complex formation. At low transferrin modification, the particles remain stable in physiologic salt concentrations and transfect K562 leukemia cells with increased efficiency over untargeted particles. The increase in transfection is eliminated when transfections are conducted in the presence of excess free transferrin. The transferrin-modified nanoparticles are appropriate for use in the systemic delivery of nucleic acid therapeutics for metastatic cancer applications.

## INTRODUCTION

One of the most challenging applications of gene therapy is its use against metastatic cancer. The delivery of nucleic acid therapeutics to disseminated tumor sites demands a vehicle capable of systemic administration that will be able to localize in tumor areas. While viral vectors containing therapeutic genes have shown anti-tumor responses via direct tumoral injections, these vectors generally suffer from immunogenicity issues that make repeat systemic administrations problematic (1, 2). Nonviral vectors, whose assets include low T-cell and humoral immunogenicity, offer a viable alternative approach. In addition, nonviral vectors can be readily modified with ligands for cell targeting.

Transferrin (Tf), an iron-binding glycoprotein, is a well-studied ligand for tumor targeting (3, 4). Iron-loaded (holo-) transferrin is recognized by and binds to transferrin receptors on cell surfaces. Transferrin is then endocytosed into acidic compartments. The drop in pH triggers the iron dissociation, and the iron-poor (apo-) transferrin is recycled to the cell surface and released (4). Expression of transferrin receptor (Tf-R) is elevated in rapidly dividing cells due to a need for iron; therefore, Tf-R is often upregulated on surfaces of malignant cells and has been used as a tumor-targeting ligand for several drug delivery systems (5).

Anticancer agents such as doxorubicin have been conjugated to transferrin for tumor targeting (6–8). Transferrin has also been used for targeting nonviral gene delivery vehicles to cancerous cells (9–19). However, the synthesis and characterization of these multicomponent materials is often not completely defined or con-

trolled. For example, doxorubicin–transferrin conjugates were initially prepared by glutaraldehyde cross-linking between the amines on the transferrin (lysine) and the doxorubicin. These conjugates exhibited cytotoxic activity to tumor cell lines (20, 21). However, polymeric products are likely to be formed using this cross-linking method, and the resulting conjugates are poorly defined from a chemical point of view (4). In addition, the binding affinities of the conjugates are significantly reduced from the affinity of the natural protein (21). The “second generation” doxorubicin–transferrin synthesis was improved by Kratz and colleagues by thiolating transferrin with Traut's reagent and then reacting it with maleimide derivatives of doxorubicin (7). Advantages of this approach include less random cross-linking and also the incorporation of a potentially reversible hydrazone linkage. However, the resulting conjugates still contained ~10% transferrin dimers that were not separated from the monomeric conjugates (7). Numerous other transferrin–doxorubicin conjugates have been prepared and one has even been explored for human use in a phase I clinical trial (22).

For targeted gene delivery, approaches include direct transferrin conjugation onto activated surfaces of polycation/nucleic acid complexes (17) or linkage via biotin/streptavidin interactions to plasmid DNA (19). One method of transferrin conjugation to poly(ethylenimine) that has yielded promising *in vivo* targeting of tumors involves oxidation of carbohydrate groups associated with the transferrin followed by reductive amination with the primary amines of poly(ethylenimine) (23). These literature examples show the potential of tumor-targeting via transferrin–Tf-R interactions.

We have developed a cyclodextrin-based polymer delivery system that has the potential of being used for systemic nucleic acid delivery (24). The delivery system consists of two components. The first component is a cyclodextrin-containing polycation that is used for nucleic acid condensation into nanoparticles (25, 26), and the

## CDP-Imid

second component is an adamantane-terminated modifier for stabilizing the particles in order to (i) minimize interactions with plasma and (ii) target cell surface receptors (27). The specific ligands contained in the second component mediate cell targeting specificity, e.g., Tf ligands for cells with Tf-R. The two components self-assemble with nucleic acids to form stable and uniform sub-100 nm particles. The modular design of this delivery system allows each component to be synthesized and characterized separately.

Here, we investigate the synthesis of transferrin-poly(ethylene glycol)-adamantane (Tf-PEG-AD) conjugates (second component of the delivery system) and their use in formulating a complete delivery system for systemic application. In subsequent reports, we will show that these delivery vehicles can successfully target and deliver either oligonucleotides (28, 29) or plasmids (30, 31) to subcutaneous tumors in nude mice. These constructs can be used as targeting ligands as described above. The process of attaching PEG to a protein is typically achieved by reacting an activated PEG reagent through either the carbohydrate moiety or through the lysine residues (32). Since a typical protein possesses a number of such groups, each having different reactivities and degrees of accessibility, the resulting product contains a family of species that is characterized by a distribution in both the number and position of attachment of the PEG group. Below, we describe an example of a fairly well-defined and characterized preparation of transferrin-PEG conjugates. We report on (i) the effect of the site of modification (lysine residue versus carbohydrate moiety), and (ii) the effect of the degree of modification (number of PEG chains per protein) on the binding affinity toward transferrin receptors. These transferrin-PEG conjugates are used to formulate transferrin-modified particles and some of their properties are presented. The particles are demonstrated to mediate transferrin-mediated delivery of nucleic acids to cultured cells.

## EXPERIMENTAL PROCEDURES

**Material Synthesis.**  *$\beta$ -Cyclodextrin Polymers (CDP-Imid).*  $\beta$ CDP was synthesized according to previously described procedures (25, 26). The number of methylene groups separating the charges in the polycation backbone was chosen to be six to maximize transfection efficiency (26). Imidazole was conjugated to the  $\beta$ CDP polymer by amidation of the primary amines at the end of the polymer with 4-imidazoleacetic acid (Aldrich, St. Louis, MO) (33). In a typical experiment, 200 mg (33.3  $\mu$ mol) of  $\beta$ CDP was dissolved in 800  $\mu$ L of 25 mM MES (pH 6.5) buffer to which was added 4-imidazoleacetic acid, sodium salt hydrate (49.3 mg, 0.333 mmol). This solution was used to dissolve 1-ethyl-3-(3-dimethylaminopropyl)car-

bodiimide (EDC) (0.128 g, 0.666 mmol). Then, *N*-hydroxy-succinimide (NHS) (3.83 mg, 33.3  $\mu$ mol) dissolved in 200  $\mu$ L of 25 mM MES (pH 6.5) buffer was added immediately to the polymer solution. The resulting solution was stirred for 24 h at room temperature and then dialyzed against water using a Spectra Por membrane 1000 MWCO. The solution was lyophilized to dryness. The imidazole content was determined by the TNBS assay (34), followed by UV measurements to quantify the amount of unreacted polymer end groups. The imidazole conjugation was 73%.

*Adamantane-PEG<sub>5000</sub> (AD-PEG).* AD-PEG was synthesized according to published procedures (27). In brief, PEG<sub>5000</sub>-SPA (Nektar AL, Huntsville, AL) was reacted with 5 equiv of 1-adamantane-methylamine (Aldrich) dissolved in dichloromethane. The resulting solution was stirred at room temperature for 4 h. The solvent was removed in vacuo, and water was added to the remaining solution. The solution was centrifuged at 15K rcf for 15 min in order to remove unreacted 1-adamantane-methylamine. The aqueous portion was collected and dialyzed (Slide-A-Lyzer 3500 MWCO, Pierce, Rockford, IL) for 24 h against water. The dialyzed solution was then lyophilized to yield a white, fluffy powder. The product was analyzed on a Beckman Coulter Gold HPLC system equipped with a Richards Scientific Sedere Evaporative Light Scattering detector using a C18 reversed phase column. The product was found to be pure (retention time of PEG<sub>5000</sub>-SPA: 10.7 min; retention time of product: 12.1 min). The product was also confirmed by mass spectroscopy Maldi-ToF analysis.

## AD-PEG

*Transferrin Conjugation via Carbohydrate Groups (Figure 1).* The synthesis involves three steps. First, Fmoc-NH-PEG<sub>5000</sub>-NHS (1) (Nektar AL, 0.2 mmol, 1 g) was added to a round-bottom flask equipped with a stir bar. To this was added *tert*-butyl carbazate (Aldrich, 1.6 mmol, 0.2112 g) dissolved in 7 mL of dichloromethane/ethyl acetate (1:1). The resulting solution was stirred overnight at room temperature. The next day, the solvents were removed in vacuo. The Fmoc group was removed by dissolving the resulting solid in 10 mL of 20% piperidine in dimethylformamide and stirring at room

**Figure 1.** Synthesis of Tf-PEG-AD by carbohydrate conjugation.

temperature for 5 h. The solvent was removed in vacuo, and the residue was redissolved in water. The solution was centrifuged to remove the undissolved Fmoc group and then dialyzed overnight in Pierce's Slide-A-Lyser, 3500 MWCO. The solution was then lyophilized to afford 790 mg of  $\text{H}_2\text{N}-\text{PEG}_{5000}-\text{NHNHCOOtBu}$  (**2**).

In the second step, *N*-hydroxysuccinimide (Aldrich, 0.24 mmol, 27.3 mg) and adamantanecarboxylic acid (Aldrich, 0.39 mmol, 71.2 mg) were dissolved in 7 mL of dichloromethane and added to **2** (0.16 mmol, 790 mg). To this resulting solution was added 1,3-dicyclohexylcarbodiimide (Aldrich, 1.6 mmol, 0.326 g) dissolved in 3 mL of dichloromethane. The resulting solution was stirred overnight at room temperature. The next day, the solid formed was filtered on a fine glass frit, and the filtrate was concentrated on a rotary evaporator under vacuum. The residue was dissolved in 10 mL of water and centrifuged to remove the unreacted adamantanecarboxylic acid. The solvent was removed in vacuo, and the residue was redissolved in 6 mL of 4 M HCl in dioxane in order to deprotect the *tert*-butoxycarbonyl group and stirred at room temperature for 4 h. The solvent was then removed in vacuo, and the residue was redissolved in water. The resulting solution was dialyzed overnight in Pierce's Slide-A-Lyser (Rockford, IL), 3500 MWCO, and lyophilized to afford 635 mg of  $\text{AD}-\text{PEG}_{5000}-\text{NHNH}_2$  (**3**). This product was analyzed on a Beckman Coulter Gold HPLC system equipped with a Richards Scientific Sedere Evaporative Light Scattering detector using a C18 reversed phase column. The product was also confirmed by mass spectroscopy Maldi-ToF analysis.

In the third step, **3** was conjugated to transferrin according to the protocol described previously by Wagner et al. (23). A solution of 100 mg (1.28  $\mu\text{mol}$ ) of human transferrin (iron poor) (Sigma-Aldrich) in 1 mL of a 30 mM sodium acetate buffer (pH 5) was subjected to gel filtration on a Sephadex G-25 (Supelco) column. The resulting 4 mL of solution containing transferrin (monitoring: UV absorption at 280 nm) was cooled to 0 °C and 80  $\mu\text{L}$  of a 30 mM sodium acetate buffer (pH 5) containing

4 mg (19  $\mu\text{mol}$ ) of sodium periodate was added. The mixture was kept in an ice bath and in the dark for 2 h. For removal of the low molecular weight products, an additional gel filtration (Sephadex G-25, 30 mM sodium acetate buffer (pH 5)) was performed. This yielded a solution containing about 85 mg (1.09  $\mu\text{mol}$ ) of oxidized transferrin. The modified transferrin solution was promptly added to a solution containing 10.9 mg (2.2  $\mu\text{mol}$ ) of  $\text{AD}-\text{PEG}_{5000}-\text{NHNH}_2$  (**3**) in 1 mL of 100 mM sodium acetate (pH 5). The resulting solution was stirred overnight at room temperature. The pH was then brought to 7.5 by addition of 1 M sodium bicarbonate, and four portions of 9.5 mg (150  $\mu\text{mol}$ ) of sodium cyanoborohydride each were added at 1 h intervals. After 4 h, the PEGylated transferrin was purified and concentrated using a Centricon YM-50,000 NMWI device (Millipore). This concentrated solution was subjected to hydrophobic interaction chromatography media (Tosoh Bioscience Butyl-650S) packed into a 10 cm bed height  $\times$  1 cm I.D. column. The products were eluted using a gradient mobile phase from 1.7 M to no ammonium sulfate in 0.1 M potassium phosphate buffered at pH 7.0. The column was run at room temperature, and the elution profile was monitored by UV absorbance at 280 nm. The UV-active fractions were then analyzed on a Beckman Coulter HPLC system equipped with a system gold 168 detector and a Butyl-NPR (Tosoh Bioscience) hydrophobic interaction column using a linear gradient from 1.7 to 0 M ammonium sulfate in 0.1 M potassium phosphate buffered at pH 7.0 at a 1 mL/min flow rate.

**Transferrin Conjugation via Lysine Groups (Figure 2).** Vinyl sulfone- $\text{PEG}_{5000}$ -NHS (**4**) (Nektar AL, 0.147 mmol, 0.5 g) was added to a round-bottom flask equipped with a stir bar and dissolved in 5 mL of DMSO. To this was added adamantanemethylamine (Aldrich, 0.147 mmol, 0.0243 g). The resulting solution was stirred 1 h at room temperature. The solvent was removed in vacuo, and the residue was redissolved in water. The resulting mixture was dialyzed overnight against a 3500 MWCO membrane

**Figure 2.** Synthesis of Tf-PEG-AD by lysine conjugation.

(Spectra Por). The solution was then lyophilized to afford 0.49 g of vinyl sulfone-PEG<sub>5000</sub>-AD (5).

In the second step, 0.49 g (0.1 mmol) of vinyl sulfone-PEG<sub>5000</sub>-AD (5) were added to a solution of 1 g (12.5  $\mu$ mol) of human transferrin (iron poor) (Sigma-Aldrich) in 30 mL of a 0.1 M sodium tetraborate buffer (pH 9.4) and stirred at room temperature for 2 h. The PEGylated transferrin was purified from the unreacted vinyl sulfone-PEG<sub>5000</sub>-AD (5) and concentrated using a Centricon plus YM-50,000 NMWI device (Millipore). This concentrated solution was subjected to hydrophobic interaction chromatography media (Tosoh Bioscience Butyl-650S) packed into a 30 cm bed height  $\times$  4 cm I.D. column. The products were eluted using a gradient mobile phase from 1.7 M to no ammonium sulfate in 0.1 M potassium phosphate buffered at pH 7.0. The column was run at room temperature, and the elution profile was monitored by UV absorbance at 280 nm. The UV active fractions were then analyzed on a Beckman Coulter HPLC system equipped with a system gold 168 detector and a Butyl-NPR (Tosoh Bioscience) hydrophobic interaction column using a linear gradient from 1.7 M to no ammonium sulfate in 0.1 M potassium phosphate buffered at pH 7.0 at a 1 mL/min flow rate (Figure 3A). The product was also confirmed by mass spectroscopy MALDI-ToF analysis (Figure 3B).

**Synthesis of Transferrin-Fluorescein.** Fluorescein-5-thiosemicarbazide, the hydrazide derivative of fluorescein (35) was conjugated to the transferrin via carbohydrate groups (23). A solution of 50 mg (0.64  $\mu$ mol) of human transferrin (iron poor) (Sigma-Aldrich) in 1 mL of ice cold 30 mM sodium acetate buffer (pH 5) was subjected to gel filtration on a Sephadex G-25 (Supelco) column. The resulting 2 mL of solution containing transferrin (monitoring: UV absorption at 280 nm) was cooled to 0  $^{\circ}$ C, and 40  $\mu$ L of a 30 mM sodium acetate buffer (pH 5) containing 2 mg (9.5  $\mu$ mol) of sodium periodate was added. The mixture was kept in an ice bath and in the dark for 2 h. For removal of the low molecular weight products an additional gel filtration (Sephadex G-25, 30 mM sodium acetate buffer, pH 5) was performed. This yielded a solution containing about 43 mg (0.55  $\mu$ mol) of oxidized transferrin. The modified transferrin solution was promptly added to 0.5 mg/mL fluorescein-5-thio-

semicarbazide. The resulting solution was stirred 30 min in the dark at room temperature. The resulting transferrin-fluorescein was then subjected to gel filtration on a Sephadex G-25 (Supelco) column.

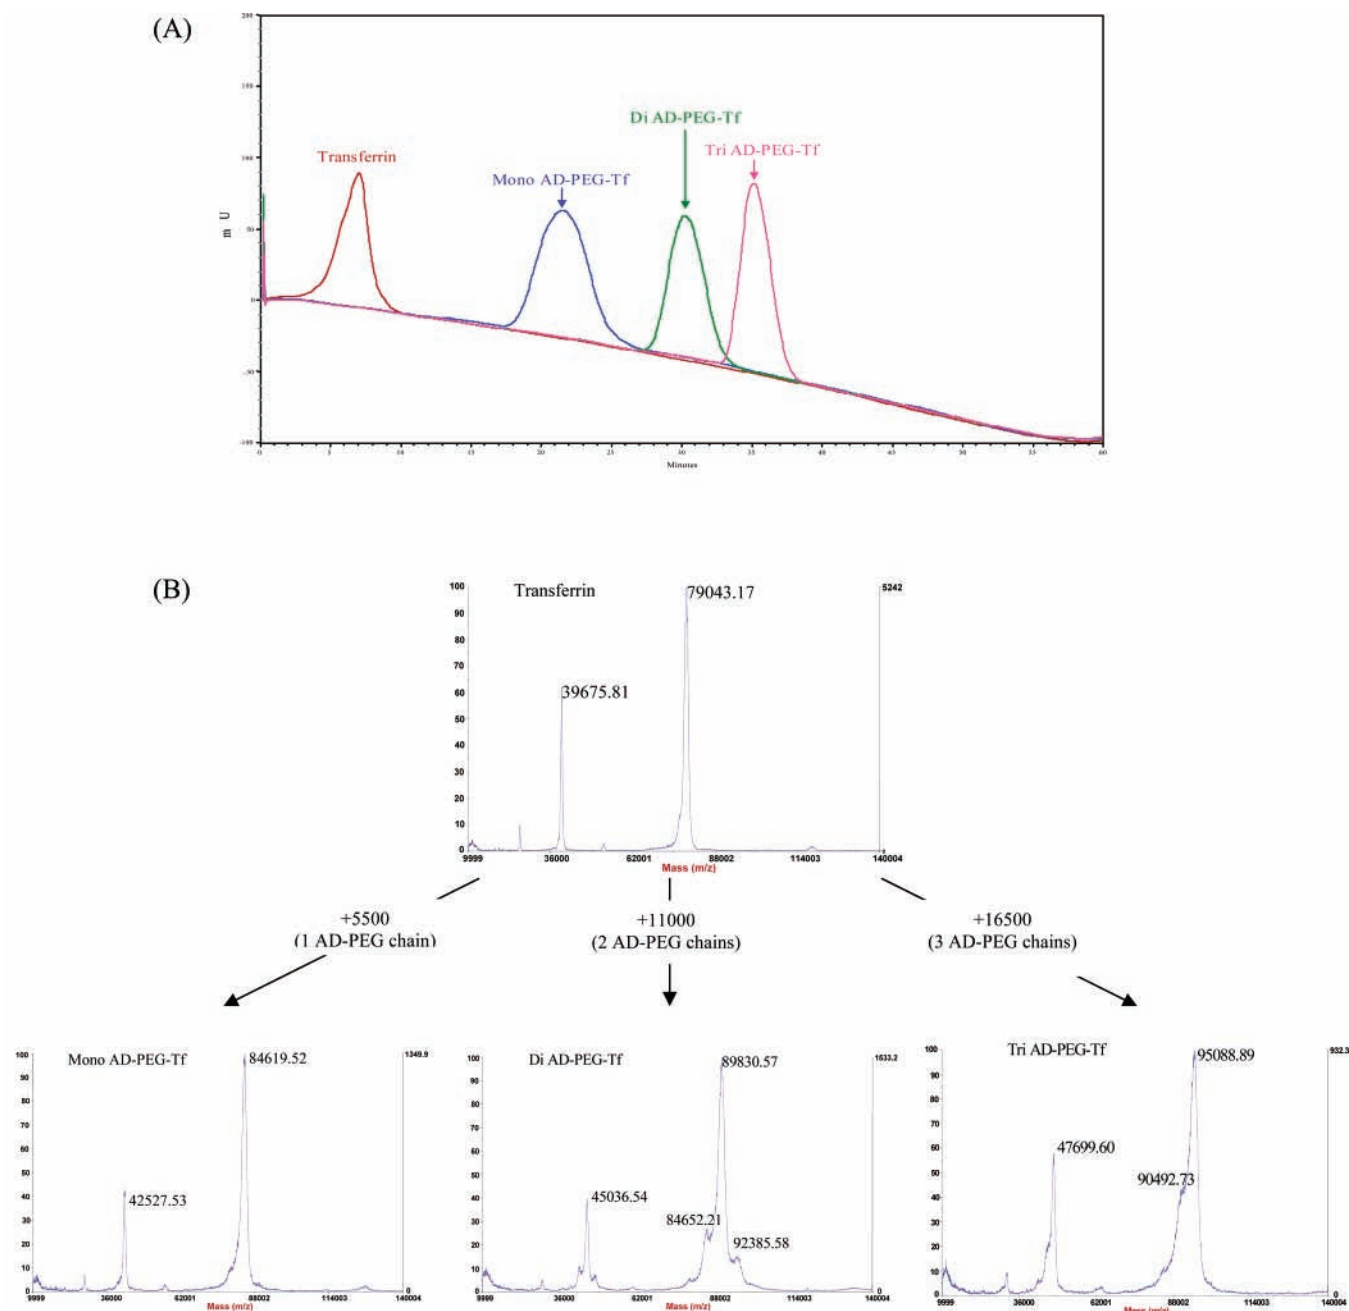

**Iron-Loading of Transferrin Conjugates.** A 40 mg amount of apo-transferrin-based compound (apo-transferrin or apo-transferrin-PEG-AD) was dissolved in 700  $\mu$ L of dH<sub>2</sub>O. To this solution was added 200  $\mu$ L of 5 mM iron citrate and 100  $\mu$ L of 84 mg/mL NaHCO<sub>3</sub>. This solution was allowed to stand for 2–3 h and then dialyzed against dH<sub>2</sub>O overnight. The iron-loading efficiency was calculated by determining the ratio of absorbance at 465 nm (from the oxidized iron) to absorbance at 280 nm (from the tryptophan residues in the protein) and normalizing to the  $A_{465}/A_{280}$  ratio of commercially available holo-transferrin (ratio is denoted as iron-loading in the figures).

**Cell Culture and Cellular Studies.** *Cells and Plasmids.* PC-3 (human prostate carcinoma) and K562 (chronic myelogenous leukemia) cells were purchased from the ATCC. Cells were cultured according to recommended procedures. Media and supplements were purchased from Gibco BRL (Gaithersburg, MD). Plasmid pGL3-CV (Promega, Madison, WI) containing the luciferase gene under the control of the SV40 promoter was amplified and purified by Elim Biopharmaceuticals (Hayward, CA).

**Competitive Binding Studies.** PC-3 cells or K562 cells were plated at 300,000 cells/well in six-well plates. After 24 h, cells were exposed to 250 nM of Tf-fluor (fluorescein-labeled transferrin) with various amounts of unlabeled transferrin or Tf-PEG-AD in MEM media containing 1% BSA. 15 min after exposure, media was removed and cells washed with PBS and prepared for analysis by flow cytometry. For competitive binding studies using particle formulations, the same procedure was followed except Tf or Tf-PEG-AD was first formulated with particles (as described in the following paragraph) and then added to the media at a final concentration of 75 nM.

**Tf-Particle Formulations.** Transferrin-modified particles were prepared at a final DNA concentration of 1 mg/mL. Equal volumes of the four components (plasmid pGL3-CV, CDP-Imid, AD-PEG, and Tf-(PEG-AD))

**Figure 3.** (A) Purification and isolation of transferrin conjugates by hydrophobic interaction chromatography and (B) confirmation of desired products Maldi-ToF mass spectroscopy.

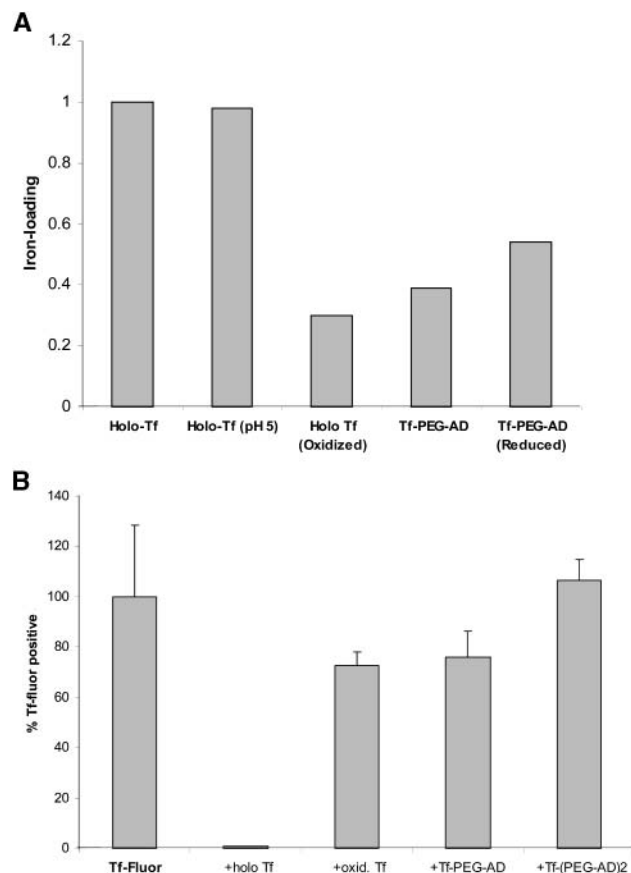

were mixed by adding the three polymer solutions (premixed) to the DNA solution and pipeting gently to mix. CDP-Imid was added at a 3  $\pm$  to DNA. AD-PEG and Tf-(PEG-AD)<sub>x</sub> were included such that the total moles of AD-PEG and Tf-(PEG-AD)<sub>x</sub> is equal to the total moles of cyclodextrin. For particle size and zeta potential determination, particles were prepared, diluted to 5  $\mu$ g/mL in dH<sub>2</sub>O, and analyzed using a ZetaPals dynamic light scattering detector (DLS, Brookhaven Instruments Corporation, Holtsville, NY).

**Tf-Particle Transfection Studies.** K562 cells were plated in 24-well plates at 40,000 cells/well in 0.2 mL Opti-MEM (Invitrogen). Particle-containing solutions (with or without holo-transferrin as a competitive inhibitor) were then added to each well. Five hours after transfection, 0.8 mL of complete media was added to each well. Cells were collected by centrifugation 48 h post-transfection, washed with PBS, lysed and analyzed for luciferase activity by addition of Promega's luciferase assay reagent and light

measurements integrated over 10 s with a Monolight 3010C luminometer (Pharmingen, San Diego, CA).

## RESULTS

**Tf-PEG-AD Synthesized by Carbohydrate Conjugation.** Transferrin-poly(ethyleneglycol)-adamantane (Tf-PEG-AD) was synthesized by carbohydrate conjugation according to literature procedures (Figure 1) (12, 23). In brief, the vicinal diols in the apo-transferrin glycan chains were oxidized to aldehydes with sodium periodate and reacted by reductive amination with adamantane-PEG-hydrazide. The Tf-PEG-AD conjugates were purified by hydrophobic interaction chromatography and iron-loaded with iron citrate in sodium bicarbonate. The iron-loading efficiency of the conjugates was measured by the ratio of the UV absorption at 465 nm (iron-loaded transferrin) to the absorption at 280 nm (total protein)

**Figure 4.** (A). Comparison of iron-loading efficiency of transferrin, oxidized transferrin, and Tf-PEG-AD (synthesized by carbohydrate conjugation). Proteins were purified at each step of the reaction by gel filtration and iron-loaded with iron citrate in sodium bicarbonate. Iron-loading efficiency was measured by the ratio of UV absorption at 465 nm to 280 nm and normalized by the  $A_{465}/A_{280}$  ratio for holo-transferrin. (B) Relative binding of Tf-PEG-AD conjugates (synthesized by carbohydrate conjugation) to Tf-R. PC-3 cells were exposed to 250 nM of Tf-fluor in the presence of transferrin or various transferrin-based conjugates for 15 min. Cells were collected, washed, and analyzed by FACS for cellular association of Tf-fluor.

and normalized by the  $A_{465}/A_{280}$  ratio for holo-transferrin (Figure 4A). The Tf-PEG-AD conjugate had only 40% iron-loading efficiency. The transferrin iron-loading efficiency was then determined at each step in the synthesis process: in the pH 5 reaction buffer, after oxidation, after reaction with AD-PEG-hydrazide, and after hydrazone reduction with sodium cyanoborohydride. Each product was isolated by gel filtration before iron-loading. Efficient iron-loading was obtained at pH 5 (98%), but was substantially reduced after oxidation with sodium periodate (30%). The loss in iron-loading efficiency of the oxidized Tf was maintained upon conjugation to the AD-PEG and was not reversible; the addition of a reducing agent only slightly increased iron-loading efficiency of the conjugated Tf (54%).

The Tf-PEG-AD conjugates were tested for transferrin receptor-binding affinity. PC-3, a human prostate carcinoma cell line that expresses elevated levels of transferrin receptor (Tf-R) (36), were exposed to 250 nM of fluorescein-labeled transferrin (Tf-fluor) and 100 nM of hTf (holo-transferrin), Tf-PEG-AD, or Tf-(PEG-AD)<sub>2</sub>, and analyzed for Tf-fluor cellular association (Figure 4B). Transferrin conjugates with high receptor binding affinities should compete efficiently against Tf-fluor for receptor binding sites, thus reducing average

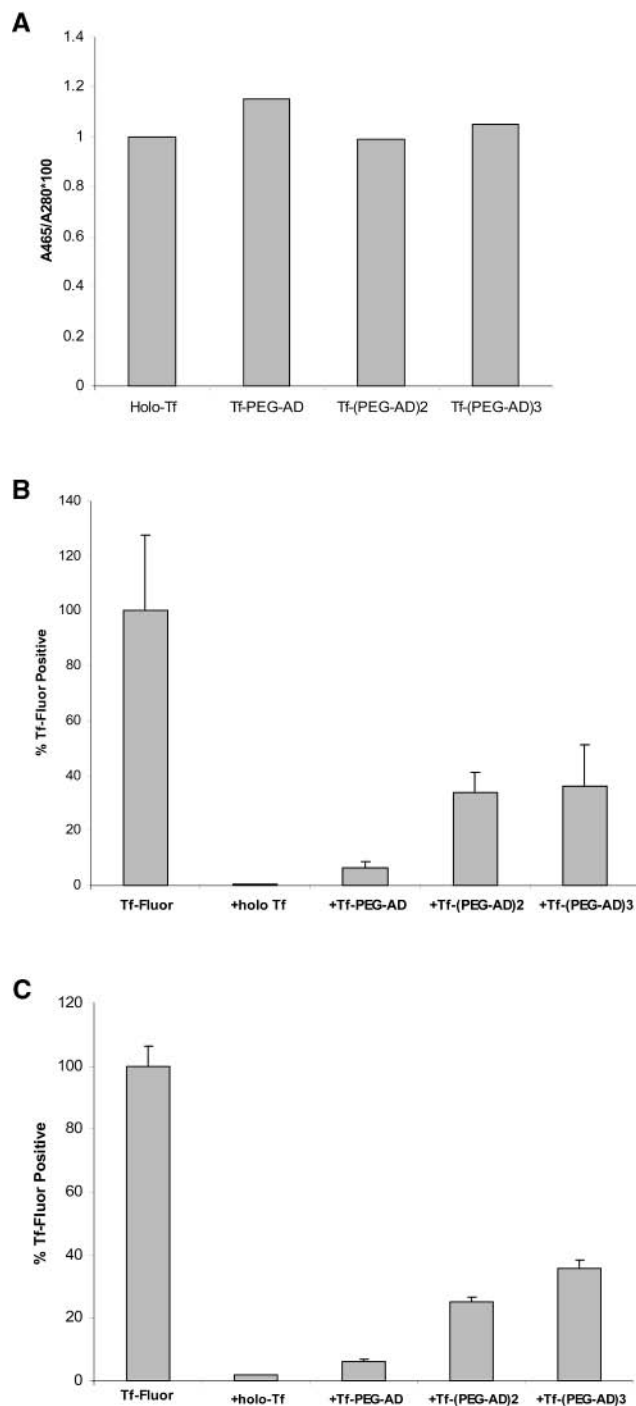

cell fluorescence. The fraction of cells in each sample with Tf-fluor/Tf-R binding above a threshold value was determined by flow cytometry and normalized by the fraction of fluorescein positive cells in samples exposed to 250 nM Tf-fluor alone. The native holo-Tf ligand has the highest binding affinity for the Tf-R and prevents Tf-fluor/Tf-R association (0.6% fluorescein positive cells), even at 40% the concentration of Tf-fluor. Oxidized transferrin has significantly reduced Tf-R binding affinity (72%), as do the purified Tf-PEG-AD (76%) and Tf-(PEG-AD)<sub>2</sub> (107%) conjugates. Because the synthesis of Tf-PEG-AD via the reductive amination scheme causes a significant reduction in the Tf/Tf-R binding, another conjugation method was pursued.

#### Tf-PEG-AD Synthesized by Lysine Conjugation.

A second approach was used to prepare Tf-PEG-AD conjugates (Figure 2). Tf was modified at surface-available lysines via reaction with adamantane-PEG-vinyl sulfone. The Tf-PEG-AD conjugates were separated and purified by hydrophobic interaction column (Figure 3A). Each conjugate (Tf-PEG-AD, Tf-(PEG-AD)<sub>2</sub>, and Tf-(PEG-AD)<sub>3</sub>), could therefore be isolated. Clean separation of the mono-, di-, and trisubstituted transferrins was demonstrated by HPLC analysis with products confirmed by MALDI-ToF mass spectroscopy (Figure 3B). Transferrin is an 80 kDa protein, and the molecular weight of PEG-AD is approximately 5300. As expected, mass spectroscopy of the transferrin yields a sharp signal at 79 kDa. The isolated fractions for Tf-PEG-AD, Tf-(PEG-AD)<sub>2</sub>, and Tf-(PEG-AD)<sub>3</sub> reveal peaks at 84.6 kDa, 89.8 kDa, and 95.1 kDa, respectively. The purified transferrin conjugates were then iron-loaded as described above. Unlike the conjugates synthesized by transferrin oxidation and Schiff base formation, Tf-PEG-AD's prepared by reaction with surface lysines retain high iron-loading efficiencies (all around 100% iron loading, Figure 5A).

The Tf-(PEG-AD), Tf-(PEG-AD)<sub>2</sub>, and Tf-(PEG-AD)<sub>3</sub> compounds were analyzed for receptor-binding to transferrin receptors on both PC-3 and K562 cells as described above (Figure 5B and 5C). The monosubstituted Tf-PEG-AD showed the highest binding affinity to Tf-R of the three conjugates and was only slightly reduced from the native holo-transferrin protein (for PC-3, 6% cells with Tf-fluor association compared with 0.6% in the presence of holo-transferrin and for K562, 6% cells with Tf-fluor association compared with 2% in the presence of holo-transferrin). The ability of Tf-(PEG-AD)<sub>2</sub> to bind to Tf-R was affected by PEG-AD conjugation (34% of PC-3 and 25% of K562 cells fluorescein positive), and Tf-(PEG-AD)<sub>3</sub> revealed the lowest receptor-binding of the three conjugates (36% cells fluorescein positive for both PC-3 and K562 cells). Therefore, the monosubstituted Tf-PEG-AD synthesized by lysine conjugation was used for all further experiments described.

**Formulation of Tf-Modified Particles.** Transferrin-modified particles were prepared by mixing the following components (prepared in water solutions) in equal volumes: (1) CDP-Imid, a linear, cyclodextrin-based polycation that condenses and protects plasmid DNA, (2) adamantane-PEG (AD-PEG), a particle modifier that provides for PEGylation to give stabilization against nonspecific interactions including self-aggregation, (3) AD-PEG-Tf (synthesized by lysine conjugation), another modifier that introduces transferrin for targeting to Tf-R-expressing cells (for controls, holo-transferrin was used instead of AD-PEG-Tf), and (4) plasmid DNA. The first three components are premixed and added to the fourth solution. Particles were prepared with various

**Figure 5.** (A) Comparison of iron-loading efficiency of transferrin and Tf-PEG-AD conjugates synthesized by lysine reaction. Iron-loading efficiency was measured by the ratio of UV absorption at 465 nm to 280 nm and normalized by the  $A_{465}/A_{280}$  ratio for holo-transferrin. Relative binding of Tf-PEG-AD conjugates (synthesized by lysine conjugation) to Tf-R to PC3 (5B) and K562 (5C) cells. Cells were exposed to 250 nM of Tf-fluor in the presence of transferrin or various transferrin-based conjugates for 15 min. Cells were collected, washed, and analyzed by FACS for cellular association of Tf-fluor.

amounts of Tf or Tf-PEG-AD (0%, 0.5%, 1%, and 2% of total cyclodextrins by mole).

The particle size and surface charge were measured by dynamic light scattering and zeta potential, respectively. Average particle diameter of all formulations was ~100 to 150 nm. Transferrin modification was verified by monitoring the average zeta potential of the particles

**Figure 6.** Zeta potential of transferrin modified particles. Transferrin-modified particles were prepared at 3 +/- (CDP-Imid to pGL3-CV) with 100% adamantane modification (total of AD-PEG and Tf-PEG-AD). Particles were analyzed using a ZetaPals dynamic light scattering detector.

(Figure 6). Transferrin is an anionic protein; therefore, transferrin association with the positively charged particles should decrease the surface charge. Addition of free transferrin decreases average particle zeta potential from +30 mV to +25 mV (at 1% and 2% transferrin to CD). The effect of transferrin on surface charge levels off at 1% (~+25 mV for both 1% and 2% transferrin). The zeta potential of particle formulations with Tf-PEG-AD also decreased with higher concentration of Tf-PEG-AD, and indicated successful modification of particles with Tf-PEG-AD. At 1% and 2% Tf-PEG-AD, average particle zeta potentials are +20 mV and +17 mV, respectively.

Transferrin-modified particles (Tf-PEG-particle) should also have higher association to transferrin receptors on cell surfaces than Tf-PEG-AD because the Tf-PEG-particle has the ability to bind to several Tf-R while Tf-PEG-AD/Tf-R binding is a single interaction event. PC-3 cells were exposed for 15 min to 250 nM of Tf-fluor and 75 nM of Tf or Tf-PEG-AD in the presence and absence of CDP-Imid-based particles (at a 2 Tf per 100 cyclodextrin mole ratio). The cells were prepared and analyzed by flow cytometry as described previously for the receptor binding assay. Particle addition alone did not affect Tf-fluor association to PC-3 cells. However, formulation of Tf-PEG-AD with particles reduces the percentage of fluorescein positive cells by 15% from the percentage when exposed directly to Tf-PEG-AD and Tf-fluor. Similarly, exposure of cells to Tf in the presence of particles only reduces the percentage by 6%.

The salt stability of various Tf-PEG-particle formulations was determined by monitoring particle size in physiological salt solutions by dynamic light scattering. Tf-PEG-particles were formulated with 0%, 0.05%, 0.1%, 0.5%, 1.0%, 2%, and 5% Tf-PEG-AD (of total cyclodextrins by mole with the remaining balance to 100% comprised of AD-PEG) in a small volume (40  $\mu$ L) of water. PBS, pH 7.2, was then added (1.2 mL) and average particle diameter recorded every minute for 5 min (Figure 7). Unmodified particles aggregated rapidly in salt (final diameter of 300 nm), but PEGylated particles remained stable with diameters of ~70 nm. The stability of Tf-modified particles depended on the amount of Tf-PEG-AD present during formulation. Formulations with 0.05%, 0.1%, and 0.5% Tf-PEG-AD were stable in salt (respective diameters of 75, 80, and 83 nm after 5 min in salt solutions) while formulations with 1%, 2%, and 5% Tf-PEG-AD aggregated slowly upon salt addition (107, 129, and 168 nm after 5 min, respectively).

**Figure 7.** Salt stability of transferrin-modified particles. Transferrin-modified particles were prepared at 3  $\pm$  (CDP-Imid to pGL3-CV) with 100% adamantane modification (total of AD-PEG and Tf-PEG-AD). PBS (1.2 mL) was added to the particle solution and average particle diameter every minute for 5 min by dynamic light scattering.

**Figure 8.** Luciferase transfection of transferrin-particles to K562 cells. K562 cells were plated in 24-well plates and exposed to 1  $\mu$ g of pGL3-CV in four formulations: particles modified with 100% AD-PEG, particles modified with 100% AD-PEG, and mixed with 0.05% holo-Tf (by mole to cyclodextrins), particles modified with 100% AD-PEG and 0.05% Tf-PEG-AD (Tf-PEG-part.), and Tf-PEG-part. mixed with 10 equiv of holo-Tf (with respect to Tf-PEG-AD). Experiments were conducted with five replicates with average values shown.

**In Vitro Transfection of Tf-Modified Particles to K562 Cells.** Tf-PEG-particles containing pGL3-CV were formulated at 0.05% Tf-PEG-AD (and 99% AD-PEG) and 3  $\pm$  charge ratio (ratio of polymer to plasmid charge by mole) and used to transfect K562 cells. Control samples included PEGylated particles (PEG-particles, 1 AD-PEG to 1 cyclodextrin by mole), PEG-particles formulated with holo-Tf (at 0.05% Tf by mole cyclodextrin), PEG-particles formulated with holo-Tf (at 0.05% Tf by mole cyclodextrin) mixed with 10 equiv of free holo-Tf, and Tf-PEG-particles mixed with 10 equiv of free holo-Tf. Transfections were carried out in serum-free media, and cells were lysed and analyzed for luciferase activity 48 h after transfection with results reported in relative light units per mg of protein (RLU/mg protein, protein levels determined by Lowry protein assay, Figure 8). The positively charged, PEGylated particles transfected K562 cells ( $4.6 \times 10^4$  RLU/mg). Formulation of these particles with holo-Tf increased delivery efficiency by 1.7-fold ( $7.7 \times 10^4$  RLU/mg). The Tf-PEG-particles, with Tf attachment to the particles via inclusion complex formation, demonstrated the highest luciferase expression ( $1.8 \times 10^5$  RLU/mg) with a 4-fold enhancement over the PEG-particles. To confirm specific transfection enhancement by Tf-mediated delivery, Tf-PEG-particle transfections were also conducted in the presence of 10

equiv of holo-Tf. These samples did not reveal much increase in luciferase gene delivery ( $4.7 \times 10^4$  RLU/mg) over the PEGylated particle. The transfection by particles formulated with holo-Tf was likewise reduced in the presence of free transferrin ( $3 \times 10^4$  RLU/mg). In addition, no toxicity was observed in any of the samples.

## DISCUSSION

The goal of this work is to develop a transferrin-mediated, tumor-targeting gene delivery system that is chemically well-defined. Although targeting to tumors via mixtures of transferrin and liposomal or polymeric delivery systems has been reported (15, 16, 18, 37), the characteristics and efficacy of these constructs are highly dependent on formulation methods. We strived to prepare stable formulations without significantly diminished interaction affinity between the transferrin targeting ligand and Tf-R on the surfaces of carcinoma cells. Here, Tf-PEG-AD conjugates were synthesized for assembly with cyclodextrin-containing particles by inclusion complex formation between the adamantanes and particle surface displayed cyclodextrins. The Tf-PEG-AD interacts with the particles through charge (anionic Tf-cationic particles) and inclusion complexation formation (AD-CD).

A Tf-PEG-AD ligand was first synthesized by sodium periodate oxidation of the apo-transferrin carbohydrate moieties followed by a reductive amination reaction with AD-PEG-hydrazide (Figure 1). The synthesis protocol was adapted from published procedures for preparing Tf-poly(L)lysine and Tf-poly(ethylenimine) conjugates (12, 13, 23). The various transferrin products were purified by hydrophobic interaction chromatography, an established method for isolation of PEGylated proteins (38, 39). The mono-, di-, and tri-PEGylated transferrins were successfully isolated and converted to the iron-loaded form by iron citrate treatment in bicarbonate. A distinct difference in color was noted between holo-Tf and holo-Tf-PEG-AD solutions at the same concentrations. This discrepancy was quantified by measuring the UV absorbance at 465 nm (for the oxidized iron) and 280 nm (for total protein concentration). The results confirmed that the Tf-PEG-AD conjugates suffered from low iron-loading efficiency. The amount of iron-loading into transferrin was therefore measured at each reaction step, and the cause of reduced iron-loading was determined to be the oxidation of transferrin with sodium periodate (Figure 4A). The oxidized transferrin was separated from excess sodium periodate by chromatography before iron citrate treatment. Iron-loading of oxidized transferrin was only 30%, and efficiency was not recovered by reaction with AD-PEG-hydrazide or by subsequent reduction with sodium cyanoborohydride. The iron-loading protocol conditions (concentration of iron citrate and iron-loading time) were also varied in an attempt to increase efficiencies, but did not result in any substantial improvements.

The binding affinity of the transferrin conjugates for Tf-R on surfaces of cultured cells was assessed by monitoring the competitive binding against fluorescently labeled transferrin (Figure 4B). Holo-transferrin completely displaces the fluorescently labeled transferrin, even at a reduced concentration (the Tf-fluor was also synthesized by reductive amination with fluorescein hydrazide and has lower receptor binding affinity than the natural ligand). The transferrin iron-loading efficiency was found to be a good indicator of receptor binding. Transferrin with low iron-loading efficiencies

(oxidized transferrin and Tf-PEG-AD conjugates) also had low receptor binding. Indeed, apo-transferrin is reported to have lower binding affinity for the transferrin receptor at physiologic pH to unloading after recycling to cell surfaces (40).

After finding that the affinity for the Tf-R was greatly reduced when conjugating AD-PEG to Tf via carbohydrate oxidation, an alternative synthetic approach was pursued. Tf-PEG-AD was synthesized by reaction of lysine amines with a vinyl sulfone that was prepared as AD-PEG-vinyl sulfone (Figure 2). The vinyl sulfone group is known to be highly selective at pH 7 for reaction with sulfhydryl groups (relative to reaction with amino groups). However, it has been shown that the reaction with lysine sites occurs slowly at pH 9.4 and is essentially complete (41). A reaction conducted at pH 7 revealed that the vinyl sulfone did not react with cysteine thiols groups of transferrin because no free thiols are available on the protein surface (as confirmed by Ellman's titration (34)). The Tf-PEG-AD conjugates were thus synthesized at pH 9.4 by reaction between the vinyl sulfone and the lysine groups. The resulting product was a physical mixture of conjugates with variable number of attachments of AD-PEG chains. These conjugates were purified and Tf-PEG-AD, Tf-(PEG-AD)<sub>2</sub>, and Tf-(PEG-AD)<sub>3</sub> were isolated by hydrophobic interaction chromatography (Figure 3A) with product confirmation by Maldi-ToF mass spectroscopy (Figure 3B). Iron-loading was efficient for all transferrin conjugates synthesized by lysine conjugation (Figure 5A). During this process, it was found that it was important to freeze the protein conjugates slowly in dry ice before lyophilization. Rapid freezing in liquid nitrogen impaired the iron-loading efficiency.

The transferrin conjugates were tested for transferrin receptor binding to both PC-3 and K562 cell lines. PC-3, an adherent cell line, and K-562, a suspension cell line, have upregulated transferrin receptors on their surfaces; K-562 cells are reported to have  $1.5 \times 10^5$  Tf-R per cell (40, 42). Unlike transferrin conjugates synthesized by carbohydrate reaction, all lysine-reacted Tf-PEG-AD were able to compete effectively with fluorescein-labeled transferrin for receptor binding in both cell lines (6–36% fluorescein positive cells for lysine-reacted conjugates compared with 76–100% fluorescein positive cells for carbohydrate-reacted conjugates, Figure 5B and 5C). The transferrin receptor binding affinity was decreased by modification with multiple PEGs. While Tf-PEG-AD demonstrated slightly lower binding constants from the natural ligand, the difference was larger for the di- and tri-PEGylated conjugates. With higher PEGylation events, it becomes more likely for the reaction site to interfere with the ligand/receptor binding site. In addition, a multi-PEGylated protein may be sterically inhibited from receptor interactions. On the basis of these receptor binding studies, the mono-Tf-PEG-AD conjugate was used for all subsequent experiments.

Transferrin-modified particles were formulated using the Tf-PEG-AD conjugate. The Tf-modified particles are composed of four components: the nucleic acid of interest, a polycation for condensation of nucleic acid, AD-PEG for particle stabilization, and AD-PEG-Tf for tumor targeting. CDP-Imid, a linear, cyclodextrin-based polycation end-modified with imidazoles, was used as the nucleic acid condensing agent. The parent cyclodextrin-based polymer has been optimized structurally for in vitro transfection and the imidazoles further boost transfection efficiency and act as buffers in endosomes (24). The increased gene expression may be occurring by

mechanisms similar to those proposed for histidylated polymers and poly(ethylenimine) (43, 44). AD-PEG<sub>5000</sub> was used because previous experiments demonstrated that a molecular weight of 5000 was necessary for stabilizing cyclodextrin-based particles in salt-containing media (27).

The particles were formulated by mixing the three polymer solutions together and then adding the polymer solution to the nucleic acid solution. The polymers and DNA self-assembled quickly (in seconds) to form particles with diameters ~100–150 nm (as measured by dynamic light scattering). The amount of Tf-PEG-AD (by mole % to cyclodextrin) included in the formulations ranged from 0% to 2% with the balance (to 100% CD) consisting of AD-PEG. This range was chosen by estimating the amount of Tf that can pack around a 100 nm sphere, subject to space constraints.

The zeta potential for each of the formulations was also measured (Figure 6). As expected, the zeta potentials decrease with increasing concentration of Tf or Tf-PEG-AD in the formulations. Transferrin, an anionic protein, decreases zeta potential as it associates with the positively charged particle surface via electrostatic interactions. Formulations with Tf-PEG-AD have a larger impact on zeta potential, likely due to the higher surface affinity resulting from both inclusion complex formation and electrostatic interactions. With both ligands, the decrease in zeta potential levels off in the formulations with 1–2% transferrin and likely indicates surface saturation.

Incorporation of the Tf-PEG-AD ligand in the particle was further confirmed by competitive receptor-binding studies. Fluorescein-labeled transferrin and either transferrin or Tf-PEG-AD were incubated with PC-3 cells, both as free ligands in solution and as a component in a particle formulation. The percentage of fluorescein-positive cells, indicating Tf-fluor binding to receptors, was determined by flow cytometry. The fluorescence profile of the cells was the same for cells exposed to 250 nM Tf-fluor alone and to 250 nM Tf-fluor/PEGylated particles (no Tf on the particles); therefore, the presence of particles alone does not affect Tf-fluor association with PC-3 cells. Formulation of 250 nM Tf-fluor/75 nM Tf-PEG-AD with the particles reduced the number of fluorescein positive cells by 15% as compared with 250 nM Tf-fluor/75 nM Tf-PEG-AD alone, while formulation of 250 nM Tf-fluor/75 nM Tf with the particles reduced the number by 6% as compared with 250 nM Tf-fluor/75 nM Tf alone. The difference in receptor binding between free ligand and ligand formulated with particles (keeping the concentration of transferrin constant) can therefore be attributed to an increase in binding affinity resulting from multidentate interactions between the ligand-modified particles and cell surface receptors. The stronger interaction between Tf-PEG-AD and the CDP-Imid particles (as opposed to Tf and particle) is reflected in the larger difference in receptor binding affinity between free ligand and ligand/particle formulations.

It has been demonstrated previously that AD-PEG imparts salt stability to cyclodextrin-based particles by forming a hydrophilic layer on the particle surface (27). It is expected that, above certain proportions, incorporation of the large and bulky Tf-PEG-AD ligand will interfere with the PEG layer and eliminate its stabilization effect. The particle sizes of several Tf-particle formulations were monitored by dynamic light scattering to determine their salt stability in 150 mM PBS (Figure 7). Formulations with 0%, 0.05%, 0.1%, and 0.5% Tf-PEG-AD were stable, whereas average particle diam-

eters of formulations with 1%, 2%, and 5% Tf-PEG-AD increased steadily after salt addition (although not to the extent of the unmodified particles).

The Tf-particle formulation was then tested for gene delivery efficiency to K562 cells (Figure 8). K562 cells are suspension cells that are notoriously difficult to transfect. The PEGylated particles are positively charged and can bind via electrostatic interaction with proteoglycans on the cell surface with eventual uptake by endocytosis (45). Formulations with 0.05% transferrin result in a 1.7-fold increase in delivery efficiency. The transferrin associates with the particles by electrostatic interactions and may facilitate cell association and uptake. The Tf-PEG-AD particle preparations (with 0.05% Tf-PEG-AD) demonstrate the highest transfection, a 4-fold increase over AD-PEG-particles. The enhanced transfection is due to transferrin-mediated uptake; the addition of excess transferrin (10 equiv) as a competitor for the Tf-R eliminates the transfection enhancement.

In summary, we describe the synthesis, purification, and in vitro use of a transferrin conjugate for targeting to tumor cells that are known to have upregulated transferrin receptors. While the potential of transferrin-mediated targeting has been clearly demonstrated by others in the field (4, 7, 8, 14, 23, 46–49), we focused on preparing delivery systems with high receptor binding affinities. To this end, monofunctionalized Tf-PEG-AD conjugates were synthesized and purified by hydrophobic interaction chromatography. Isolation of the monofunctionalized transferrin is important for maintaining high receptor binding affinity. Sato et al. also isolated Tf-DNA conjugates by selecting conjugates that bind strongly to Tf-R affinity columns (19). However, most other conjugation chemistries for transferrin impair receptor binding or result in polymeric products. Glutaraldehyde cross-linking of transferrin with drug molecules forms polymeric products (4) with receptor binding affinities half that of transferrin (21), SPDP cross-linking of Tf with polycations yields multiple populations (including polymeric products) (50), and reaction by carbohydrate oxidation adversely affects receptor binding (as described previously). The transferrin conjugates described here are monofunctionalized and retain high receptor binding affinity. Physicochemical characterization and in vitro studies demonstrate that these conjugates should be useful in providing transferrin receptor-targeted drug delivery systems. The synthesis and purification protocols discussed here can also be extended to prepare transferrin conjugates for small molecule delivery. Applications of the transferrin-modified nucleic acid delivery system described herein are currently being investigated for the in vivo delivery of both oligonucleotide and plasmids in mouse xenograph models (29, 31).

# Inter- and Intramolecular Fluorescence Quenching of Organic Dyes by Tryptophan

Nicole Marmé,<sup>†</sup> Jens-Peter Knemeyer,<sup>†</sup> Markus Sauer,<sup>\*,‡</sup> and Jürgen Wolfrum<sup>†</sup>

Physikalisch-Chemisches Institut, Universität Heidelberg, Im Neuenheimer Feld 253, 69120 Heidelberg, Germany and Fakultät für Physik, Angewandte Laserphysik und -spektroskopie, Universität Bielefeld, Universitätsstrasse 25, 33615 Bielefeld, Germany. Received July 23, 2003; Revised Manuscript Received September 23, 2003

Steady-state and time-resolved fluorescence measurements were performed to elucidate the fluorescence quenching of oxazine, rhodamine, carbocyanine, and bora-diaza-indacene dyes by amino acids. Among the natural amino acids, tryptophan exhibits the most pronounced quenching efficiency. Especially, the red-absorbing dyes ATTO 655, ATTO 680, and the oxazine derivative MR 121 are strongly quenched almost exclusively by tryptophan due to the formation of weak or nonfluorescent ground-state complexes with association constants,  $K_{\text{ass}}$ , ranging from 96 to 206 M<sup>-1</sup>. Rhodamine, fluorescein, and bora-diaza-indacene derivatives that absorb at shorter wavelengths are also quenched substantially by tyrosine residues. The quenching of carbocyanine dyes, such as Cy5, and Alexa 647 by amino acids can be almost neglected. While quenching of ATTO 655, ATTO 680, and the oxazine derivative MR121 by tryptophan is dominated by static quenching, dynamic quenching is more efficient for the two bora-diaza-indacene dyes Bodipy-FL and Bodipy630/650. Labeling of the dyes to tryptophan, tryptophan-containing peptides, and proteins (streptavidin) demonstrates that knowledge of these fluorescence quenching processes is crucial for the development of fluorescence-based diagnostic assays. Changes in the fluorescence quantum yield of dye-labeled peptides and proteins might be used advantageously for the quantification of proteases and specific binding partners.

## INTRODUCTION

To date, the use of fluorescently labeled proteins and nucleic acids in various biological and medical relevant assays represents standard technology. Usually, the presence or absence of target molecules is monitored by an increase or decrease in fluorescence intensity of one dye interacting via short-range electronic or long-range dipole–dipole interactions with a second dye (1–5). Deteriorations of the interaction geometry or efficiency are caused, for example, by specific binding or cleavage events. Especially, the use of fluorescence resonance energy transfer (FRET) between a donor, D, and an acceptor dye, A, has increased considerably in the field of biondiagnostics during the past decade (6–8). Other important methods rely on two-color cross-correlation to monitor specific binding events at the single molecule level (9–11). That is, probe and target molecule are labeled with two spectrally distinguishable fluorescent dyes. The two dyes are excited using two different lasers or two-photon excitation with a single laser line and their fluorescence is recorded on two spectrally separated detectors. Colocalization of the two dyes in the observation volume is reflected by a higher cross correlation amplitude.

On the other hand, the absorption and emission spectra, fluorescence quantum yield, and fluorescence lifetime of dyes often vary with environmental conditions. Hence, instead of using interactions between two extrinsic probes, many fluorescent dyes can be used as sensors

to probe their local environments in biological and analytical applications. For example, interactions of fluorophores with DNA bases can be used for the specific detection of DNA or RNA sequences at the single molecule level (12, 13). Nucleobase-specific interactions have been reported for coumarin (14), rhodamine (15–17), oxazine (12, 13, 18), and bora-diaza-indacene (19) dyes. Nucleobase-specific quenching relies on the differences in specific properties of naturally occurring nucleotides, in particular, the low oxidation potential of the DNA base guanosine (14, 20) and the tendency of many fluorophores to aggregate in aqueous environment to decrease their water accessible area. Thus, dependent on the reduction potential of the fluorophore used, efficient photoinduced electron transfer (PET) can occur between the first excited singlet-state of the dye and the ground-state guanosine (18, 21). With careful design of conformationally flexible probes, e.g. DNA-hairpins that carry several guanosine residues in the complementary stem sequence and the use of appropriate fluorophores (rhodamine and oxazine dyes are well suited candidates), efficient single molecule sensitive DNA-hairpins can be produced (12). If quenching interactions between the fluorophore and the guanosine residue are deteriorated upon specific binding to the target, for example, due to binding of a complementary DNA sequence, or due to cleavage by an endonuclease enzyme, fluorescence of the DNA-hairpin is restored. Although this quenching effect is not always desirable, it can be used to develop new, highly sensitive probes for the detection of specific DNA sequences or proteins (12, 13, 18).

Intra- and intermolecular fluorescence quenching experiments with different dyes and amino acids in water have revealed that a similar mechanism holds true for

**Figure 1.** Molecular structures of fluorescein, rhodamine B, tetramethylrhodamine (TMR), Bodipy-FL, MR 121, ATTO 590, and Bodipy 630/650 investigated in inter-, and intramolecular quenching experiments. The molecular structures of some of the investigated dyes are available, while for other dyes the structures are proprietary (Alexa 647, ATTO 655, ATTO 680).

some amino acids. It has been shown that the fluorescence quantum yield of some fluorescein and bora-diazaindacene derivatives is quenched substantially by tryptophan, and to a smaller degree partly by tyrosine and methionine residues (22–24). The oxidation potential,  $E_{ox}$ , of tryptophan is  $\sim 1V$  (25, 26) even lower than that of dG, so the resulting quenching efficiency can be expected to be relatively strong. The strong fluorescence quenching efficiency of oxazine derivatives by tryptophan residues has been used in oxazine-labeled peptide epitopes to detect the presence of p53-autoantibodies in serum samples of patients (27). The underlying method involves the detection of reversible fluorescence quenching of dyes by tryptophan residues in labeled short peptides derived from the antibody recognition sequence of p53. In the free peptide in aqueous solution fluorescence is reduced, due to the formation of ground-state complexes between the dye and the tryptophan residue and subsequent efficient fluorescence quenching. Binding to the antibody via the tryptophan-containing recognition sequence initiates a spontaneous conformational change in the peptide accompanied by a strong increase in fluorescence intensity. Similar quenching interactions between an oxazine derivative and a tryptophan residue have been used to study intramolecular contact formation in peptides at the single molecule level (28). In contrast to electronic energy transfer-based systems where long-range dipole–dipole interactions occur, efficient electron transfer-based fluorescence quenching within these peptides requires close contact between the fluorophore and the tryptophan.

Consideration of these quenching effects of fluorescent dyes in peptides or proteins by neighboring amino acids is crucial for the development of new fluorescence-based assays. Motivated by these considerations, we measured steady-state and time-resolved intermolecular fluores-

cence quenching of different fluorophores (MR121, ATTO 655, ATTO 680, Cy5, ATTO 590, Alexa 647, tetramethylrhodamine, rhodamine B, Bodipy-FL, Bodipy 630/650, and fluorescein) by several amino acids. Among the fluorophores investigated, the red-absorbing oxazine derivative MR121 and the dyes ATTO 655 and ATTO 680 show the most pronounced quenching efficiency by tryptophan. Other amino acids (tyrosine, phenylalanine, methionine, and histidine) showed only minor quenching efficiencies. The fluorescence intensity and lifetime of the carbocyanine dyes Cy5 and Alexa 647 are only slightly influenced by the presence of amino acids. To investigate intramolecular fluorescence quenching, the fluorophores were covalently attached to amino acids, a tryptophan-containing peptide, and streptavidin. Each hydrophobic binding pocket of streptavidin contains four tryptophan residues that are involved in strong biotin binding (23, 29). We demonstrate that knowledge of the fluorescence quenching behavior of fluorophores by amino acids has to be considered for the design of biological or medical assays.

## EXPERIMENTAL PROCEDURES

**Fluorescent Dyes and Conjugates.** The dyes used in this study were obtained as free carboxy acids, or *N*-hydroxysuccinimidyl esters. ATTO 590, ATTO 655, and ATTO 680 were purchased from ATTO-TEC (Siegen, Germany), Cy5 from Amersham Pharmacia Biotech (Freiburg, Germany), fluorescein, rhodamine B (RB) and tetramethylrhodamine (TMR), Bodipy 630/650, and Bodipy-FL from Molecular Probes (Göttingen, Germany). The oxazine derivative MR121 was kindly provided by K. H. Drexhage (Universität-Gesamthochschule, Siegen). Molecular structures of the fluorophores investigated are shown in Figure 1. When dissolved in water, *N*-hydroxy-

succinimidyl esters are believed to be deactivated within minutes to hours. MR121 and RB were converted into their *N*-hydroxysuccinimyl esters using an equimolar amount of *N*-(3-dimethylaminopropyl)-*N*-ethylcarbodiimide hydrochloride (EDC) and *N*-hydroxysuccinimide (NHS) in acetonitrile. For coupling to the amino groups of amino acids or peptides, 20  $\mu$ L of the activated dyes (0.1 mM in acetonitrile) was mixed with an excess of amino acids or peptides in 50  $\mu$ L of carbonate buffer (0.1 M, pH 8.3). Fluorescent dyes were coupled to the amino group of the lysine residue of the *N*-terminal protected peptide lysine-glycine-glycine-glycine-tryptophan (KGGGW). The reaction solution was incubated for 6 h at room temperature, and the product was purified by HPLC (Hewlett-Packard, Böblingen, Germany) using a reversed-phase column (Knauer, Berlin, Germany) with octadecylsilane-hypersil C18. Separation was performed in 0.1 M triethylammonium acetate, using a linear gradient from 0% to 75% acetonitrile in 20 min. Yields >90% were obtained. To ensure low labeling degrees, the coupling to streptavidin was carried out in 50  $\mu$ L carbonate buffer (0.1 M, pH 8.3) using 20  $\mu$ L of the activated dye solution (0.1 mM in acetonitrile) and a 100-fold excess of streptavidin. Purification of the product was performed with NAP-columns (Sephadex G-25). Absorption measurements revealed an average label degree of <1.

**Spectroscopy.** Absorption spectra were taken on a Cary 500 UV-vis-NIR spectrometer (Varian, Darmstadt, Germany). Corrected fluorescence spectra were performed using a Cary Eclipse fluorescence spectrometer (Varian, Darmstadt, Germany). To avoid reabsorption and reemission effects, concentrations were kept strictly below 1  $\mu$ M (typically 0.1  $\mu$ M) in all measurements. Relative fluorescence quantum yields,  $\Phi_{f,rel}$ , of the fluorescently labeled constructs were measured with respect to the fluorescence intensity of the free dyes under otherwise similar conditions.

Ensemble fluorescence lifetime measurements were performed on a 5000MC spectrometer (IBH, Glasgow, U.K.) using the time-correlated single-photon counting (TCSPC) technique. As excitation sources served a pulsed laser diode emitting at 635 nm with a pulse length of  $\sim$ 200 ps (fwhm), or LEDs emitting at 495 or 590 nm with pulse lengths of  $\sim$ 1 ns (fwhm) at repetition rates of 1 MHz. With this setup, instrument response functions (IRFs) of 220 ps (fwhm) for the laser diode and  $\sim$ 1 ns for the LEDs (fwhm) were measured. The apparatus enables the measurement of fluorescence lifetimes down to 40 ps (for the pulsed laser diode), and  $\sim$ 200 ps (for the pulsed LED). Typically, 3000–5000 photon counts were collected in the maximum channel using 4096 channels. The decay parameters were determined by least-squares deconvolution, and their quality was judged by the reduced  $\chi^2$  values and the randomness of the weighted residuals. In the case that a monoexponential model was not adequate to describe the measured decay, a multiexponential model was used to fit the decay (eq 1),

$$I(t) = I(0) \sum a_i \tau_i \quad (1)$$

where  $a_i$  are the preexponential factors that describe the ratio of the excited species and  $\tau_i$  denote their lifetimes.

## RESULTS AND DISCUSSION

**Intermolecular Fluorescence Quenching of Dyes by Tryptophan.** To investigate intermolecular fluorescence quenching efficiencies, steady-state fluorescence experiments with tetramethylrhodamine (TMR), ATTO

**Table 1. Relative Fluorescence Quantum Yields,  $\Phi_{f,rel}$ , of Fluorescein, Bodipy-FL, TMR, ATTO 590, MR121, ATTO 655, ATTO 680, and Cy5 in Unbuffered Water in the Presence of 30 mM L-Tryptophan (Trp), L-Tyrosine (Tyr), L-Phenylalanine (Phe), L-Methionine (Met), and L-Histidine (His)<sup>a</sup>**

$\Phi_{f,rel}$	Trp	Tyr	Phe	Met	His
fluorescein	0.57 (0.89)	0.83 (0.96)	0.98	0.86	0.94
Bodipy-FL	0.48 (0.85)	0.70 (0.92)	0.95	0.81	0.93
TMR	0.43 (0.77)	0.66 (0.91)	0.89	0.92	0.88
ATTO 590	0.42 (0.80)	0.60 (0.88)	0.96	0.98	1.00
MR 121	0.17 (0.63)	0.82 (0.96)	0.95	0.98	0.98
ATTO 655	0.13 (0.54)	0.83 (0.97)	1.00	1.00	0.99
ATTO 680	0.16 (0.64)	0.91 (0.98)	1.00	1.00	1.00
Cy5	0.91 (0.97)	1.00	1.00	1.00	1.00

<sup>a</sup> Due to lower solubility of Tyr, measurements were performed with 6 mM. The values given (30 mM Tyr) were calculated assuming a linear dependence of fluorescence intensity from quencher concentration. Measured values for 6 mM Tyr are given in brackets. For better comparison, the values in brackets given for Trp quenching are measured from solutions containing 6 mM Trp.

590, Bodipy-FL, fluorescein, MR121, ATTO 655, ATTO 680, and Cy5 were performed with the most potent fluorescence quenchers among the natural amino acids, i.e., the amino acids methionine (Met) and histidine (His), as well as the aromatic amino acids tryptophan (Trp), tyrosine (Tyr), and phenylalanine (Phe). The results are summarized in Table 1. As expected (22–24), among the amino acids investigated, tryptophan exhibits the most pronounced fluorescence quenching. In addition, for the green/yellow-absorbing fluorophores Bodipy-FL, TMR, and ATTO 590, substantial quenching by tyrosine is observed. On the other hand, the quenching efficiency of tyrosine is much less pronounced for most of the red-absorbing fluorophores (MR 121, ATTO 655, and ATTO 680). All other amino acids show only small quenching efficiencies. To summarize, the red-absorbing oxazine derivative MR121 as well as the two ATTO dyes ATTO 655 and ATTO 680 are almost exclusively quenched by tryptophan. On the other hand, rhodamine, and boradiaz-indacene derivatives that absorb at shorter wavelengths, are also quenched substantially by tyrosine residues. The quenching of the carbocyanine dye Cy5 by amino acids is generally very low.

In the following intermolecular studies we restricted our investigations to fluorescence experiments with the most efficient quencher tryptophan. To interpret intermolecular quenching efficiencies of tryptophan, bimolecular quenching experiments with the fluorophores were performed in aqueous solution. Bimolecular static and dynamic quenching constants,  $k_{q,s}$ , and  $k_{q,dyn}$ , were determined from steady-state and time-resolved fluorescence quenching experiments using Stern–Volmer analysis (eqs 2 and 3),

$$F_0/F = 1 + K_s[Q] = 1 + k_{q,s}\tau_0[Q] \quad (2)$$

$$\tau_0/\tau = 1 + K_{dyn}[Q] = 1 + k_{q,dyn}\tau_0[Q] \quad (3)$$

where  $\tau_0$  and  $F_0$  are the fluorescence lifetime and intensity in the absence of a quencher,  $\tau$  and  $F$  are the fluorescence lifetime and intensity in the presence of the quencher  $Q$  with the concentration  $[Q]$ , and  $K_s$  and  $K_{dyn}$  denote the static and dynamic Stern–Volmer constant, respectively. All quenching experiments yielded identical results, within error, in phosphate-buffered saline (PBS) pH 7.4 and unbuffered H<sub>2</sub>O. The fluorescence decays of all fluorophores investigated remain almost monoexpo-

**Figure 2.** Static and dynamic bimolecular Stern–Volmer plots of the bora-diaza-indacene dye Bodipy-FL (A), the carbocyanine dye Cy5 (B), and the oxazine derivative MR121 (C) with Trp in PBS buffer, pH 7.4.

**Table 2.** Fluorescence Lifetimes,  $\tau_0$ , of  $10^{-7}$  M Solutions of Fluorescent Dyes in the Absence of Trp in PBS Buffer, pH 7.4<sup>a</sup>

	$\tau_0$ (ns)	$k_{q,dyn}$ ( $\times 10^9$ M <sup>-1</sup> s <sup>-1</sup> )	$K_{dyn}$ (M <sup>-1</sup> )	$K_{ass.}$ (M <sup>-1</sup> )
fluorescein	3.98	2.4	9.6	16.0
Bodipy-FL	5.80	4.0	23.0	12.0
RB	1.52	4.3	6.5	9.3
TMR	2.25	4.3	9.7	14.0
ATTO 590	3.96	4.0	16.0	15.0
Bodipy 630/650	4.23	3.3	14.0	7.7
MR121	1.81	4.0	7.3	96.0
ATTO 655	1.79	5.1	9.1	206.0
ATTO 680	1.71	4.5	7.7	144.0
Alexa 647	1.0	2.3	2.3	
Cy5	1.0	3.9	3.9	

<sup>a</sup> Fluorescence lifetimes were measured at the emission maxima ( $\chi^2 = 0.90$ –1.15). In addition, the dynamic Stern–Volmer and bimolecular dynamic quenching constants  $K_{dyn}$  and  $k_{q,dyn}$ , respectively, and the association constants,  $K_{ass.}$ , are given (3 $\sigma$ -error estimation: 10% for  $k_{q,s.}$  and  $k_{q,dyn}$ ).  $K_{ass.}$  was determined at Trp concentrations 0–10 mM.  $K_{q,dyn}$  was determined from the longer, quencher-dependent fluorescence lifetime.

nential independent of the Trp concentration. In some cases an additional shorter or longer fluorescence decay component appeared with an amplitude smaller than 0.05. Therefore, bimolecular dynamic quenching constants,  $k_{q,dyn}$ , were calculated from the quencher dependent fluorescence lifetime with an amplitude > 0.95 (Table 2). Figure 2a–c show three typical static and dynamic Stern–Volmer plots. Bodipy-FL (Figure 2a) shows a combination of dynamic and static quenching while Cy5 exhibits only weak dynamic quenching (Figure 2b). In the case of the oxazine derivative MR121, and the two dyes ATTO 655 and ATTO 680, the Stern–Volmer plots are dominated by strong static quenching (Figure 2c). In addition, Stern–Volmer plots obtained from steady-state measurements display upward curvatures for almost all dyes investigated. These deviations from linearity with increasing quencher concentration indicate the presence of at least two populations of fluorophores. The fact that (i) static quenching is much higher than expected for a diffusion-controlled bimolecular reaction and (ii) all dyes investigated show almost monoexponential fluorescence decays independent of the quencher concentration, strongly support the idea of the formation of weak or nonfluorescent ground-state complexes between the fluorophores and Trp in aqueous solutions. Dependent on the relative conformations and resulting interaction geometries, the complexes can be considered as essentially nonfluorescent. Then, the association constant,  $K_{ass.}$ , can be calculated via eq 4 by plotting  $(F_0/F)/(\tau_0/\tau)$  versus the quencher concentration (Figure 2a and 2c).

$$\frac{F_0}{F} = (1 + K_{dyn}[Q])(1 + K_{ass.}[Q]) \quad (4)$$

**Table 3.** Relative Fluorescence Quantum Yields,  $\Phi_{f,rel}$ , of Fluorescein, Bodipy-FL, and ATTO 655 Amino Acid Conjugates

$\Phi_{f,rel}$	Trp-dye	Tyr-dye	Phe-dye	Met-dye	His-dye
fluorescein	0.25	0.55	0.95	0.77	0.79
Bodipy-FL	0.02	0.15	0.91	0.30	0.70
ATTO 655	0.03	0.63	1.00	0.99	1.00

As can be seen in Table 2, bimolecular dynamic quenching constants,  $k_{q,dyn}$ , vary between  $2.0$  and  $5.0 \times 10^9$  M<sup>-1</sup> s<sup>-1</sup> for all dyes investigated. On the other hand, the bimolecular static quenching efficiencies calculated at low quencher concentrations (0–10 mM) differ significantly. Here, the red-absorbing dyes MR121, ATTO 655, and ATTO 680 exhibit the highest association constants,  $K_{ass.}$ , of 96–206 M<sup>-1</sup> with Trp. Fluorescence quenching is dominated by the formation of nonfluorescent ground-state complexes, i.e., static quenching. Quenching of ATTO 590, fluorescein, TMR, and RB by Trp comprises static and dynamic quenching with comparable efficiency while for the two bora-diaza-indacene dyes Bodipy-FL and Bodipy630/650, dynamic quenching is more efficient than static quenching (compare  $K_{dyn}$  and  $K_{ass.}$  in Table 2). Carbocyanine derivatives, such as Cy5 and Alexa 647, show solely dynamic quenching (Table 2).

**Intramolecular Fluorescence Quenching of Dyes by Tryptophan in Peptides and Proteins.** Table 3 shows the relative fluorescence quantum yields,  $\Phi_{f,rel}$ , measured for fluorescein, Bodipy-FL, and ATTO 655 coupled to the aliphatic amino group of the amino acids Trp, Tyr, Phe, Met, and His. As expected from intermolecular quenching experiments (Table 1), ATTO 655 is almost exclusively quenched when directly coupled to Trp. Besides the Trp-conjugate, only the Tyr-conjugate exhibits measurable fluorescence quenching. Comparison of the fluorescence quantum yield and fluorescence decay of the ATTO 655-labeled Trp conjugate (Figure 3a) demonstrates mainly static quenching. This supports the idea that fluorescence quenching is dominated by the formation of weak or nonfluorescent ground-state complexes that exhibit fluorescence lifetimes shorter than the time-resolution of our apparatus used to measure the time-resolved fluorescence decays (~40 ps). The short fluorescence lifetime of 230 ps with an amplitude of 0.16 measured for the ATTO 655-Trp conjugate (Table 4) cannot account for a relative fluorescence quantum yield,  $\Phi_{f,rel}$  of 0.03. The main part of the fluorescence decay is dominated by the nearly unquenched fluorescence lifetime of the free dye of ~1.8 ns with an amplitude of 0.84. Similar fluorescence characteristics were measured for the MR121 and ATTO 680 Trp-conjugate (Table 4).

The fluorescence quantum yields of the Bodipy-FL amino acid conjugates show the following sequence: Trp < Tyr < Met < His < Phe (Table 3).  $\Phi_{f,rel}$  for the Trp-conjugate is similar to the value measured for the ATTO 655 Trp-conjugate indicating strong quenching interactions. Furthermore, both Bodipy-FL and ATTO 655

**Figure 3.** Fluorescence decays of the free dyes (gray) and Trp conjugates (black) (A) ATTO 655, and (B) Bodipy-FL in PBS buffer, pH 7.4. In addition, the instrument response functions (IRFs) are given. Excitation was performed using a pulsed LED (490 nm) or a laser diode emitting (635 nm). Fluorescence was detected at the emission maxima (12.5 ps/channel).

exhibit similar bimolecular dynamic quenching constants,  $k_{q,dyn}$ , of  $\sim 4 \times 10^9 \text{ M}^{-1} \text{ s}^{-1}$  (Table 2). However, as ATTO 655 shows a high association constant ( $206 \text{ M}^{-1}$ ) promoting the formation of weak or nonfluorescent ground-state complexes, the tendency of Bodipy-FL to associate with Trp is less pronounced. That is, most of the ATTO 655 molecules are associated with the Trp residue in ground-state complexes whereas Bodipy-FL molecules are either still accessible for dynamic quenching or Bodipy-FL/Trp complexes exhibit a less optimal interaction geometry for efficient quenching. This is reflected in the fluorescence decay of the Bodipy-FL conjugate (Figure 3). The fluorescence decay can be fitted almost monoexponentially revealing a short fluorescence lifetime of 440 ps with an amplitude of 0.95 (Table 4).

As can be seen in Table 2, static and dynamic quenching efficiencies measured from intermolecular fluorescence quenching experiments with fluorescein and amino acids are similar. The corresponding fluorescein conjugates show only moderate fluorescence quenching with relative fluorescence quantum yields,  $\Phi_{f,rel}$ , ranging from 0.25 for the Trp-conjugate to 0.95 for the Phe-conjugate (Table 3). In the case of the Trp-conjugate, the measured fluorescence lifetimes of 1.10 ns and 1.85 ns with amplitudes of 0.20 and 0.80, respectively (Table 4), account almost for the observed decrease in fluorescence intensity.

To further evaluate the quenching interactions between organic dyes and Trp residues and, in particular, the distance dependence of quenching, the dyes were

**Figure 4.** Model for the formation of weak or nonfluorescent ground-state complexes between the oxazine derivative MR121 and the Trp residue in the peptide MR121-Lys-(Gly)<sub>3</sub>-Trp. Due to the flexibility of the glycine residues, the oxazine derivative MR121 (red) can adopt a nearly coplanar stacking conformation with respect to the Trp residue (blue).

coupled to the terminal lysine residue of the peptide: Lys-Gly-Gly-Gly-Trp. Because of the relatively flexible glycine residues intramolecular contact and complex formation between the dyes and the Trp residue is possible. Table 4 shows the relative fluorescence quantum yields and fluorescence lifetimes of the Trp and peptide conjugates of MR121, ATTO 655, ATTO 680, Bodipy-FL, fluorescein, and Cy5. For all dyes investigated, fluorescence quenching is diminished in the peptide conjugates. The low fluorescence quantum yields measured for MR121, ATTO 655, and ATTO 680 demonstrate again the formation of weak or nonfluorescent ground-state complexes between the dyes and the terminal Trp residue (Figure 4). The fluorescence lifetimes are slightly reduced and can be fitted satisfactorily using a monoexponential model. Only in the case of the MR 121 conjugate does a second shorter decay component of 500 ps with an amplitude of 0.07 appear. For the Bodipy-FL conjugate the quantum yield increases substantially from 0.02 for the Trp conjugate to 0.27 for the peptide conjugate (Table 4). In addition, the fluorescence lifetime increases from 440 ps to 2.52 ns. This indicates that static quenching within ground-state complexes plays only a minor role in these peptides. For fluorescein, the fluorescence quantum yield and lifetime increase while Cy5 is only slightly quenched in all conjugates investigated.

Assuming quenching electron transfer from the Trp residue to the dye, at least two mechanisms have to be considered (30): through-space and through-bond. Due to the flexibility of the peptide used in our studies, a clear answer cannot be given. However, our data indicate that contact formation between the Trp residue and the chromophore is required for efficient quenching. This implies that electron transfer through-bond is only of minor importance. Hence, the distinct dynamic quenching measured for dyes such as Bodipy-FL might reflect

collisions between the terminal Trp residue and the dye due to the flexibility of the peptide. That is, the fluorescence lifetime of Bodipy-FL-labeled peptides that contain a Trp residue might eventually be used to reveal contact formation rates in peptides (28, 31).

The results demonstrate that knowledge of the spectroscopic behavior of the dyes used to label peptides or proteins is crucial for the design of biological relevant applications. Because of the importance of the biotin-streptavidin techniques, dyes were covalently attached to streptavidin and the effect of biotin binding was investigated (Table 4). The strong binding of biotin to the 60 kDa protein streptavidin ( $K_D = 10^{-15}$  M) has become a standard tool in molecular biology (32, 33). Each hydrophobic binding pocket of streptavidin contains four tryptophan residues that are involved in strong biotin binding (22). With the exception of Cy5, the fluorescence of all streptavidin conjugates is substantially quenched (Table 4). While the increase in fluorescence quantum yield is less pronounced in the case of the fluorescein conjugate,  $\Phi_{f,rel}$  of the MR 121, ATTO 655, ATTO 680, and Bodipy-FL conjugate shows a dramatic increase upon addition of an excess biotin (Table 4). As in the case of the peptide and Trp conjugates, it is likely that the strong reduction in fluorescence intensity is caused by reversible quenching of the dye with tryptophan residues of streptavidin. The strong increase in fluorescence intensity of the MR121, ATTO 655, ATTO 680, and Bodipy-FL streptavidin conjugate upon binding to biotin is advantageous for biological applications where washing steps have to be avoided.

## CONCLUSIONS

The fluorescence quenching of various fluorescent dyes by amino acids, and in particular by tryptophan, is studied and compared using steady-state and time-resolved fluorescence spectroscopy. The red-absorbing oxazine derivative MR121 and the two ATTO dyes ATTO 655 and ATTO 680 are almost exclusively quenched by tryptophan while rhodamine and bora-diaza-indacene derivatives that absorb at shorter wavelengths are also quenched substantially by tyrosine residues. The quenching of the carbocyanine dye Cy5 by amino acids is generally very low. Fluorescence quenching of the red-absorbing dyes MR 121, ATTO 655, and ATTO 680 by tryptophan is dominated by the formation of nonfluorescent ground-state complexes, i.e., static quenching, with association constants,  $K_{ass.}$ , ranging from of 96–206 M<sup>-1</sup>. On the other hand, quenching of various rhodamine derivatives and fluorescein comprises static and dynamic quenching with comparable efficiency. For the two bora-diaza-indacene dyes Bodipy-FL and Bodipy630/650, dynamic quenching is more efficient than static quenching. Selective fluorescence quenching of dyes by tryptophan residues in proteins has great potential for the development of diagnostic applications (21, 27), and new methods for the direct measurement of submicrosecond intramolecular contact formation in biopolymers at the single molecule level (28). Furthermore, the data show that changes in the fluorescence quantum yield of dye-labeled peptides might be used in developing fluorescence-based assays, e.g., protease assays.

## ACKNOWLEDGMENT

The authors wish to thank Prof. K. H. Drexhage (Universität-Gesamthochschule Siegen) for providing the oxazine derivative MR121. This work was supported

by the Bundesministerium für Bildung, Wissenschaft, Forschung und Technologie (Grants 311864 and 13N8349).

# DNA Electrochemistry as a Probe of Base Pair Stacking in A-, B-, and Z-Form DNA

Elizabeth M. Boon and Jacqueline K. Barton\*

Division of Chemistry and Chemical Engineering, California Institute of Technology,  
Pasadena, California 91125. Received August 5, 2003; Revised Manuscript Received September 11, 2003

DNA-mediated charge transport (CT) chemistry is sensitive to DNA structure and base pair stacking. In an electrochemical assay based upon DNA CT, DNA-modified electrode surfaces are used to examine the electrochemical reduction of methylene blue (MB), a small molecule that binds to the DNA film by intercalation. Here electrochemically we probe CT in the three primary conformations of double-stranded nucleic acids, A-, B-, and Z-form DNA. The A-form is examined in the context of a DNA/RNA hybrid duplex and Z-DNA, in duplexes containing d(mCG)<sub>8</sub> sequences at high Mg<sup>2+</sup> concentrations. We find that both A- and B-DNA support efficient DNA CT as measured by MB reduction in the DNA film; a lower level of reduction is evident with the Z-form film. Furthermore, mismatches incorporated into A-form duplexes, as in B-form duplexes, disrupt MB reduction, thus providing a strategy for mutation detection through testing of RNA transcripts at DNA electrodes.

## INTRODUCTION

Charge transport (CT) through double helical DNA has been shown to be exquisitely sensitive to coupling within the base pair stack (1–11). Sequence-dependent DNA structure, including the presence of mismatches or base lesions, as well as conformational dynamics and local flexibility, all contribute to this coupling and thus to the efficiency of DNA CT chemistry. This sensitivity to base stacking provides the foundation for applications of DNA CT to probe nucleic acid structure, particularly those utilizing electrochemistry experiments on DNA films (12–20).

In DNA CT measurements by electrochemistry at DNA films, DNA oligonucleotide duplexes modified with a thiol linker are self-assembled on gold electrode surfaces (12–20). A redox-active intercalator, such as methylene blue (MB), is bound noncovalently to the close-packed DNA films. We have shown that noncovalent intercalators bind near the solution-accessible interface of these densely packed DNA-modified surfaces and that the ratio of intercalator to DNA oligonucleotide duplex is approximately 1:1, eliminating the need for covalent labeling (12, 16–20). The reduction of the intercalator at the top of the film through a DNA-mediated reaction serves as the probe for DNA base pair stacking within the film: if the stacking is intact, MB is efficiently reduced at the DNA-modified film; however, the presence of an intervening mismatch or other stacking perturbation results in an attenuation of MB reduction (15–19). The signal from MB can be amplified in an electrocatalytic cycle in which reduced MB is used as a catalyst for the reduction of a species diffusing in solution outside of the DNA film (usually ferricyanide) (16, 17, 19). Importantly, whether the direct or catalytic reduction of MB is monitored, reduction of MB has been shown to take place via CT through the DNA base stack (12, 20).

DNA-mediated CT electrochemistry therefore provides an exquisitely sensitive means to monitor nucleic acid

structure and stacking. Even small perturbations in base pair stacking, as is associated with some base lesions, diminish the efficiency of MB reduction (15–19). Using this technique, all single base mismatches within a DNA duplex have been detected as well as several common DNA base damage products (17). Furthermore, the electrochemical reduction of DNA intercalators bound to DNA-modified electrodes has been used to monitor DNA–protein interactions (18) as well as the hybridization of antisense oligonucleotides (19). Due to this sensitivity to very small changes in DNA base pair stacking, this electrochemical assay may be generally exploited in probing nucleic acid structure and stacking.

In that context, we examine here three primary conformations of double-stranded nucleic acids, A-, B-, and Z-form DNA (21, 22). RNA duplexes as well as dehydrated DNA duplexes adopt A-form helical structure. In addition, DNA/RNA hybrids adopt a helical structure that is very similar to A-form DNA (23–26). Within these hybrid duplexes in solution, the RNA strand generally maintains A-form characteristics, while the DNA strand adopts a sequence dependent structure intermediate between A- and B-form DNA. DNA/RNA hybrid duplexes are common *in vivo* as a product of reverse transcriptase activity (e.g. HIV reverse transcriptase), normal transcription of DNA into mRNA, as well as during DNA replication as an intermediate in lagging strand synthesis, and antisense therapy (27–30).

The third major nucleic acid duplex structure is Z-form DNA (21, 22, 31). Z-DNA is a left-handed helix, in contrast to right-handed A- and B-form helices. This structure is generally adopted by oligonucleotides that have sequences of alternating pyrimidines and purines (usually alternating dGdC) in the presence of high salt concentrations. Physiologically, Z-form DNA is thought to form *in vivo* during transcription as a result of torsional strain generated by a moving polymerase and it is suspected to play a role in gene regulation (32–38).

To demonstrate the utility of our DNA CT-based electrochemical assay in reporting on changes in DNA structure and  $\pi$ -stacking, here we demonstrate the

application of electrochemistry at DNA-modified electrode surfaces to probe stacking in DNA/RNA hybrids as well as Z-form DNA duplexes (Figure 1).

#### EXPERIMENTAL PROCEDURES

**Materials.** DNA oligonucleotides were synthesized on an ABI DNA Synthesizer using standard solid-phase techniques. Incorporation of 5-methyl-cytidine (5-Me-C) was accomplished using the respective phosphoramidite. All DNA synthesis reagents were obtained from Glen Research. Purified RNA single strands were purchased from Dharmacon Research, Inc., in the 2'-bis(acetoxy-ethoxy)methyl ether form and deprotected and desalted immediately prior to hybridization. Unless otherwise indicated, all reagents and solvents were purchased in their highest available purity and used without further purification.

**Preparation of DNA-Modified Surfaces.** Thiol-modified oligonucleotides were prepared as previously described (12–20). After stringent purification by HPLC (Hewlett-Packard HPLC using a reverse-phase C18 column and an acetonitrile/ 50 mM ammonium acetate gradient), the single strands were quantitated by UV–visible spectroscopy (Beckman) using the standard extinction coefficients for the nucleotides. For DNA and DNA/RNA hybrids of mixed sequence, these thiol-modified single strands were hybridized in a 1:1 molar ratio to purified unmodified complements. The 5'-(CG)<sub>8</sub>-3' duplexes were made by mixing the thiol strand in a 1:5 ratio with the unmodified strand so that statistically each duplex would have only one or no thiols to avoid dithiol duplexes in the self-assembly mixture. Duplex structure was characterized by CD spectroscopy (Aviv CD spectrometer).

The resultant duplexes were deposited on polycrystalline gold electrodes for 12–24 h (100  $\mu$ M duplex in 5 mM phosphate, 50 mM NaCl buffer, pH 7; 100 mM MgCl<sub>2</sub> is added to the duplexes after hybridization just prior to self-assembly). Unless otherwise noted, before electrochemical measurements, the electrodes were rinsed thoroughly with 5 mM phosphate, 50 mM NaCl buffer, pH 7. As electrodes containing a high surface coverage of DNA are most useful for our experiments, surfaces were routinely assayed for coverage by monitoring the attenuation of the oxidation of ferrocyanide (12).

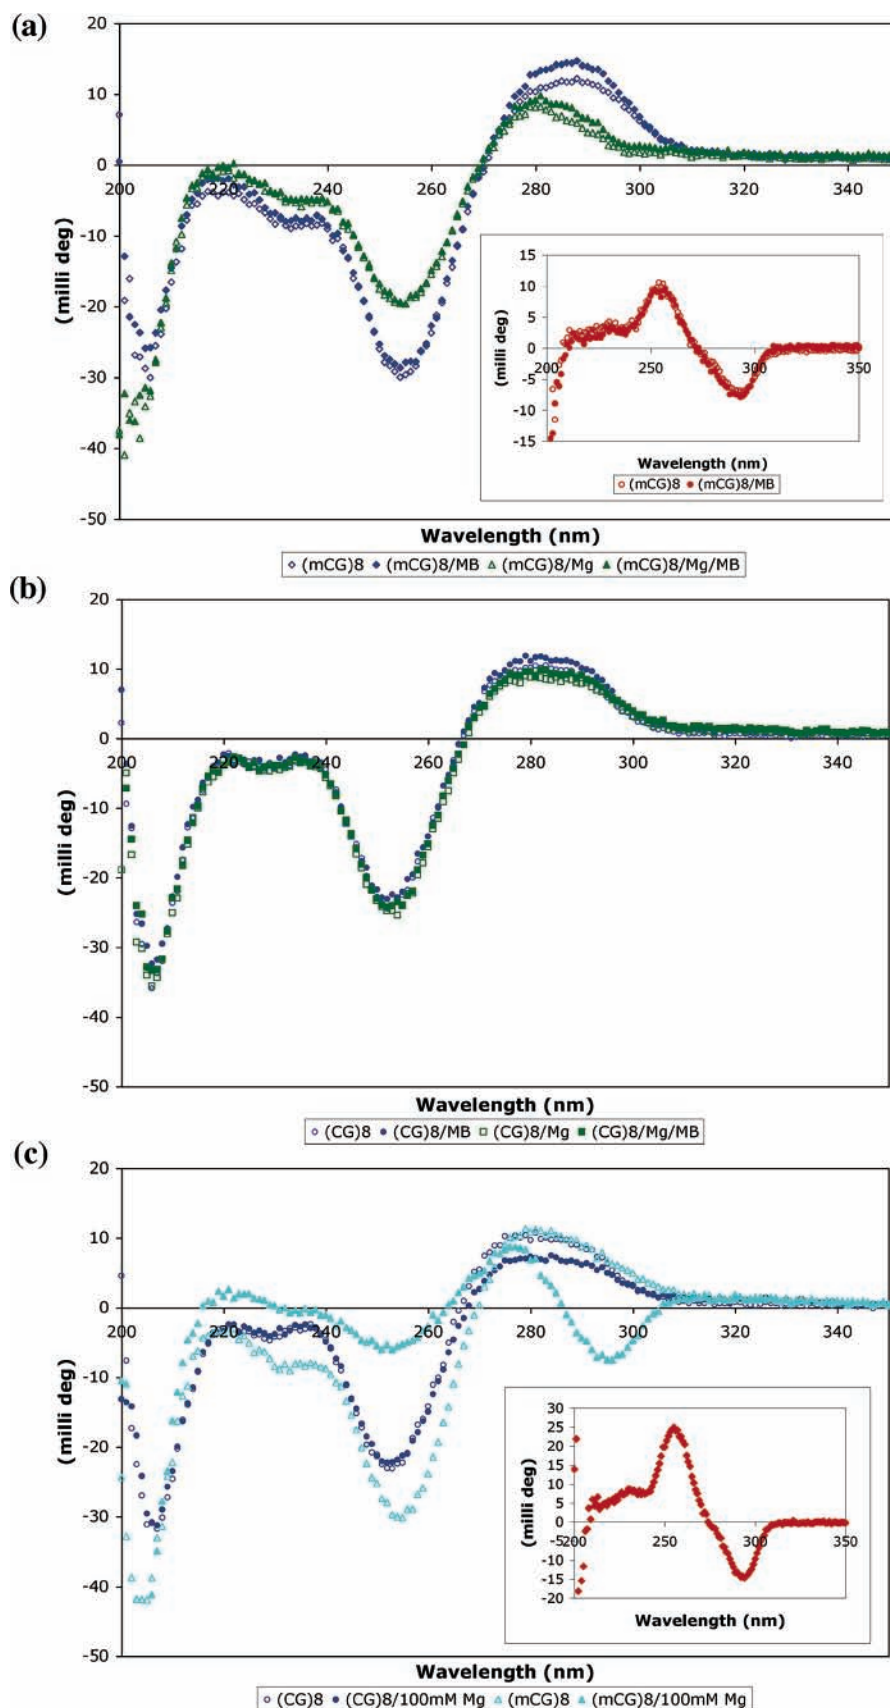

**Electrochemical Measurements.** Cyclic voltammetry and chronocoulometry was carried out on 0.02 cm<sup>2</sup> gold electrodes using a Bioanalytical Systems (BAS) Model CV-50W electrochemical analyzer. A normal three-

electrode configuration consisting of a modified gold-disk working electrode, a saturated calomel reference electrode (SCE, Fisher Scientific), and a platinum wire auxiliary electrode was used. A modified Luggin capillary separated the working compartment of the electrochemical cell from the reference compartment. Potentials are reported versus SCE. Volumes of 3 mL were typically employed. Unless specifically noted, all measurements were recorded at  $20 \pm 2$  °C in 5 mM sodium phosphate containing 50 mM NaCl, pH 7, that had been thoroughly degassed with Ar.

#### RESULTS

**Electrochemical Probe of Base Pair Stacking in Z-Form DNA Duplexes.** Duplexes with uninterrupted sequences of (CG)<sub>n</sub> usually form Z-DNA at very high ionic strength. MB binding to DNA is inhibited at high ionic strength; however, binding to DNA films is reduced by about 50% at 50 mM MgCl<sub>2</sub> (20, 40). Thus, to examine stacking in Z-form DNA, the duplexes 5'-(mCG)<sub>8</sub>-3' and 5'-(CG)<sub>8</sub>-3' were synthesized. Methylation of cytosine has been shown to stabilize Z-form structure at lower ionic strength than normally required to form Z-DNA within an alternating GC duplex (39). We hypothesized we could promote Z-form DNA in the methylated (5'-(mCG)<sub>8</sub>-3') but not wildtype (5'-(CG)<sub>8</sub>-3') duplex at low ionic strength (10 mM Mg<sup>2+</sup>), giving B- and Z-form DNA to compare by electrochemistry at DNA-modified surfaces.

CD and UV–vis experiments were thus carried out to monitor the conformations of 5'-(mCG)<sub>8</sub>-3' and 5'-(CG)<sub>8</sub>-3' at various ionic strengths. Each duplex (3  $\mu$ M) was incubated with either 10 or 100 mM Mg<sup>2+</sup> overnight in 5 mM Pi, pH 7. B- to Z-form structural transitions in the methylated duplex, but not the wildtype duplex, are very clearly seen in Z–B difference spectra using both 10 and 100 mM Mg<sup>2+</sup> (Figure 2). A maximum peak of about 25 millidegrees at 254 nm, a minimum of 15 millidegrees at 293 nm, and isochromism at 277 nm were observed in the difference spectra and are indicative of B- to Z-transition. Importantly, CD spectra taken after the addition of 3  $\mu$ M MB do not disrupt this structure. UV–visible spectroscopy was especially useful in examining MB binding to both 5'-(mCG)<sub>8</sub>-3' and 5'-(CG)<sub>8</sub>-3'. Hypochromism of the MB absorption band at 668 nm shows that MB stacks with the B- and Z-form duplexes in the presence of 10 mM Mg<sup>2+</sup> to similar extents, 6% for the methylated duplex, 10% for the un-methylated duplex. At 100 mM Mg<sup>2+</sup> there is very little MB binding to either duplex, as expected for such a high ionic strength (20, 40).

**Figure 2.** Circular dichromism of 5'-(CG)<sub>8</sub>-3' and 5'-(mCG)<sub>8</sub>-3' duplexes in the presence of MgCl<sub>2</sub> and MB. (a) CD of 5'-(mCG)<sub>8</sub>-3' (3  $\mu$ M duplex) in 5 mM phosphate, pH 7 buffer only (open blue), with 10 mM MgCl<sub>2</sub> (open green), with 3  $\mu$ M MB (closed blue), and with 10 mM MgCl<sub>2</sub> and 3  $\mu$ M MB (closed green). The inset shows the Z-B difference spectra (with MgCl<sub>2</sub> – no MgCl<sub>2</sub>) for this duplex with (closed red) and without (open red) MB. (b) CD of 5'-(CG)<sub>8</sub>-3' (3  $\mu$ M duplex) in 5 mM phosphate, pH 7 buffer only (open blue), with 10 mM MgCl<sub>2</sub> (open green), with 3  $\mu$ M MB (closed blue), and with 10 mM MgCl<sub>2</sub> and 3  $\mu$ M MB (closed green). (c) CD of 5'-(CG)<sub>8</sub>-3' (blue) and 5'-(mCG)<sub>8</sub>-3' (cyan) in 5 mM phosphate, pH 7 buffer only (open) and with 100 mM MgCl<sub>2</sub> (closed). The inset shows the Z-B difference spectrum (with MgCl<sub>2</sub> – no MgCl<sub>2</sub>) for 5'-(mCG)<sub>8</sub>-3'.

**Figure 3.** Cyclic voltammetry of  $2 \mu\text{M MB}^+$  at a gold electrodes modified with the thiol-terminated duplex  $\text{SH-5'-(CG)}_8\text{-3'}$  (black; B-form) or  $\text{SH-5'-(mCG)}_8\text{-3'}$  (red; Z-form) in 5 mM phosphate, 50 mM NaCl, 10 mM  $\text{MgCl}_2$  buffer, pH 7. Voltammograms were obtained with scan rate ( $\nu$ ) = 100 mV/s, electrode area ( $A$ ) =  $0.02 \text{ cm}^2$ .

The UV-vis and CD experiments clearly indicate that at 10 mM  $\text{MgCl}_2$ , a B- to Z-form transition takes place only in the methylated duplexes and that MB binds to both B- and Z-form DNA at this ionic strength (41, 42). The structural mode of binding to the Z-form is not clear, however. Nonetheless, these experiments provide us with a system to compare the effect of differing nucleic acid structure on the efficiency of MB reduction at a DNA film, as we are able to form both B- and Z-DNA at equivalent ionic strengths within alternating CG duplexes, and MB binds to both types of DNA film.

To determine the efficiency of charge transport in Z-form DNA, the DNA duplexes  $\text{SH-5'-(mCG)}_8\text{-3'}$  and  $\text{SH-5'-(CG)}_8\text{-3'}$  were both incubated with 100 mM  $\text{Mg}^{2+}$  overnight to promote the Z-form structure in the methylated duplexes (Figure 2c) followed by self-assembly on clean gold electrode surfaces for an additional 12 h, still in the presence of 100 mM  $\text{Mg}^{2+}$ . After assembly of the DNA, the electrodes were rinsed with 5 mM Pi, 50 mM NaCl, 10 mM  $\text{Mg}^{2+}$ , pH 7, and electrochemistry experiments with  $2 \mu\text{M MB}$  in 10 mM  $\text{Mg}^{2+}$ , 5 mM Pi, 50 mM NaCl, pH 7 buffer solution were carried out. The electrochemistry was carried out at lower  $\text{Mg}^{2+}$  concentrations due to reduced MB binding at high ionic strength (20, 40). In all cases, however, the electrochemistry was accomplished within minutes of reducing the ionic strength of the DNA films, thus there was not sufficient time for a Z- to B-conversion, considering the very slow nature of this structural transition, and that at 10 mM  $\text{Mg}^{2+}$ , Z-form DNA is favorable in the methylated duplexes (Figure 2a).

Figure 3 shows the cyclic voltammograms for MB reduction on B- and Z-form DNA films. It is evident that there is less MB reduction within the Z-form duplex ( $\text{SH-5'-(mCG)}_8\text{-3'}$ ) than within the B-form duplex ( $\text{SH-5'-(CG)}_8\text{-3'}$ ), despite evidence of MB binding to both duplexes. Nonetheless, some reduction is evident with both conformations. There is a decrease in the peak current as well as a positive shift in the potential of the MB electrochemical signal in this experiment as compared to analogous experiments conducted with B-form DNA without  $\text{Mg}^{2+}$  in the electrochemistry solution (see Figure 5 for example). We have previously studied the effect of ionic strength on the electrochemistry of MB at DNA-modified electrodes (20) and this is the expected conse-

**Figure 4.** Cyclic voltammetry of  $2 \mu\text{M MB}^+$  at a gold electrodes modified with the thiol-terminated duplex  $\text{SH-5'-(mCG)}_8\text{-3'}$  in 5 mM phosphate, 50 mM NaCl, 10 mM  $\text{MgCl}_2$  buffer, pH 7 (red; Z-form) and after incubation in 5 mM phosphate, 50 mM NaCl (no  $\text{MgCl}_2$ ) buffer, pH 7 overnight (black; converted to B-form). Voltammograms were obtained with scan rate ( $\nu$ ) = 100 mV/s, electrode area ( $A$ ) =  $0.02 \text{ cm}^2$ .

**Figure 5.** Cyclic voltammetry of  $2 \mu\text{M MB}^+$  at a gold electrode modified with the thiol-terminated sequence  $\text{SH-5'-AGTA-CAGTCATCGCG}$  hybridized to a fully base paired DNA (black; B-form) and RNA (blue; A-form) complements in 5 mM phosphate, 50 mM NaCl buffer, pH 7. Voltammograms were obtained with scan rate ( $\nu$ ) = 100 mV/s, electrode area ( $A$ ) =  $0.02 \text{ cm}^2$ .

quence of 10 mM  $\text{Mg}^{2+}$ . It should be noted that the asymmetrical MB signal observed with both B- and Z-form (and A-form, see Figure 5) DNA is typical for MB electrochemistry at gold electrode surfaces. This is attributed to the lower DNA binding affinity of MB in its reduced form (20).

A critical experimental observation is that when the same Z-form DNA electrode is rinsed and incubated overnight in 5 mM Pi, 50 mM NaCl, pH 7 buffer (no  $\text{Mg}^{2+}$ ), the electrochemical behavior is similar to the B-form DNA films (Figure 4), indicating that a Z- to B-form structural transition has taken place on the electrode surface. Importantly, this experiment suggests that the initial attenuation of MB reduction is due to the Z-form helical structure.

Therefore we can conclude that at an electrode surface under conditions where Z-form DNA is formed and MB can bind, reduction of MB mediated by the Z-form structure is attenuated. Whether this occurs primarily owing to poor coupling of MB within the Z-form structure

or poor coupling within the Z-form DNA stack itself cannot be established. Intercalation into Z-form DNA has been studied with several intercalators, but not MB (41). More commonly, binding of the intercalator promotes a transition to the B-form (42). Given that an overnight incubation of the Z-form-modified electrode at low ionic strengths is required for return of the B-form signal, MB clearly does not cause this structural transition within the film; possibly this is due to the smaller size and weaker binding of MB compared, for example, to daunomycin (16), an intercalator that does promote a Z- to B-structural transition. It should be noted that intercalation into Z-form DNA has also been reported to support a polarized intercalation site (43).

**Electrochemical Probe of Base Pair Stacking In DNA/RNA Hybrid Duplexes.** To compare the stacking of DNA/RNA hybrid duplexes (A-form) to DNA duplexes (B-form), gold electrode surfaces were modified with SH-5'-AGTACAGTCATCGCG-3' hybridized to either a DNA or RNA single stranded complementary oligonucleotide. Following rinsing with 5 mM phosphate, 50 mM NaCl, pH 7 buffer, these nucleic acids films were incubated with 2  $\mu$ M MB in the same buffer and investigated by cyclic voltammetry. Intercalation of MB within A-DNA or DNA/RNA hybrids has not been systematically studied, but intercalators, such as ethidium (42, 45, 46), daunomycin (42), and anthraquinone (47), have been shown to bind to DNA/RNA hybrids. The electrochemical data presented here provide additional evidence that MB binds to the DNA/RNA hybrids used in these studies. Figure 5 illustrates that both surfaces facilitate efficient reduction of MB, comparable to that seen for the reduction of MB at DNA films (17). This result therefore suggests that the base pair stacking in the DNA/RNA hybrid A-form (44) supports DNA CT.

**Mutation Detection in DNA/RNA Hybrid Duplexes.** Because efficient MB reduction is observed in A-form DNA/RNA hybrids, indicating the base pair stacking supports DNA CT, the effect of base stacking perturbations on this alternate duplex structure was examined. We incorporated all possible single base mismatches into DNA/RNA hybrid duplexes formed using SH-5'-AGTACAGTCATCGCG-3' (the surface-bound strand was DNA and the complements were RNA). As electrocatalysis has been shown to increase sensitivity to minor changes in base pair stacking, particularly when followed by chronocoulometry (see especially ref 17), we used electrocatalytic reduction of ferricyanide ( $\text{Fe}(\text{CN})_6^{3-}$ ) by MB to evaluate mismatch detection in DNA/RNA hybrids (16, 17, 19). Due to poor DNA CT in Z-form DNA, we did not further investigate the effect of mismatches within this type of helix.

In separate experiments, electrode surfaces modified with DNA/RNA hybrid duplexes incorporating all possible single base mismatches (Table 1) were interrogated in electrocatalytic chronocoulometric analyses, monitoring charge accumulation at  $-350$  mV (vs SCE), the reduction potential of MB, with  $0.5$   $\mu$ M methylene blue (MB) as the intercalated catalyst and  $2.0$  mM  $\text{Fe}(\text{CN})_6^{3-}$  as the solution-borne substrate. Incorporation of a mismatch into the duplex significantly attenuates the electrocatalytic response of methylene blue at these DNA/RNA hybrid films (Figure 6); all possible mutations were easily detected. In fact, sensitivity to mutations was almost identical to our previously published DNA/DNA results (17). Mismatch detection in this system is amplified due to the catalytic nature of the detection system. In this assay, fewer MB molecules are reduced at the mismatched DNA electrode due to reduced efficiency of

<sup>a</sup> Integrated charge after 5 s of electrocatalysis at  $-350$  mV. Values are based on more than five trials each, and results are comparable for experiments run side by side or from different sample preparation. <sup>b</sup> SH-5' stands for  $\text{SH}(\text{CH}_2)_2\text{CONH}(\text{CH}_2)_6\text{NHCO}$  attached to the 5' OH of the DNA single strand.

**Figure 6.** Chronocoulometry at  $-350$  mV of  $2.0$  mM  $\text{Fe}(\text{CN})_6^{3-}$  plus  $0.5$   $\mu$ M MB<sup>+</sup> at a gold electrode modified with the thiol-terminated sequence SH-5'-AGTACAGTCATCGCG hybridized to a fully base paired RNA complement (Ta) and complements that introduce single base mismatches into the DNA/RNA hybrid. Red lines are purine-purine mismatches, blue are pyrimidine-purine mismatches, and green are pyrimidine-pyrimidine mismatches.

the DNA-mediated CT reaction: the steady-state concentration of active catalyst is lower, and a diminished overall catalytic rate results (48). Improved signal differentiation is achieved with increasing sampling time, a result that reflects the catalytic nature of this assay. The error analysis for each mismatch is presented in Table 1.

## DISCUSSION

**MB Reduction at DNA-Modified Surfaces is a Sensitive Assay of DNA Structure and Base Pair Stacking.** In the experiments reported here, efficient

DNA-mediated CT, as measured by MB reduction at DNA-modified electrodes, was observed in A- and B-form DNA, but not appreciably in Z-form DNA. These results are consistent with previous reports of CT in DNA/RNA hybrid duplexes as well as part ribose, part deoxyribose chimeric duplexes (45, 47, 49). It was determined that these mixed A-form/B-form nucleic acids do facilitate long range DNA-mediated CT chemistry as measured by guanine oxidation, fluorescence quenching, and transient absorption spectroscopy. In addition, we have previously found efficient reduction of MB bound to DNA/RNA hybrid antisense duplexes on gold electrodes (19).

In our previous experiments at DNA-modified electrodes, we have shown the reduction of bound intercalators to be a direct measurement of the integrity of DNA base pair stacking (15–19). Thus, these results suggest that DNA/RNA hybrids are well stacked. This is fully consistent with what is known about the structure and stacking of this type of nucleic acid duplex. Although the overall structure of DNA and DNA/RNA hybrids are significantly different (21–26), both types of nucleic acid duplexes appear to be well stacked as estimated by base overlap for DNA and DNA/RNA dinucleotides (45). Furthermore, experimental and theoretical determinations of stacking energies have also indicated that both types of duplexes display similar extents of stacking between adjacent base pairs (50–55). The structural dynamics of DNA/RNA hybrid duplexes has been studied by NMR (56–58) and found to be different than of DNA duplexes; for example, the base pair lifetime of an r(A–U) base pair in an RNA duplex is significantly shorter than the d(A–T) base pair lifetime in a DNA duplex, a consequence of A-form structure, not substitution of U for T (56). This suggests there is increased dynamics in A-form DNA over that in B-form DNA. In line with increased dynamics in A-form duplexes, DNA CT studies have shown that increased dynamics and flexibility aids, rather than hinders, DNA CT (7, 49, 59). Thus both A- and B-form duplexes are well stacked, but there is increased flexibility and dynamics in A-form DNA and this increased dynamical motion helps facilitate DNA CT.

Less efficient, but not completely attenuated, charge transport chemistry was observed with Z-form DNA at gold surfaces. This is understood based on the differences in base stacking in this nucleic acid structure. Z-DNA differs structurally and dynamically from B-form (21, 22, 31). Due to the alternating syn–anti sugar puckers present in Z-form DNA, there is some *inter*-strand stacking, but not *intra*-strand stacking as in A- and B-form DNA. The distance between base pairs is farther, 3.8 Å, as compared to 3.4 Å seen in A- and B-form DNA, which probably contributes reduced electronic coupling between base pairs. Significantly, the base-pair opening rate of Z-DNA, as measured by proton exchange, is much slower than it is in B-form DNA (60). Additionally, EPR and thermal measurement suggest that Z-DNA is a more rigid structure than B-DNA (61–63). Consistent with the hypothesis that some flexibility and dynamical motion helps DNA CT, it is expected that the converse would also be true, and, indeed, we do not observe efficient CT in our electrochemical system with Z-DNA.

It is additionally possible that less MB reduction is observed in the Z-form films because MB does not intercalate within Z-form DNA, and thus the signal observed in these experiments is due exclusively to intercalation into a B-form duplex. Although we cannot rigorously eliminate this possibility, the hypochromism observed in the MB absorption band upon addition of Z-form DNA in solution is consistent with some level of

DNA binding. Our data furthermore are not consistent with MB inducing a Z- to B-form structural transition (41, 42). Instead these data indicate that poor stacking within the Z-form film and/or between MB and the Z-form helix limits CT. It should be noted that long-range DNA CT as measured by guanine oxidation has been observed in a hairpin Z-form DNA structure (64). These data were explained in terms of hole hopping by the guanine radical cation to effect damage at long range. In the experiments here on DNA films, we monitor a reduction of the bound intercalator and on a much slower time scale. These differences may be important in distinguishing between these experiments.

**Mismatch Biosensors Based on Charge Transport through DNA/RNA Hybrids.** We have been interested in developing sensors based on DNA CT to efficiently detect mismatches within nucleic acid duplexes for clinical applications (15–17). As efficient reduction of MB bound to DNA/RNA hybrid duplexes was observed (Figure 5) and found to be sensitive to mismatches (Figure 6), these hybrid duplexes are candidates for DNA CT applications. Furthermore, due to the presence of DNA/RNA hybrids as a part of cellular biochemistry, as well as, in general, higher copy numbers of mRNA than genomic DNA within the cell, in assays for interrogating cellular samples, it may be preferable to test mRNA transcripts rather than genomic DNA. In this scenario, patient mRNA would be hybridized to a chip or electrode modified with single stranded DNA, resulting in DNA/RNA hybrids. With the high sensitivity of mismatch detection we have demonstrated in electrochemical detection based on DNA CT and the possibility of a high copy number of mRNA within the cell, it may be possible to screen for mutations without the use of amplifying techniques such as PCR.

Mismatches are generally stacked in a DNA duplex but undergo greater dynamical motion than well paired bases (65–67). Thus it seems that *some* added DNA dynamics and flexibility is helpful for DNA-mediated CT, but too much motion, leading to destacking, can severely hamper the charge transport reaction. Base pair lifetime measurements within B-form DNA have indicated that mismatches do significantly decrease the base pair lifetime locally at the mismatched site (8). Presumably, mismatches within A-form DNA also provide too much flexibility and motion for efficient charge transport chemistry. Within A-form RNA duplexes, mismatches, especially GA mismatches, are common, but the mismatches are not well stacked, and thus our electrochemical detection assay is well-suited to detection of mismatches in A- as well as B-form DNA.

DNA CT is now a well studied phenomenon. Many different experiments have shown that efficient CT reactions can take place in well stacked DNA duplexes, causing many researchers to search for physiological consequences of this DNA-mediated reaction. Given the presence of A-, B-, and Z-form DNA *in vivo*, and their differing abilities to sustain CT reactions, this might raise new possibilities for CT *in vivo* as well as in practical clinical applications.

#### ACKNOWLEDGMENT

We are grateful to the National Institutes of Health (GM61077) for their financial support of this research and to Melanie O'Neill for assistance with DNA figures.

# Multivalent Conjugates of Poly- $\gamma$ -D-glutamic Acid from *Bacillus licheniformis* with Antibody F(ab') and Glycopeptide Ligands

Emmanuel J. F. Prodhomme,<sup>†</sup> Alison L. Tutt,<sup>‡</sup> Martin J. Glennie,<sup>‡</sup> and Timothy D. H. Bugg<sup>\*,†</sup>

Department of Chemistry, University of Warwick, Coventry CV4 7AL, U.K., and Tenovus Research Laboratory, General Hospital, Tremona Road, Southampton SO16 6YD, U.K.. Received February 22, 2002;

Revised Manuscript Received August 28, 2003

Poly- $\gamma$ -D-glutamic acid from *Bacillus licheniformis* is a water-soluble, nontoxic, nonimmunogenic exopolymer. Using synthetic linkers, the  $\alpha$ -carboxylate side chains of PGA were conjugated to an exposed thiol side chain of an antibody F(ab') fragment, Mc109F4. Analysis of the PGA–Mc109F4 conjugate by gel filtration HPLC revealed a mixture of multivalent conjugates. The PGA–Mc109F4 conjugate retained biological activity, but showed a lower binding affinity to target BCL3B3 cells than free Mc109F4 F(ab')<sub>2</sub> by flow cytometry, and a lower efficacy for BCL3B3 growth inhibition than free Mc109F4 F(ab')<sub>2</sub>. PGA was also conjugated with the free amino group of glycopeptide antibiotic vancomycin. The PGA–vancomycin conjugate showed slightly lower antibacterial activity than free vancomycin versus susceptible *Bacillus subtilis*, but slightly higher activity versus intrinsically resistant *Leuconostoc mesenteroides*.

## INTRODUCTION

Microorganisms which can survive in the human body commonly utilize nonimmunogenic cell surface exopolymers to evade the human immune system. These biopolymers are therefore attractive reagents for the formation of conjugates which could operate successfully in the human body. One such exopolymer is poly- $\gamma$ -D-glutamic acid (Figure 1), a  $\gamma$ -linked polypeptide of D-glutamic acid of molecular mass 100–300 kDa, found in several strains of *Bacillus* (1), including soil bacterium *Bacillus licheniformis* (1, 2), and the human pathogen *Bacillus anthracis* (1, 3). We have previously shown that  $\gamma$ -PGA from *Bacillus licheniformis* can be covalently modified in aqueous solution with amines bearing a UV chromophore (4), giving a modified polymer of reduced molecular weight (10–15 kDa). Early literature reports of PGA conjugates (5, 6) suggested that this biopolymer would be a useful template for functionalization with bioactive molecules. In this paper we describe methods for conjugation of PGA with an antibody F(ab'), and with a glycopeptide antibiotic.

Targeting of cytotoxic drugs via comodification of the drug to a water-soluble polymer with a cell-specific antibody is an attractive approach for anticancer chemotherapy (7). Tumor-specific antibody F(ab') fragments have been successfully conjugated to *N*-(2-hydroxypropyl)methacrylamide (HPMA) with cytotoxic agents adriamycin (8) or doxorubicin (9) to give cytotoxic conjugates. Methods have also been developed for the attachment of antibody F(ab') fragments, via a reactive thiol group, to poly- $\alpha$ -lysine (10, 11), poly[2-(dimethylamino)ethyl methacrylate] (12), and poly(ethylene oxide)-poly(propylene oxide) triblock copolymers (13). In this study, we used the F(ab') fragment of antibody Mc109G4, a monoclonal

**Figure 1.** Structure of poly- $\gamma$ -D-glutamic acid.

rat IgG2a antibody (mAb) with activity against idiotype determinants carried by the IgM molecule of the BCL<sub>1</sub> lymphoma (14).

The glycopeptide antibiotic vancomycin exerts its antibacterial effects via complexation of the peptidyl-D-Ala-D-Ala termini of peptidoglycan on the surface of Gram-positive bacterial cell walls (15). Recent studies by Williams et al. have demonstrated that members of the vancomycin group of glycopeptide antibiotics form dimers, and that the dimerization is cooperative with ligand binding (15, 16). Thus, multivalent derivatives of vancomycin which are able to bind the target ligands cooperatively might have enhanced affinity for bacterial peptidoglycan, particularly for vancomycin-resistant strains containing peptidyl-D-Ala-D-Lac termini, for which vancomycin shows low affinity (15). Synthetic dimers (17) and trimers (18, 19) of vancomycin have been reported to show enhanced binding of L-Lys-D-Ala-D-Ala and enhanced antibacterial activity against vancomycin-resistant strains. Polymers derived from a vancomycin-containing monomer have also been reported to show enhanced antibacterial activity (20, 21). We therefore also investigated the effects of conjugating vancomycin to  $\gamma$ -PGA.

## EXPERIMENTAL SECTION

**General.** Poly- $\gamma$ -D-glutamic acid was prepared from *Bacillus licheniformis* ATCC 9945a by the method of Troy (2) and was stored as a powder at 4 °C. *N*-butoxycarbonyl-1,2-diamine was prepared by the method of Krapcho and Kuell (22). Chemicals and biochemicals were purchased from Sigma-Aldrich.

*N*-Butoxycarbonyl-[2,2'-(ethylenedioxy)bis-ethylamine] was prepared by a modification of the method of Krapcho and Kuell (22). A solution of di-*tert*-butyl dicarbonate (2.18 g, 10 mmol) in dioxane (30 mL) was added

<sup>†</sup> Abbreviations used: PGA, poly- $\gamma$ -D-glutamic acid; FITC, fluorescein isothiocyanate; EDC, *N*-ethyl-*N*-(3-dimethylaminopropyl)carbodiimide hydrochloride.

to 2,2'-(ethylenedioxy)bis-ethylamine (7.3 mL, 5 equiv) in dioxane (30 mL) over 2.5 h. The reaction mixture was stirred at room temperature for 22 h. Solvent was then removed under reduced pressure. Water (50 mL) was added to the residue, and the insoluble bis-substituted product removed by filtration. The filtrate was extracted with dichloromethane (3  $\times$  50 mL), the extracts were combined and dried (MgSO<sub>4</sub>), and the solvent was evaporated at reduced pressure to give the product as a clear oil (2.2 g, 63%).  $R_f$  0.10 (9:1 CH<sub>2</sub>Cl<sub>2</sub>/EtOH);  $\delta_H$  (300 MHz, CDCl<sub>3</sub>) 5.65 (1H, br s, NH), 3.55 (4H, s, OCH<sub>2</sub>-CH<sub>2</sub>O), 3.45 (4H, m, NHCH<sub>2</sub>CH<sub>2</sub>O), 3.25 (2H, m, BocNHCH<sub>2</sub>-CH<sub>2</sub>O), 2.80 (2H, t,  $J$  = 7 Hz, H<sub>2</sub>NCH<sub>2</sub>CH<sub>2</sub>O), 1.40 (9H, s, tBu) ppm;  $\delta_C$  (75 MHz, CDCl<sub>3</sub>) 156.0, 78.7, 73.3, 70.1, 66.9, 41.6, 40.2, 28.3 ppm.

**Preparation of *N*-Carboxyalkylmaleimides 1a,b.** A solution of maleic anhydride (2.94 g, 30 mmol) in acetic acid (100 mL) was added to a solution of 6-aminocaproic acid (3.94 g, 30 mmol) in acetic acid (100 mL). The reaction was stirred for 3 h at room temperature, yielding a white precipitate, which was filtered, yielding *N*-maleamyl-6-aminocaproic acid (4.6 g, 67%).  $R_f$  0.25 (9:1 CH<sub>2</sub>Cl<sub>2</sub>/EtOH); mp 159–161 °C;  $\delta_H$  (300 MHz, *d*<sub>6</sub>-DMSO) 9.15 (1H, br, COOH), 6.40 (1H, d,  $J$  = 11 Hz, CH=C), 6.25 (1H, d,  $J$  = 11 Hz, CH=C), 3.15 (2H, q,  $J$  = 6 Hz, NCH<sub>2</sub>), 2.20 (2H, t,  $J$  = 7 Hz, CH<sub>2</sub>COOH), 1.45 (4H, m), 1.30 (2H, m) ppm;  $\delta_C$  (75 MHz, *d*<sub>6</sub>-DMSO) 174.5, 165.5, 165.4, 133.1, 131.8, 40.4, 33.6, 28.2, 26.0, 24.2 ppm;  $m/z$  (ES<sup>+</sup>) 230.1 (MH<sup>+</sup>, 60%).

*N*-Maleamyl-6-aminocaproic acid (0.92 g, 4.0 mmol) was dissolved in dry toluene (100 mL), to which was added triethylamine (1.1 mL, 8.0 mmol). The reaction was refluxed for 1 h in a Dean–Stark apparatus, with removal of water. The toluene solution was decanted and evaporated under reduced pressure to give a solid, which was dissolved in water (20 mL), acidified (HCl) to pH 2.0. The product was extracted with ethyl acetate (2  $\times$  20 mL), washed with sat. sodium chloride solution (5 mL), dried (MgSO<sub>4</sub>), and evaporated at reduced pressure to give *N*-carboxypentylmaleimide **1b** as a white solid (0.42 g, 50%).  $R_f$  0.72 (9:1 CH<sub>2</sub>Cl<sub>2</sub>/EtOH); mp 79–80 °C; UV/vis  $\lambda_{max}$  319 nm;  $\delta_H$  (300 MHz, *d*<sub>6</sub>-acetone) 10.1 (1H, br, COOH), 6.70 (2H, s, CH=C), 3.30 (2H, t,  $J$  = 6 Hz, NCH<sub>2</sub>), 2.15 (2H, t,  $J$  = 7 Hz, CH<sub>2</sub>COOH), 1.45 (4H, qui,  $J$  = 7 Hz), 1.20 (2H, qui,  $J$  = 7 Hz) ppm;  $\delta_C$  (75 MHz, *d*<sub>6</sub>-acetone) 206.0, 174.3, 134.9, 37.7, 33.7, 28.7, 26.6, 24.9 ppm.

The same procedure was used to prepare *N*-carboxymethylmaleimide **1a** from glycine, in 46% overall yield.  $R_f$  0.35 (9:1 CH<sub>2</sub>Cl<sub>2</sub>/EtOH); mp 113–114 °C; UV/vis  $\lambda_{max}$  318 nm;  $\delta_H$  (300 MHz, *d*<sub>6</sub>-acetone) 6.35 (2H, s, CH=C), 4.15 (2H, s, CH<sub>2</sub>) ppm;  $\delta_C$  (75 MHz, *d*<sub>6</sub>-acetone) 206.0, 168.8, 135.4, 38.6 ppm.

**Preparation of *N*-Boc-ethylenediaminylcarboxyalkylmaleimides 2a,b.** Isobutyl chloroformate (129  $\mu$ L, 1.0 mmol) was added to a solution of *N*-carboxypentylmaleimide (0.21 g, 1.0 mmol) and triethylamine (0.2 mL) in THF (10 mL) at 0 °C, and the reaction was stirred for 15 min at room temperature. A solution of *N*-butoxycarbonylethylenediamine (0.16 g, 1.0 mmol) and triethylamine (0.2 mL) in THF (10 mL) was then added, and the reaction was stirred for 16 h at room temperature. The solution was filtered and solvent evaporated under reduced pressure. The resulting oil was triturated with diethyl ether to give *N*-butoxycarbonyl-*N*-6-(*N*-maleimyl)-aminoethanylethylenediamine **2b** as a pale yellow gum (0.165 g, 45%).  $R_f$  0.70 (9:1 CH<sub>2</sub>Cl<sub>2</sub>/EtOH);  $\delta_H$  (300 MHz, CDCl<sub>3</sub>) 6.60 (2H, s, CH=C), 6.15 (1H, br s, NH), 4.90 (1H, br s, NH), 3.45 (2H, t,  $J$  = 6 Hz, NCH<sub>2</sub>), 3.2–3.3

(4H, m, NHCH<sub>2</sub>CH<sub>2</sub>NH), 2.10 (2H, t,  $J$  = 7 Hz, CH<sub>2</sub>CO), 1.55 (4H, qui,  $J$  = 7 Hz), 1.35 (9H, s, tBu), 1.25 (2H, qui,  $J$  = 7 Hz) ppm;  $\delta_C$  (75 MHz, CDCl<sub>3</sub>) 174.0, 171.0, 159.7, 134.2, 80.2, 40.9, 40.4, 37.8, 36.6, 28.5, 28.4, 26.5, 25.2 ppm;  $m/z$  (ES<sup>+</sup>) 354.3 (MH<sup>+</sup>, 100%).

The same procedure was used to prepare *N*-butoxycarbonyl-*N*-6-(*N*-maleimyl)aminoethanylethylenediamine **2a** from *N*-carboxymethylmaleimide (**1a**) and *N*-butoxycarbonylethylenediamine, in 51% yield. Mp 133–135 °C;  $\delta_H$  (300 MHz, CDCl<sub>3</sub>) 7.0 (1H, br s, NH), 6.70 (2H, s, CH=C), 5.05 (1H, br s, NH), 4.10 (2H, s, NCH<sub>2</sub>), 3.2–3.3 (4H, m, NHCH<sub>2</sub>CH<sub>2</sub>NH), 1.35 (9H, s, tBu) ppm;  $\delta_C$  (75 MHz, CDCl<sub>3</sub>) 170.0, 167.0, 158.0, 134.2, 80.0, 41.7, 40.9, 40.4, 28.5 ppm;  $m/z$  (ES<sup>+</sup>) 298.2 (MH<sup>+</sup>, 100%).

**Preparation of Boc-protected Maleimides 3a,b.** Isobutyl chloroformate (129  $\mu$ L, 1.0 mmol) was added to a solution of *N*-carboxypentylmaleimide (0.21 g, 1.0 mmol) and triethylamine (0.2 mL) in THF (10 mL) at 0 °C, and the reaction was stirred for 15 min at room temperature. A solution of *N*-butoxycarbonyl-[2,2'-(ethylenedioxy)bis-ethylamine] (0.248 g, 1.0 mmol) and triethylamine (0.2 mL) in THF (10 mL) was then added, and the reaction was stirred for 16 h at room temperature. The solution was filtered and solvent evaporated under reduced pressure. The resulting oil was triturated with diethyl ether to give maleimide **3b** as a pale yellow gum (0.176 g, 40%).  $R_f$  0.75 (9:1 CH<sub>2</sub>Cl<sub>2</sub>/EtOH);  $\delta_H$  (300 MHz, CDCl<sub>3</sub>) 6.60 (2H, s, CH=C), 6.15 (1H, br s, NH), 5.65 (1H, br s, NH), 3.55 (4H, s, OCH<sub>2</sub>CH<sub>2</sub>O), 3.50 (2H, t,  $J$  = 6 Hz), 3.40 (4H, m), 3.25 (2H, m), 2.85 (2H, t,  $J$  = 7 Hz, BocNHCH<sub>2</sub>-), 2.1 (2H, t,  $J$  = 7 Hz, CH<sub>2</sub>CO), 1.55 (4H, m), 1.40 (9H, s, tBu), 1.30 (2H, m) ppm;  $\delta_C$  (75 MHz, CDCl<sub>3</sub>) 173.8, 171.2, 157.0, 134.4, 78.7, 73.1, 70.3, 67.2, 41.9, 39.9, 37.7, 36.4, 28.4, 28.2, 26.3, 24.9 ppm;  $m/z$  (ES<sup>+</sup>) 442.3 (MH<sup>+</sup>, 45%).

The same method was used to prepare *N*-Boc maleimide **3a** from maleimide acid **2a**, in 48% yield.  $R_f$  0.64 (9:1 CH<sub>2</sub>Cl<sub>2</sub>/EtOH);  $\delta_H$  (300 MHz, CDCl<sub>3</sub>) 6.70 (2H, s, CH=C), 6.40 (1H, br s, NH), 4.95 (1H, br s, NH), 4.15 (2H, s, NCH<sub>2</sub>CO), 3.60 (4H, s, OCH<sub>2</sub>CH<sub>2</sub>O), 3.50 (4H, m), 1.40 (9H, s, tBu) ppm;  $\delta_C$  (75 MHz, CDCl<sub>3</sub>) 170.3, 167.8, 158.0, 134.7, 79.8, 73.8, 70.3, 70.1, 41.9, 41.4, 39.9, 28.5 ppm;  $m/z$  (ES<sup>+</sup>) 387.2 (MH<sup>+</sup>, 40%).

**Preparation of Maleimide Linkers 4a,b and 5a,b.** Boc-protected maleimide **2b** (90 mg, 0.25 mmol) was stirred in a 1:1 mixture of trifluoroacetic acid and dichloromethane (10 mL) at room temperature for 30 min. Solvent was removed under reduced pressure, and the residue was coevaporated with toluene to remove excess trifluoroacetic acid, to give the deprotected maleimide **4b** (trifluoroacetate salt) as a brown oil (61 mg, 96%).  $\delta_H$  (300 MHz, CDCl<sub>3</sub>) 7.90 (2H, br s, NH), 6.60 (2H, s, CH=C), 6.35 (1H, br s, NH), 3.50 (2H, t,  $J$  = 6 Hz, NCH<sub>2</sub>), 3.25 (2H, q,  $J$  = 5 Hz, NHCH<sub>2</sub>), 3.05 (2H, m, NHCH<sub>2</sub>), 2.15 (2H, t,  $J$  = 7 Hz, CH<sub>2</sub>CO), 1.60 (4H, qui,  $J$  = 7 Hz), 1.25 (2H, qui,  $J$  = 7 Hz) ppm;  $\delta_C$  (75 MHz, CDCl<sub>3</sub>) 174.4, 172.1, 133.7, 40.7, 39.6, 37.5, 36.3, 28.2, 26.0, 24.7 ppm;  $m/z$  (ES<sup>+</sup>) 254.1 (MH<sup>+</sup>, 100%).

The same procedure was used to prepare maleimide **4a** from Boc-protected maleimide **2a**, in 94% yield.  $\delta_H$  (300 MHz, CDCl<sub>3</sub>) 8.05 (2H, br s, NH), 7.05 (1H, br s, NH), 6.70 (2H, s, CH=C), 4.10 (2H, s, NCH<sub>2</sub>), 3.20 (2H, t,  $J$  = 5 Hz, NHCH<sub>2</sub>), 3.05 (2H, m, NHCH<sub>2</sub>) ppm;  $\delta_C$  (75 MHz, CDCl<sub>3</sub>) 170.0, 167.0, 134.2, 41.7, 40.9, 40.4 ppm;  $m/z$  (ES<sup>+</sup>) 198.3 (MH<sup>+</sup>, 100%).

The same procedure was used to prepare maleimide **5a** from Boc-protected maleimide **3a**, in 95% yield.  $\delta_H$  (300 MHz, CDCl<sub>3</sub>) 7.80 (2H, br s, NH), 6.75 (2H, s, CH=C), 6.20 (1H, br s, NH), 4.10 (2H, s, NCH<sub>2</sub>CO), 3.65 (4H,

s, OCH<sub>2</sub>CH<sub>2</sub>O), 3.55 (4H, m), 3.35 (2H, m), 3.15 (2H, m, NCH<sub>2</sub>) ppm;  $\delta_C$  (75 MHz, CDCl<sub>3</sub>) 170.8, 168.3, 134.2, 71.5, 70.8, 70.2, 41.3, 41.1, 38.9 ppm;  $m/z$  (ES<sup>+</sup>) 287.5 (MH<sup>+</sup>, 60%).

The same procedure was used to prepare maleimide **5b** from Boc-protected maleimide **3b**, in 93% yield.  $\delta_H$  (300 MHz, CDCl<sub>3</sub>) 8.30 (2H, br s, NH), 6.60 (2H, s, CH=C), 6.10 (1H, br s, NH), 3.60 (4H, s, -OCH<sub>2</sub>CH<sub>2</sub>O-), 3.45 (2H, t,  $J$  = 6 Hz), 3.35 (2H, m), 3.25 (2H, m), 3.15 (2H, m), 2.65 (2H, t,  $J$  = 7 Hz, NHCH<sub>2</sub>), 2.10 (2H, t,  $J$  = 7 Hz, CH<sub>2</sub>CO), 1.50 (4H, m), 1.20 (2H, m) ppm;  $\delta_C$  (75 MHz, CDCl<sub>3</sub>) 173.6, 170.7, 134.1, 73.9, 70.2, 67.7, 41.7, 39.1, 37.1, 36.5, 28.9, 27.1, 25.3 ppm;  $m/z$  (ES<sup>+</sup>) 342.5 (MH<sup>+</sup>, 50%).

#### Preparation of *N*-Succinylethane 1,2-Diamine (**6**).

Succinic anhydride (0.86 g, 1.1 equiv) was added to a solution of *N*-Boc-ethylene 1,2-diamine (1.25 g, 7.85 mmol) in toluene (250 mL). The reaction was heated at 60 °C for 4 h, then cooled. The product, which crystallized upon cooling, was filtered and dried to give *N*-Boc *N*-succinylethylene 1,2-diamine as white crystals (1.826 g, 90%). Mp 124–126 °C;  $\delta_H$  (300 MHz, *d*<sub>6</sub>-DMSO) 12.05 (1H, br s, COOH), 7.85 (1H, br s, NH), 6.75 (1H, br s, NH), 3.05 (2H, t,  $J$  = 7 Hz, NCH<sub>2</sub>), 2.95 (2H, t,  $J$  = 7 Hz, NCH<sub>2</sub>), 2.40 (2H, t,  $J$  = 7 Hz, COCH<sub>2</sub>), 2.30 (2H, t,  $J$  = 7 Hz, COCH<sub>2</sub>), 1.40 (9H, tBu) ppm;  $\delta_C$  (75 MHz, CD<sub>3</sub>OD) 176.2, 174.8, 158.4, 80.0, 40.7, 40.5, 31.4, 30.2, 28.7 ppm;  $m/z$  (ES<sup>+</sup>) 261.4 (MH<sup>+</sup>, 100%).

*N*-Boc-*N*-succinylethylene 1,2-diamine (0.2 g, 0.77 mmol) was added to a 1:1 mixture (10 mL) of trifluoroacetic acid and dichloromethane at room temperature for 30 min. Solvent was removed under reduced pressure, and the residue was coevaporated with toluene to remove excess trifluoroacetic acid, to give *N*-succinylethylene 1,2-diamine **6** (trifluoroacetate salt) as a brown oil (0.117 g, 95%).  $\delta_H$  (300 MHz, *d*<sub>6</sub>-DMSO) 11.70 (1H, br s, COOH), 8.20 (1H, br s, NH), 7.85 (2H, br s, NH), 6.75 (1H, br s, NH), 3.25 (2H, t,  $J$  = 7 Hz, NCH<sub>2</sub>), 2.85 (2H, t,  $J$  = 7 Hz, NCH<sub>2</sub>), 2.40 (2H, t,  $J$  = 7 Hz, COCH<sub>2</sub>), 2.30 (2H, t,  $J$  = 7 Hz, COCH<sub>2</sub>) ppm;  $\delta_C$  (75 MHz, *d*<sub>6</sub>-DMSO) 175.0, 172.2, 39.4, 38.7, 31.2, 29.7 ppm;  $m/z$  (ES<sup>+</sup>) 161.0 (MH<sup>+</sup>, 10%).

**Toxicity of Poly- $\gamma$ -D-glutamic Acid.** PGA was incubated with the EHRB human B cell line at 20 and 100  $\mu$ g/mL concentration for 24 h, then stained with propidium iodide to detect apoptotic cells, as described by Nicoletti et al. (23). Uptake of <sup>3</sup>H-thymidine into EHRB cells was also assayed, at 100 and 10  $\mu$ g/mL concentrations of PGA, as previously described (24). Animal toxicity was assessed by injection of PGA (1 mg) intra-peritoneally into mice. No signs of toxicity (morbidity, coat appearance, diarrhea) were observed.

**Modification of Poly- $\gamma$ -D-glutamic Acid with Maleimide Linkers.** Poly- $\gamma$ -D-glutamic acid (35 mg, 0.27 mmol available sites) was dissolved in water (10 mL), to which was added the appropriate amine (0.27 mmol), triethylamine (38  $\mu$ L, 0.3 mmol), *N*-ethyl-*N*-(3-dimethylaminopropyl)carbodiimide hydrochloride (53 mg, 0.27 mmol), and hydroxybenzotriazole (37 mg, 0.27 mmol). The reaction mixture was stirred for 24 h at room temperature, then dialyzed against water (1 L), and freeze-dried, to give the PGA–maleimides as pale brown solids. Maleimide-modified polymers were characterized by UV and NMR spectroscopy. Observed  $\lambda_{\max}$  values: PGA–**4a**, 306 nm; PGA–**4b**, 317 nm; PGA–**5a**, 304 nm; PGA–**5b**, 299 nm.

**Conjugation of Poly- $\gamma$ -D-glutamic Acid with Antibody Mc109F4 F(ab').** Buffers: 1 M NTE8 buffer stock contains 25 mM Tris, 12.5 mM EDTA, and 1 M NaCl, adjusted to pH 8.0, which was diluted 5-fold for use. AE

buffer contains 50 mM sodium acetate and 0.6 mM EDTA, adjusted to pH 5.2 with acetic acid. PBS buffer contains 10 mM sodium phosphate (pH 7.4) and 150 mM NaCl.

F(ab')<sub>2</sub> fragments were obtained by proteolytic digestion of antibody Mc109F4, as previously described (25). F(ab')<sub>2</sub> fragments (5–12 mg/mL, 1.0 mL) in 0.2 M NTE8 buffer were reduced by addition of 100  $\mu$ L of 200 mM  $\beta$ -mercaptoethanol, followed by incubation at 30 °C for 30 min, then cooled to 4 °C. Reduced F(ab')SH was separated from reducing agent by passage through a Sephadex G25 column (80  $\times$  2.4 cm) in 50 mM AE buffer. Fractions from the G25 column were analyzed by HPLC gel filtration (Phenomenex BioSep-SEC–S3000 column, 1.0 mL/min flow rate, monitored at 280 nm, retention times F(ab')<sub>2</sub> 8.6 min, F(ab')SH 9.4 min,  $\beta$ -mercaptoethanol 12.5 min).

Fractions containing F(ab')SH and free of  $\beta$ -mercaptoethanol were pooled and immediately treated with a solution of maleimide-activated PGA (160 mg) in water (1 mL). The molar ratio of reagents was 5:1 PGA–maleimide (moles of glutamic acid):antibody F(ab'). The mixture was left to react at 4 °C for up to 14 days and monitored by HPLC gel filtration (retention time of conjugate 7.3 min). The conjugate was purified by passage through two AcA44 gel filtration columns (120  $\times$  2.0 cm) in series, in 0.2 M NTE8 buffer. Two main protein peaks were observed: the first being the PGA–F(ab') conjugate, and the second being unreacted F(ab')<sub>2</sub> and F(ab')SH. The PGA–F(ab') conjugate was pooled, concentrated using an Amicon device, and dialyzed into PBS.

HPLC gel filtration was carried out using a Phenomenex BioSep-SEC–S3000 column, eluting with 50 mM sodium acetate buffer pH 5.2 containing 0.5 mM EDTA at a flow rate of 1.0 mL/min. Molecular weight calibration was carried out using authentic samples of poly- $\alpha$ -D-glutamic acid (Sigma): 12000–14000 Da (9.1 min); 16000–32000 (8.2 min); 45000–65000 (6.6 min).

**Analysis of Interaction of PGA–**5b**–Mc109F4 Conjugate with BCL3B3 Cells.** BCL<sub>1</sub> 3B3 cells were analyzed by indirect immunofluorescent staining using a FACS vantage (Becton Dickinson, Mountain View, CA), as described previously (14). BCL3B3 cells were incubated for 30 min with the conjugate or control antibody, then washed and incubated with goat anti-rat IgG-FITC (Strattech Scientific Ltd, Luton UK), then washed and analyzed by flow cytometry. Protein concentration of 25  $\mu$ g/mL was used in each assay. Concentration of F(ab') in PGA–**5b**–Mc109F4 estimated by measurement of A<sub>280</sub> and comparison with standard sample of Mc109F4.

A growth assay to assess direct effects of mAb or derivatives on BCL<sub>1</sub>3B3 target tumor cells in vitro was carried out as described previously (24). The cells (5  $\times$  10<sup>4</sup>) were grown in various concentrations (1–25  $\mu$ g/mL) of antibodies for 42 h, then pulsed with <sup>3</sup>H-thymidine and harvested 6 h later, and growth was assessed by <sup>3</sup>H incorporation.

**Preparation of PGA–Vancomycin Conjugates.** Poly- $\gamma$ -D-glutamic acid (30 mg, 0.23 mmol available sites) was dissolved in water (5 mL), to which was added the *N*-succinylethane 1,2-diamine (**6**, 30 mg, 0.23 mmol), triethylamine (32  $\mu$ L, 0.25 mmol), *N*-ethyl-*N*-(3-dimethylaminopropyl)carbodiimide hydrochloride (45 mg, 0.23 mmol), and hydroxybenzotriazole (32 mg, 0.23 mmol). The reaction mixture was stirred for 15 min at room temperature. Vancomycin hydrochloride (35 mg, 0.23 mmol, Sigma) and triethylamine (32  $\mu$ L, 0.25 mmol) were then added, and the reaction mixture was stirred overnight at room temperature. The mixture was then

**Scheme 1. Synthesis of Maleimide Linkers 4, 5<sup>a</sup>**

<sup>a</sup> a, AcOH; b,  $\text{NEt}_3$ , toluene,  $\Delta$ , 46% ( $n = 1$ ) and 34% ( $n = 5$ ); c,  $\text{BocNHCH}_2\text{CH}_2\text{NH}_2$ , isobutyl chloroformate,  $\text{NEt}_3$ , THF, 51% ( $n = 1$ ) and 45% ( $n = 5$ ); d,  $\text{BocNH}(\text{CH}_2\text{CH}_2\text{O})_2\text{CH}_2\text{CH}_2\text{NH}_2$ , isobutyl chloroformate,  $\text{NEt}_3$ , THF, 48% ( $n = 1$ ), 40% ( $n = 5$ ); e,  $\text{CF}_3\text{COOH}$ ,  $\text{CH}_2\text{Cl}_2$ , 90–96%; f, PGA, EDC, HOBT,  $\text{NEt}_3$ ,  $\text{H}_2\text{O}$ .

dialyzed against water (1 l) and freeze-dried, to give the PGA–6–vancomycin conjugate (30 mg) as a fluffy off white solid. The PGA–vancomycin conjugate was prepared using the same method, omitting linker 6, and using 0.1 equiv of EDC, HOBT, vancomycin, and triethylamine. PGA–vancomycin conjugates were analyzed by BioSep S3000 HPLC gel filtration, as described above.

**Assay of Antibacterial Activity of PGA–Vancomycin Conjugates.** Overnight cultures of *Bacillus subtilis* W23 and *Lactobacillus casei* subsp. *casei* (ATCC393) were grown in Luria broth at 37 °C and then spread onto the surface of an LB plate, and excess liquid was removed. Filter disks (Whatman no.1, 20 mm) were placed onto the plate, and an aliquot (100  $\mu\text{l}$ ) of a 1 mg/mL solution of the antibiotic or conjugate was added to the disk. The plate was then grown overnight at 37 °C. A zone of growth inhibition was observed around each filter disk, whose radius from the outside of the disk was measured.

**RESULTS**

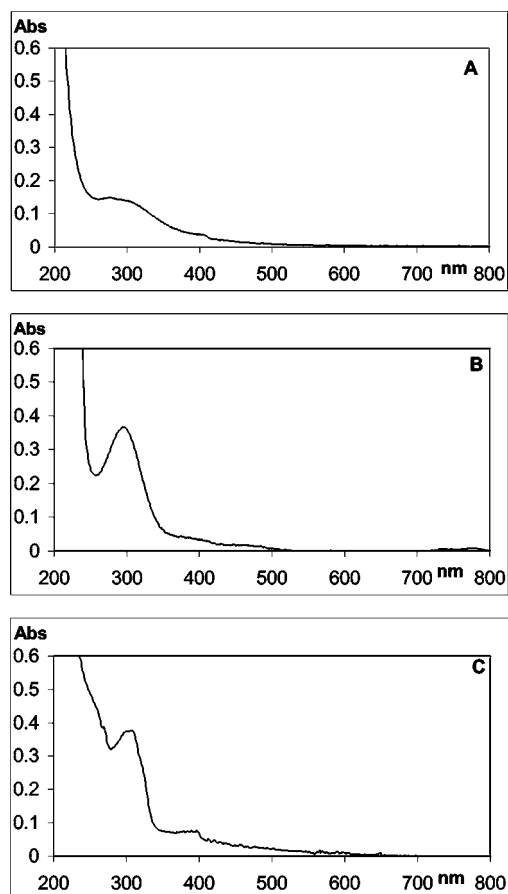

**Toxicity of Native PGA.** Poly- $\gamma$ -D-glutamic acid (PGA) was prepared from *Bacillus licheniformis* ATCC 9945a using the procedure of Troy (2), yielding approximately 120 mg of pure polymer from a 100 mL culture, as a freeze-dried powder. The toxicity of PGA was tested in cell culture, against a sensitive EHRB cell line. Using the method of Nicoletti et al. to measure % apoptotic cells (23), no toxicity was observed at 20  $\mu\text{g}/\text{mL}$  PGA (11.2%) compared to a control (11%), although slight toxicity was observed at 100  $\mu\text{g}/\text{mL}$  (18.1%). Using a  $^3\text{H}$ -thymidine uptake assay (24) on EHRB cells, 100 and 10  $\mu\text{g}/\text{mL}$  PGA showed 78% and 88% counts compared to untreated cells. Injection of a 1 mg dose of PGA into mice resulted in no observable toxicity.

**Synthesis and Attachment of Maleimide Linkers to PGA.** Proteolytic digestion of IgG immunoglobulins, followed by reduction of the  $\text{F}(\text{ab}')_2$  dimer product (100 kDa), generates an antibody  $\text{F}(\text{ab}')_1$  fragment (50 kDa) bearing a unique reactive thiol group (25). To conjugate an antibody  $\text{F}(\text{ab}')_1$  to PGA, a synthetic linker is required

which can be attached to the  $\alpha$ -carboxyl group of PGA and subsequently selectively with the thiol group. Preliminary experiments using bromoacetyl- and iodoacetyl-containing linkers revealed that thiol conjugation with these linkers required high pH conditions and proceeded in low yield; therefore, the synthesis of linkers containing reactive maleimide groups was undertaken. The maleimide functional group, known to react selectively with thiol nucleophiles (26), was attached via a variable length chain to a primary amine group, which could be attached to PGA.

The synthesis of four maleimide-containing linkers is illustrated in Scheme 1. Maleic anhydride was reacted with glycine to give the corresponding maleamic acid, which was converted to maleimide **1a** by treatment with triethylamine in refluxing toluene (27). In a similar fashion, 6-aminohexanoic acid was converted to maleimide **1b**. Each maleimide acid was coupled to mono-Boc-ethylenediamine, to give maleimides **2a,b**, and also to a longer, more polar linker containing an ethylene glycol spacer, yielding maleimides **3a,b**. Deprotection under acidic conditions gave the deprotected maleimide linkers **4a,b** and **5a,b** containing 9, 13, 15, and 19 atom spacers, respectively.

Each linker was attached to PGA using water-soluble carbodiimide EDC, and the modified polymers were dialyzed and lyophilized. The attachment of maleimide linkers to PGA was monitored by UV and NMR spectroscopy. Maleimides **4** and **5** showed characteristic UV/visible absorption peaks at  $\lambda_{\text{max}}$  300–315 nm, due to the maleimide chromophore. PGA–maleimide conjugates showed peaks at 300–315 nm by UV/visible spectroscopy, demonstrating that immobilization of the maleimide had taken place (see Figure 2). NMR signals for the maleimide group could also be observed at  $\delta_{\text{H}}$  6.75 ppm and  $\delta_{\text{C}}$  135 ppm in the  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra of the modified polymer (see Figure 3). After storage for >24 h, the UV absorption of the modified polymers gradually decreased, suggesting that intramolecular reaction was taking place between the maleimide groups and free carboxylate side chains of the polymer. Therefore, samples of activated

**Figure 2.** UV/visible spectra of (A)  $\gamma$ -PGA; (B) linker **4a**; (C) PGA modified by linker **4a**. The absorption of the maleimide chromophore can be seen at  $\lambda_{\max}$  300 nm.

polymer for conjugation reactions were prepared immediately prior to use.

**Conjugation with Antibody Mc109F4 F(ab').** Antibody Mc109F4 IgG was subjected to proteolytic cleavage by treatment with bromelain, to give the F(ab')<sub>2</sub> dimer (100 kDa). Treatment with  $\beta$ -mercaptoethanol then gave the F(ab')-SH monomer (50 kDa), which was separated from excess reducing agent by G25 gel filtration chromatography. Preparation of F(ab')-SH could be conveniently monitored by HPLC gel filtration, using a Phenomenex BioSep-S3000 column, which could resolve F(ab')<sub>2</sub> and F(ab') with retention times 8.6 and 9.4 min, respectively (see Figure 4B,C). Freshly reduced F(ab')-SH was mixed with the maleimide-activated polymer, in a 1:1 ratio of reduced F(ab')-SH to maleimide linker, in 50 mM acetate buffer pH 5.2, and left to react at 4 °C.

Reaction of the maleimide-activated polymer with reduced F(ab')-SH was monitored by HPLC gel filtration. Analysis of native PGA gave a single peak at 5.5 min (Figure 4A), whereas the maleimide-activated polymers gave peaks at 9.0–9.2 min, implying that fragmentation of the native polymer had taken place during modification, as observed previously (4). Molecular weight calibration was attempted using samples of poly- $\alpha$ -D-glutamic acid, which gave the following retention times: 44–64 kDa, 6.6 min; 17–31 kDa, 8.2 min; 11–13 kDa, 9.1 min. Using these data, we can tentatively assign a molecular weight for the activated PGA of 11–13 kDa, which matches previous estimates (4), and a  $M_r$  for native PGA of  $110 \pm 40$  kDa. The reason for the fragmentation of PGA upon modification is not known: it may be due to EDC-mediated cleavage (4) or the existence of a depolymerase enzyme (28).

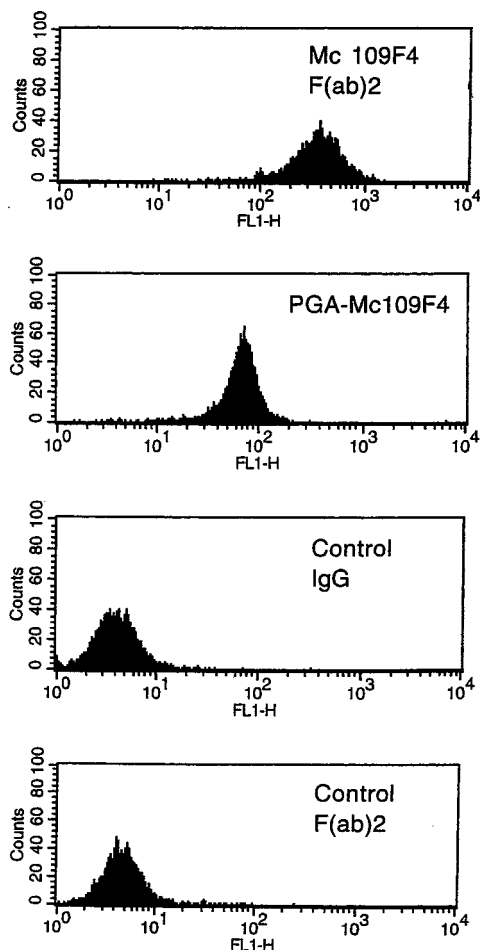

**Figure 3.** 300 MHz <sup>1</sup>H NMR spectra of (A)  $\gamma$ -PGA; (B) linker **4b**; (C) PGA modified by linker **4b**. The position of the maleimide C=CH is indicated by arrows in B and C.

**Figure 4.** HPLC gel filtration (Bio-Sep S3000) analysis of (A) native PGA, (B) Fab<sub>2</sub> (50 kDa), (C) Fab-SH (25 kDa), (D) Fab-PGA conjugate. Retention times of poly- $\alpha$ -D-glutamic acid standards: 44–64 kDa, 6.6 min; 17–31 kDa, 8.2 min; 11–13 kDa, 9.1 min.

Analysis of the PGA–Mc109F4 conjugate by HPLC gel filtration gave a large, broad peak at 5.8–8.7 min, followed by small peak at 9.1 min (see Figure 4D). The peak at 9.1 min probably corresponds to residual activated polymer. A slight shoulder is visible at 8.2 min, which (from the difference in retention times of the F(ab') and F(ab')<sub>2</sub> peaks) probably corresponds to the 1:1 PGA–F(ab') conjugate, and the remainder of the peak to higher PGA(F(ab'))<sub>n</sub> conjugates. Maximum absorbance is observed at retention time 7.3 min, suggesting that the most abundant conjugates are PGA(F(ab'))<sub>2</sub> and PGA–(F(ab'))<sub>3</sub>.

**Figure 5.** Binding of PGA-5b-Mc109F4 conjugate to BCL3B3 cells assessed by flow cytometry. Procedure described in Experimental Section. Samples of control IgG and F(ab)<sub>2</sub> antibodies were included, which have no interaction with BCL3B3 cells. Each protein sample was assayed at 25  $\mu$ g/mL concentration. Strength of binding interaction assessed by mean channel fluorescence ( $x$ -axis).

Conjugation of activated PGA to F(ab')-SH was found to take place slowly, requiring several days at 4  $^{\circ}$ C to reach completion, with most successful conjugation using PGA-5a and PGA-5b. The reactivity of samples of activated PGA was variable, low reactivity being observed for stored samples, perhaps due to intramolecular reaction of carboxylate side chains of PGA with maleimide groups, and 'burying' of maleimide groups in the hydrophobic core of PGA. However, by carrying out the functionalization of PGA with the PEG-maleimide linkers rapidly, coupling of antibody F(ab')-SH was successfully achieved. The PGA-5a-F(ab') and PGA-5b-F(ab') conjugates were purified by AcA44 gel filtration and concentrated prior to storage.

#### Biological Activity of PGA-Mc109F4 Conjugate.

The PGA-5b-Mc109F4 conjugate was tested for binding to target BCL3B3 cells (14) using flow cytometry, as shown in Figure 5. BCL3B3 cells were incubated for 30 min with the conjugate or control antibody, washed and incubated with anti-antibody conjugated to fluorescent dye FITC, and then washed and analyzed by flow cytometry. Antibody Mc109F4 IgG and F(ab)<sub>2</sub> showed a mean channel fluorescence of 600 and 400 units, respectively, at 25  $\mu$ g/mL concentration, respectively, whereas the PGA-Mc109F4 conjugate recorded only 70 units at 25  $\mu$ g/mL concentration. A control antibody F(ab)<sub>2</sub> gave a reading of only 4 units at 25  $\mu$ g/mL concentration. Thus,

**Figure 6.** Growth inhibition of BCL3B3 cells of Mc109F4 IgG (open squares), Mc109F4 F(ab)<sub>2</sub> (open circles), and PGA-5b-Mc109F4 conjugate (filled circles) assessed by <sup>3</sup>H-thymidine incorporation (in cpm), at 0.1–6  $\mu$ g/mL protein concentration. Procedure described in Experimental Section. Result of control assay (addition of medium only) is indicated.

the PGA-Mc109F4 conjugate does bind to BCL3B3 cells, but less strongly than the parent antibody F(ab'), indicating that conjugation to the polymer has reduced its biological activity.

Since antibody Mc109F4 is known to inhibit the growth of BCL3B3 (14), the effect of the PGA-5b-Mc109F4 conjugate upon BCL3B3 growth was also investigated, as shown in Figure 6. The cells ( $5 \times 10^4$ ) were grown in various concentrations of antibodies for 42 h, pulsed with <sup>3</sup>H-thymidine, and harvested 6 h later, and growth was assessed by <sup>3</sup>H incorporation (24). Approximately 20% growth inhibition was observed at 1  $\mu$ g/mL PGA-Mc109F4; however, only 25% inhibition was observed at 6.25  $\mu$ g/mL conjugate (and 30% inhibition at 25  $\mu$ g/mL conjugate), whereas 5  $\mu$ g/mL Mc109F4 F(ab)<sub>2</sub> caused 50% growth inhibition. In conclusion, the conjugated antibody fragment does retain its biological activity, but has reduced efficacy compared with the free antibody.

**Conjugation of  $\gamma$ -PGA with Vancomycin.** The glycopeptide antibiotic vancomycin is a very interesting ligand for immobilization to PGA, since the dimerization of the antibiotic is believed to promote its antibacterial effects (15). The presence of a free primary amine, on the vancosamine sugar of the glycopeptide, provided a convenient point of conjugation to PGA, as shown in Scheme 2.

Two conjugates of PGA with vancomycin were prepared. Conjugation of PGA directly to vancomycin was carried out, using the water-soluble carbodiimide EDC. A second conjugate was also prepared, using an eight-atom spacer 6, prepared from Boc-ethylene 1,2-diamine and succinic anhydride, as shown in Scheme 2.

Analysis of the PGA-vancomycin and PGA-6-vancomycin conjugates by BioSep S3000 gel filtration gave new single peaks at retention times 16.7 and 16.4 min, respectively ( $\gamma$ -PGA 5.5 min, vancomycin 11.3 min), indicating that conjugates had been formed. The high retention times are indicative of an interaction between

**Scheme 2. Preparation of PGA–Vancomycin Conjugate<sup>a</sup>**

<sup>a</sup> a. Succinic anhydride, toluene, 90%; b. CF<sub>3</sub>COOH, CH<sub>2</sub>Cl<sub>2</sub>, 95%; c. γ-PGA, EDC, HOBT, Et<sub>3</sub>N, H<sub>2</sub>O; d., vancomycin, EDC, HOBT, Et<sub>3</sub>N, H<sub>2</sub>O.

**Table 1. Antibacterial Activities of PGA–Vancomycin Conjugates**

zone of inhibition vs	<i>Bacillus subtilis</i> (Vm-sensitive), mm	<i>Lactobacillus casei</i> (Vm-resistant), mm
vancomycin (1 mg/mL)	14	3
PGA–vancomycin conjugate (1 mg/mL)	8	5
PGA–6–vancomycin conjugate (1 mg/mL)	9	5

the glycoside portion of vancomycin and the column, as observed for other glycoside derivatives (data not shown); therefore, it is not possible to estimate an  $M_r$  for the conjugates.

**Antibacterial Activity of PGA–Vancomycin Conjugates.** The antibacterial activities of the two PGA–vancomycin conjugates were assessed by filter disk assays on agar plates and compared directly with free vancomycin. Measurement of the zone of growth inhibition around the filter disk containing the antibiotic provides a measure of antibacterial potency. The results are summarized in Table 1.

Against a vancomycin-susceptible strain of *Bacillus subtilis*, the PGA–vancomycin and PGA–6–vancomycin conjugates were found to show antibacterial activity (8 mm and 9 mm zones, respectively) at 1 mg/mL concentration. At the same concentration, free vancomycin showed a 14 mm zone of inhibition. Thus, it appears that the immobilized vancomycin retains its biological activity, but with somewhat reduced biological efficacy.

High-level vancomycin resistance, both plasmid-mediated resistance in *Enterococcus* strains (29) and intrinsic resistance in lactic acid bacteria (30), is known to be associated with the presence of peptidyl-D-Ala-D-Lac termini in the cell wall peptidoglycan, for which vancomycin has low affinity, since one hydrogen bond between

vancomycin and the terminal D-alanine is absent. Synthetic vancomycin dimers (17) and vancomycin-based polymers (20) have been reported to show higher activity against vancomycin-resistant strains. Therefore, the antibacterial activity of the PGA–vancomycin conjugates was also assayed against a vancomycin-resistant strain of *Lactobacillus casei*, using the filter disk assay. Both conjugates showed a 5 mm zone of inhibition, whereas free vancomycin showed a 3 mm zone of inhibition. It appears, therefore, that the PGA–vancomycin conjugates possess slightly higher antibacterial activity against vancomycin-resistant strains, although not markedly higher activity.

**DISCUSSION**

We have previously shown that small molecular weight amines can be immobilized onto PGA in aqueous solution using a water-soluble carbodiimide, EDC (4). In this paper we describe the preparation of linkers for the attachment of protein ligands to PGA via thiol side chains. The most successful linker was found to be maleimide linker 5b, containing an ethylene glycol spacer capable of hydrogen bonding with the aqueous solvent. Using this linker, we were able to conjugate the Mc109F4 F(ab'), to give a mixture of PGA(F(ab'))<sub>n</sub> conjugates. The conjugated antibody F(ab') was found to retain its biological recognition properties, but showed reduced binding efficacy and cell growth inhibition, compared with the free antibody F(ab'). We have also immobilized the glycopeptide antibiotic vancomycin to PGA and have shown that the immobilized ligand also retains its biological activity, but with slightly reduced efficacy. In this case, however, there is some indication of enhanced biological activity against vancomycin-resistant strains, against which the free ligand shows low affinity.

This work establishes the feasibility of attaching bioactive molecules and macromolecules such as cell-specific antibody F(ab') fragments to nontoxic, nonimmunogenic biopolymers such as PGA. The observation that the immobilized ligands retain their biological activity implies that antibody–polymer conjugates could in principle be used to target cytotoxic drugs in the human body (7), although the reduced biological efficacy of the immobilized F(ab') implies that there are inherent practical difficulties in this approach. Biopolymers such as PGA provide interesting alternatives to man-made polymers for antibody F(ab') immobilization (8–13), which may prove to have certain advantages for biocompatibility.

Received March 11, 2003; Revised Manuscript Received June 27, 2003

The objective of this study was to develop biodegradable polypeptide–lipid conjugates for the design of polymer-coated long-circulating liposomes (LCL). Lipid conjugates of poly(hydroxyalkyl L-asparagine/L-glutamine) were synthesized and incorporated into 0.15  $\mu\text{m}$  dipalmitoyl phosphatidylcholine (DPPC)–cholesterol liposomes. Circulation times and biodistribution were assessed in rats using a radioactive lipid marker. Evaluation of the therapeutic activity of prednisolone phosphate loaded in 0.1  $\mu\text{m}$  PHEA–DPPC–cholesterol liposomes in a rat experimental arthritis model was performed to demonstrate the drug-targeting potential of the polymer-coated liposomes. Coating of liposomes with poly(hydroxyethyl L-asparagine) (PHEA) and poly(hydroxyethyl L-glutamine) (PHEG) extended the circulation half-life to a similar extent as poly(ethylene glycol) (PEG), which is normally used for the preparation of LCL. Glutamine polymers with a hydroxypropyl or a hydroxybutyl group instead of hydroxyethyl group also yield prolonged circulation, however, not to the same extent as PHEA/G. The pharmacokinetic properties of PHEA-liposomes were independent of the lipid dose even at very low lipid doses of around 50 nmol per rat. PLP was successfully entrapped in PHEA-liposomes. These liposomes were shown to be stable in the circulation and equally effective in rat experimental arthritis as PLP encapsulated in PEG-liposomes. PHEA and PHEG are attractive alternative polymers for the design of LCL: their performance is similar to that of PEG-liposomes but they have the advantage of being biodegradable.

## INTRODUCTION

Liposomes are small spherical particles that consist of one or more lipid bilayers enclosing an aqueous interior (1). Liposomes are highly suitable as drug carriers, as they are composed of natural lipids and offer the opportunity to incorporate a wide variety of therapeutic agents for the purpose of drug-targeting (2). Biodistribution studies in laboratory animals showed that intravenously (iv) injected liposomes predominantly home to cells of the mononuclear phagocyte system (MPS) that is present in liver, spleen, and bone marrow. As a result, liposomes show generally a short circulation half-life after iv administration (3, 4).

The development of bilayer surface modifications that were able to reduce rapid uptake by the MPS represented a major step forward to the successful clinical application of liposomes (5). Incorporation of a lipid conjugate of the

water-soluble polymer poly(ethylene glycol) (PEG) results in a polymeric layer around the liposome, which reduces the adhesion of plasma proteins that would otherwise cause rapid recognition of the liposomes by MPS-phagocytes. With a PEG-coating, liposomes oppose rapid uptake by the MPS and acquire a prolonged circulation property. With these so-called 'long-circulating liposomes' (LCL) drug-targeting to tissues other than liver, spleen, and bone marrow became possible. Indeed, LCL were shown to selectively accumulate at sites of enhanced vascular permeability as found in tumors and inflamed areas in the body (6, 7). This form of targeted drug delivery resulted in increased therapeutic efficacy and/or reduced toxicity of several cytostatic, antifungal, and antibacterial drugs and led to the market approval of liposomal doxorubicin as the first commercially available liposomal cytostatic agent (8–11).

Besides PEG a few other polymers have also been shown to induce prolonged circulation behavior of liposomes upon attachment to their surface (12). Woodle and co-workers investigated oxazoline-derived polymers, Maruyama et al. designed poly(glycerol)-coated liposomes, while Torchilin and co-workers developed several water-soluble vinyl-based polymers for the creation of long-circulating liposomes. All groups reported circulation half-lives comparable to PEG-liposomes (13–18). Up to now, PEG-liposomes are the only polymer-coated lipo-

some that have been approved for clinical use. However, despite the fact that low-molecular weight PEG has been shown to be nontoxic and to be readily excreted by the kidneys, the biological fate of (liposome-associated) PEG after cellular uptake is not known (19, 20). Since PEG is expected not to be easily intracellularly degraded, it cannot be excluded that PEG may affect cell functioning at the long term (21).

It was the objective of this study to design a biodegradable and biocompatible polymer–lipid conjugate for the development of LCL. To achieve minimal toxicity of the polymer as well as the compounds that are formed upon biodegradation, we selected natural L-amino acids as starting material for the synthesis of polymer–lipid conjugates in this study. Besides the advantage of being intracellularly degradable, such poly(L-amino acid)–lipid conjugates are expected to be degraded by proteolytic enzymes that are present at pathological target tissues such as tumors and sites of inflammation. Therefore, these polymer–lipid conjugates may allow the incorporation of bilayer functionalities that have to remain shielded in the circulation until arrival at the pathological target sites where they can perform their specific function.

The present study investigates the feasibility of polymers based on hydroxyalkyl derivatives of L-glutamine and L-asparagine as monomers. Poly(hydroxyethyl L-glutamine) (PHEG) was selected as a starting polymer, as PHEG is known to be water-soluble, biocompatible, and degradable by isolated enzymes (e.g. papain, chymotrypsin, and Pronase) as well as cocktails of lysosomal extracts and kidney homogenates (22–25). Subsequently, structure–activity relationships were established by replacing the hydroxyethyl side group with other hydroxyalkyl groups and selecting L-asparagine as backbone monomer instead of glutamine. Different lipid molecules were evaluated to ensure stable anchoring of the polymer–lipid conjugates in the liposome bilayer. In addition, the effect of the polymer grafting density on the liposome surface and the effect of lipid dose on the circulation half-life were assessed. Finally, the feasibility of liposomal incorporation and targeting an antiinflammatory glucocorticoid to inflamed sites in an experimental animal model of arthritis was evaluated.

## MATERIALS AND METHODS

**Synthesis and Characterization of Different PEG–Lipid Conjugates.** PEG5000–lipid conjugates were synthesized from methoxy-PEG5000-isocyanate, commercially available from Shearwater Polymers, Huntsville, AL, and long-chain alkylamines: octadecylamine (stearylamine)  $\text{NH}_2\text{-C}_{18}\text{H}_{37}$  (ODA), having a single  $\text{C}_{18}$ -tail, and dioctadecylamine (distearylamine)  $\text{NH-(C}_{17}\text{H}_{35})_2$  (DODA) and 1-heptadecyl-octadecylamine  $\text{NH}_2\text{-CH-(C}_{17}\text{H}_{35})_2$  (HOA), both with a double alkyl tail. Isocyanate groups reacted with these primary and secondary alkylamines rapidly at room temperature to form ureas of a general formula:  $\text{mPEG-NH-CO-NH-R}$  in case of a primary amine (ODA,  $\text{R} = \text{C}_{18}\text{H}_{37}$  or HOA,  $\text{R} = \text{CH(C}_{17}\text{H}_{35})_2$ ) or  $\text{mPEG-NH-CO-N-R}_2$  in case of a secondary amine (DODA,  $\text{R}$  being a  $\text{C}_{18}$ -tail).

All three PEG5000 derivatives were synthesized in exactly the same way. For the synthesis of the PEG5000-stearyl derivative, a solution of 300 mg of methoxy-PEG-isocyanate (0.06 mmol, MW 5000, Shearwater Polymers) and 18 mg (0.07 mmol) of ODA in 1.5 mL of chloroform was stirred at room temperature for ca. 0.5–1 h. The solution was then precipitated into 20–30 mL petroleum ether. A fine white powder (220 mg, 75%) was obtained

after filtration and drying.  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ,  $\delta$  in ppm relative to TMS): PEG: 3.6 ( $\text{CH}_2\text{O}$ ); stearyl anchor: 1.2 ( $\text{CH}_2$ ) and 0.8 ( $\text{CH}_3$ ). The ratio of PEG and stearyl peak integrals confirms the presence of one stearyl group per PEG moiety. MALDI-TOF confirms the molecular structure of the PEG–lipid conjugates: e.g.  $\text{Na}^+$ -adduct of the most abundant peaks of the PEG–stearyl conjugate:  $m/z$  5459 ( $n = 115$ ), 5503 ( $n = 116$ ), 5547 ( $n = 117$ ), etc.

**Synthesis and Characterization of PHEA–DODASuc.** Synthesis of poly(L-hydroxyethyl asparagine)-*N*-succinyldioctadecylamine (PHEA–DODASuc) is schematically represented in Scheme 1 A. To a solution of 3 g of  $\beta$ -benzyl L-aspartate *N*-carboxy anhydride (NCA) (synthesized as described by Fuller et al. (26)) dissolved in 9 mL of dry dimethylformamide (DMF) (Aldrich-Chemie, Steinheim, Germany) was added 0.3 mL of a 2 M solution of methylamine in tetrahydrofuran (THF) (Aldrich) as initiator. The solution (initially clear, after ca. 2 h cloudy) was stirred for 1 day under a nitrogen atmosphere at room temperature and then precipitated into water (150 mL), collected by filtration, and dried. Yield: 2 g of poly(benzyl L-aspartate) (PBLA).

Polymer–lipid coupling was performed to obtain the PBLA–DODASuc conjugate. Briefly, a solution of 2 g of PBLA in 5 mL of chloroform containing ca. 150 mg of triethylamine (Merck, Darmstadt, Germany) was added to a solution of 200 mg of dicyclohexylcarbodiimide (DCC) (Acros Chimica, Geel, Belgium), 15 mg of 4-(dimethylamino)pyridinium 4-toluenesulfonate (DPTS) (Acros), and 350 mg of *N*-succinyldioctadecylamine (DODASuc; for synthesis see (27)) in 6 mL of chloroform that had been stirred for 1 h. The mixture was stirred for 1 day and then precipitated into methanol. The polymeric product was filtered off and dried in vacuo. Yield: 1.4 g of PBLA–DODASuc. Aminolysis of 1.4 g of PBLA–DODASuc was performed with ca. 4 mL of ethanolamine (Aldrich), using 0.4 g of 2-hydroxypyridine (Aldrich) as a catalyst, in 10 mL of DMF solution at 40 °C for 1 day, yielding PHEA–DODASuc. Yield: 0.8 g after dialysis (molecular weight cut off 500) and freeze-drying. Characterization:  $^1\text{H}$  NMR ( $\text{DMSO-}d_6$ ) ( $\delta$  in ppm relative to TMS): distearyl: 0.8 ( $\text{CH}_3$ ), 1.2 ( $\text{CH}_2$ ), 1.4 ( $\text{CH}_2\text{N}$ ); PHEA: 2.4–2.8 ( $\beta\text{-CH}_2$ ), 3.2 and 3.4 (hydroxyethyl), 4.6 ( $\alpha\text{-CH} + \text{OH}$ ), 7.8–8.5 (NH). From the ratio of integrals of the distearyl signals and the  $\alpha\text{-CH}$  signal, the molecular weight of the polymer part of the conjugate was calculated to be ca. 3000 g/mol.

MALDI-TOF confirms the molecular structure of the PHEA–DODASuc conjugate as depicted in Scheme 1 A.  $\text{Na}^+$ -adduct:  $m/z$  2397.5 ( $n = 11$ ), 2555.6 ( $n = 12$ ), 2713.6 ( $n = 13$ ), 2871.9 ( $n = 14$ ), etc.

**Synthesis and Characterization of Poly(L-hydroxyalkyl glutamine)–DODASuc Conjugates.** Synthesis of poly(hydroxyethyl glutamine) (PHEG)–lipid conjugates is schematically shown in Scheme 1B. To a solution of 3 g of  $\gamma$ -benzyl L-glutamate NCA (for synthesis see (26)) in 8 mL of dry DMF was added a solution of 0.1 g of *N*-BOC-1,4-diaminobutane (Fluka, Zwijndrecht, The Netherlands) in chloroform as initiator. This solution was stirred for 1 day under a nitrogen atmosphere at room temperature. After precipitation into ca. 100 mL of methanol, the polymer was filtered off and dried, yielding 2 g of PBLG with a BOC-protected amino end group. To remove BOC, a solution of 1.7 g of PBLG–diaminobutane-BOC in 12 mL of 2 M HCl/dioxane was stirred for 4 h and then added dropwise to ca. 150 mL of water in which approximately 10 g of  $\text{NaHCO}_3$  was dissolved. The product was filtered off, washed with water, and dried in vacuo. Yield: 1.4 g of PBLG–diaminobutane.

**Scheme 1. Synthesis of Poly(hydroxylalkyl L- asparagines/glutamine)–Lipid Conjugates<sup>a</sup>**

<sup>a</sup> (A) Schematic representation of PHEA–DODASuc synthesis strategy. (B) Schematic representation of the synthesis of PHEG–DODASuc. Note that DODASuc is attached to PHEA at the amino end group (on the right) of the poly(amino acid) backbone, whereas to PHEG it is attached to the carboxylic end (on the left, using diaminobutane to connect the poly(amino acid) backbone to DODASuc).

Deprotection was complete as demonstrated by NMR analysis.

To obtain the PBLG–DODASuc conjugate, 340 mg of DODASuc, 180 mg of DCC, and 15 mg of DPTS were dissolved in 5 mL of chloroform. The solution was stirred for 1 h at room temperature. Next, a solution of 1.4 g of PBLG–diaminobutane and 120 mg of triethylamine in 8 mL of chloroform was added. After stirring overnight at room temperature the obtained solution was added dropwise to an excess of methanol (ca. 150 mL). The polymeric product was filtered off, washed, and dried. Yield: 1.2 g of PBLG–DODASuc. <sup>1</sup>H NMR (CDCl<sub>3</sub>) ( $\delta$  in ppm relative to TMS): distearyl signals at 0.8–0.9 (CH<sub>3</sub>) and 1.2–1.4 (methylene protons); PBLG: 2.2 and 2.6 ( $\beta,\gamma$ -CH<sub>2</sub>), 4.0 ( $\alpha$ -CH), 5.0 (benzyl CH<sub>2</sub>), 7.3 (phenyl).

Aminolysis with ethanolamine was performed to obtain PHEG–DODASuc: 1.2 g of PBLG–DODASuc (see above) and 0.5 g of 2-hydroxypyridine were dissolved in 10 mL

of DMF. Then ca. 4 mL of ethanolamine was added dropwise. After being stirred for 24 h at 40 °C under a nitrogen atmosphere, the solution was precipitated into ca. 200 mL of diethyl ether. The precipitate was dissolved in water, dialyzed (molecular weight cut off 500), and subsequently freeze-dried yielding 0.8 g of PHEG–DODASuc conjugate. Characterization: <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>) ( $\delta$  relative to TMS): distearyl signals at 0.8–0.85 (CH<sub>3</sub>) and 1.2–1.5 (methylene protons); PHEG: 1.7–2.2 ( $\beta,\gamma$ -CH<sub>2</sub>), 3.1 and 3.3 (hydroxyethyl), 4.2 ( $\alpha$ -CH), 4.7 (OH), 7.8 and 8.2 (NH). From the ratio of integrals of the distearyl signals and the  $\alpha$ -CH signal molecular weight of PHEG was calculated to be ca. 4000. By varying the monomer/initiator ratio, similar conjugates with different PHEG molecular weights (3000 and 8000) were synthesized.

MALDI-TOF confirms the molecular structure of the PHEG–DODASuc conjugate as depicted in Scheme 1B.

Na<sup>+</sup>-adduct:  $m/z$  3064.5 ( $n = 13$ ), 3236.1 ( $n = 14$ ), 3408.7 ( $n = 15$ ), 3580.6 ( $n = 16$ ), 3752.9 ( $n = 17$ ), 3924.7 ( $n = 18$ ), 4096.7 ( $n = 19$ ), 4268.4 ( $n = 20$ ), 4441.1 ( $n = 21$ ), 4613.3 ( $n = 22$ ), 4785.1 ( $n = 23$ ), etc.

The same procedure of aminolysis but with 3-propanolamine instead of ethanolamine yielded PHPG-DODASuc. Characterization: <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>) ( $\delta$  in ppm relative to TMS): distearyl signals at 0.8–0.85 (CH<sub>3</sub>) and 1.2–1.5 (methylene protons); PHPG: 1.7–2.2 ( $\beta$ , $\gamma$ -CH<sub>2</sub>), 1.5 and 3.1 and 3.3 (hydroxypropyl), 4.2 ( $\alpha$ -CH), 4.6 (OH), 7.8 and 8.2 (NH). MALDI-TOF: Na<sup>+</sup>-adduct:  $m/z$  3623 ( $n = 15$ ), 3810 ( $n = 16$ ), 3996 ( $n = 17$ ), 4182 ( $n = 18$ ), 4368 ( $n = 19$ ), 4555 ( $n = 20$ ), etc.

To obtain PHBG-DODASuc, the same procedure of aminolysis of PBLG-DODASuc was repeated with 4-butanolamine (Merck). Stirring was performed for 48 h instead of 24 h at 40 °C. <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>) ( $\delta$  in ppm relative to TMS): distearyl signals at 0.8–0.85 (CH<sub>3</sub>) and 1.2–1.5 (methylene protons); PHBG: 1.7–2.2 ( $\beta$ , $\gamma$ -CH<sub>2</sub>), 1.4 and 3.1 and 3.3 (hydroxybutyl), 4.2 ( $\alpha$ -CH), 4.5 (OH), 7.8 and 8.2 (NH).

**Preparation of Radiolabeled Liposomes for Comparative Pharmacokinetics.** Liposomes were prepared as described previously (28). Briefly, a lipid mixture in ethanol with a molar ratio composition of 1.85:0.15:1.0 (DPPC:polymer-lipid conjugate:cholesterol) was prepared. Such molar ratio results in liposomes containing 7.5% polymer-lipid conjugate as a percentage of the total amount of phospholipid. To the mixture was added [<sup>3</sup>H]-cholesteryl oleyl ether as a nondegradable liposome lipid phase marker. A lipid film was created by rotary evaporation under reduced pressure. The lipid film was hydrated with phosphate-buffered saline (PBS) at an initial total lipid concentration of 20  $\mu$ mol/mL. The liposomes were sized by multiple extrusion using a medium-pressure extruder equipped with two stacked polycarbonate membrane filters, one with a pore size of 200 nm on top of one with 100 nm pores. Components that were not incorporated in liposomes were removed by gel filtration on a PD-10 column (Pharmacia, Uppsala, Sweden) eluted with PBS.

**Characterization of Liposome Preparations.** Radioactivity of the liposomal dispersions was assayed in an Ultima Gold liquid scintillation cocktail purchased from Hewlett Packard (Groningen, The Netherlands) and counted in a Philips PW 4700 liquid scintillation counter. Lipid content of the liposomal dispersion was determined by assessing the radioactivity of the liposomes before and after preparation. The mean particle size of the liposomes was determined by dynamic light scattering (29) with a Malvern 4700 system (Malvern, UK). The mean size ranged between 140 and 160 nm. In addition to the mean particle size, the system reports a polydispersity index (a value between 0 and 1; 0 indicating that a complete monodisperse system is obtained, whereas 1 indicates maximal variation in particle size). All liposome preparations used had a polydispersity index of below 0.15. In Table 1 the composition and characteristics of the different liposome types are summarized. Liposome preparations were stored under nitrogen at 4 °C and used within one week after preparation.

**Comparative Pharmacokinetics of Polymer-Coated <sup>3</sup>H-Labeled Liposomes in Rats.** Male Wistar rats with an approximate body weight of 200 g were used (outbred, SPF-quality, Utrecht University, The Netherlands). Besides the different poly(hydroxyalkyl L-amino acid)-coated liposomes, nonpolymer-coated ('bare') liposomes and liposomes coated with PEG2000 coupled to distearyl phosphatidylethanolamine (PEG-DSPE) were

prepared and evaluated as 'negative' and 'positive' controls, respectively. Single-dose intravenous injections of liposomal preparations containing 5  $\mu$ mol of total lipid and approximately 50 kBq of radioactivity were given in the tail vein. Blood samples of 100  $\mu$ g were collected from the opposite tail vein of each rat at the following time points postinjection: 5 min and 1, 4, 8, 24, and 48 h. Radioactivity in blood samples was determined by adding Solvable tissue solubilizer (NEN, Dreieich, Germany) and 35% hydrogen peroxide. After overnight incubation, the samples were assayed in Ultima Gold scintillation cocktail (Packard BioScience B. V., Groningen, The Netherlands) and counted for radioactivity with a Philips PW 4700 liquid scintillation counter. At 48 h postinjection liver and spleen were dissected, homogenized and processed according to the same method as described for the blood samples. Besides tissue and blood samples, the radioactivity of the injected dose was also counted. The % injected dose in the organs was calculated by dividing the total radioactivity of the organs by the injected dose. The total radioactivity of the blood was calculated by multiplying the radioactivity of the blood samples with the total mass of the blood of each rat, which is defined as 7% of the total body weight. The results are presented as the mean  $\pm$  standard deviation of the percentage of the injected dose of four rats.

**Liposome Preparation for Assessing Drug-Targeting Potential.** Liposomes containing the antiinflammatory glucocorticoid prednisolone phosphate (PLP) were prepared as described previously (30). In brief, a lipid film containing 7.5% PHEA-DODASuc or PEG-DSPE was created by rotary evaporation and hydrated with a solution of 100 mg/mL prednisolone phosphate (PLP) (Bufo, Uitgeest, The Netherlands) in water at a initial lipid concentration of 100  $\mu$ mol of lipid per mL dispersion. Liposomes were sized to approximately 90 nm by multiple extrusion. A smaller size than the liposomes used in the comparative pharmacokinetic studies was chosen, as this may further increase target localization of the liposomes. PLP was removed by repeated dialysis using Slide-A-Lyzer dialysis cassettes with a molecular weight cut off of 10 000 (Pierce, UK) against PBS. Phospholipid content was determined with a phosphate assay in the organic phase after extraction of the liposomal preparations with chloroform (31). The aqueous phase after extraction was used for determining the PLP content by HPLC. Each milliliter of liposomal preparation contained around 5 mg of PLP and approximately 60  $\mu$ mol of phospholipid.

**Pharmacokinetics of PLP Encapsulated in Polymer-Coated Liposomes.** For assessment of in vivo stability in the circulation and pharmacokinetic behavior of PLP in polymer-coated liposomes, the PLP plasma concentration was measured at the time of injection, at

**Figure 1.** Pharmacokinetics and distribution to the MPS of PEG5000 conjugated with different anchor molecules incorporated with a grafting density of 7.5% in 150 nm DPPC-cholesterol liposomes. (A) % Injected dose in blood-curves of PEG5000-ODA (closed diamonds), PEG5000-DODA (closed squares), PEG5000-HOA (closed triangles), PEG5000-DSPE (closed circles), and bare liposomes without polymer-lipid conjugate (open circles). (B) Distribution to spleen (open bars), liver (gray bars), and total distribution to the MPS (liver and spleen) (black bars). Results are expressed as the mean percentage of the injected dose of four rats  $\pm$  SD.

24 and 48 h postinjection. The PLP-plasma concentration was compared with PLP in PEG-liposomes, as the latter has been shown to be completely stable in the circulation by comparing the plasma concentration of a radioactive liposome marker to the plasma concentration of encapsulated PLP (30). In the same study, plasma levels of PLP could hardly be detected after iv injection of free PLP, which strongly suggests that all PLP measured in plasma after injection of liposomal PLP must be liposome-associated. To measure PLP in plasma samples, plasma was extracted according to a method reported by Derendorf et al. (32). The extracts were assayed with a reversed-phase HPLC method, using UV-absorption detection at 254 nm.

**Therapeutic Activity of PLP-Containing Polymer-Coated Liposomes in Adjuvant Arthritis.** The Dutch Committee of Animal Experiments approved the animal studies. Male inbred Lewis rats between 7 and 9 weeks of age (170–200 g) were obtained from Maastricht University, Maastricht, The Netherlands. Adjuvant arthritis was induced according to Koga and Pearson (33). Briefly, incomplete Freund's adjuvant containing heat-inactivated *Mycobacterium tuberculosis* was subcutaneously injected at the base of the tail. Paw inflammation started around day 10 after the immunization and reached maximal severity around day 20, after which the inflammation process gradually resolved. The rats were daily scored for the visual signs of inflammation. All rats were treated on day 15 postimmunization, when the average score of all rats in the experiment is about half the maximal scores reached in these experiments. The effect of treatment on clinical scores and body weight was monitored up to 4 weeks posttreatment.

**Statistical Analysis.** For statistically assessing and comparing therapeutic efficacy in different groups, the nonparametric Wilcoxon/Kruskal-Wallis test (rank sums) was used. For evaluating differences between groups regarding other parameters, one-way analysis of variance was used. *P* values of less than 0.05 were considered significant.

## RESULTS

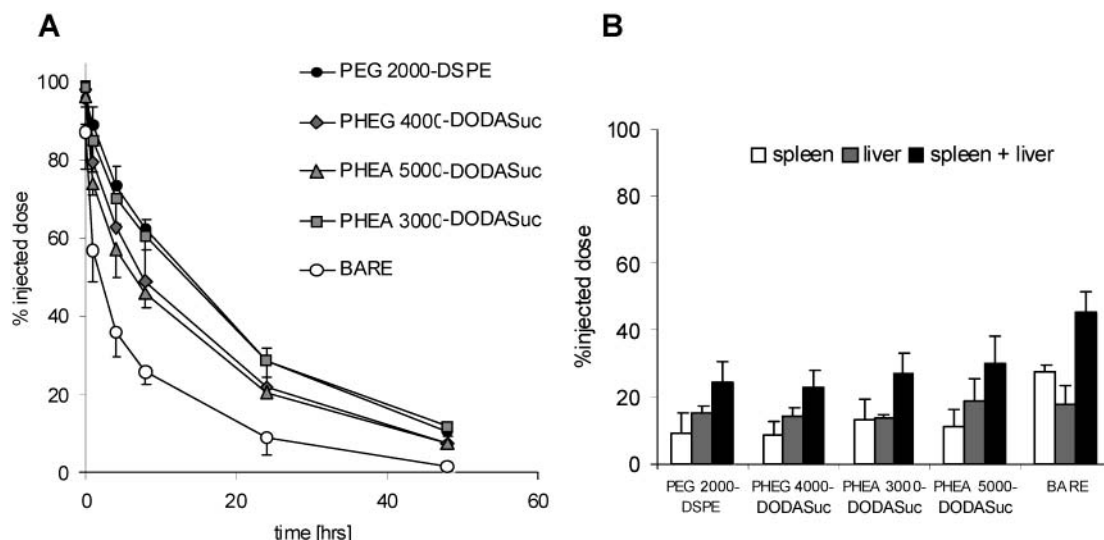

**Synthesis of PHEA- and PHEG-DODASuc Conjugates.** Poly(hydroxyethyl L-asparagine) (PHEA) and

poly(hydroxyethyl L-glutamine) (PHEG) were synthesized starting from benzyl L-aspartate NCA and benzyl L-glutamine NCA, respectively, as shown in Scheme 1. Polymerization of these L-amino acid benzyl ester NCA monomers was followed by aminolysis with alkanolamines. Molecular weights in the range of 2000–5000 were obtained via a primary amine initiated polymerization of these side group-protected amino acid NCA monomers. The molecular weight of the polymer is controlled by the molar ratio of monomer/initiator. *N*-Succinyldioctadecylamine (DODASuc) (lipid anchor) could be coupled to the polypeptide's amino end group. Polymerization of benzyl L-aspartate initiated by a primary amine (e.g., methylamine) yields a polypeptide (PBLA) with an amino end group. In contrast, polymerization of benzyl glutamate NCA initiated by a primary amine results in the formation of a polypeptide (PBLG) without an amino end group. As could be concluded from MALDI-TOF, a five-membered lactam end group is formed by an intramolecular reaction of the amino end group with the benzyl ester group. The terminal amino group is lost.

Conjugation of DODASuc to PBLG, therefore, requires a slightly modified approach: first, benzyl L-glutamate NCA is polymerized using BOC-butanediimine (one amino group is BOC (tertiary butoxycarbonyl)-protected; the other amino group is not) as an initiator. The resulting PBLG containing a protected amino group is deprotected and then coupled to DODASuc using dicyclohexylcarbodiimide (DCC). Amphiphilic conjugates resulted after the polypeptides were made water-soluble by the aminolysis reaction of the benzyl ester side groups with alkanolamines (e.g., ethanolamine).

**Preparation and Characterization of Polymer-Coated Liposomes.** In Table 1 the characteristics of the polymer-coated liposomes are presented. The resulting mean diameter and polydispersity of PHEG-, PHPG-, PHBG-, and PHEA-coated liposomes are comparable to those of PEG-liposomes. All preparations appeared to be physically stable upon storage, and no signs of aggregation were found.

**Selection of Suitable Anchor Molecules.** Figure 1A shows the plasma concentration-time profiles of liposomes coated with different PEG5000 conjugates after iv injection. For the evaluation of the anchor molecules,

**Figure 2.** Pharmacokinetics and distribution to the MPS of PHEA and PHEG versus PEG incorporated with a grafting density of 7.5% in 150 nm DPPC-cholesterol liposomes. (A) %-injected dose in blood-curves of PEG2000-DSPE (closed circles), PHEG4000-DODASuc (gray diamonds), PHEA5000-DODASuc (gray triangles), PHEA3000-DODASuc (gray squares), and bare liposomes without polymer-lipid conjugate (open circles). (B) Distribution to spleen (open bars), liver (gray bars) and total distribution to the MPS (liver and spleen) (black bars). Results are expressed as the mean percentage of the injected dose of four rats  $\pm$  SD.

PEG5000 was chosen instead of PEG2000, as a molecular mass of PEG5000 more closely resembles the molecular mass of most of the polymers tested in this study. We coupled PEG5000 to a series of lipid anchor molecules and compared liposomes coated with these conjugates to liposomes without PEG ('bare' liposomes). Clearly, octadecylamine (ODA) as a lipid anchor results in little prolongation of circulation time, suggesting that one single  $C_{18}$ -tail is not sufficient for stable grafting. Dioctadecylamine (DODA) and heptadecyl octadecylamine (HOA) yield improved prolongation of circulation behavior, similar to the phospholipid anchor distearyl phosphatidylethanolamine (DSPE), which is generally used for stable grafting of PEG on the liposome bilayer. Apparently, two alkyl tails are required for sufficient grafting stability. We selected DODA as the standard anchor molecule for synthesis of PHEA-and the different poly(hydroxyalkyl L-glutamine)-lipid conjugates.

Figure 1B shows the tissue distribution to the MPS organs. The DODA- and HOA-PEG conjugates significantly reduce the hepatosplenic uptake of liposomes. As hepatosplenic uptake is the main cause of liposome elimination from the circulation, these data are in agreement with plasma concentration-time profiles shown in Figure 1A.

**Successful Prolongation of Circulation Half-Life with PHEG- and PHEA-DODASuc.** In Figure 2A it is shown that coating liposomes with 7.5% PHEG4000 or PHEA3000 and PHEA5000 all coupled to *N*-succinyl-DODA (DODASuc) results in almost similar circulation behavior as compared to 7.5% PEG2000-DSPE, the conjugate which is most often used for the preparation of LCL. These results are in line with the tissue distribution data shown in Figure 2B, which shows that all four polymer-lipid conjugates significantly reduce MPS uptake from the circulation.

**Selection of Optimal Grafting Density with PHEG-DODASuc.** In Table 2 the effect of different grafting densities of PHEG4000 on circulation behavior and hepatosplenic uptake is shown. Although plasma concentration-time profiles show little differences at 4 and 24 h, hepatosplenic uptake at 48 h indicates that decreasing the grafting density to 2.5% and 1% or

**Table 2. Percentage of Injected Dose<sup>a</sup> of PHEG-Liposomes in the Circulation at 4 and 24 h Postinjection and Uptake by MPS Organs at 48 h**

PHEG grafting density, %	blood circulation		liver uptake	spleen uptake
	4 h	24 h	48 h	48 h
1	55 $\pm$ 2	22 $\pm$ 1	52 $\pm$ 9	11 $\pm$ 6
2.5	56 $\pm$ 8	22 $\pm$ 1	38 $\pm$ 7	15 $\pm$ 2
7.5	61 $\pm$ 6	23 $\pm$ 4	23 $\pm$ 5	7 $\pm$ 2
15	49 $\pm$ 4	17 $\pm$ 3	32 $\pm$ 5	9 $\pm$ 1

<sup>a</sup> Mean  $\pm$  SD of four rats per group.

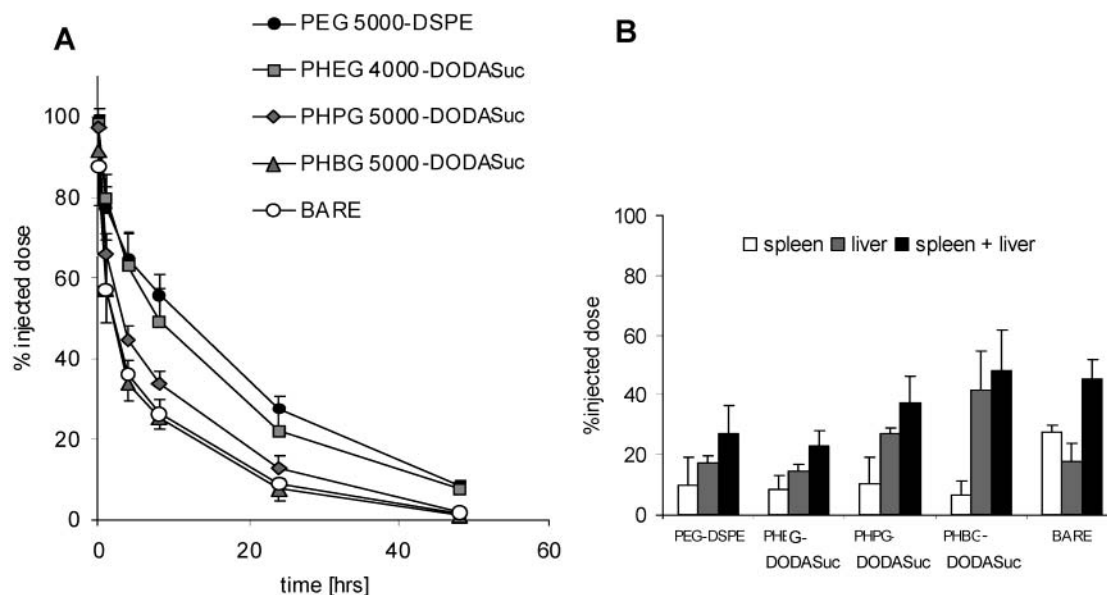

increasing the density to 15% leads to enhanced removal of liposomes by the MPS.

**Effect of the Side Group.** Introduction of longer hydroxyalkyl side groups to the poly(L-glutamine) backbone, such as hydroxypropyl and hydroxybutyl instead of hydroxyethyl, results in reduced prolongation of circulation time and enhanced MPS uptake to the level of 'bare' liposomes (Figure 3). The hydroxyethyl side group appears to be the optimal side group for the poly(hydroxyalkyl L-glutamine)-lipid conjugates.

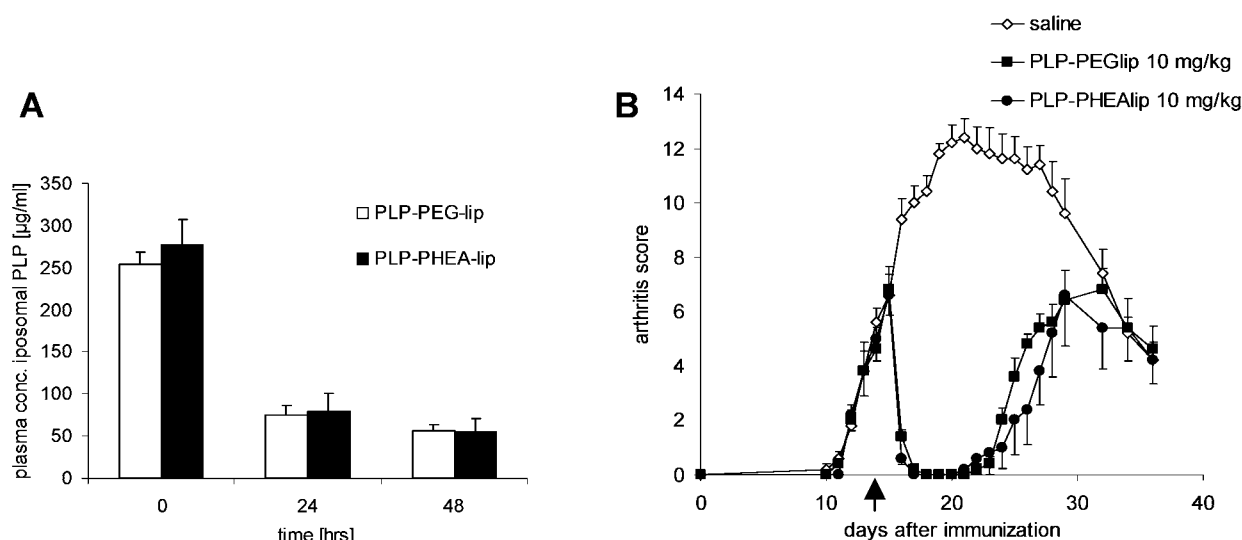

**Effect of Lipid Dose.** Table 3 shows the % injected dose of liposomes still present in the circulation at 4 and 24 h postinjection of PEG-coated liposomes and PHEA-coated liposomes, both at 4 different dose levels ranging from 0.005 to 5  $\mu$ mol lipid per rat. At a dose of 0.05  $\mu$ mol and especially at 0.005  $\mu$ mol, PHEA-liposomes show improved circulation behavior as compared to PEG-liposomes. PEG-liposomes are very rapidly eliminated at the 5 nmol dose level, and they are hardly present in the circulation at 24 h postinjection, whereas 9% of the injected PHEA-liposomes still circulates at 24 h at the same dose level.

**Drug-Targeting Potential.** Prednisolone phosphate (PLP) was encapsulated in both PEG- and PHEA-liposomes and injected in adjuvant arthritis rats. In this experimental arthritis model we previously showed that the therapeutic activity of PLP was dramatically increased by encapsulation in PEG-liposomes. Figure 4A shows the plasma concentration of liposomally encapsulated PLP. The % fractions of the injected dose of PLP in PHEA-liposomes in the circulation at 24 and 48 h equals

Results are expressed as the mean concentration ( $\mu$ g/mL) of five rats  $\pm$  SD. (B) Daily arthritis score after induction of adjuvant arthritis at day 0 and treatment at day 15 (arrow) with 10 mg/kg PLP (120  $\mu$ mol/kg phospholipid) in PHEA-liposomes (closed circles), 10 mg/kg in PEG-liposomes (closed squares), and saline (open diamonds). Results are expressed as the mean of five rats  $\pm$  SEM.

**Table 3.** Percentage of the Injected Dose<sup>a</sup> of Liposomes in Circulation at 4 and 24 h Postinjection

lipid dose, $\mu$ mol	PEG-liposomes		PHEA-liposomes	
	4 h	24 h	4 h	24 h
5	66 $\pm$ 7	29 $\pm$ 6	57 $\pm$ 4	27 $\pm$ 9
0.5	71 $\pm$ 10	26 $\pm$ 5	57 $\pm$ 5	18 $\pm$ 2
0.05	46 $\pm$ 7	12 $\pm$ 3	61 $\pm$ 4	20 $\pm$ 1
0.005	5 $\pm$ 3	1 $\pm$ 1	33 $\pm$ 5	9 $\pm$ 2

<sup>a</sup> Mean  $\pm$  SD of four rats per group.

PLP in PEG-liposomes. As PLP-PEG-liposomes composed of DPPC and cholesterol have been shown not to leak PLP in the circulation, such may therefore also be assumed for PLP-PHEA-liposomes. The circulation half-life of these liposomes is somewhat longer than reported with the radiolabeled liposomes in this study. However,

this is most likely a result of a relatively small diameter of approximately 90 nm as compared to the radiolabeled liposomes (between 140 and 160 nm). Figure 4B shows that 10 mg/kg PLP-PHEA-liposomes induces a similar reversal of the inflammation reaction as 10 mg/kg PLP-PEG-liposomes. Both preparations induce a strong anti-inflammatory effect lasting for two weeks.

## DISCUSSION

In this paper biodegradable polymer-lipid conjugates based on amino acids are evaluated regarding their capacity to confer a long-circulation property to liposomes upon attachment to their lipid bilayer surface. Besides the polymer itself, also the choice of the lipid bilayer anchor deserves attention, as stable grafting of a polymer to the liposome bilayer is essential for achieving long-

circulating behavior. Therefore, in this study the suitability of different lipid anchor molecules was evaluated with PEG5000 as a model polymer (Figure 1). The results show that successful prolongation of liposome circulation time can only be realized with anchor molecules with two stearyl chains. PEG coupled to DODA and HOA resulted in similar prolongation of circulation behavior as PEG-DSPE, which is at present most often used in liposome technology. In agreement with the findings of Webb et al., coupling of the polymer to a single alkyl chain yielded inferior results, most likely due to insufficient grafting stability (34). As DODA was easier to obtain from commercial sources than HOA, all polypeptides were tested in subsequent experiments with DODA as liposome anchor molecule.

The approach of L-amino acid-based polymer-lipid conjugates proved to be successful with PHEG4000 and PHEA3000 and -5000, all coupled to DODASuc. The plasma concentration-time profiles as well as uptake by liver and spleen showed that these polymer-lipid conjugates prolonged the circulation time and reduced the uptake by the MPS to the same extent as PEG2000-DSPE (Figure 2). As has been shown in the literature for PEG, lowering the grafting density of PHEG to 1 mol % resulted in increased uptake by the MPS (35). Interestingly, also a grafting density of 15 mol % PHEG increased MPS-uptake. However, the circulation times of liposomes grafted with 1, 2.5, 7.5, and 15 mol % PHEG did not differ significantly.

The results in this study show that coating the liposomes with poly(L-glutamine) with longer hydroxyalkyl side chains (PHPG and PHBG) instead of PHEG resulted in decreased circulation half-lives (Figure 3). An explanation for this observation may be found in the conformation of the polymers when dissolved in water. It has been suggested that suitable stealth polymers should be flexible and adopt a random conformation (36). For example, dextran has a lower chain flexibility than PEG due to its carbohydrate backbone. When grafted on liposomes, dextran is not able to prolong circulation times (37). Altschuler et al. showed that for poly(hydroxyalkyl-L-glutamine)s the degree of conformational freedom is optimal with hydroxyethyl as a side group and conformational freedom decreases for longer hydroxyalkyl groups. The use of hydroxypropyl and, even more so, hydroxybutyl resulted in the formation of  $\alpha$ -helices in the polymer (38). The decrease in flexibility of these polymers correlates with the observed decrease of circulation half-life.

An important advantage of polymer-coated LCL over LCL without polymer-lipid conjugates is that incorporation of PEG leads to dose-independent pharmacokinetics over a broad dose range (39). To evaluate whether this phenomenon also applies to liposomes coated with poly(hydroxyalkyl L-amino acid)-lipid conjugates, pharmacokinetics of PHEA-liposomes were compared with PEG-liposomes at four different lipid doses ranging from 0.005 to 5  $\mu$ mol total lipid per rat. The lowest dose level at which the PEG-liposomes appeared to show dose-independent kinetics was around 500 nmol/rat (Table 3) which corresponds with earlier reported data (40). Interestingly, with PHEA-liposomes dose-dependency of the pharmacokinetics was less pronounced even at a 10-fold lower dose. PHEA-liposomes may therefore offer an additional advantage over PEG-liposomes in cases when very low lipid doses are preferred, such as in scintigraphic detection of sites of pathology (7).

The final aim of this study was to show that successful drug targeting is possible, with liposomes exposing

biodegradable polypeptide-lipid conjugates. Within the scope of this thesis, a PEG-liposomal formulation of prednisolone phosphate (PLP) was developed that was shown to efficiently contain the drug in the circulation and to highly effectively deliver the encapsulated drug to inflamed joints in experimental arthritis (30). Incorporation of PEG increased the circulation half-life of the liposomal formulation from 6 h to 18 h, which was shown to be necessary to achieve sufficient local delivery for complete reversal of the development of joint inflammation. The present study shows that the use of PHEA-liposomes as PLP carrier results in a similar pharmacokinetic profile of encapsulated PLP. Also, the therapeutic activity of 10 mg/kg PLP-PHEA-liposomes in rat adjuvant arthritis was equal to that of 10 mg/kg PLP-PEG-liposomes. We reported earlier that nonencapsulated PLP was inactive at this dose level (30). The observation that a dramatic improvement of the therapeutic effect of PLP can be achieved with PHEA-liposomes clearly points to the drug targeting potential of this formulation.

In conclusion, we present a novel sterically stabilized liposome formulation performing similarly to PEG-liposomes regarding in vivo long-circulation behavior and drug-targeting potential. These novel polymer-coated liposomes are the first that are sterically stabilized with a biodegradable polymer coating.

Nitric oxide is a gaseous, short-living free radical which behaves as an important signaling molecule with pleiotropic capacities including vasodilatation, neurotransmission, and microbial and tumor cell killing, as well as in tissue damage and organ-specific autoimmune disorders. Here, a synthesized, dinuclear copper complex system in vitro obtained by the simple aza-phenolic ligand 2,6-bis{[bis-(2-aminoethyl)amino]methyl}phenol (L) and Cu(II) ion has been used. The stability constants of ligand L with Cu(II) ion were determined through potentiometric measurements in aqueous solution ( $37.1 \pm 0.1$  °C,  $I = 0.15$  M of NaCl) to mimic the biological medium. The measurements demonstrated that  $[\text{Cu}_2\text{H}_-1\text{L}(\text{OH})]^{2+}$  (DCu) is the predominant species present in solution at pH 7.4. The molecular structure of the ligand in this species permits the cooperation of the two copper ions in assembling the substrate, thus the complex can be used as a receptor for small molecules such as NO. As a biological model, we chose the production of NO catalyzed by inducible nitric oxide synthase obtained from RAW 264.7 murine macrophage cell line stimulated with LPS, which enabled us to prove that NO is coordinated by the DCu complex, modifying its EPR spectra. The coordination of NO with DCu reduces the level of nitrite in the culture medium of stimulated RAW 264.7 macrophages without any inhibition in the expression of iNOS.

## INTRODUCTION

Nitric oxide (NO) can be synthesized by several cell types in mammalian tissues and the mechanism of its synthesis and functions have been the focus of wide investigation (1). NO plays a role as an autocrine and paracrine mediator in several physiological conditions. In particular, the effect of NO in the regulation of vascular homeostasis, as well as its involvement in neurotransmission and in host defense against infectious agents, has been demonstrated (2–4).

However, it has also been reported that imbalances in intracellular NO levels may be responsible for various pathological alterations, such as septic shock, hypertension, stroke, and neurodegenerative disease (5). The production of nitric oxide is catalyzed by the enzyme nitric oxide synthase (NOS). NOS is constituted by a family of enzymes that catalyze the NADPH-dependent conversion of L-arginine to nitric oxide and L-citrulline. Three isoforms of nitric oxide synthase have been identified and cloned (6). Brain (nNOS or type I) and endothelial (eNOS or type III) enzymes are constitutively expressed, and their enzymatic activity is regulated by changes in concentration of free  $\text{Ca}^{2+}$  (7–9). The third member of the family is the inducible (type II) nitric oxide synthase (iNOS), which is expressed in many different cell types after induction and produces high levels of NO

(6). In fact, iNOS is regulated at the transcriptional level by endotoxin and cytokines and is independent of calcium concentration in the physiological range. When activated by endotoxin, macrophages elicit the formation of inflammatory cytokines, which then activate macrophages and other cells to promote iNOS gene induction. Overproduction of NO, primarily by iNOS, has been implicated in a wide variety of disease states (10). Therefore, it is crucial to regulate the excess NO produced by iNOS when considering inflammatory reactions. Most of the currently used pharmacological inhibitors of iNOS may also affect the other two isoforms of NOS and interfere with unrelated metabolic cell pathways to some degree (2, 3). One strategy for the inhibition of NO is to scavenge or remove excess NO produced during pathological processes, avoiding inhibition of the NO metabolic pathway. For this purpose we have used a dinuclear copper complex  $[\text{Cu}_2\text{H}_-1\text{L}(\text{OH})]^{2+}$  (DCu) as a scavenger for NO.

Binuclear transition metal complexes play a central role in a variety of fields. In fact, binuclear metal complexes are successful devices for the recognition and assembly of external species of various nature such as inorganic and organic species (11–14). Many natural biological sites, such as the active centers of several metalloenzymes, are produced by two transition metal ions; thus synthetic binuclear receptors can be used to mimic the active centers (15–18). Recently, we reported the synthesis and the coordination properties of the noncyclic ligand L (Figure 1) containing a phenol moiety separating two triaza-polyamine fragments toward several M(II) metal cations (19–22). Solid-state and solution studies highlighted the ability of L to assemble two transition metal ions in close proximity. In this way, the two metals cooperate to bind a new species ( $\text{OH}^-$ ,  $\text{Cl}^-$ ,  $\text{R-O}^-$ ,  $\text{N}_3^-$ ,  $\text{O}_2$ , and others), which is coordinated in a

**Figure 1.** Ligand L.**Figure 2.** Coordination models of the  $[M_2(H-1L)]^{2+}$  complex with a potential guest.

bridge disposition between the two metals as schematically depicted in Figure 2.

The data demonstrate that the DCu species was able to lower nitrite levels (an indicator of NO presence), in the culture supernatant produced by LPS-stimulated RAW 264.7 macrophage cell line. It is also demonstrated that, through electron paramagnetic resonance (EPR) spectra analysis, the ability of the DCu species to bind the NO produced in vitro.

Here it is shown that the DCu species decreases the free NO level but does not interfere with the expression of iNOS protein in macrophage cell line.

#### MATERIAL AND METHODS.

**Synthesis.** Ligand 2,6-bis{[bis(2-aminoethyl)amino]methyl}phenol L and its solid copper complex  $[Cu_2H-1L(OH)](ClO_4)_2$  were prepared as previously described (19). An aqueous solution at pH 7.4 of this copper complex was freshly prepared by dissolving a known amount of  $[Cu_2H-1L(OH)](ClO_4)_2$  in water and adjusting to pH 7.4 and promptly used. Solvents and starting materials were used as purchased.

**EMF Measurements.** Equilibrium constants for protonation and complexation reactions with L were determined by pH-metric measurements ( $pH = -\log [H^+]$ ) in 0.15 M NaCl at  $T = 37.1^\circ C$ , using the fully automatic equipment previously described (23); the EMF data were acquired with the PASAT computer program. The combined glass electrode was calibrated as a hydrogen concentration probe by titrating known amounts of HCl with  $CO_2$ -free NaOH solutions and determining the equivalent point by Gran's method (24, 25), which gives the standard potential  $E^\circ$  and the ionic product of water ( $pK_w = 13.40$  (1) at  $T = 37.1^\circ C$  in 0.15 M NaCl). At least three potentiometric titrations were performed for each system in the pH range 2.5–11, using different molar ratios of Cu(II)/L ranging from 1:1 to 2:1.

The HYPERQUAD computer program was used to process the potentiometric data (26, 27). All titrations were treated either as single sets or as separate entities without significant variation in the values of the determined constants.

**UV-vis Spectroscopy.** UV absorption spectra were recorded at  $T = 37.1^\circ C$  on a Varian Cary-100 spectrophotometer equipped with a temperature control unit.

**Cell Culture.** All experiments were performed on mouse macrophage cell line RAW 264.7 (kindly supplied by Prof. Umberto Benatti, Genova) cultured in DMEM

supplemented with 10% heat-inactivated foetal calf serum (FCS), 2.0 mM glutamine, and 1% antibiotics. Cultures were maintained in exponential growth at  $37^\circ C$  in a humidified atmosphere of 95% air–5%  $CO_2$ .

**Cell Activation.** RAW 264.7 cells were incubated for 24 h in FCS-free DMEM culture medium at  $37^\circ C$  at 80% of confluence. Cell stimulation to promote iNOS synthesis in intact murine macrophages was achieved by adding 1  $\mu g/mL$  lipopolysaccharide (LPS) from *Escherichia coli* (serotype 0111:B4, Sigma, St. Louis, MO) for 30 min, and then the cells were washed and maintained in the serum free (without phenol red) DMEM medium with several concentrations (0.001–10.0  $\mu M$ ) of DCu or ligand L or  $Cu(ClO_4)_2$  for 18 h to elicit the expression of iNOS and the production of NO.

**Cellular Toxicity.** RAW 264.7 cells were seeded in 96-well plates (Greiner, International PBI, Italy) at a concentration of  $1 \times 10^4$  cells/mL (100  $\mu L$ /well) and treated with several concentrations of DCu or ligand L or  $Cu(ClO_4)_2$  (0.1–10.0  $\mu M$ ) for 24 h.

The in vitro toxicity of RAW 264.7 cells in the presence of several compounds was tested by MTT assay (28, 29). Briefly, 5 mg/mL of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) in PBS was sterilized by filtration. At the time indicated, 10  $\mu L$  of MTT solution was added, and plates were incubated at  $37^\circ C$  for 4 h. Then 100  $\mu L$  of 0.4% of 0.04 N HCl in 2-propanol was added and thoroughly mixed to dissolve the dark blue crystals. The plates were then read on a Microplate Reader (Benchmark, Bio-Rad), using a test wavelength of 570 nm and a reference wavelength of 630 nm. The experiments were run in quadruplicate.

**Measurement of Nitrate/Nitrite.** Total nitrate and nitrite was measured by enzymatic reduction of nitrate to nitrite analysis using the Griess assay (30) which provides a measure of total NO produced by the RAW 264.7 cells. Nitrate was converted to nitrite by the action of nitrate reductase from *Aspergillus niger* (Sigma, Milan, Italy). Briefly, after RAW 264.7 cells were treated with several concentrations of DCu, ligand L, or  $Cu(ClO_4)_2$  in the presence of LPS, the supernatants were immediately centrifuged at 750g in an Eppendorf microcentrifuge to remove cells in suspension. Then 100  $\mu L$  aliquots of culture supernatants were incubated with 50  $\mu M$  NADPH, 5  $\mu M$  FAD, and 0.01 U of nitrate reductase for 20 min at  $37^\circ C$ . After this incubation, the medium was mixed with 100  $\mu L$  of Griess reagent (1% sulfanilamide, 0.1% N-(1-naphthylethylenediamine dihydrochloride in 5%  $H_3PO_4$ ) and incubated at room temperature for 10 min. The absorbance at 540 nm was measured with a spectrophotometer. Nitrite levels were determined using  $NaNO_2$  as a standard.

**Detection of iNOS by Western Blot Analysis.** iNOS in the RAW 264.7 macrophage cell line was detected by Western blot as described previously (31). Briefly, after cells ( $1 \times 10^6$  cells/dishes) ( $\Phi$  35 mm, Sarstedt, Italy) were stimulated with LPS and treated with tested compounds, they were scraped and lysed with a lysis buffer containing 50 mM Tris-HCl, pH 7.6, 0.25 M sucrose, 2% (w/v) SDS, 2  $\mu g/mL$  leupeptin, 1  $\mu g/mL$  pepstatin, 2 mM phenylmethylsulfonyl fluoride (PMSF), 5 mM EDTA, and 5 mM N-ethylenemaleimide. Cellular extracts were immediately boiled for 5 min, sonicated to shear the DNA, and centrifuged at 10 000g in an Eppendorf microcentrifuge to remove insoluble debris. Protein content was assayed by Lowry's method (32). Equal amounts of protein extracts (20  $\mu g$ ) were resolved on 8% SDS-polyacrilamide gels, transferred to nitrocellulose membranes (Amersham Pharmacia Biotech, UK), and then detected with an

antibody specific against iNOS (M-19, Santa Cruz Biotechnology Inc., Santa Cruz, CA). The secondary antibody was horseradish peroxidase-conjugated goat anti-rabbit IgG and immune complexes were visualized with the ECL detection kit (Amersham Life Science, UK) according to the manufacturer's instructions. Membranes were stripped and reprobed with an antibody against actin (Sigma, Milan, Italy). Immunoreactive bands were quantitated by laser densitometry and iNOS levels were normalized to actin.

**EPR Analysis: Samples and Instrumentation.** For EPR analyses, the media from culture supernatant was collected in 2 mm glass tubes sealed at both sides and stored in liquid nitrogen before the measurements. EPR spectra were recorded by means of a EMX-Bruker spectrometer operating at X band (9.5 GHz) and interfaced to a IBM PC computer (Bruker software) for data acquisition and handling. The temperature was controlled with a Bruker ST3000 variable-temperature assembly.

The spectra were considered valid only on condition of reproducibility of the spectral line shape. Radical survival was nevertheless controlled by reproducibility of the EPR signal intensity. No variation of the EPR spectra was found after 1 day, after storing the samples in liquid nitrogen.

## RESULTS

**Chemical and UV Analysis.** Table 1 and Table 2 report the protonation constant and the stability constants of ligand L with Cu(II), respectively, for both equilibrium reactions determined potentiometrically in aqueous 0.15 M NaCl solution at 37.0 °C. The constants values are similar to those determined in 0.15 M N(CH<sub>3</sub>)<sub>4</sub>-Cl solution at 25.0 °C previously discussed (19). The experimental condition was chosen to mimic the same culture medium condition of the dinuclear system used in the in vitro studies. The distribution diagram of the species of the L/Cu(II) system as a function of pH is reported in Figure 3. The diagram shows that in the culture medium at pH 7.4, the species [Cu<sub>2</sub>H<sub>-1</sub>L(OH)]<sup>2+</sup> (DCu) is prevalent in solution and thus can be considered the active species for the interaction with nitric oxide.

**Figure 3.** Distribution diagrams of the species as a function of pH in 0.15 M NaCl aqueous solution at 37.0 °C for the system L/Cu(II): [Cu<sup>2+</sup>] = 2 × 10<sup>-3</sup> M; [L] = 1 × 10<sup>-3</sup> M.

The crystal structure of the DCu species was previously reported (19), and it can be depicted as in Figure 2; in this case, the guest is OH<sup>-</sup> anion.

To understand whether the environment of the two copper ions was modified in the presence of the biological medium, UV spectra were recorded in aqueous solutions containing L and Cu(II) in a 1:2 molar ratio at pH 7.4 using either NaCl ionic strength of the potentiometric measurements or culture medium at 37 °C. Dinuclear complex dissolved in the culture medium was used in the 0.5–100 mM range. The spectrum recorded at pH 7.4 in 0.15 M NaCl aqueous solution, where the DCu species is prevalent in solution, shows two bands at λ<sub>max</sub> 243 (ε = 9300 cm<sup>-1</sup> mol<sup>-1</sup> dm<sup>3</sup>) and 288 (ε = 4900 cm<sup>-1</sup> mol<sup>-1</sup> dm<sup>3</sup>) nm, due to the phenolate moiety engaged in the coordination of the metals; in the visible region, two more bands showing λ<sub>max</sub> 408 nm (ε = 450 cm<sup>-1</sup> mol<sup>-1</sup> dm<sup>3</sup>) attributed to phenolate metal charge transfer and a large band showing λ<sub>max</sub> 725 nm (ε = 420 cm<sup>-1</sup> mol<sup>-1</sup> dm<sup>3</sup>), due to the d–d electron transfer, are also observed. These four bands, having approximately the same profiles and ε, are also present in the culture medium, suggesting that the DCu species are preserved.

**Effects of DCu on Nitrite Level.** Nitrite production was measured in the culture medium of RAW 264.7 murine macrophage cell line treated with DCu species or ligand L or Cu(ClO<sub>4</sub>)<sub>2</sub> (0.001–10.0 μM) as described in Materials and Methods.

Nitrite levels in stimulated macrophages, whether treated or not with ligand L or Cu(ClO<sub>4</sub>)<sub>2</sub> at the several concentrations tested, did not show any differences (Figure 4). On the contrary, stimulated macrophages treated with DCu showed a reduced level of nitrite. The percentage of inhibition of nitrite level is shown in Figure 4.

All the compounds used were tested to exclude any toxic effect on the cell line. Data are shown in Figure 5.

**Effects of DCu on iNOS Expression.** To examine the effect of DCu, ligand L, or Cu(ClO<sub>4</sub>)<sub>2</sub> on iNOS protein expression, RAW 264.7 cells were stimulated with 1 μg/mL of LPS for 30 min and subsequently treated with the above-mentioned compounds for 18 h. The cellular extracts were prepared and tested for iNOS expression by western blot analysis as described in Materials and Methods.

The evaluation of iNOS levels by laser densitometry of the immunoreactive band normalized to actin is reported (Figure 6).

Immunoblot analysis of unstimulated macrophage cellular extracts revealed no iNOS expression (Figure 6, lane 1). LPS-activated cells treated with DCu at several

**Figure 4.** Effects of DCu on nitrite level. Cells ( $1 \times 10^6$  cells) were incubated for 30 min with LPS ( $1 \mu\text{g/mL}$ ) and further incubated for 18 h in DMEM (without phenol red) culture medium with several concentrations of DCu (column black), ligand L (column gray) or  $\text{Cu}(\text{ClO}_4)_2$  (column white). Nitrite levels in the supernatants of culture medium were measured using Griess reagent as described in Materials and Methods. The values are the mean  $\pm$  SD of three different experiments. For all samples:  $p \leq 10^{-3}$  (vs LPS stimulated).

**Figure 5.** MTT assay in RAW 264.7 cells. Murine macrophage cell line ( $10^4/\text{well}$ ) was incubated for 24 h with different concentrations (0.1–10  $\mu\text{M}$ ) of DCu (column black), ligand L (column gray), or  $\text{Cu}(\text{ClO}_4)_2$  (column white). Each data point represents the mean  $\pm$  SD of quadruplicate samples from two different experiments.

**Figure 6.** iNOS expression in stimulated RAW 264.7 cells. Immunoblot analysis of iNOS levels in murine macrophages not stimulated (lane 1) and LPS stimulated (lane 2–11). DCu was present at the concentration of 0.001  $\mu\text{M}$  (lane 3); 0.01  $\mu\text{M}$  (lane 4); 0.1  $\mu\text{M}$  (lane 5); 0.5  $\mu\text{M}$  (lane 6); 1.0  $\mu\text{M}$  (lane 7); 2.0  $\mu\text{M}$  (lane 8); 4.0  $\mu\text{M}$  (lane 9); 8.0  $\mu\text{M}$  (lane 10); and 10.0  $\mu\text{M}$  (lane 11). Blots were probed with anti iNOS and actin antibodies. More details on the stimulation protocol are described in Materials and Methods.

concentrations (0.001–10.0  $\mu\text{M}$ ) showed no significant effect on the iNOS protein level (Figure 6, lanes 2–11).

Even when ligand L or  $\text{Cu}(\text{ClO}_4)_2$  were used, the iNOS expression was not affected (data not shown).

**EPR Analysis.** EPR experiments were performed on DCu or ligand L dissolved in NaCl 0.15 M aqueous solution at pH 7.4 or in culture medium. Murine macrophages stimulated with LPS or unstimulated were grown in the presence or absence of DCu or ligand L, and on these media, EPR spectra were performed. Spectra

**Figure 7.** EPR spectra at  $-196^\circ\text{C}$  of DCu (a) and of murine macrophages stimulated with LPS, grown in the absence (b) and in the presence of DCu (c).

obtained from culture medium alone were also recorded as negative control.

All the EPR spectra were recorded at different temperatures,  $37^\circ\text{C}$ ,  $-103^\circ\text{C}$ , and at  $-196^\circ\text{C}$ . Spectra of DCu or ligand L in 0.15 M NaCl aqueous solution in the culture medium or in media obtained from unstimulated macrophages in the presence or absence of the two compounds appeared EPR silent at all temperatures. This is expected since dinuclear copper complexes in solution show a detectable signal only at temperatures low enough to provide a powder spectrum, due to spin-exchange effect, ferro- or ferri-magnetic properties correlated to fast relaxation (33–38). On the contrary, DCu in the presence of NO generated by LPS-stimulated macrophages showed a detectable EPR signal. The EPR signals, obtained at  $-196^\circ\text{C}$  for stimulated cells in the absence and in the presence of DCu, and for DCu alone, are shown in Figure 7. The broad line, centered at  $g = 2.004$  ( $g$  values were measured compared to diphenylpicryl hydrazide-DPPH ( $g = 2.0036$ ) added as an external reference) is attributed, on the basis of similar spectra reported in the literature, to the perpendicular adsorption of mononuclear copper complexes and shows a partial resolution of the hyperfine coupling between the unpaired electron and the nuclear spins of nitrogen nuclei ( $a_{\text{N}}$  = 65 G). The parallel adsorptions, centered at  $g_{\text{N}}$ , approximately 2.21, are poorly resolved and not shown. No further EPR lines were found in different field ranges. The spectrum at  $37^\circ\text{C}$  is a very noisy broad signal (not shown) centered at  $g$ , approximately 2.1. The signals shown in Figure 7 address the purpose of the present study: a significant spectral variation occurs because of the linking of NO, produced by stimulated cells, to the dinuclear  $\text{Cu}(\text{II})$  complex. The spectrum resulting from mononuclear  $\text{Cu}(\text{II})$ , in the presence of NO, indicates that the NO coordination influences the environment of copper ions in DCu. This can occur through the formation of a structure similar to that reported in the literature for an equivalent DCu complex coordinating  $\text{NO}^-$  (39), and probably an electron transfer also occurs between NO and  $\text{Cu}(\text{II})$ .

## DISCUSSION

In this *in vitro* biological model, exposure of macrophages to the proinflammatory bacteria LPS induces the expression of iNOS and the consequent production of a large amount of NO responsible for tissue damage and

autoimmune diseases. Therefore, the reduction of NO concentration without interfering with NOS enzyme is desirable.

Recent attention has been directed toward the development of synthetic metal receptors, formed by transition metal ions capable of coordinating NO molecules (40). Many of the synthetic metal receptors present copper ion as the coordinating center (41, 42).

Synthetic dinuclear complexes, in which the two metal ions are placed in close proximity, are good metal receptors for small molecules; the binding center is formed by both metal ions and they cooperate to bind the molecule in a stable, coordinated bridge disposition between the two metal ions (19, 21, 43). This knowledge prompted us to synthesize a dinuclear copper complex (DCu) having the two Cu(II) ions placed close to each other and to investigate whether DCu acts as a NO scavenger, forming a stable complex.

The selectivity of this scavenger for the nitric oxide responsible for pathological effects is not based on specificity for any particular enzyme, but rather on compartmental localization and rate of reaction with NO. To prove that DCu in a physiological environment, such as the culture medium, is the active species for NO coordination, potentiometric and UV/Vis measurements were performed; the formation constants of the complexed species for the system L/Cu(II) calculated by potentiometric measurements in 0.15 M NaCl aqueous solution at 37 °C revealed the presence of a stable dinuclear complex (DCu) in solution (Table 2 and Figure 3), representing the only species present at pH 7.4. Moreover, UV/Vis spectra on L/Cu(II) in aqueous solution or in culture medium proved that the DCu complex is preserved in the biological medium and therefore can be considered the active species interacting with NO. MTT experiments on DCu showed no toxicity on RAW 264.7 in the concentration range tested. The biological experiments show that it is the DCu complex and not the ligand L or Cu(ClO<sub>4</sub>)<sub>2</sub> that was able to reduce nitrite accumulation in the culture medium of the LPS-stimulated RAW 264.7 macrophage cell line (Figure 4) without inhibiting iNOS protein expression as shown in Figure 6.

To determine if the DCu complex is involved in NO reduction, EPR experiments were performed to exploit the magnetic properties of both DCu and NO species. As expected, the DCu complex is EPR silent in all media used in absence of NO; this property is due to the closeness of the two Cu(II) ions which, in solution, produce a spin-exchange effect correlated to fast relaxation. As well, the medium containing NO alone is also EPR silent. At the same time, the EPR spectra recorded in the presence of both NO and DCu show detectable signals below -103 °C that could be generated by the presence of a stable DCu-NO complex. These spectra are due to the mononuclear copper complex, and they can be obtained by a spatial separation of the two copper ions in DCu which can be achieved by the coordination of a molecule of NO in a bridge disposition as observed in similar studies (39). However, redox processes involving coordinated NO and Cu(II) ions cannot be excluded although they should represent a minority since the oxidation products of NO (nitrite or nitrate) decrease in the experiments. Certainly, the EPR signals are due to Cu(II) ion when NO binding occurs. This could be explained by the separation of the two Cu(II) ions in the complexed species which behave, for EPR experiments, as a mononuclear complex. In this case, it results that NO acts on DCu complex generating an EPR signal and probably facilitates the electron transfer between the

metal ions and the ligand. Currently, inorganic chemical studies on the NO-DCu system in aqueous solution are in progress to elucidate these aspects.

In fact, all the experiments performed in biological conditions are not suitable to unequivocally identify the stoichiometry of the complex DCu-NO formed, mainly due to the low concentration of the solutions used. However, previous studies (19, 21) on the coordination properties of DCu indicate that it binds external species through cooperation of both metal ions; thus it is possible to hypothesize that DCu binds only one NO molecule in a bridge disposition as shown in Figure 2, preserving the oxidation state of the two copper ions.

Our model provides unequivocal evidence that DCu reduces nitrite accumulations in RAW 264.7-stimulated cell line by scavenging NO produced while not inhibiting iNOS expression. The low toxicity of DCu, together with its activity in the cells studied, indicates a potential use in biological models where the removal of NO is advisable. Moreover, the success of DCu as a NO scavenger in vitro points out the potential of the synthesis and investigation of new dinuclear copper complexes suitable for the detection of NO produced in vitro/vivo.

Hemoglobin (Hb) vesicles (particle diameter, ca. 250 nm) have been developed as Hb-based oxygen carriers in which a purified Hb solution is encapsulated with a phospholipid bilayer membrane. The oxidation of Hb to nonfunctional ferric Hb (metHb) was caused by reactive oxygen species, especially hydrogen peroxide ( $\text{H}_2\text{O}_2$ ), in vivo in addition to autoxidation. We focused on the enzymatic elimination of  $\text{H}_2\text{O}_2$  to suppress the metHb formation in the Hb vesicles. In this study, we coencapsulated catalase with Hb within vesicles and studied the rate of metHb formation in vivo. The Hb vesicles containing  $5.6 \times 10^4$  unit  $\text{mL}^{-1}$  catalase decreased the rate of metHb formation by half in comparison with Hb vesicles without catalase. We succeeded in prolonging the oxygen-carrying ability of the Hb vesicle in vivo by the coencapsulation of catalase.

## INTRODUCTION

Ferrous hemoglobin (Hb) reversibly binds oxygen molecules to carry oxygen to terminal tissues and is gradually autoxidized to nonfunctional ferric Hb (metHb). In red blood cells, reduction systems such as NADH-cytochrome  $b_5$ , NADPH-flavin, glutathione, and ascorbic acid reduce metHb to ferrous Hb. Superoxide dismutase (SOD) and catalase exist in the cell to eliminate the superoxide anion ( $\text{O}_2^{\cdot-}$ ) and hydrogen peroxide ( $\text{H}_2\text{O}_2$ ), respectively, and the percentage of metHb in red blood cells is normally maintained at less than 1.0% (1, 2).

At present, several hemoglobin (Hb)-based oxygen carriers, which have been developed as red blood cell substitutes (3–5), are generally classified into two types: one is the acellular-type modified Hb molecules such as intramolecularly cross-linked Hb (6), recombinant cross-linked Hb (7), intermolecularly polymerized Hb (8), and poly(ethylene glycol) (PEG)-conjugated Hb (9). The other is a cellular-type Hb such as Hb vesicles (10) or liposome-encapsulated Hb (11), in which Hb molecules are encapsulated with a phospholipid bilayer membrane. Some of the acellular-type Hb modifications have advanced to phase III clinical trials (12, 13). Though the Hb vesicles have not yet been clinically studied, their excellent oxygen-carrying ability and high safety have been confirmed in vivo (10, 14–19).

When using Hb-based oxygen carriers, the oxidation of ferrous Hb to metHb is an important issue (20). Enzymes such as SOD and catalase, and enzymes in metHb reduction systems have been used to limit the metHb formation (21, 22). In the case of acellular Hb, the rate of metHb formation in blood circulation was suppressed compared with that in vitro, because metHb was reduced by reductants contained in the plasma such as ascorbic acid and glutathione. For example, about 40% glutaraldehyde-polymerized bovine Hb was reported to be oxidized to metHb at 72 h after a 90% exchange transfusion in ovines, and no further increase in the metHb percentage was observed (23). In the dextran-

conjugated Hb, the metHb percentage was maintained at 35%, 12 h after the 50% exchange transfusion in guinea pigs (24). On the other hand, in the Hb vesicles, the reductants in plasma are not available because of their low membrane permeability. Among the reactive oxygen species (ROS) such as nitric oxide (NO),  $\text{O}_2^{\cdot-}$ , and  $\text{H}_2\text{O}_2$ , which are known to promote metHb formation,  $\text{H}_2\text{O}_2$  can permeate through the bilayer membrane, and a relatively large amount of  $\text{H}_2\text{O}_2$  such as 4–5  $\mu\text{M}$  is constantly generated in normal human plasma (25). Therefore, we considered that such exogenous  $\text{H}_2\text{O}_2$  should be a cause of the metHb formation in addition to the autoxidation of Hb and endogenous  $\text{H}_2\text{O}_2$  generated by the autoxidation of Hb in the Hb vesicles. Therefore, the metHb formation of Hb vesicles was expected to be suppressed by  $\text{H}_2\text{O}_2$  elimination.

Although the rate of metHb formation was actually suppressed in vitro by the coencapsulation of catalase, the rate was dramatically increased in vivo. This was because catalase, which was purchased for laboratory use, was contaminated with LPS, and the resulting catalase-coencapsulated Hb vesicles were also highly contaminated with LPS ( $>10$  EU  $\text{mL}^{-1}$ ). We considered that the LPS would promote the rate of metHb formation in vivo because the inflammatory reaction would produce reactive oxygen species. In this study, we prepared the Hb vesicles coencapsulating LPS-free catalase (below 0.1 EU  $\text{mL}^{-1}$ ) and administered the Hb vesicle dispersion to Wistar rats (20  $\text{mL kg}^{-1}$ ) to study the suppression of the rate of metHb formation by the coencapsulation of catalase.

## MATERIALS AND METHODS

**1. Removal of Lipopolysaccharide (LPS) from Catalase.** A catalase solution (from bovine liver, Sigma, St Louis, MO) was mixed with a 10% Triton X-114 solution (Pierce Chemical, Rockford, IL) and incubated at 4 °C for 30 min. After the mixed solution was incubated at 37 °C for 40 min to separate into two phases, the aqueous phase containing catalase was centrifuged at 5000 rpm for 20 min, and the catalase solution was dialyzed against the water for injection at 4 °C for 24 h.

\* To whom correspondence should be addressed. E-mail: eishun@waseda.jp.

The determination of LPS was carried out with limulus assay (Limulus ES-II, Wako Pure Chemical, Osaka). The catalase solution was mixed with the LAL reagent, and the concentration of LPS was determined from the gelation time (Toxinometer ET-201, Wako Pure Chemical). The catalase activity was measured from the decreasing rate of the absorbance at 240 nm when the 0.06% (v/v)  $\text{H}_2\text{O}_2$  solution (2.9 mL) was mixed with the catalase solution (0.1 mL) at 25 °C.

**2. Preparation of Hb Vesicles Coencapsulating Catalase (26–28).** Hb was purified from outdated human red blood cells donated from Japanese Red Cross Blood Center (27). After the hemolyzed solution was separated from stromata, the ligand exchange of Hb from  $\text{O}_2$  to carbon monoxide (CO) was carried out by CO gas flowing. The proteins other than carbonylHb (HbCO) were denatured by heat treatment (60 °C for 12 h) and removed as precipitates. Pyridoxal 5'-phosphate (PLP, Sigma) as an allosteric effector was added to the HbCO solution (36 g  $\text{dL}^{-1}$ ) at a 2.5:1 molar ratio of PLP to Hb, and the catalase solution was added to it. Mixed lipid [1,2-dipalmitoyl-*sn*-glycero-3-phosphatidylcholine (DPPC, Nippon Fine Chemical, Osaka)/cholesterol (Nippon Fine Chemical)/1,5-dipalmitoyl-L-glutamate-*N*-succinic acid (DPEA, Nippon Fine Chemical)/1,2-distearoyl-*sn*-glycero-3-phosphatidylethanolamine-*N*-PEG (PEG molecular weight was 5000, Sunbright DSPE-50H, H-form, NOF Co., Tokyo), 5/5/1/0.033 by molar ratio] powder was dispersed with the HbCO solution, and the dispersion was stirred at 10 °C for 12 h. The resulting dispersion of multilamellar vesicles was extruded through the membrane filters (FM series, pore size; 3.00, 0.80, 0.65, 0.45, 0.30, 0.22  $\mu\text{m}$ , Fuji Film Co., Tokyo) with a Remolino (Millipore Co., Ltd., Bedford, MA). The Hb vesicles with an average diameter of 250 nm were prepared after extrusion through the membrane filter with 0.22  $\mu\text{m}$  pore size. After the separation of unencapsulated Hb by ultracentrifugation (10000g, 60 min), the precipitate of the Hb vesicles was redispersed into saline. Finally, the Hb concentration of the dispersion was adjusted to 10 g  $\text{dL}^{-1}$ . After Hb vesicles were solubilized with Triton X, the concentration of Hb was determined by a cyanometHb method. In this study,  $[\text{catalase}]_{\text{fed}}$  was defined as the catalase concentration at the mixed solution of Hb and catalase used in the preparation of the Hb vesicles.

The particle diameter of the Hb vesicles was measured by a dynamic light scattering method (N4 PLUS, Beckman Coulter, Fullerton, CA).

**3. Measurement of the Rate of methHb Formation of the Hb Vesicle in Vivo.** Wistar rats (195–210 g) were used in the experiments. They were anesthetized with diethyl ether, and the Hb vesicle dispersion was administered to the tail vein (20 mL  $\text{kg}^{-1}$ ). The sample was the Hb vesicles coencapsulating catalase (0–5.6  $\times 10^4$  unit  $\text{mL}^{-1}$ ). The blood withdrawn from the tail vein was centrifuged (12000g, 5 min) to collect the Hb vesicles in the upper phase of the precipitate. The methHb percentage was calculated based on the intensity ratio at 405 and 430 nm, which were identified as methHb and deoxyHb, respectively, under the nitrogen condition.

## RESULTS AND DISCUSSION

The catalase from bovine liver purchased for laboratory use was contaminated with LPS and was not acceptable for in vivo administration. We tried to remove LPS from the catalase solution using a nonionic detergent, Triton X-114. A solution of Triton X-114, which has a cloud point at 20 °C, is homogeneous below this point and is

separated into an aqueous phase and a detergent phase above that point (29). LPS is highly lipophilic and is transferred from an aqueous phase containing catalase into the organic phase of Triton X-114. We mixed a catalase solution ( $2.5 \times 10^3$  unit  $\text{mL}^{-1}$ ) with a Triton X-114 solution (10%, v/v) at 4 °C and separated the mixed solution into two phases at 37 °C to collect the aqueous phase containing catalase. The LPS concentration of the resulting catalase solution was reduced to 0.0038 EU  $\text{mL}^{-1}$  from  $>10$  EU  $\text{mL}^{-1}$  without significant dilution. We coencapsulated this purified catalase with Hb in the vesicles.

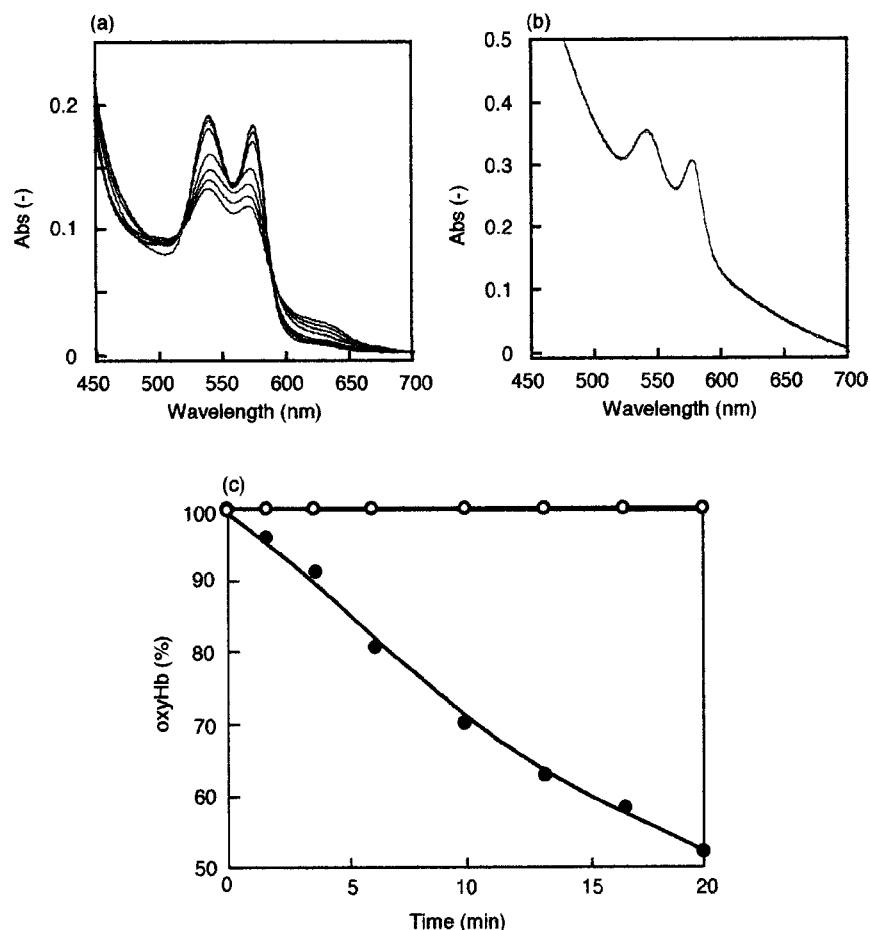

We then examined the stability of the catalase activity in a solution state at 37 °C. The catalase activities after incubation for 24, 48, and 56 h were 82, 82, and 81%, respectively. The constant activity of around 80% at 37 °C for more than 56 h indicate that the catalase should be tolerable during the in vivo study because the circulation half-life of the Hb vesicles was around 24 h in rats (20 mL  $\text{kg}^{-1}$ ).

The particle diameter of the Hb vesicles was  $251 \pm 80$  nm, and the oxygen affinity ( $P_{50}$ ) was 30 Torr. For all the Hb vesicles used in this study, oxyHb and methHb were more than 97% and less than 3%, respectively. Neither HbCO nor ferrylHb was detected. After the catalase-coencapsulated Hb vesicles were dissolved by the addition of Triton X, the resulting solution was analyzed by electrophoresis (IEF-PAGE). From the band of catalase, it was confirmed that the catalase was exactly coencapsulated in the Hb vesicles. We tried to measure the catalase activity of the Hb vesicles, however, due to the catalase-like activity of Hb, this activity could not be determined. Therefore,  $[\text{catalase}]_{\text{fed}}$  was defined as the catalase concentration at the mixed solution of Hb and catalase in the preparation process.

The LPS concentration in the resulting Hb vesicle dispersion ( $[\text{Hb}] = 10$  g  $\text{dL}^{-1}$ ) was below 0.1 EU  $\text{mL}^{-1}$ , which was measured by limulus assay after the solubilization of the Hb vesicles with poly(ethylene glycol) 10-lauryl ether (30).

We studied the reactivity of the Hb vesicles against ROS ( $\text{O}_2^{\cdot -}$  and  $\text{H}_2\text{O}_2$ ). The rate of  $\text{O}_2^{\cdot -}$  produced in a 106  $\mu\text{M}$  hypoxanthine/0.32 unit  $\text{mL}^{-1}$  xanthine oxidase system was 0.9  $\mu\text{M s}^{-1}$ , which was determined by cytochrome *c* (31). Catalase was also added to this system to eliminate  $\text{H}_2\text{O}_2$  from the immediate dismutation of  $\text{O}_2^{\cdot -}$  ( $k = 8.5 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$ ). As shown in Figure 1a, for the Hb solution, the peaks at 542 and 577 nm, identified as oxyHb, were gradually converted to the peak at 630 nm, identified as methHb, indicating that Hb underwent a one-electron oxidation to methHb by  $\text{O}_2^{\cdot -}$ . On the other hand, in the Hb vesicle dispersion, the UV-vis spectrum, where a large decline in the baseline from the lower wavelength typically shows the turbidity of the vesicles, did not change at all as shown in Figure 1b. This indicated that  $\text{O}_2^{\cdot -}$  could not permeate through the bilayer membrane due to the electrostatic repulsion from the negatively charged membrane (Figure 1c). Therefore, if the exogenous  $\text{O}_2^{\cdot -}$  would attack the Hb vesicles, it should have little influence on the methHb formation.

Next, we analyzed the reaction of  $\text{H}_2\text{O}_2$  with the Hb vesicles as shown in Figure 2a ( $[\text{heme}] = 12 \mu\text{M}$ ,  $[\text{H}_2\text{O}_2] = 120 \mu\text{M}$ ); oxyHb was converted to methHb via ferrylHb as an intermediate. In our previous report (19),  $\text{H}_2\text{O}_2$  permeated through the bilayer membrane, and Hb in the vesicles reacted with  $\text{H}_2\text{O}_2$  in a catalase-like reaction to produce methHb or ferrylHb ( $\text{Fe}^{\text{IV}}=\text{O}$ ) in the presence of excess  $\text{H}_2\text{O}_2$ . In the case of the Hb vesicles coencapsulating catalase ( $[\text{catalase}] = 4.2 \times 10^4$  unit  $\text{mL}^{-1}$ , Figure

**Figure 1.** Spectral changes of (a) the Hb solution and (b) the Hb vesicle dispersion ( $[\text{heme}] = 12 \mu\text{M}$ ) during the reaction with  $O_2^{\cdot-}$  at  $37^\circ\text{C}$  ( $0.9 \mu\text{M s}^{-1}$ ). The repetitive scanning was started at a 2 min interval. (c) Changes of the oxyHb in the Hb solution (●) and the Hb vesicle dispersion (○) during the reaction with  $O_2^{\cdot-}$ .

**Figure 2.** Spectral changes of (a) the Hb vesicle dispersion ( $[\text{heme}] = 12 \mu\text{M}$ ) and (b) catalase-coencapsulating Hb vesicle dispersion ( $[\text{heme}] = 12 \mu\text{M}$ ,  $[\text{catalase}]_{\text{fed}} = 4.2 \times 10^4 \text{ unit mL}^{-1}$ ) during the reaction with  $H_2O_2$  at  $37^\circ\text{C}$ . The repetitive scanning was started at a 2 min interval.

2b), a very small amount of oxyHb was converted to metHb without the formation of ferrylHb. This is because the reaction of Hb or catalase with  $H_2O_2$  should be competitive in the vesicles. Most of the  $H_2O_2$  should be eliminated by catalase, and a small amount of  $H_2O_2$  should react with Hb to form metHb (the elimination rate of catalase is about a thousand times greater than that of Hb). We measured the time course of the oxyHb percentage after the addition of 10-fold excess  $H_2O_2$  to oxyHb in the vesicles and calculated the initial decreasing rate of oxyHb (Figure 3). The Hb vesicles without catalase showed a decreasing rate of  $42\% \text{ min}^{-1}$ , whereas the Hb

vesicles with catalase showed a lower decreasing rate, depending on the concentration of catalase ( $[\text{catalase}]_{\text{fed}}$ ). The rate decreased to  $5.0\% \text{ min}^{-1}$  when more than  $5.0 \times 10^4 \text{ unit mL}^{-1}$  was coencapsulated within the vesicle. In this case, the ratio of Hb to catalase was calculated to be 35. We confirmed that the metHb formation of the Hb vesicles by exogenous  $H_2O_2$  could be effectively suppressed by catalase-coencapsulation.

We next examined the catalase encapsulation effect on the autooxidation-derived  $H_2O_2$ , namely endogenous  $H_2O_2$ . We measured the rate of metHb formation in the Hb vesicles at 40 Torr of oxygen partial pressure ( $PO_2$ ) in

**Figure 3.** The relationship between the decrease rate of oxyHb in the vesicle ([heme] = 12  $\mu$ M) and the coencapsulated catalase during the reaction with  $\text{H}_2\text{O}_2$  ( $[\text{H}_2\text{O}_2]$  = 120  $\mu$ M).

vitro. When the  $\text{PO}_2$  is approximately the  $P_{50}$  of Hb, the rate of metHb formation tends to show a maximum (32, 33), and the average oxygen partial pressure in mixed venous blood is estimated to be 40 Torr. Therefore, we used the constant oxygen partial pressure of 40 Torr to measure the rate of metHb formation of the Hb vesicle dispersion for estimation of the *in vivo* behavior. As shown in Figure 4a, the rate of metHb formation in the Hb vesicles was 3.5%  $\text{h}^{-1}$ , and in the case of the catalase-coencapsulating Hb vesicles, the rate of metHb formation was significantly reduced from 2.8 to 2.0%  $\text{h}^{-1}$  with an increase in the encapsulated catalase concentration from  $2.8 \times 10^3$  to  $1.7 \times 10^4$  unit  $\text{mL}^{-1}$ . However, the rate of metHb formation was not reduced even when  $2.0 \times 10^4$  unit  $\text{mL}^{-1}$  catalase was coencapsulated (Figure 4b). Inside the vesicle, Hb is autoxidized to metHb with the production of  $\text{O}_2^{\cdot-}$ , and the resulting  $\text{O}_2^{\cdot-}$  immediately caused a one-electron oxidation of Hb to metHb and the  $\text{O}_2^{\cdot-}$  became  $\text{H}_2\text{O}_2$ . On the other hand, the  $\text{O}_2^{\cdot-}$  was immediately dismutated to  $\text{H}_2\text{O}_2$ . As previously reported, the resulting endogenous  $\text{H}_2\text{O}_2$  also autoxidizes Hb to metHb, or metHb via ferrylHb. Therefore, the autoxidation of Hb should trigger a further oxidation accompanied by the production of reactive oxygen species. In fact, in the group of catalase-coencapsulating Hb vesicles, the reduction of the metHb formation rate indicates that the metHb formation was suppressed by the elimination of the endogenous  $\text{H}_2\text{O}_2$ . The 2.0%  $\text{h}^{-1}$  rate of metHb formation of the Hb vesicles coencapsulating more than  $1.7 \times 10^4$  unit  $\text{mL}^{-1}$  catalase showed that the metHb formation by  $\text{H}_2\text{O}_2$ , which was produced by the autoxidation of Hb in the vesicle, could be completely suppressed by catalase.

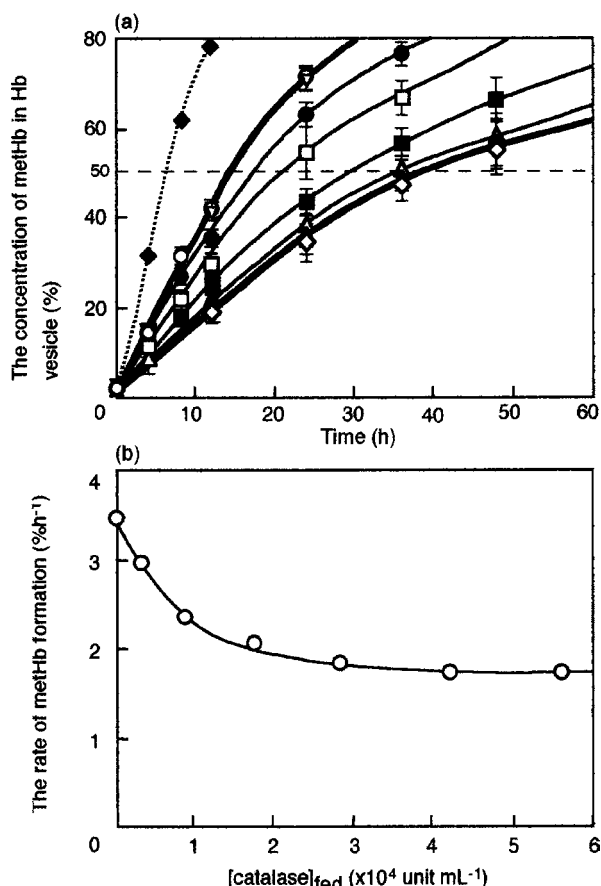

It is expected that SOD, which dismutates two  $\text{O}_2^{\cdot-}$  and two  $\text{H}^+$  to  $\text{H}_2\text{O}_2$  and  $\text{O}_2$ , should contribute to the reduction of the metHb formation rate. In the Hb solution ([Hb] = 2.0 g  $\text{dL}^{-1}$ ) containing SOD ( $2.0 \times 10^3$  unit  $\text{mL}^{-1}$ ) and catalase ( $2.0 \times 10^4$  unit  $\text{mL}^{-1}$ ), the rate of the metHb formation at 37  $^\circ\text{C}$  under atmospheric conditions was 1.3%  $\text{h}^{-1}$ , which was reduced to 74% compared with a bare Hb solution (1.8%  $\text{h}^{-1}$ ). However, the rate was almost the same as that of the Hb solution containing catalase (1.4%  $\text{h}^{-1}$ , [catalase] =  $2.0 \times 10^4$  unit  $\text{mL}^{-1}$ ). From this experiment, we used only catalase as an effective prolongation tool of the Hb function in the Hb vesicles.

To study the rate of the metHb formation *in vivo*, the Hb vesicles were injected into the rat tail vein (20 mL  $\text{kg}^{-1}$ ). It was confirmed that the LPS concentration in

**Figure 4.** (a) Changes of metHb percentage in the Hb vesicles at 40 Torr of oxygen partial pressure ([Hb] = 2.0 g  $\text{dL}^{-1}$ ). The control is catalase-free Hb vesicles ( $\circ$ ). The encapsulated catalase in the Hb vesicle was  $2.8 \times 10^3$  ( $\bullet$ ),  $8.4 \times 10^3$  ( $\square$ ),  $1.4 \times 10^4$  ( $\blacksquare$ ),  $1.7 \times 10^4$  ( $\triangle$ ), and  $2.0 \times 10^4$  unit  $\text{mL}^{-1}$  ( $\blacktriangle$ ). (b) The relationship between  $[\text{catalase}]_{\text{enc}}$  and the rate of metHb formation.

these samples was below 0.1 EU  $\text{mL}^{-1}$ , approved for *in vivo* administration. If LPS-contaminated Hb vesicles were injected, the rate of metHb formation should dramatically increase. In the catalase-coencapsulated Hb vesicles ( $[\text{catalase}] = 2.8 \times 10^4$  unit  $\text{mL}^{-1}$ ), where the LPS concentration was 10 EU  $\text{mL}^{-1}$ , the rate of metHb formation was 8.0%  $\text{h}^{-1}$  (dotted line in Figure 5a), whereas the rate was 2.9%  $\text{h}^{-1}$  in the catalase-coencapsulated sample of which the LPS concentration was 0.1 EU  $\text{mL}^{-1}$ . LPS is a major constituent of the outer envelope of Gram-negative bacteria; therefore, it is an extremely potent stimulator of the mammalian immune system and causes the activation of macrophages (34, 35), which should increase the rate of metHb formation by elevation of the reactive oxygen species concentration such as  $\text{H}_2\text{O}_2$ . In this case, there was no effect of the encapsulation with catalase in the Hb vesicles. The effect of such inflammation should exceed the effect of catalase coencapsulation. Therefore, we used the samples where the LPS concentration was below 0.1 EU  $\text{mL}^{-1}$  in order to accurately measure the rate of metHb formation. In the catalase-free Hb vesicles, the rate of the metHb formation was 3.4%  $\text{h}^{-1}$ , and the time for 50% metHb formation ( $T_{50\% \text{metHb}}$ ) was 14 h. On the other hand, in the groups of catalase-coencapsulated Hb vesicles ( $[\text{catalase}] = 2.8 \times 10^3$ ,  $8.4 \times 10^3$ ,  $1.7 \times 10^4$ ,  $2.8 \times 10^4$ ,  $4.2 \times 10^4$ , and  $5.6 \times 10^4$  unit  $\text{mL}^{-1}$ ), the rates of metHb formation were 2.9, 2.3, 2.0, 1.8, 1.7, and 1.7%  $\text{h}^{-1}$ , respectively, and the  $T_{50\% \text{metHb}}$  were 18, 22, 29, 36, 38, and 39 h, respectively. Figure 5a

**Figure 5.** (a) Changes of metHb percentage in the Hb vesicles in vivo (20 mL kg<sup>-1</sup>, Wistar rat). The control is catalase-free Hb vesicles (○) and the mixture of the Hb vesicle dispersion and the catalase solution ( $5.6 \times 10^4$  unit mL<sup>-1</sup>, ▽). The encapsulated catalase in the Hb vesicle was  $2.8 \times 10^3$  (●),  $8.4 \times 10^3$  (□),  $1.7 \times 10^4$  (■),  $2.8 \times 10^4$  (△),  $4.2 \times 10^4$  (▲), and  $5.6 \times 10^4$  unit mL<sup>-1</sup> (◇). The dotted line (◆) is the LPS-contaminated Hb vesicles ([catalase] =  $2.8 \times 10^4$  unit mL<sup>-1</sup>). (b) The relationship between [catalase]<sub>fed</sub> and the rate of metHb formation.

showed the changes in the metHb concentration, indicating that the rest of metHb in the Hb vesicles was the functional ferrous Hb (oxyHb). In the case of the administration of the mixture of the catalase-free Hb vesicle dispersion and catalase solution ( $5.6 \times 10^4$  unit mL<sup>-1</sup>), there was no significant difference from the control groups (catalase-free Hb vesicles) as shown in Figure 5a. These results showed that the administered catalase rapidly disappeared from the blood stream and could not eliminate hydrogen peroxide.

It was confirmed that, by catalase-coencapsulation, the rate of metHb formation was reduced and the  $T_{50\% \text{metHb}}$  was also prolonged. As shown in Figure 5b, the rate of metHb formation was saturated when the catalase concentration was over  $4.2 \times 10^4$  unit mL<sup>-1</sup> in comparison with  $1.7 \times 10^4$  unit mL<sup>-1</sup> in vitro as shown in Figure 4b. Such a high catalase concentration in vivo suggests that metHb formation should be caused by the exogenous H<sub>2</sub>O<sub>2</sub> from the blood circulation in addition to the endogenous H<sub>2</sub>O<sub>2</sub>. It is indicated that the saturated metHb formation rate should be due to the substantial autooxidation of Hb because of the elimination of endogenous and exogenous H<sub>2</sub>O<sub>2</sub>.

## CONCLUSION

Catalase coencapsulated in the Hb vesicle could eliminate H<sub>2</sub>O<sub>2</sub>, which was not only produced by the Hb

autooxidation in the vesicle but also generated in vivo, and the rate of metHb formation in the Hb vesicle could thus be effectively suppressed by catalase coencapsulation. We succeeded in substantially prolonging the oxygen-carrying ability of the Hb vesicles in vivo by coencapsulating catalase.

# Evaluation of the Human Melanoma Targeting Properties of Radiolabeled $\alpha$ -Melanocyte Stimulating Hormone Peptide Analogues

Yubin Miao,<sup>†,‡</sup> Donna Whitener,<sup>†</sup> Weiwei Feng,<sup>†,||</sup> Nellie K. Owen,<sup>§</sup> Jianqing Chen,<sup>†,||</sup> and Thomas P. Quinn<sup>\*,†,‡</sup>

Departments of Biochemistry, Radiology, and Internal Medicine, University of Missouri—Columbia, Columbia, Missouri 65211, and Harry S. Truman Memorial Veterans Hospital, Columbia, Missouri 65201. Received May 5, 2003; Revised Manuscript Received August 20, 2003

The purpose of this study was to evaluate the human MC1 receptor-mediated melanoma targeting properties of two metal cyclized  $\alpha$ -MSH peptide analogues,  $^{188}\text{Re}-(\text{Arg}^{11})\text{CCMSH}$  and  $^{188}\text{Re}\text{-CCMSH}$ . Initially, the presence and density of the MC1 receptor were determined on a bank of human melanoma cell lines. All eight human melanoma cell lines tested in this study displayed the MC1 receptor at a density of 900 to 5700 receptors per cell. Receptor affinity and biodistribution properties of  $^{188}\text{Re}-(\text{Arg}^{11})\text{CCMSH}$  and  $^{188}\text{Re}\text{-CCMSH}$  were evaluated in a cultured TXM13 human melanoma-xenografted Scid mouse model. Biodistribution results demonstrated that  $3.06 \pm 0.68\%$  ID/g of  $^{188}\text{Re}-(\text{Arg}^{11})\text{CCMSH}$  accumulated in the tumors 1 h postinjection and greater than 65% of the activity at 1 h postinjection remained in the tumors at 4 h after dose administration. Whole body clearance of  $^{188}\text{Re}-(\text{Arg}^{11})\text{CCMSH}$  was very rapid, with approximately 82% of injected dose cleared through urinary system at 4 h postinjection. There was very little activity in blood and major organs such as liver, lung, and muscle except for the kidney.  $^{188}\text{Re}\text{-CCMSH}$  exhibited similar tumor uptake and retention in TXM13 human melanoma-xenografted Scid mice as  $^{188}\text{Re}-(\text{Arg}^{11})\text{CCMSH}$ . However, the kidney uptake value of  $^{188}\text{Re}\text{-CCMSH}$  was two times higher than that of  $^{188}\text{Re}-(\text{Arg}^{11})\text{CCMSH}$ . The results of this study indicate that the MC1 receptor is present on the surface of a large number of human melanoma cells, which makes the MC1 receptor a good imaging or therapeutic target. Moreover, the biodistribution properties of  $^{188}\text{Re}-(\text{Arg}^{11})\text{CCMSH}$  and  $^{188}\text{Re}\text{-CCMSH}$  highlight their potential as therapeutic agents for human melanoma.

## INTRODUCTION

Malignant melanoma has become a serious public health problem due to its increase in incidence (1). In 2001, it was estimated that there were 51 400 cases of malignant melanoma newly reported and 7800 fatalities in the United States (1). It is estimated that more than 1.3% of Americans will develop malignant melanoma during their lifetimes (2). Moreover, metastatic melanoma deposits are difficult to discover and are resistant to conventional chemotherapy and external beam radiation therapy (2). Therefore, there is a great need to develop novel treatment approaches for metastatic melanoma.

Radiolabeled antibodies and antibody fragments have been investigated extensively to target melanoma and its metastases (3–5). However, their success has been limited because of the intrinsic limitations of radiolabeled antibodies and antibody fragments, such as slow circulation clearance (6, 7) and reduced rates of tumor penetra-

tion (8, 9). Recently,  $^{123}\text{I}$ -labeled *N*-(2-diethylaminoethyl)-4-iodobenzamide ( $^{123}\text{I}$ ]BZA) and *N*-(2-diethylaminoethyl)-3-iodo-4-methoxybenzamide ( $^{123}\text{I}$ ]IMBA) have exhibited high tumor uptake value ranging from 5 to 20 %ID/g in B16 tumor model (10, 11). However, their clinical application may be impeded due to the disadvantages of iodine-123, such as routine availability and high cost. More promising results were obtained with  $^{131}\text{I}$ -labeled *N*-(2-diethylaminoethyl)benzamide derivatives (12). In comparison with  $^{123}\text{I}$ ]BZA and  $^{123}\text{I}$ ]IMBA, superior tumor uptake and retention of (4-acetamido-*N*-(2-diethylaminoethyl)-5- $^{131}\text{I}$ ]iodo-2-methoxybenzamide) provided considerable potential for melanoma imaging and radionuclide therapy. However, the high liver uptake (9.86 %ID/g at 6 h pi) and slow clearance (3.72 %ID/g at 24 h pi) might limit its therapeutic application.

Another class of promising agents for melanoma imaging and therapy are  $\alpha$ -melanocyte stimulating hormone ( $\alpha$ -MSH) peptide analogues. Wild-type  $\alpha$ -MSH is a small tridecapeptide (Ac-Ser<sup>1</sup>-Tyr<sup>2</sup>-Ser<sup>3</sup>-Met<sup>4</sup>-Glu<sup>5</sup>-His<sup>6</sup>-Phe<sup>7</sup>-Arg<sup>8</sup>-Trp<sup>9</sup>-Gly<sup>10</sup>-Lys<sup>11</sup>-Pro<sup>12</sup>-Val<sup>13</sup>-NH<sub>2</sub>), which is involved in the control of skin pigmentation. The biological activity of  $\alpha$ -MSH is mediated through interactions with the melanocortin 1 (MC1) receptor (13). The melanocortin receptors belong to the superfamily of G-protein-coupled receptors (GPCRs). At the present time, five melanocortin receptors, namely MC1 receptor to MC5 receptor, have been identified and cloned (37–43). The MC1 receptor is mainly expressed in melanocytes and leukocytes and involved in skin pigmentation and animal coat coloration (13, 37, 44). The MC2 receptor has been found in the

adrenal gland and regulates glucocorticoneogenesis (37). The MC3 receptor and MC4 receptor have been identified in the brain for the control of feeding behavior and energy homeostasis (45). The MC5 receptor is expressed in a variety of peripheral tissues and participated in mediating exocrine gland function (46). Among the members of melanocortin receptors, the MC1 receptor has been the most widely studied (13–16, 44). The MC1 receptor has been identified both on human and mouse melanoma cells (14, 15). More than 80% of human metastatic melanoma tumor samples have been found to bear MC1 receptor (16). Nanomolar receptor affinity of  $\alpha$ -MSH and many of its analogues for the MC1 receptor make MC1 receptor an attractive target for the development of new melanoma targeting peptide pharmaceuticals.

Recently, several  $\alpha$ -MSH analogues have been examined for their abilities to target melanoma (17–20, 52–53). In our lab, a novel class of metal-cyclized  $\alpha$ -MSH analogues has been developed for melanoma imaging and therapy (21–23). Three cysteine were introduced into the amino acid sequence of CCMSH (Ac-Cys<sup>3</sup>-Cys<sup>4</sup>-Glu<sup>5</sup>-His<sup>6</sup>-D-Phe<sup>7</sup>-Arg<sup>8</sup>-Trp<sup>9</sup>-Cys<sup>10</sup>-Lys<sup>11</sup>-Pro<sup>12</sup>-Val<sup>13</sup>-NH<sub>2</sub>) to site-specifically coordinated radiometals such as <sup>99m</sup>Tc and <sup>188</sup>Re. Peptide cyclization with <sup>99m</sup>Tc and <sup>188</sup>Re made the molecules resistant to chemical and proteolytic degradation in vivo while retaining high bioactivities (22, 23). Both <sup>99m</sup>Tc-CCMSH and <sup>188</sup>Re-CCMSH exhibited excellent tumor uptake and retention and rapid whole body clearance in B16/F1 murine melanoma bearing C57 mice (22, 23). However, the presence of nonspecific kidney activity associated with <sup>188</sup>Re-CCMSH administration indicated that nephrotoxicity might be a problem with high doses used in melanoma therapy trials. Therefore two strategies, chemical modification of the peptide and amino acid coinfusion, were investigated to reduce renal uptake of <sup>188</sup>Re-CCMSH in our previous report (23). The substitution of Lys at 11th position of <sup>188</sup>Re-CCMSH with Arg yielded <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH, which possessed superior tumor uptake and lower renal activity accumulation in B16/F1 murine melanoma bearing C57 mice. The renal uptake value of <sup>188</sup>Re-CCMSH was significantly decreased by amino acid coinfusion as well (approximately 50%); however, the tumor/kidney ratio of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH was higher than that of <sup>188</sup>Re-CCMSH with amino acid coinfusion (23). The superior tumor uptake and lower kidney accumulation of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH greatly enhanced its potential as a melanoma therapeutic agent.

The receptor binding characteristics and in vivo biodistribution properties of radiolabeled  $\alpha$ -MSH peptides are most often analyzed in the murine melanoma B16 series of cell lines and in the C57–B16/F1 syngenic murine melanoma mouse model (48, 57). However, if radiolabeled  $\alpha$ -MSH peptides are to be effective in melanoma imaging and therapy, they must be able to bind a wide variety of human melanoma cells and show favorable biodistribution properties in human melanoma xenografts. Differences between the human and murine MC1 receptor, tumor morphology, and physiology could have a significant impact on the imaging and therapeutic potential of radiolabeled MSH peptide analogues. In this study, the prevalence of the MC1 receptor on human melanoma was determined in a bank of human melanoma cell lines. The tumor targeting properties of two <sup>188</sup>Re cyclized  $\alpha$ -MSH peptide analogues, namely <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH and <sup>188</sup>Re-CCMSH, were determined in a TXM13 human melanoma-xenografted, severely compromised immunodeficient (Scid) mouse model. The in vitro receptor binding affinities of (Arg<sup>11</sup>)CCMSH, CC-

MSH, and nonradioactive rhenium-conjugated Re-(Arg<sup>11</sup>)-CCMSH and Re-CCMSH in TXM13 human melanoma cells were examined by a competitive displacement cell binding assay using <sup>125</sup>I-Tyr<sup>2</sup>-NDP ([Nle<sup>4</sup>, D-Phe<sup>7</sup>] $\alpha$ -MSH). Pharmacokinetic properties of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH and <sup>188</sup>Re-CCMSH were determined in TXM13 human melanoma-xenografted Scid mice to evaluate their potential for human melanoma therapy. Results presented in this study demonstrated that both <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH and <sup>188</sup>Re-CCMSH exhibited substantial tumor uptake and good retention in TXM13 human melanoma-xenografted Scid mice, which highlighted their potential as therapeutic agents for human melanoma.

## MATERIALS AND METHODS

**Chemicals and Reagents.** Amino acids and resin were purchased from Advanced ChemTech Inc (Louisville, KY). <sup>188</sup>ReO<sub>4</sub><sup>-</sup> was obtained from a <sup>188</sup>W/<sup>188</sup>Re generator from Oak Ridge National Laboratory. All chemicals used in this study were purchased from Fischer Scientific and used without further purification. The human melanoma cell lines were obtained from National Cancer Institute except for the TXM13 cell line was supplied by Dr. Isaiah J. Fidler and Dr. Janet Price from the Cell Biology Department, University of Texas M. D. Anderson Cancer Center.

**MC1 Receptor Quantitation Assay.** The  $B_{\max}$  of the human melanoma cell lines were determined by a method previously described (23). Briefly,  $1 \times 10^6$  human melanoma cells were incubated at 37 °C for 1.5 h in the presence of an increasing concentration of <sup>125</sup>I-(Tyr<sup>2</sup>)-NDP (1.56 nCi to 200 nCi) in 0.5 mL of binding media (MEM with 25 mM HEPES, pH 7.4, 0.2% BSA, 0.3 mM 1,10-phenanthroline). The reaction media was aspirated after incubation. Cells were rinsed with 0.5 mL of ice-cold pH 7.4, 0.2% BSA/0.01 M PBS three times. The activity in cells was measured in a NaI well counter. Nonspecific binding was determined by incubating cells and <sup>125</sup>I-(Tyr<sup>2</sup>)-NDP with nonradioactive NDP at a final concentration of 10  $\mu$ M. Scatchard plots were obtained by plotting the ratio of specific binding to free <sup>125</sup>I-Tyr<sup>2</sup>-NDP vs concentration of specific binding (fmole/million cells). The  $B_{\max}$  was the X intercept of linear regression line.

**Peptide Purification.** High performance liquid chromatography (HPLC) analysis was performed on an ISCO system (Lincoln, NE) equipped with absorption detector and Packard radiometric detector (Meriden, CT). Water containing 5 mM hydrogen chloride and acetonitrile were used as HPLC solvents A and B, respectively. A C-18 reverse phase column (218TP54, Vydac, Hesperia, CA) was used to purify <sup>188</sup>Re conjugates with a flow rate of 1.0 mL/min. A 20-min gradient of 18–28% acetonitrile in H<sub>2</sub>O/5 mM HCl was used for radiolabeled peptide purification.

**Preparation of <sup>188</sup>Re-Labeled  $\alpha$ -MSH Peptides.** The  $\alpha$ -MSH peptide analogues, CCMSH and (Arg<sup>11</sup>)-CCMSH, were synthesized by using Fmoc chemistry on amide resin with a Synergy 432A desktop solid-phase peptide synthesizer (Applied Biosystems, Foster City, CA) as previously described (23). The peptides were deprotected, cleaved from the resin, and purified by RP-HPLC. The identities of peptides were confirmed by electrospray ionization mass spectrometry (Mass Consortium Corp., San Diego, CA).

Radiolabeling of <sup>188</sup>Re- $\alpha$ -MSH peptides was accomplished by a method previously described (23). Briefly, 200  $\mu$ L of 6 mg/mL SnCl<sub>2</sub> in an aqueous 0.2 M sodium glucoheptonate solution and 200  $\mu$ L of fresh <sup>188</sup>ReO<sub>4</sub><sup>-</sup>

eluant (1–4 mCi) were added into a reaction vial. The mixture was incubated at 75 °C for 30 min. Ten microliters of a 1 mg/mL peptide solution were added into the mixture. After being adjusted to pH 8.5 with 1 N NaOH, the resulting solution was incubated at 75 °C for 30 min. The radiolabeled peptide was purified to single species by RP-HPLC. Purified peptide samples were purged with N<sub>2</sub> gas for 20 min to remove the acetonitrile. The pH of final solution was adjusted to 5 with 0.1 N NaOH and normal saline for animal studies. Quality controls were performed by RP-HPLC (Figure 3).

**Competitive Binding Assay.** The IC<sub>50</sub> values for the  $\alpha$ -MSH peptide analogues were determined by competitive binding assays with <sup>125</sup>I-Tyr<sup>2</sup>-NDP (Amersham Pharmacia Biotech, UK) in TXM13 human melanoma cells. Briefly, TXM13 cells were harvested from the culture flasks with a 0.02% EDTA solution, seeded into a 24-well cell culture plate (5 × 10<sup>5</sup>/well), and incubated at 37 °C overnight. After being washed once with binding media (MEM with 25 mM HEPES, pH 7.4, 0.2% BSA, 0.3 mM 1,10-phenanthroline), the cells were incubated at 37 °C for 2 h with approximately 100 000 cpm of <sup>125</sup>I-Tyr<sup>2</sup>-NDP in the presence of increasing concentrations of  $\alpha$ -MSH analogues in 0.3 mL of binding media. The reaction media was aspirated after incubation. Cells were rinsed with 0.5 mL of ice-cold pH 7.4, 0.2% BSA/0.01 M PBS twice and lysed in 0.5 mL of 1 N NaOH for 5 min. The activity in cells was measured in a NaI well counter. The competitive binding curves were obtained by plotting the percentage of <sup>125</sup>I-Tyr<sup>2</sup>-NDP bound to cells vs concentrations of displacing peptides. The IC<sub>50</sub> values for the peptides were calculated by using the Graft software (Erithacus Software Limited, UK).

**In Vivo Pharmacokinetics Studies.** The pharmacokinetics of <sup>188</sup>Re-CCMSH and <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH were performed in TXM13 human melanoma-xenografted Scid female mice (Harlan, Indianapolis, IN). The Scid mice were housed in sterile microisolator cages in a temperature and humidity-controlled room. The animals were fed with autoclaved food and water for a week prior to the tumor cell inoculation. The Scid mice were inoculated subcutaneously with 5 × 10<sup>6</sup> TXM13 human melanoma cells in the both flanks. After four weeks, when the weight of tumors reached approximately 0.3 g, 3–8  $\mu$ Ci of <sup>188</sup>Re-labeled peptide was injected into each mouse through the tail vein for in vivo pharmacokinetics studies. Groups of five mice per each time point were used for the biodistribution studies. The mice were sacrificed at 1, 4, and 24 h postinjection, and tumors and organs of interest were harvested, weighed, and counted. Blood values were taken as 6.5% of the whole body weight. The results were expressed as percent injected dose/gram (%ID/g) and as percent injected dose (%ID). All the animal studies were conducted in compliance with Institutional Animal Care and Committee Approval. Statistical analysis was performed using the Student's *t*-test for unpaired data. A 95% confidence level was chosen to determine the significance between compounds, with *p* < 0.05 being significantly different.

## RESULTS AND DISCUSSION

A bank of human melanoma cell lines were examined for presence and number of MC1 receptors. The human melanoma cell lines were derived from metastatic deposits from various organs as well as from primary tumors that were either producing melanin (melanonic) or not melanin producing (amelanonic). All of the human melanoma cell lines displayed MC1 receptors. The recep-

**Figure 1.** Structure of Re-(Arg<sup>11</sup>)CCMSH; Ac-Cys-Cys-Glu-His-D-Phe-Arg-Trp-Cys-Arg-Pro-Val-NH<sub>2</sub>.

**Table 1.** MC1 Receptor Numbers on Human Melanoma Cells

cell line	receptor number (sites/cell)
TXM13	5700

SKMEL5	1000
SKMEL28	900
3M	5000
UACC257	2800
LOX	1000

tor numbers ranged from 900 to 5700 receptors per cell (Table 1). There was no correlation between the experimentally determined receptor number and melanonic state of the cells or the location of the original isolate. All of the human melanoma cell lines exhibited 1.4–8 times fewer receptor numbers per cell than the murine B16/F1 cell line. These results suggest that in general human melanoma cells have fewer MC1 receptors than the B16/F1 murine melanoma cell line. Lower MC1 receptor numbers may translate into lower melanoma tumor uptake of radiolabeled  $\alpha$ -MSH peptide analogues in vivo and certainly highlight the need to produce and administer high specific activity preparations for imaging and therapy.

The biodistribution and tumor targeting properties of two <sup>188</sup>Re-cyclized  $\alpha$ -MSH peptide analogues (<sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH and <sup>188</sup>Re-CCMSH) were determined in the TXM13 human melanoma-xenografted Scid mice. The TXM13 human melanoma xenograft model is robust and well characterized for tumor establishment and metastatic potential, making it attractive for biodistribution analyses as well as future therapy studies (47). Initially, the binding affinities of the Re-cyclized and apo  $\alpha$ -MSH peptide analogues were examined in cultured TXM-13 human melanoma cells. The  $\alpha$ -MSH peptide analogues, namely CCMSH, (Arg<sup>11</sup>)CCMSH, Re-CCMSH and Re-(Arg<sup>11</sup>)CCMSH were synthesized and purified by RP-HPLC, and the identities of peptides were confirmed by electrospray ionization mass spectrometry. An illustration of the Re-(Arg<sup>11</sup>)CCMSH structure is shown in Figure 1. Results from in vitro competitive binding assay of peptides performed in TXM13 human melanoma cells revealed that both the peptides with or without nonradioactive rhenium cyclization bound to the human melanoma cells with nanomolar range affinities (Figure 2). The introduction of the ReO core in the peptide sequence slightly decreased the binding affinity of the peptide (Table 2). A list of the peptide sequences, IC<sub>50</sub> values, and molecular weights of CCMSH, (Arg<sup>11</sup>)CCMSH, and their Re-cyclized derivatives is presented in Table 2. The

low nanomolar binding affinities of the  $\alpha$ -MSH peptide analogues for the human MC1 receptors on the TXM-13 cells were similar to the affinity values determined for the murine MC1 receptor on B16/F1 cells. Similarity in ligand affinities between the human and mouse MC1 receptors was consistent with their shared amino acid identity of 75% (37). However, sequence alignments also revealed gaps and stretches of nonconservative amino acid substitutions that could result in ligand selectivity difference between the two receptors.

The pharmacokinetics and tumor targeting properties of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH and <sup>188</sup>Re-CCMSH were determined in TXM13 human melanoma-xenografted Scid mice. CCMSH and (Arg<sup>11</sup>)CCMSH were labeled with <sup>188</sup>Re through a glucoheptonate transchelation reaction, using stannous chloride as a reducing agent. <sup>188</sup>Re-CCMSH and <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH were separated completely from their nonlabeled counterparts by RP-HPLC. Quality control of the purified <sup>188</sup>Re-CCMSH and <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH for animal studies was performed by RP-HPLC (Figure 3). The biodistribution of <sup>188</sup>Re-CCMSH and <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH in TXM13 tumor-bearing Scid mice at 1 h, 4 h, and 24 h postinjection is shown in Table 3. Substantial tumor uptake of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH was exhibited in TXM13 human melanoma-xenografted Scid mice. For example, there was  $3.06 \pm 0.68\%$  ID/g of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH accumulated in the tumors 1 h after dose administration. Greater than 65% of the activity at 1 h postinjection remained in the tumors at 4 h after dose administration. Even 24 h later, there was  $0.93 \pm 0.49\%$  ID/g of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH remaining in the tumors. The tumor uptake of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH was similar to the tumor uptake values of <sup>111</sup>In-labeled bombesin (53)

**Figure 3.** HPLC quality control of <sup>188</sup>Re-CCMSH and <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH.

and minigastrin (54) evaluated in human tumor xenograft models. For example, <sup>111</sup>In-labeled bombesin and minigastrin exhibited up to 3.63 %ID/g and 5 %ID/g at 1 h postinjection (53, 54) compared to <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH that displayed 3.06 %ID/g at the same time point. The corresponding <sup>90</sup>Y-labeled bombesin and minigastrin analogues displayed therapeutic efficacy in their respective human tumor xenograft models (55, 56). It is expected that the uptake of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH will be sufficient to show therapeutic effects in human melanoma-xenografted Scid mouse model.

Whole body clearance of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH was very rapid, with approximately 82% of injected dose cleared through urinary system at 4 h postinjection. Greater than 98% of the injected dose was washed out of body by 24 h postinjection. There was very little activity in blood and major organs such as liver, lung, and muscle except for the kidneys. High tumor/blood and tumor/normal tissue uptake ratios were demonstrated as early as 1 h postinjection (Table 4). Although the majority of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH in the kidneys cleared rapidly, there was still  $6.24 \pm 1.14\%$  ID/g of activity present in the kidneys at 4 h after injection. Hence, nephrotoxicity would likely be a dose-limiting factor if <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH was used for melanoma therapy trials. In comparison with <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH, <sup>188</sup>Re-CCMSH exhibited similar tumor uptake and retention properties. However, the kidney uptake value of <sup>188</sup>Re-CCMSH was two times higher than that of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH at 1 h and 4 h postinjection, which would compromise its application for melanoma therapy. The biodistribution data of <sup>188</sup>Re-CCMSH demonstrated that whole body clearance of <sup>188</sup>Re-CCMSH was rapid as well. Approximately 91% of injected dose was washed out of body through urinary system at 4 h postinjection. Greater than 99% of the injected dose was cleared out of body by 24 h postinjection. The accumulation of <sup>188</sup>Re-CCMSH activity in blood and blood rich organs such liver and lung was similar to that of <sup>188</sup>Re-(Arg<sup>11</sup>)CCMSH. In contrast to <sup>188</sup>Re-CCMSH, slightly

more  $^{188}\text{Re}$ -(Arg $^{11}$ )CCMSH activity was excreted through GI system, indicating that the lipophilicity of  $^{188}\text{Re}$ -(Arg $^{11}$ )CCMSH was higher than that of  $^{188}\text{Re}$ -CCMSH. This hypothesis was consistent with HPLC results, in which  $^{188}\text{Re}$ -(Arg $^{11}$ )CCMSH exhibited a greater retention time than  $^{188}\text{Re}$ -CCMSH under the same reverse-phase elution gradient (Figure 3).

The tumor uptake of  $^{188}\text{Re}$ -CCMSH and  $^{188}\text{Re}$ -(Arg $^{11}$ )CCMSH were lower 1 h and 4 h postinjection in the TXM13 human melanoma-xenografted Scid mice than in the B16/F1 murine melanoma model (23). For example, the uptake of  $^{188}\text{Re}$ -CCMSH and  $^{188}\text{Re}$ -(Arg $^{11}$ )CCMSH in the B16/F1 murine melanoma mouse model was  $9.78 \pm 2.00$  %ID/g and  $16.37 \pm 3.27$  %ID/g at 4 h postinjection and  $1.94 \pm 0.47$  %ID/g and  $3.50 \pm 2.32$  %ID/g 24 h postinjection (23) compared to  $2.02 \pm 0.24$  %ID/g and  $2.20 \pm 0.27$  %ID/g at 4 h postinjection and  $0.87 \pm 0.33$  %ID/g and  $0.93 \pm 0.49$  %ID/g 24 h postinjection in the TXM13 human melanoma xenograft model. The significant tumor uptake value difference between B16/F1 murine melanoma and TXM13 human melanoma models were attributed to MC1 receptor density and the in vivo behavior differences between two cell lines. In this report, it was shown that the MC1 receptor density on human melanoma cells, including TXM13, was lower than that of B16/F1 cells. Moreover, based on the histopathological results showed in our previous report, TXM13 cells formed amelanonic solid tumors with extensive necrotic centers as opposed to the nonnecrotic gelatinous composition of B16/F1 murine melanoma tumors (22). Differences in tumor morphology could significantly affect the tumor uptake of radioactivity on a per gram basis. Necrotic centers present in the TXM13 human melanoma tumors contribute to the total mass of the tumors but contain few viable melanoma cells capable of  $^{188}\text{Re}$ -CCMSH and  $^{188}\text{Re}$ -(Arg $^{11}$ )CCMSH uptake. Rhenium-188-CCMSH uptake is likely to be localized to rapidly proliferating melanoma cells located around the surface of the TXM13

human melanoma tumors (22). Therefore, the overall percent activity per gram of TXM13 human melanoma tumors is reduced when compared to B16/F1 murine melanoma tumors that lack significant necrotic regions and are almost entirely composed of viable melanoma cells capable of rhenium-188-CCMSH uptake.

Numerous  $\alpha$ -MSH analogues, based on the high affinity NDP sequence [Nle $^4$ ,D-Phe $^7$ ]- $\alpha$ -MSH, have been synthesized and characterized as tumor targeting agents (18–20, 50). NDP radiolabeled with  $^{125}\text{I}$  or  $^{18}\text{F}$  exhibited high receptor affinities in vitro and rapid pharmacokinetics in vivo; however, they did not display high tumor uptake and retention (20, 50). Recently, Froidevaux et al. (51, 52) described the characterization of a novel 8 amino acid DOTA-conjugated MSH analogue, DOTA-MSH $_{(\text{oct})}$ , that was based on the high affinity NDP MSH sequence. Indium-111-labeled DOTA-MSH $_{(\text{oct})}$  displayed rapid pharmacokinetics and good tumor uptake, highlighting its melanoma imaging potential. Tumor uptake values were  $4.31 \pm 0.30$  %ID/g at 4 h and  $1.17 \pm 0.13$  %ID/g 24 h postinjection in the B16/F1 murine melanoma mouse model (52). Murine melanoma uptake of  $^{111}\text{In}$ -DOTA-MSH $_{(\text{oct})}$  was 2 times and 1.2 times greater than  $^{188}\text{Re}$ -(Arg $^{11}$ )CCMSH in human melanoma at 4 and 24 h postinjection. This difference was expected since we routinely see a 5–10-fold reduction in xenografted human melanoma compared to B16/F1 murine melanoma tumors. No characterization of  $^{111}\text{In}$ -DOTA-MSH $_{(\text{oct})}$  was reported for a human melanoma-xenografted model making direct biodistribution comparisons difficult. However, a comparison of  $^{111}\text{In}$ -DOTA-MSH $_{(\text{oct})}$  with  $^{111}\text{In}$ -DOTA-ReCCMSH(Arg $^{11}$ ) in the B16/F1 murine melanoma mouse model showed that  $^{111}\text{In}$ -DOTA-ReCCMSH(Arg $^{11}$ ) displayed 4 times the tumor uptake 4 h and 7 times the uptake of  $^{111}\text{In}$ -DOTA-MSH $_{(\text{oct})}$  at 24 h postinjection (49). Moreover, the kidney uptake of  $^{111}\text{In}$ -DOTA-ReCCMSH(Arg $^{11}$ ) was 1.8 and 1.2 times less than  $^{111}\text{In}$ -DOTA-MSH $_{(\text{oct})}$  at 4 h and 24 h postinjection (49). Although  $^{111}\text{In}$ -

DOTA-MSH<sub>(oct)</sub> exhibited high affinity for the MC1 receptor, it may be cleared too rapidly from the blood stream for optimal tumor uptake.

Nonspecific kidney accumulation is a common problem associated with radiolabeled peptide and small protein administration (24–26). Cationic peptides and proteins bind to the negatively charged surface of tubule cells via electrostatic interaction when they are generally filtered in the glomerulus and reabsorbed in the cells of the proximal tubule (24). Therefore, two strategies of chemical modification of the molecule and basic amino acid coinfusion have been employed to decrease renal accumulation by masking the electrostatic interaction between molecule and the surface of tubular cells (24–31). For instance, Kim and Kobayashi et al. reported the use of 2,3,5,6-tetrafluorophenyl (TFP)-glycolate to neutralize the positive charges and lower the isoelectric point of anti-Tac disulfide-bonded variable region single-chain Fv fragments (dsFv) and humanized anti-Tac Fab fragments. Their findings indicated that neutralizing the positive charges decreased the kidney accumulation of the glycolated conjugates without impairing their tumor uptake (32–35). Recently, Akizawa et al. investigated the effect of molecular charges on renal uptake of <sup>111</sup>In-DTPA-conjugated peptide by substitution of the N-terminal D-phenylalanine of <sup>111</sup>In-DTPA-D-Phe<sup>1</sup>-Octreotide with L-aspartic acid, L-lysine, L-methionine, and L-phenylalanine. They found that the net charges of <sup>111</sup>In-DTPA-D-Phe<sup>1</sup>-Octreotide derivatives significantly affected their kidney uptake. The strategy of increasing negative charges in peptide molecules might be used to decrease the renal uptake of <sup>111</sup>In-DTPA-conjugated low molecular weight peptides (36). An analysis of biodistribution comparison of <sup>188</sup>Re-CCMSH and <sup>188</sup>Re-(Arg<sup>11</sup>)-CCMSH in this work revealed that the charge distribution of peptide molecule might be another important factor, which affected the renal uptake of peptide. Theoretically, the positive charge of Arg is same as Lys; however, the positive charge distribution is different between the Arg guanidinium group and Lys primary amine. The biodistribution data demonstrated that the kidney uptake value of <sup>188</sup>Re-(Arg<sup>11</sup>)-CCMSH was approximately 50% of that of <sup>188</sup>Re-CCMSH 1 h and 4 h postinjection. Moreover, coinfusion of positively charged amino acids reduced the kidney retention of <sup>188</sup>Re-CCMSH by more than 50% while only reducing that of <sup>188</sup>Re-(Arg<sup>11</sup>)-CCMSH by 40% in our previous report (23). This supports the assertion that difference in charge distribution on the side chain greatly influences nonspecific charge–charge interaction and could be responsible for reduced kidney retention of <sup>188</sup>Re-(Arg<sup>11</sup>)-CCMSH. Arg at 11th position of CCMSH peptide sequence played a critical role in decreasing the renal uptake value of <sup>188</sup>Re-labeled CCMSH peptide analogues. The coinfusion of basic amino acid or amino acids combination, such as L-lysine, L-arginine, D-lysine, and combination of L-lysine and L-arginine, have been proved to be effective in decreasing the renal uptake of radiolabeled peptides and antibodies (24–31). It was also clearly demonstrated by our previous report that L-lysine coinjection could significantly decrease the renal uptake of <sup>188</sup>Re-CCMSH and <sup>188</sup>Re-(Arg<sup>11</sup>)-CCMSH in B16/F1 murine melanoma bearing C57 mice (23). Hence, the strategy of L-lysine coinfusion could potentially be employed to enhance the therapeutic efficacy of <sup>188</sup>Re-(Arg<sup>11</sup>)-CCMSH by further decreasing the nephrotoxicity in human melanoma therapy trials.

In conclusion, all eight human melanoma cell lines tested in this study displayed the MC1 receptor. Bio-

distribution results demonstrated that both <sup>188</sup>Re-(Arg<sup>11</sup>)-CCMSH and <sup>188</sup>Re-CCMSH exhibited substantial tumor uptake and good retention, coupled with rapid whole body clearance in TXM13 human melanoma-xenografted Scid mice model. Human melanoma-targeting properties of <sup>188</sup>Re-(Arg<sup>11</sup>)-CCMSH and <sup>188</sup>Re-CCMSH accentuated their potential as therapeutic agents for human melanoma.

#### ACKNOWLEDGMENT

The authors would like to thank Drs. Wynn A. Volkert, Susan L. Deutscher, Silvia S. Jurisson, and Timothy J. Hoffman for their helpful discussion, and Gary L. Sieckman and Dana G. Mazuru for their technical assistance. This work was supported by a grant (ER61661) from the Department of Energy (to T.P.Q.) and a grant from the University of Missouri Life Science Mission Enhancement Postdoctoral Fellowship (to Y.M.).

# Growth of Large Polymer–Actin Complexes

Akira Kakugo,<sup>†</sup> Kazuhiro Shikinaka,<sup>†</sup> Kanae Matsumoto,<sup>†</sup> Jian Ping Gong,<sup>\*,†,‡</sup> and Yoshihito Osada<sup>†</sup>

Graduate School of Science Hokkaido University, and Presto, JST,  
Sapporo 060-0810, Japan. Received May 6, 2003; Revised Manuscript Received August 28, 2003

Polymer–actin complexes as large as 10–50  $\mu\text{m}$  with filamentous, branched, stranded, and ring shapes are obtained when fluorescent phalloidin-labeled F-actin is mixed with some synthetic polymers carrying positive charges such as poly-L-lysine,  $x,y$ -ionene bromide polymers. All growth of these complexes occurs cooperatively at some certain critical polymer concentrations, regardless of the chemical structure of the polymer, while the morphology of the complexes is substantially influenced by the chemical structure of the polymer. Poly-Lys–actin complex grows preferentially along the filament axis even above the critical concentration. 3,3-ionene–actin complexes show completely homogeneous filaments below the critical concentration but forms bundles at a higher concentration. Occasionally, ring shape complexes can be observed in the 6,6-ionene–actin complex.

## INTRODUCTION

Recently, we have constructed an adenosine triphosphate (ATP)-fueled soft gel machine constructed from chemically cross-linked actin gel and myosin gel (1). Actins and myosins are major components of muscle proteins and play an important role in dynamic motion of creatures that is caused by the molecular deformation using the chemical energy released by hydrolysis of ATP. We have found that chemically cross-linked giant actin gel filaments, several tens of times the length of native actin filaments, move along a chemically cross-linked myosin fibrous gel with a velocity as high as that of native actins, by coupling to ATP hydrolysis. This result indicates that muscle proteins can be tailored into desired shape and size without sacrificing their bioactivities. The above-described giant actin gel filaments were obtained by forming complexes with poly-L-Lysine (p-Lys) by subsequent chemical cross-linking (1). However, the self-organized growth process of actin-p-Lys complexes has not been clarified yet.

In this paper we systematically study the complex formation between actins and various kinds of polycations, such as p-Lys and  $x,y$ -ionene bromide polymers ( $x = 3$  or 6;  $y = 3, 4, 6, 10$ , or 12).  $x,y$ -ionene polymers are cationic polymers having positive charges on their chain backbone with periodical alkyl spacers  $x$  and  $y$  (Chart 1). Native actins (G-actin), which are globular proteins of 5 nm in diameter, form thin filaments with a diameter about 9 nm in living muscle. In physiological ionic solution (F-buffer), G-actins extracted from muscles undergo self-assembly reaction polymerization transferring to a single-stranded filament with a pitch of 5.9 nm which resembles the actin filaments within sarcomere (2). This actin filament polymerized from G-actin in physiological ionic solution is called F-actin. The F-actins of several nanometers in length can be conveniently observed under a fluorescence microscope by binding fluorescent phalloidin to the F-actins. Since the isoelectric point of actins is pH 4.7, F-actins in F-buffer of pH 7.2 are negatively

**Chart 1. Molecular Structure of  $x,y$ -ionene Bromide Polymers**

charged. Therefore, they were assumed to form complexes with cationic polymers through electrostatic interaction. When synthetic polymers carrying positive charges are mixed with fluorescent phalloidin-labeled F-actin, polymer–actin complexes grew with time. The complex growth kinetics and thermodynamics are investigated and compared with the morphological features of the complexes by using fluorescent optical images and transmission electron microscope (TEM) images.

## EXPERIMENTAL PROCEDURES

**Sample Preparations.**  $x,y$ -ionene ( $x = 3$  or 6;  $y = 3, 4, 6, 10$ , or 12) bromide polymers ( $x,y$ -ionene), which have the chemical structures as shown in Chart 1, were synthesized by the method reported previously (3). The intrinsic viscosities of 6,6- and 6,12-ionene polymers in 0.4 M LiBr aqueous solution at 25  $^\circ\text{C}$  were 0.19 and 0.22 dL/g, respectively. The viscosity value of the 6,6-ionene polymer corresponds to a weight-average molecular weight of  $1.9 \times 10^4$ . Poly-L-lysine hydrochloride (p-Lys) and poly-D-glutamic acid sodium salt (p-Glu) were purchased from Peptide Institute Inc. Deoxyribonucleic acid sodium salt (DNA) was purchased from Sigma Chemical Co. Poly(ethylene glycol) (PEG) was purchased from Aldrich Chemical Co., Inc.

G-actins (0.1 mg/mL) were obtained from scallops by the method of Spudich et al. (4). Fluorescently labeled F-actins were obtained by stoichiometrically mixing G-actins and rhodamine–phalloidin (Molecular Probes No. 4171) in F-buffer (5 mM HEPES (pH 7.2), 0.2 mM ATP, 0.2 mM  $\text{CaCl}_2$ , 100 mM KCl, 2 mM  $\text{MgCl}_2$ ) for 24 h at 4  $^\circ\text{C}$ . Phalloidin bonds to G-actin stoichiometrically and stabilizes the F-actin against depolymerization at a decreased critical concentration of actin.

**Measurement.** The rhodamine–phalloidin-labeled F-actin (later denotes as F-actin) solution was diluted to 0.001 mg/mL with F-buffer and mixed with various kinds

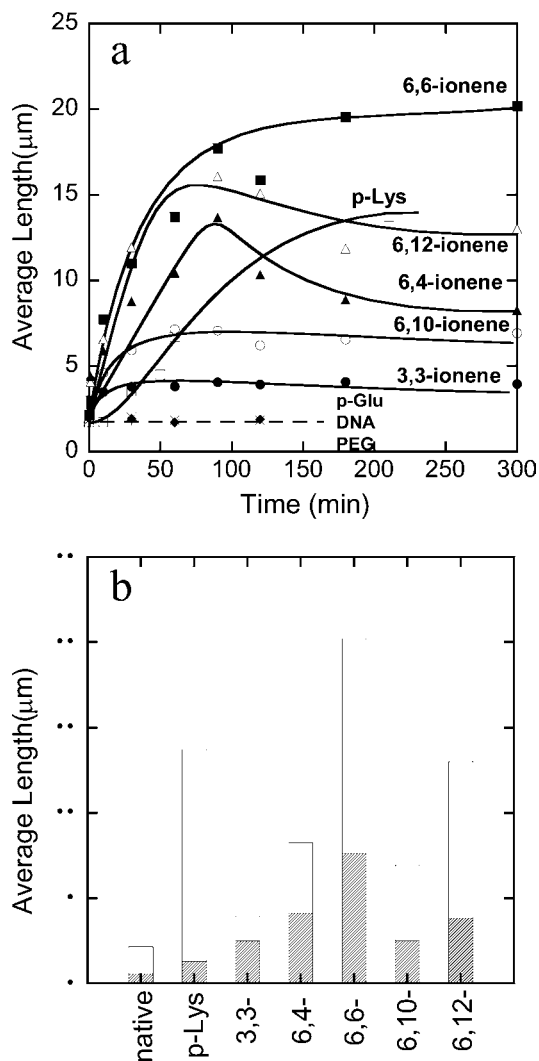

**Figure 1.** Fluorescence microscope images of polymer-actin complexes formed by mixing F-actin and various cationic polymers at room temperature. (a) p-Lys, (b) 3,3-ionene, (c) 6,6-ionene, (d) 6,12-ionene, (e) F-actin only. The molar ratio of ammonium cation of polymer to monomeric actin was kept constant at 30:1 for *x,y*-ionene polymers and 100:1 for p-Lys, which corresponding-to-weight ratios of [3,3-ionene]/[actin] = 0.41 g/g, [6,6-ionene]/[actin] = 0.61 g/g, [6,12-ionene]/[actin] = 0.81 g/g, [p-Lys]/[actin] = 0.35 g/g. Actin concentration was 0.001 mg/mL.

of polymers with a prescribed weight ratio of [polymer]/[F-actin] at room temperature. A cover glass was placed on a slide glass equipped with two spacers 1.1–1.4 mm high at both sides to form a flow-cell. Solution of F-actin and polymer mixture about 30  $\mu\text{m}$  was introduced into the flow-cell by a micropipet at a prescribed time after mixing. The flow-cell was then placed on the stage of a fluorescence microscope (Olympus BX 50) and observed under a  $\times 60$  objective. F-actins and its complexes with polymers absorbed on the slide glass surface can be clearly visualized under a microscope. The fluorescence images were recorded by a CCD-camera (Olympus CD-300T-RC), and images of filament length were analyzed by using a computer-analyzing program (MetaMorph, Nippon ROPER). The length of filaments, measured from the contour length of long axis, was the average over 50 samples. Transmission electron microscopy (TEM) was performed by using a JEOL (JEM-1200EX) at 120 kV acceleration voltage. A drop of F-actin-polymer mixture of about 10  $\mu\text{L}$  was put on carbon-coated 200-mesh grids that were rendered hydrophilically by glow discharge in a reduced pressure. After waiting for 180 s for adsorption, the grids were stained by one drop of phosphotungstic acid (pH 7.2). The length or width of filament was the average over 20 samples.

## RESULTS AND DISCUSSION

Figure 1a–d shows some examples of fluorescence microscope images of polymer-actin complexes obtained by mixing F-actins with p-Lys (Figure 1a) and *x,y*-ionene polymers (Figure 1b–d) for 120 min. One can see that large filamentous, stranded and branched complexes of 20–30  $\mu\text{m}$  in size are formed in the presence of p-Lys and 3,3-, 6,6-, 6,12- ionene polymers and their morphological nature, both of size and shape, are strongly in contrast to that of native F-actin (Figure 1e). Figure 2a shows time courses of the average length of the complexes in the presence of various kinds of polymers. Polymers have been mixed with following weight ratios keeping the actin concentration constant at 0.001 mg/mL as well as the molar ratio of ammonium cation of polymer to actin monomer of F-actin as 100:1 for p-Lys and 30:1 for ionene polymers: [p-Lys]/[actin] = 0.35 g/g, [3,3-ionene]/[actin] = 0.41 g/g, [6,4-ionene]/[actin] = 0.54 g/g, [6,6-ionene]/[actin] = 0.61 g/g, [6,10-ionene]/[actin] = 0.74 g/g, [6,12-ionene]/[actin] = 0.81 g/g.

The number-average length of fluorescence image of F-actins is 2.14  $\mu\text{m}$  with a standard deviation of 0.11  $\mu\text{m}$  (average over 784 samples) in the F-buffer. However, polymer-actin complexes grow with time and reach as large as 5–20  $\mu\text{m}$  within one or 2 h, which is about 2–10 times larger than that of native F-actin. The growth profiles depend on the chemical structure of the

**Figure 2.** (a) Time courses of polymer-actin complexes growth. (●): 3,3-ionene-actin complexes, (▲): 6,4-ionene-actin complexes, (■): 6,6-ionene-actin complexes, (○): 6,10-ionene-actin complexes, (△): 6,12-ionene-actin complexes, (□): p-Lys-actin complexes, (◆): p-Glu-actin complexes, (×): [DNA-actin complexes, (+): PEG-actin complexes. (b) Average length of polymer-actin complexes observed from fluorescence microscope images (white columns) and from transmission electron microscopy (TEM) images (shade columns) at 210–300 min. The molar ratio of ammonium cation to monomeric actin was 30:1 for *x,y*-ionene polymers and 100:1 for p-Lys. The corresponding weight ratios were as follows: [3,3-ionene]/[actin] = 0.41 g/g, [6,4-ionene]/[actin] = 0.54 g/g, [6,6-ionene]/[actin] = 0.61 g/g, [6,10-ionene]/[actin] = 0.74 g/g, [6,12-ionene]/[actin] = 0.81 g/g, [p-Lys]/[actin] = 0.35 g/g, [p-Glu]/[actin] = 0.36 g/g, [DNA]/[actin] = 0.77 g/g, [PEG]/[actin] = 0.10 g/g. Actin concentration: 0.001 mg/mL.

polycations. P-Lys shows a relatively slow growth profile but gives out a large complex. On the other hand, 3,3-ionene polymer gives the smallest complexes. These results indicate that hydrophobicity and charge density of the ionene polymers are important in complex formation. The average lengths of actin-polymer complexes are shown in Figure 2b. To confirm that this kind of actin growth is due to the complex formation via electrostatic interaction between the negatively charged actins and positively charged polymers, we further studied the actin growth in the mixture solution of actins and negatively charged polymers such as p-Glu, DNA, and neutral polymer, such as PEG at a molar ratio of monomeric units of polymer to F-actin of 100:1, which corresponding-to-weight ratios of [p-Glu]/[actin] = 0.36 g/g, [DNA]/[actin] = 0.77 g/g, [PEG]/[actin] = 0.10 g/g. As shown in Figure 2a, the F-actins do not grow into large filaments with time in the presence of these anionic or neutral polymers. Therefore, the formation of polymer-actin complexes should be attributed to the electrostatic interaction between actins and cationic polymers. As shown in Figure 2a, although 3,3-ionene has a similar high charge density as that of p-Lys that has charged moiety on its side chain, it shows a much less ability of complex growth. This indicates that although the complex formation is initiated by the electrostatic interaction, the flexibility of the charged moiety is important. The complicated  $x,y$  value dependence of the complex growth observed in  $x,y$ -ionene polymers might be associated with the complementary effect between the charge density and the flexibility of the charged moiety. Both 3,3-ionene and 6,10-ionene form short complexes because the former has a high charge density but with a less flexibility, while the latter has a high flexibility but with a low charge density. 6,6-Ionene gives longest complex due to its proper charge density and flexibility. Here, we could not find a clear role related to the hydrophobicity of the  $x,y$ -ionene polymers. The decrease in the filament length after 100 min of complex formation observed for 6,4- and 6,12-ionene complexes seems to be due to the aggregation of the complex.

Since the formation of polymer-actin complexes is an equilibrium reaction, the morphological features of the product should depend not only on time and polymer structure, but also on concentrations of actins and polymers. Figure 3a shows the effect of actin concentration on the equilibrium size of the polymer-actin complexes when mixed with p-Lys of a constant concentration ( $3.5 \times 10^{-4}$  mg/mL). When the actin concentration exceeds 0.001 mg/mL, the actin complexes increase the length steeply with the increase in the concentration and then saturate to a length around 15–20  $\mu$ m. Figure 3b shows the effect of p-Lys concentration on the relative length  $\beta$  of polymer-actin complexes in the equilibrium at a constant actin concentration (0.001 mg/mL). Here  $\beta$  is defined as a ratio of average length to maximum length of actin-polymer complex. No actin growth is observed at all when the mixing ratio of p-Lys to actin is lower than 0.14 g/g, indicating that the polymer-actin complex does not form at such a low concentration. However, the length of polymer-actin complexes abruptly increases when the mixing ratio of p-Lys to F-actin exceeds 0.21 g/g. Thus, there exists a critical p-Lys concentration to form complex, indicating that the complex formation is cooperative. The similar cooperative behavior was also observed in the complex formation with ionene polymers, and the critical mixing ratios of 3,3-, 6,4-, 6,6-, 6,10-, and 6,12-ionene to F-actin were about 0.81, 0.054, 0.12, 0.024, and 0.022 g/g at a constant

**Figure 3.** Average length of polymer-actin complexes as a function of F-actin concentration (a) and dependence of  $\beta$  on the mixing ratio of polymer to actin (b). Here  $\beta$  is defined as the ratio of average length to maximum length of actin-polymer complex. (●): p-Lys; (○): 3,3-ionene; (■): 6,4-ionene; (□): 6,6-ionene. Data in part a were obtained at [p-Lys] =  $3.5 \times 10^{-4}$  mg/mL at 60 min and in part b at an actin concentration of 0.001 mg/mL at 90 min.

F-actin concentration (0.001 mg/mL), respectively (Figure 3b). These results explain why we observed a shortest complex length of 3,3-ionene in Figure 2a performed at [3,3-ionene]/[actin] = 0.41 g/g, which was less than the critical value of 0.81 g/g. Now, we can conclude that interaction between polymers and actins behave cooperatively, and polymer-actin complexes are formed only when both F-actin concentration and the mixing ratio exceed the critical values.

From Figure 3b we can obtain the binding constant ( $K$ ) as well as the other thermodynamic parameters of the actin-polymer interaction by the following equation (5–7).  $K = K_0 u = 1/(C_s)_{0.5}$ , where  $K_0$  is the binding constant of the cationic polymer bound to an isolated binding site on the actin filament (initiation process),  $(C_s)_{0.5}$  is the cationic polymer concentration at  $\beta = 0.5$  ( $\beta$  is defined as a ratio of average length to maximum length of actin-polymer complex), and  $u$  is the cooperative parameter which tells the extra interaction energy between the binding sites (propagation process). The value of  $u$  can be calculated from the slope of the growth profile at the half-length point.  $(d\beta/d \ln C_s)_{0.5} = \sqrt{u/4}$ .  $K_0$  and  $u$  as well as the total binding energy ( $\Delta F_{\text{total}} = -RT \ln K$ ) and cooperative energy change ( $\Delta F_{\text{coop.}} = -RT \ln$

**Table 1.** Thermodynamic Interaction Parameters of Complex Formation between F-Actin and Various Cationic Polymers

polymer	$K$ [ $10^6$ ]	$u$	$K_0$ [ $10^5$ ]	$\Delta F_{\text{total}}$ [ $\text{kJ mol}^{-1}$ ]	$\Delta F_{\text{coop.}}$ [ $\text{kJ mol}^{-1}$ ]
p-Lys	3.7	31	1.2	-37	-8.5
3,3-	0.3	32	0.1	-31	-8.6
6,4-	2.9	4.4	6.6	-37	-3.7
6,6-	2.4	20	1.2	-36	-7.4
6,10-	1.1	7.0	1.5	-34	-4.8
6,12-	1.6	2.2	7.1	-35	-1.9

$u$ ) were calculated, and the results are summarized in Table 1. One can see a large value of the cooperative parameter ( $u$ ) and therefore a large cooperative energy ( $\Delta F_{\text{coop.}}$ ) change for p-Lys and 3,3-ionene, and the smallest value of cooperative parameter is observed for 6,12-ionene, which is 1 order of magnitude smaller than the  $u$  value of the other polymers. On the contrary, 6,12-ionene shows the highest binding constant of the initiation process ( $K_0$ ).

The growth of polymer-actin complexes in size is accompanied by a substantial decrease in the number of actin filament. Figure 4 shows a logarithmic plot of the number ( $N$ ) as a function of the length ( $L$ ) of polymer-actin complexes at various actin concentrations at a constant mixing ratio of [p-Lys]/[actin] = 0.35 g/g. As shown in the figure, the number of complexes ( $N$ ) decreases with increase in the length ( $L$ ), and they follow a power law as  $N \propto L^{-\alpha}$ . The exponent  $\alpha$  that is the fractal dimension ( $\delta$ ) should characterize the growth process of the complexes. If  $\alpha$  is 1, the complexes grow one-dimensionally, i.e., the actins aggregate along the axis of filament. If  $\alpha > 1$ , lateral growth occurs simultaneously with the longitudinal growth. When the fractal dimension  $\alpha$  is plotted against the concentration of actin, we obtain Figure 4 (insert) which shows an abrupt increase in  $\alpha$  at an actin concentration of 0.0033 mg/mL. When the concentration of actin is lower than this concentration,  $\alpha$  is ca. 1.4, but abruptly increases to 2.2 when it exceeds this concentration. In other words, at low concentration the complexes grow preferentially along the filament axis extending their length, but above the critical concentration, they begin to grow in lateral direction as well.

As shown in Figure 2 that among  $x,y$ -ionenes, 6,6-ionenes form the longest polymer-actin complexes which is followed by 6,12-, 6,4-, 6,10-, and 3,3-ionene. Therefore, we further investigate the fractal dimension of the complexes with  $x,y$ -ionenes. It is found that  $\alpha$  values were 2.1, 2.9, 2.2, 3.5, and 2.3, for 3,3-, 6,4-, 6,6-, 6,10-, and 6,12-ionenes, respectively, at a constant actin concentration (0.001 mg/mL) and molar ratio of ammonium cation to actin monomer unit (30:1). These results indicate that 6,4-, 6,10-, and 6,12-ionenes grow in a three-dimensional direction, and 3,3-, 6,6-ionene promotes a preferential growth along the filament direction with a less vague growth in the lateral direction. Since the complex length of 3,3-ionene is much shorter than that of 6,6-ionene, we can expect that much thinner filaments were formed in 3,3-ionene than that in 6,6-ionene.

As the lateral structures of the polymer-actin complexes are too small to be clearly observed by fluorescent optical microscope, we further studied polymer-actin complexes by TEM, using the negative staining technique. Figure 5 shows the TEM images of the actin complexes prepared at a molar ratio of ammonium cation of polymer to monomeric actin as 100:1 for p-Lys and 30:1 for ionene polymers at a constant F-actin concentration

**Figure 4.** Logarithmic plot of number of p-Lys-actin complexes ( $N$ ) as a function of length ( $L$ ) for different F-actin concentration after 90 min.  $N$  and  $L$  follow a power law  $N \propto L^{-\alpha}$  where the exponent  $\alpha$  depends on actin concentration as shown in the inserted figure. Actin concentration: (closed circle): 0.001 mg/mL, (closed square): 0.002 mg/mL, (open circle): 0.0033 mg/mL, (open square): 0.0066 mg/mL, (closed triangle): 0.01 mg/mL. The molar ratio of ammonium cation to monomeric actin was 100:1.

0.001 mg/mL. As shown in Figure 5a, actin forms a relatively homogeneous and thin filament in the presence of p-Lys, which agrees well with the small fractal dimension at a F-actin concentration 0.001 mg/mL in Figure 4 (insert). We also found that actin is able to form an extremely homogeneous nanoscale wire (nanowire) with 3,3-ionene (Figure 5b), and this is also in agreement with the prediction from the fractal dimension value. Filamentous complexes are observed in the presence of 6,6-ionene, (Figure 5c). Occasionally, a ring-shaped complex (nano-ring) is observed in a 6,6-ionene-actin complex (Figure 5d).

The average width of the p-Lys-actin complex is 21.0 nm with a standard deviation of 2.6 nm. Compared with the native F-actins that have an average width of 12.1 nm with a standard deviation of 1.2 nm, p-Lys-actin complexes are only slightly thicker than that of the native F-actin with almost the same width scattering. 3,3-ionene complexes also showed a very thin and homogeneous wirelike morphology showing an average width of 16.1 nm with a standard deviation of 1.7 nm. However, from Figure 3b, we know that at a molar ratio of ammonium cation to actin monomer as 30:1, the 3,3-ionene polymer concentration is still below the critical concentration. Since the complex morphology is strongly dependent on the polymer concentration, we further investigated the 3,3-ionene-actin complex at a molar ratio of ammonium cation to actin monomer of 300:1 ([3,3-ionene]/[actin] = 4.1 g/g), which is above the critical concentration of complex formation. As shown in Figure 5e, bundles of thin filaments are formed when the 3,3-ionene polymer exceeds the critical concentration. Similar morphology are observed for other  $x,y$ -ionene polymers above their critical concentration. Actin-6,4-, 6,6-, 6,10-, and 6,12-ionene complexes have an average width of 79.0 nm, 59.3, 38.7, and 66.1 nm with a standard deviation of 60, 29, 21, and 27 nm, respectively (Figure 6a). The large scattering in the width of actin-6,4-, 6,6-, 6,10-, and 6,12-ionene complexes quantitatively indicates the randomness of the morphology of the complexes.

**Figure 5.** Transmission electron microscopy (TEM) images of polymer–actin complexes formed by mixing F-actin and various polymers at room temperature for 240 min. (a) p-Lys, (b) 3,3-ionene, (c) 6,6-ionene, (d) 6,6-ionene, (e) 3,3-ionene, (f) F-actin only. Mixing molar ratios are the same as fluorescence microscope observation (Figure 1), except for part e which is carried out at 300:1 ([3,3-ionene]/[actin] = 4.1 g/g). Actin concentration: 0.001 mg/mL.

**Figure 6.** Average width of polymer–actin complexes obtained at 240 min by TEM images (a), and axial ratios of polymer–actin complexes evaluated by dividing the average length of complex obtained from fluorescence image by the average width obtained from TEM images (b). Error bar means standard deviation.

The average length of the complexes as observed by TEM showed a similar dependence on the polymers, but the absolute values of the length are about 2 times shorter than that obtained from fluorescent observations (Figure 2b). This discrepancy is due to the breakage of the long filament during the sample drying process for TEM measurements.

The axial ratio of polymer–actin complexes, which is the ratio of the average length from fluorescence image (Figure 2b) to the average width from TEM images, was estimated (Figure 6b). We find that the axial ratios are 653, 245, 104, 340, 179, and 196 for p-Lys, 3,3-, 6,4-, 6,6-, 6,10-, and 6,12-ionene, respectively. This tendency in the axis ratio values well coincides with that of the growth fractal dimension  $\alpha$  as estimated from the fluorescent images of the complex during growth process. For example, P-Lys showed a smallest fractal dimension (Figure 4) which agrees well with the highest axial ratio. Furthermore, 3,3-, and 6,6-ionene showed a relatively smaller fractal dimension, and this is in agreement with a relatively high axial ratio of the complex as shown in Figure 6b.

As a conclusion, p-Lys keeps the axial growth even above the critical concentration of cooperative growth, forming long and thin filaments, while  $\alpha,\gamma$ -ionene polymers change their growth mode from axial to lateral at the critical concentration and their average width at the concentration which gives half-length point is dominated by the cooperative energy ( $F_{\text{coop}}$ ) between actin and ionene polymers. Thus, designed micro-order polymer–actin complexes could be obtained by changing the structure of cationic polymer and other conditions. The motility of these actin–ionene complexes will be explored in future studies.

# Fully Detachable Molecular Umbrellas as Peptide Delivery Agents

Bingwen Jing, Vaclav Janout, and Steven L. Regen\*

Department of Chemistry, Lehigh University, Bethlehem, Pennsylvania 18015. Received May 7, 2003;  
Revised Manuscript Received October 8, 2003

A persulfated molecular umbrella, derived from cholic acid and spermidine, has been covalently attached to H-Tyr-D-Ala-Gly-Phe-D-Leu-OH (DADLE) by use of an *o*-dithiobenzyl carbamate linkage. Treatment of the resulting conjugate (**1**) with glutathione in solution resulted in the liberation of the free form of the peptide. Addition of **1** to glutathione-entrapped liposomes, prepared from 1-palmitoyl-2-oleoyl-*sn*-glycero-3-phosphocholine (POPC), 1-palmitoyl-2-oleoyl-*sn*-glycero-3-phosphatidylglycerol (POPG), and cholesterol [POPC/POPG/cholesterol, 72/4/24 (mol/mol/mol)], resulted in the delivery of DADLE into their aqueous interior.

## INTRODUCTION

Molecular umbrellas are a unique class of amphiphiles that are capable of shielding an attached agent from an incompatible environment. Typically, such molecules are composed of a central scaffold that contains two or more facially amphiphilic units (*1*). When a hydrophilic agent is attached to an umbrella molecule, immersion in water favors an exposed conformation such that intramolecular hydrophobic interactions are maximized (*2*). Alternatively, when immersed in a hydrophobic environment, the molecular umbrella can shield the agent by providing a hydrophobic exterior (*2*). A stylized illustration of shielded and exposed conformers is shown in Scheme 1. Here, the shaded and unshaded rectangles represent hydrophobic and hydrophilic faces, respectively.

Recent mechanistic studies have provided strong evidence that facial amphiphilicity plays a major role in umbrella transport across lipid bilayers (*3*). The fact that facial amphiphilicity is more important than the hydrophobic/hydrophilic balance of such molecules, in promoting bilayer transport, lends strong support for an umbrella mechanism; that is, a permeation pathway involving monolayer insertion of a shielded conformer, transbilayer diffusion and entry to the opposite membrane/water interface.

Previous molecular umbrellas that we have designed for peptide transport have employed a 2-nitrobenzoyl-5-dithio moiety as a detachable handle (*3*). When these conjugates enter the aqueous interior of a liposome that contains glutathione (GSH), the peptide is released by means of a thiolate–disulfide exchange reaction (Scheme 2) (*4*). The fact that mammalian cells contain millimolar concentrations of GSH within their cytoplasm adds relevance to such a strategy from a prodrug standpoint. Two distinct limitations associated with this approach, however, are the need of a cysteine residue for umbrella attachment/detachment, and the peptide is released in a non-native state; that is, as a glutathione conjugate.

In this paper, we introduce a new design strategy for the synthesis of molecular umbrella–peptide conjugates that (i) takes advantage of GSH-based thiolate–disulfide interchange reactions, (ii) circumvents the need for a

Scheme 1

Scheme 2

cysteine residue for attachment of the peptide to the umbrella, and (iii) allows for the release of the native form of the peptide.

## EXPERIMENTAL SECTION

**General Methods.** Unless stated otherwise, all reagents were obtained from commercial sources and used without further purification. House-deionized water was purified using a Millipore Milli-Q-filtering system containing one carbon and two ion-exchange stages. All <sup>1</sup>H NMR spectra were recorded on a 360 MHz instrument; chemical shifts are reported in ppm relative to residual solvent. All UV spectra were recorded using a Carey 300 Bio UV–Visible spectrophotometer operating at ambient temperature. MALDI spectra were obtained using an Applied Biosystems DE-STR MALDI-TOF instrument operating in the linear, negative mode with an accuracy of ±0.2%; reflector mode analyses afforded an accuracy of ±0.02%. A standard buffer that was used in this work (referred to as “buffer”) was composed of 10 mM NaCl, 1.0 mM EDTA, and 2 mM PIPES, pH 7.2. The synthetic route that was used to prepare **1** is outlined in Scheme 3.

**2-(Methoxycarbonyldithio)benzyl Alcohol.** A solution of 1.4 g (9.99 mmol) of 2-mercaptobenzyl alcohol in 20 mL of dichloromethane was added, dropwise, to a

\* To whom correspondence should be addressed. E-mail: slr0@lehigh.edu.

Scheme 3

cooled (0 °C) solution prepared from 1 mL (10.98 mmol) of methoxycarbonylsulfonyl chloride and 60 mL of dichloromethane, under a nitrogen atmosphere. After stirring for 2 h, the mixture was washed, sequentially, with saturated sodium bicarbonate, and saturated sodium chloride, and the organic layer then dried over anhydrous MgSO<sub>4</sub>. Removal of solvent under reduced pressure, followed by column chromatographic purification [silica, chloroform/ethyl acetate (10/1, v/v)] afforded 1.20 g (52%) of 2-(methoxycarbonyldithio)benzyl alcohol having an  $R_f$  = 0.47 and <sup>1</sup>H NMR (CDCl<sub>3</sub>, 360 MHz)  $\delta$  ppm: 7.65–7.27 (m, 4 H), 4.85 (s, 2 H, CH<sub>2</sub>OH), 3.83 (s, 3 H, OCH<sub>3</sub>), 2.99 (s, 1H, OH). FAB for C<sub>9</sub>H<sub>10</sub>O<sub>3</sub>S<sub>2</sub> (M<sup>+</sup>) calcd: 230. found 230.

**3,3'-Dithiopropionic Acid Bis-3-hydroxyl-1,2,3-benzotriazin-4(3H)-onyl Ester.** A solution was prepared from 0.500 g (2.378 mmol) of dithiopropionic acid, 1.008 g (6.18 mmol) of 3-hydroxyl-1,2,3-benzotriazin-4(3H)-one, 1.135 g (5.5 mmol) of *N,N*-dicyclohexylcarbodiimide (DCC), and 20 mL of CH<sub>2</sub>Cl<sub>2</sub>. After stirring the mixture overnight at room temperature, the resulting insoluble urea was removed by filtration. The filtrate was then poured into 100 mL of a saturated aqueous NaHCO<sub>3</sub> solution. The organic layer was separated and concentrated under reduced pressure, and the residue was purified by recrystallization from ethanol to give 1.31 g (75%) of the desired diester having <sup>1</sup>H NMR(CD<sub>3</sub>OD):  $\delta$  ppm: 8.43 (dd, 2 H), 8.41 (dd, 2 H), 8.22 (td, 2 H), 8.07 (td, 2 H), 3.40 (t, 4 H), 3.27 (t, 4 H). FAB for C<sub>20</sub>H<sub>16</sub>N<sub>6</sub>O<sub>6</sub>S<sub>2</sub> (MH<sup>+</sup>) calcd: 501. found 501.

***N,N'*-Bis[*N,N'*-spermidinebischoleamideyl]-3,3'-dithiopropionebisamide, Persulfate (2).** To a solution

of 1.186 g (1.28 mmol) of *N,N'*-spermidinebis(choleamide) in 10 mL of DMF was added 669  $\mu$ L (3.84 mmol) of diisopropylethylamine (DIPEA) (2). After stirring for 10 min, 315 mg (0.63 mmol) of 3,3'-dithiopropionic acid bis-3-hydroxyl-1,2,3-benzotriazin-4(3H)-one ester was directly added as a powder. After stirring overnight, the mixture was concentrated under reduced pressure. Purification by column chromatography [silica, chloroform/methanol/water (30/9/1, v/v/v)] afforded 970 mg (75%) of the corresponding bis-steroid dimer having  $R_f$  = 0.57 and <sup>1</sup>H NMR (CD<sub>3</sub>OD)  $\delta$  ppm: 3.89 (s, 4 H), 3.74 (s, 4 H), 3.26 (m, 4 H), 3.14–3.11 (m, 8 H), 2.90 (brs, 4 H), 2.74 (brs, 4 H), 2.30–2.10 (m, 8 H), 2.10–2.00 (m, 8 H), 1.95–1.00 (m, 100 H), 1.04 (s, 12 H), 0.97 (s, 12 H), 0.66 (s, 12 H).

Sulfation was then carried out using standard procedures (5). Thus, 320 mg (0.148 mmol) of the bis-steroid dimer was dissolved in 10 mL of DMF at 0 °C, followed by direct addition of 848 mg (5.33 mmol) of Pyr-SO<sub>3</sub>. After the mixture was stirred for 5.5 h at room temperature, 10 mL of cold water was added, followed by addition of saturated sodium bicarbonate until the pH of the mixture was 10. The combined solvent was removed under reduced pressure, and the residue was purified by column chromatography [silica, chloroform/methanol/water (5/4/1, v/v/v)] to give 323 mg (67%) of the hexasulfated dimer (Na<sup>+</sup> salt) having  $R_f$  = 0.29 and <sup>1</sup>H NMR (CD<sub>3</sub>OD)  $\delta$  ppm: 4.67 (s, 4 H), 4.45 (s, 4 H), 4.13 (s, 4 H), 3.35–3.10 (m, 16 H), 2.99 (br, 4 H), 2.83 (br, 4 H), 2.40–0.90 (m, 120 H), 0.76 (s, 12 H). MALDI for C<sub>116</sub>H<sub>184</sub>N<sub>6</sub>O<sub>54</sub>S<sub>14</sub>Na<sub>11</sub> (M–Na) calcd: 3226. found 3231.

***N*<sup>1</sup>,*N*<sup>3</sup>-(Spermidine-bis-choleamideyl)-*N*<sup>2</sup>-(3-dithio-2-hydroxymethyl-1-phenyl)propionamide, Persulfate **3**.** The sulfated dimer conjugate **2** (1.81 g, 0.556 mmol) was dissolved in 20 mL of a 1.0 M phosphate buffer (pH 7.3) and mixed with 10 mL of a 1.0 M phosphate buffer containing 240 mg (0.835 mmol) of tris-(2-carboxyethyl)phosphine hydrochloride (TCEP), which was adjusted to pH 7.3. After stirring for 50 min at room temperature, the solution was concentrated under reduced pressure, and the residue dissolved in 100 mL of methanol (the inorganic salts were removed by filtration). The solution, which contained the corresponding thiol monomer, was concentrated to ca. 50 mL, and 140  $\mu$ L (1.0 mmol) of triethylamine then added to it. To the resulting solution was added, dropwise, a second solution, which was prepared from 307 mg (1.335 mmol) of 2-(methoxycarbonyldithio)benzyl alcohol plus 50 mL of methanol. After addition was complete, the mixture was stirred at room temperature for 5 h. Subsequent removal of solvent under reduced pressure and purification by column chromatography [silica, chloroform/methanol/water (60/40/10, v/v/v)] afforded 804 mg (41%) of **3** having  $R_f$  = 0.42 and  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ )  $\delta$  ppm: 7.76 (m, 1 H), 7.47 (m, 1 H), 7.30 (m, 2 H), 4.77 (s, 2 H), 4.65 (s, 2 H), 4.43 (s, 2 H), 4.12 (br, 2 H), 3.31 (m, 2 H), 3.15 (m, 6 H), 2.95 (m, 2 H), 2.73 (m, 2 H), 2.35–0.85 (m, 66 H), 0.75 (s, 6 H). MALDI (reflector mode  $\pm 0.02\%$ ) for  $\text{C}_{65}\text{H}_{99}\text{N}_3\text{O}_{28}\text{S}_8\text{Na}_5(\text{M}-\text{Na})$  calcd: 1740. found 1740.

**{3-(*N*<sup>2</sup>-Propionamideyl-*N*<sup>1</sup>,*N*<sup>3</sup>-spermidine-bis-choleamideyl)-2-dithiobenzyl-DADLE-carbamate, Persulfate **1**.** To a solution made from 35.3 mg (0.02 mmol) of **3** and 1 mL of DMF were added 51.2 mg (0.2 mmol) of *N,N*-disuccinimidyl carbonate (DSC) and 28  $\mu$ L (0.2 mmol) of triethylamine. The mixture was stirred for 15 h under a nitrogen atmosphere at room temperature, followed by removal of most of the solvent under reduced pressure; a small amount of DMF remained in order to keep the product in solution. Addition of 10 mL of acetone resulted in the precipitation of the DSC-activated ester, which was washed thoroughly with acetone, collected by filtration and freeze-dried for 2 h. This activated ester was then dissolved in 1 mL of DMF, and the resulting solution then added, dropwise, to a solution made from the sodium salt of DADLE [prepared by treating 13 mg (0.0228 mmol) of DADLE with 2 equiv of  $\text{NaHCO}_3$  in a minimum volume of water, followed by freeze-drying] plus 0.5 mL of DMF. The resulting mixture was stirred for 10 h at room temperature. The solvent was then removed under reduced pressure, and the umbrella-peptide conjugate was purified once by preparative thin-layer chromatography [silica, chloroform/methanol/water (60/40/10, v/v/v);  $R_f$  = 0.3], twice by reverse phase preparative thin-layer chromatography [C-18 silica (VWR Scientific), methanol/water (3/2, v/v)], and one final

preparative thin-layer chromatography [silica, chloroform/methanol/water (60/40/10, v/v/v)] to give 10 mg of **1** having  $R_f$  = 0.51, and  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 360 MHz)  $\delta$  ppm: 7.75 (m, 1 H), 7.35–7.10 (m, 8 H), 7.08 (d, 2 H), 6.71 (d, 2 H), 5.20 (m, 2 H), 4.65 (s, 3 H), 4.45 (s, 2 H), 4.33 (m, 2 H), 4.15 (br, 3 H), 3.95 (m, 2 H), 3.30 (m, 2 H), 3.15–2.85 (m, 12 H), 2.68 (m, 2 H), 2.45–0.90 (m, 72 H), 0.73 (m, 12 H). MALDI (reflector mode  $\pm 0.02\%$ ) for  $\text{C}_{95}\text{H}_{135}\text{N}_8\text{O}_{36}\text{S}_8\text{Na}_6(\text{M}-\text{Na})$  calcd: 2358. found 2358.

**Efflux of DADLE from Cholesterol-Rich Liposomes.** A unilamellar liposomal dispersion (ca. 200 nm diameter) was prepared by standard extrusion methods using 42 mg of a mixture of POPC/POPG/cholesterol (72/4/24, mol/mol/mol) and 1.40 mL of buffer that was 1.0 mM in DADLE (**6**). The dispersion was dialyzed (three times) against 1 L of buffer for 24 h, using a dialysis tubing having a 300 kDa MW cutoff. The dispersion was then placed into a 2 mL dialysis cell, equipped with a 100 nm Nuclepore membrane. An analysis for the release of DADLE from the liposomes was made by monitoring the receiving side (23  $^\circ\text{C}$ ) by withdrawing 0.5 mL and reacting it with 0.1 mL of a 2.0 mM fluorescamine solution in acetone for 5 min. The fluorescence intensity at 480 nm was then recorded and compared with a calibration curve. Immediately after withdrawing the 0.5 mL aliquot, 0.5 mL of fresh buffer was added to the receiving side in order to maintain a constant volume of 1.0 mL.

To test for binding of DADLE to the liposomes, a related experiment was carried out in which empty liposomes were first incubated with an external solution of DADLE for 24 h, and then the resulting dispersion was dialyzed against an equal volume of buffer. In principle, if the binding of DADLE to the liposomes were negligible, then exactly 50% of the total quantity of DADLE that was added to the dispersion should be present in the receiving side of the dialysis cell, that is, the side that does not contain liposomes. Thus, 430  $\mu$ L of a liposomal dispersion that was devoid of DADLE was incubated with 430  $\mu$ L of a 50  $\mu\text{M}$  solution of DADLE in buffer for a period of 24 h. Subsequent dialysis against 860  $\mu$ L of buffer for 24 h, and analysis of the receiving side showed the presence of 50% of the total DADLE that was incubated with the liposomes. These results indicate, therefore, that there is negligible binding of DADLE to the liposomes.

**Reaction of **1** with GSH in Solution.** A solution of **1** in buffer (1.00 mM, 0.80 mL) was mixed with 0.80 mL of 3.0 mM in glutathione in buffer at room temperature. The course of the reaction was monitored by UV (264 nm) and also by thin-layer chromatography. For UV analysis, 140  $\mu$ L-aliquots were withdrawn and diluted with 240  $\mu$ L of buffer, and the UV absorption was recorded. Analysis by thin-layer chromatography (silica gel,  $\text{CHCl}_3/\text{CH}_3\text{OH}/\text{H}_2\text{O}$ , 60/40/10, v/v/v) showed the complete disappearance of **1** ( $R_f$  0.3) after 8 h. At that time, a portion of the liberated DADLE was isolated by thin-layer chromatography (silica gel,  $\text{CHCl}_3/\text{CH}_3\text{OH}/\text{H}_2\text{O}$ , 65/30/2, v/v/v) using 10  $\mu$ L aliquots of the solution. The band corresponding to the free peptide ( $R_f$  0.65) was extracted with  $2 \times 0.5$  mL of buffer and filtered using glass wool. A 0.5 mL portion was then analyzed after reaction with 100  $\mu$ L of 2 mM fluorescamine in acetone for 5 min. The fluorescence intensity at 480 nm was then compared with a calibration curve.

**Delivery of DADLE to the Aqueous Interior of Cholesterol-Rich Liposomes.** A unilamellar liposomal dispersion (200 nm diameter) was prepared by standard extrusion methods using 60 mg of a mixture of POPC/

**Scheme 4**

POPG/cholesterol (72/4/24, mol/mol/mol) plus 2.0 mL of buffer containing 3.0 mM glutathione (**6**). The dispersion was dialyzed (three times) against 1 L of buffer for 28 h using dialysis tubing with a 300 kDa MW cutoff. The absence of external glutathione was confirmed by taking an 800- $\mu$ L aliquot and subjecting it to dialysis for 35 min against 800  $\mu$ L of buffer, using a dialysis cell that was equipped with a 100 nm Nuclepore membrane. Under these conditions, the half-life for permeation of glutathione across this membrane is 33 min. Analysis of the receiving side, by use of Ellman's assay [5,5'-dithiobis-(2-nitrobenzoic acid), DTNB], indicated that  $<0.9$   $\mu$ M of external thiol was present in the dispersion. An analysis of the glutathione that was entrapped within the vesicles was then made by dissolving a 20  $\mu$ L aliquot of the dispersion in a solution that was made from 0.266 mL of ethanol plus 0.133 mL of buffer that contained 20% of sodium dodecyl sulfate (w/w). To this mixture was added 20  $\mu$ L of 2.0 mM DTNB in buffer. The glutathione concentration of the resulting solution was found to be 427  $\mu$ M.

To 0.99 mL of the glutathione-entrapped dispersion was added 0.99 mL of a 80  $\mu$ M solution of **1** in buffer at 23  $^{\circ}$ C. Aliquots (200  $\mu$ L) of the resulting dispersion were withdrawn as a function of time and were mixed with 200  $\mu$ L of a solution that was made from 0.133 mL of ethanol plus 0.066 mL of buffer containing 20% of sodium dodecyl sulfate (w/w). The absorbance at 264 nm was then measured after 1 min of mixing. It should be noted that under these dilute conditions, the rate of reaction of glutathione with **1** is negligible (i.e.,  $<0.7\%$ ).

After the transport experiment was completed, 550  $\mu$ L of the dispersion was dialyzed for 2.5 h at 23  $^{\circ}$ C against 550  $\mu$ L of buffer and analyzed, separately, for glutathione (Ellman's assay) and for amino group content (fluorescamine assay). Specifically, 300  $\mu$ L of the receiving side of the dialysis cell was reacted with 20  $\mu$ L of 2.0 mM DTNB, and the absorbance measured at 410 nm. The concentration of glutathione was found to be 0.82  $\mu$ M. In a separate experiment, 250  $\mu$ L of the receiving side was diluted with an equal volume of buffer, followed by addition of 100  $\mu$ L of a 2.0 mM solution of fluorescamine in acetone. The DADLE concentration (total amino group concentration minus the glutathione concentration) was 1.54  $\mu$ M.

## RESULTS AND DISCUSSION

**Design and Synthesis of a Fully Detachable Molecular Umbrella–Peptide Conjugate.** To create a fully detachable molecular umbrella conjugate, we have chosen to follow a prodrug strategy that has previously been introduced by Senter (7,8). Specifically, this strategy involves a thiol-induced reductive fragmentation of a benzyl carbamate disulfide (Scheme 4). In the present work, umbrella–peptide conjugate (**1**) was designed as

a synthetic target in order to test the feasibility of such an approach for the construction of a fully detachable molecular umbrella. In essence, conjugate **1** was deemed as a target worthy for three reasons. First, there has been considerable interest in finding ways to improve the transport of opioid peptides such as H-Tyr-D-Ala-Gly-Phe-D-Leu-OH (DADLE) across hydrophobic barriers (9–12). Thus, conjugates such as **1** could have direct therapeutic relevance. Second, an *o*-dithiobenzyl carbamate was selected as a linkage unit due to the ready availability of 2-mercaptobenzyl alcohol from commercial sources. Third, a persulfated form of molecular umbrella was used to ensure reasonable water solubility of the resulting conjugate. Previous studies from our laboratory have shown that such umbrella molecules can transport GSH across phospholipid bilayers (13).

Our synthesis of **1** was accomplished via the sequence of reactions that are summarized in Scheme 3. Thus, acylation of *N,N*-spermidinebis(choleamide) with an activated form of 3,3'-dithiopropionic acid [activated with 3-hydroxy-1,2,3-benzotriazin-4*H*(3*H*)-one], followed by sulfation with Pyr-SO<sub>3</sub> yielded umbrella dimer **2**. Subsequent reduction with TCEP to give the corresponding umbrella thiol and coupling with an activated form of 2-mercaptobenzyl alcohol (prepared by reaction with methoxycarbonylsulfonyl chloride) afforded **3**. Finally, activation of the benzylic hydroxyl group with *N,N*-disuccinimidyl carbonate (DSC), followed by direct coupling with DADLE produced the desired conjugate, **1**.

**Impermeability of Cholesterol-Rich Phospholipid Membranes toward DADLE.** To confirm that DADLE, itself, does not readily cross cholesterol-rich phospholipid bilayers, this pentapeptide was entrapped within the aqueous interior of unilamellar liposomes (200 nm diameter), which were prepared using a POPC/POPG/cholesterol composition of 72/4/24 (mol/mol/mol). Upon removal of nonentrapped DADLE by gel filtration, subsequent dialysis revealed negligible release of the peptide ( $<0.3\%$ ) from the liposomes after 72 h at 23  $^{\circ}$ C. Related experiments that were carried out, in which empty liposomes were incubated with buffer solutions of DADLE, further revealed that this peptide has negligible affinity to such membranes (see Experimental Section for details).

**Reaction of **1** with Glutathione in Solution.** Before attempting the delivery of DADLE to the aqueous interior of liposomes, we first confirmed the ability of GSH to release DADLE from **1** in homogeneous solution. For this purpose, an aqueous solution of **1** was treated with 1.5 mM GSH in PIPES buffer at 23  $^{\circ}$ C. During the course of the reaction, the solution became effervescent and a UV absorption emerged at 264 nm (Figure 1). The putative *o*-thiobenzoquinone methide product and/or cyclic oligomers are presumed to be responsible for this absorbance (14). A plot of the increase in the UV absorbance as a function of time obeyed simple first-order kinetics (Figure 2). When the UV absorption reached a maximum, thin-layer chromatography confirmed the complete disappearance of **1** and the appearance of the free form of DADLE. Isolation of DADLE from the product mixture by preparative thin-layer chromatography afforded a ca. 82% isolated yield of the peptide.

**Delivery of DADLE into Cholesterol-Rich Liposomes.** Peptide delivery experiments were next carried out with **1**, using liposomal targets that were made from a lipid mixture that was similar to the one used to demonstrate the impermeability of DADLE. In this case, glutathione was first entrapped within the aqueous interior of the liposomes and **1** was added, externally, to

**Figure 1.** Changes in UV spectrum upon reaction of 0.50 mM of **1** with 1.5 mM GSH at 23 °C in PIPES buffer.

**Figure 2.** Increase in UV absorbance at 264 nm as a function of time (data taken from Figure 1). The solid lines represents a theoretical curve for a first-order process.

the dispersion. Using procedures that are described in the Experimental Section, the progress of the reaction could be followed by monitoring the increase in the UV absorption at 264 nm. For this analysis, aliquots of the dispersion were destroyed by addition of an ethanolic solution of sodium dodecyl sulfate (SDS) in order to avoid interference from light scattering by the liposomes. It should be noted that GSH and **1** undergo a significant dilution upon addition of the ethanolic solution. This results in a minimal extent of reaction, provided that the UV measurement is made within ca. 2 min of the addition. Similar to what was found in homogeneous solution, the increase in the absorbance at 264 nm followed first-order kinetics (Figure 3). The fact that the observed first-order rate constant was directly proportional to the concentration of entrapped GSH (i.e., the pseudo first-order rate constant increased from  $2.47 \times 10^{-2} \text{ h}^{-1}$  to  $5.87 \times 10^{-2} \text{ h}^{-1}$  on going from 1.25 to 3.00 mM entrapped GSH) indicates that the rate of peptide delivery is controlled by chemical reaction, and that permeation across the bilayer is a relatively fast process (Figure 3).

To confirm that DADLE was, in fact, released within the aqueous interior of the vesicles, we sought evidence that (i) leakage of entrapped glutathione was negligible and (ii) DADLE was fully retained by the dispersion upon dialysis. If leakage of glutathione were negligible, this would provide compelling evidence that chemical reaction has taken place within the aqueous interior of the vesicles. Since we have found that DADLE exhibits negligible binding to POPC/POPG/cholesterol-based liposomes, complete retention of DADLE by such a dispersion, after being subjected to dialysis, would provide

**Figure 3.** Increase in UV absorption at 264 nm as a function of time for reaction of 40  $\mu\text{M}$  of **1** with 200 nm diameter liposomes made from POPC/POPG/cholesterol ratio of 72/4/24 (mol/mol/mol), (19 mM in total lipid concentration present in the dispersion), which contained (●) 1.25 mM and (▲) 3.00 mM of entrapped GSH at 23 °C. The solid lines represent theoretical curves for first-order processes.

compelling evidence that this peptide is entrapped within the vesicle interior. With this rationale in mind, we carried out a delivery experiment similar to the one that is described above. Upon completion of the reaction (UV analysis), a portion of the dispersion was subjected to dialysis for 2.5 h using an equal volume of buffer. Analysis of the source and receiving side of the dialysis cell showed that more than 99.6% of the glutathione was present in the source (liposome) side. Given the fact that glutathione crosses such dialysis membranes with a half-life of ca. 33 min, we can conclude that leakage of glutathione from the vesicles is negligible. In a separate analysis, we have found that >96% of the DADLE was associated with the source (liposome) side of the dialysis cell. Since the half-life for permeation of free DADLE across this dialysis membrane is ca. 53 min, this results provides strong evidence that DADLE has become entrapped within these vesicles.

In summary, the results reported herein demonstrate the feasibility of creating a fully detachable molecular umbrella that can deliver a peptide into model cells containing physiologically relevant concentrations of entrapped glutathione. Efforts aimed at exploiting such systems, with a view toward drug delivery, are currently in progress.

# No Enhancement of Nuclear Entry by Direct Conjugation of a Nuclear Localization Signal Peptide to Linearized DNA

Mitsuhide Tanimoto,<sup>†,‡</sup> Hiroyuki Kamiya,<sup>†,‡</sup> Noriaki Minakawa,<sup>†</sup> Akira Matsuda,<sup>†</sup> and Hideyoshi Harashima<sup>\*,†,‡</sup>

Graduate School of Pharmaceutical Sciences, Hokkaido University, Kita-12, Nishi-6, Kita-ku, Sapporo 060-0812, Japan and CREST, Japan Science and Technology, Japan. Received May 8, 2003;

Revised Manuscript Received October 6, 2003

Efficient nuclear entry of exogenous DNA is one of the key factors toward gene therapy success with nonviral vectors. To re-address the effects of a nuclear localization signal (NLS) peptide attached directly to DNA, we prepared three dumbbell-shaped, green fluorescent protein (GFP)-encoding DNAs containing one or two NLS peptides. The peptide was conjugated to the loop-forming oligodeoxynucleotides by cross-linking reactions between the peptide and a modified uracil base with a dioxaoctylamino linker, and the oligonucleotides were then ligated to the DNA molecules. The NLS-conjugated DNA dumbbells were microinjected into the cytosols and nuclei of simian COS-7 cells. In addition, unconjugated DNA dumbbells, with or without a modified uracil base, were also examined for comparison. The GFP gene was expressed with efficiencies in the order of the unmodified DNA  $\geq$  the NLS-conjugated DNA  $>$  the unconjugated DNA with the base modification, with both cytosolic and intranuclear microinjections. Thus, we concluded that (i) one or two NLS peptide(s) did not dramatically improve the nuclear entry of DNA and that (ii) chemical modification of DNA reduced the transcription efficiency or stability in the nucleus.

## INTRODUCTION

Nonviral vectors are highly attractive in gene therapy due to their excellent safety profile, despite their low transgene expression efficiency in comparison to viral vectors. The intracellular disposition, especially the DNA entry into the nucleus, is a very important issue for high transgene expression (1). Intranuclear microinjections of DNA result in about 100- to 1000-fold more efficient expression than cytoplasmic microinjections (2, 3). Thus, the nuclear entry pathway(s) of exogenous DNA are of great interest. One proposed mechanism is the trafficking of DNA when the nuclear membrane disappears at the M phase of cell division (4). However, the nuclear entry occurs in nondividing cells (5) and at a very early time point during the transfection (6), suggesting that DNA could enter the nucleus in the presence of the nuclear membrane. We and others pointed out the possibility that the cationic liposomal lipid and the nuclear envelope may fuse, and thus the exogenous DNA may enter the nucleus (4, 6). An alternative explanation is the nuclear pore complex (NPC)-mediated import of DNA. Although the contribution of this putative pathway to the nuclear entry of DNA is unclear, it has been proven to be useful for the delivery of a protein conjugated with nuclear localization signal (NLS) peptides (7).

Recently, chemical conjugations of the NLS peptide to DNA molecules have been attempted to improve the nuclear entry. Sebestyén et al. used a cross-linker to conjugate the NLS peptide to the N3-position of adenine bases in double-stranded DNA (8). The introduction of 60–100 NLS peptides/kbp DNA was efficient for nuclear

uptake in digitonin-permeabilized cells. However, no increase in the nuclear uptake of the modified DNA was observed after microinjection into the cytoplasm of living cells, and the transgene expression was completely abolished due to the high modification level. In contrast, Zanta et al. synthesized a loop-forming oligodeoxynucleotide (ODN) cross-linked with the NLS peptide, and this modified loop-forming ODN was then enzymatically ligated to linearized double-stranded DNA (9). This NLS–DNA was transfected with a cationic polymer, polyethylenimine (PEI), and a single NLS peptide reportedly could enhance transgene expression from ten- to hundreds-fold, depending on the cell lines used. However, the nuclear entry effects of the NLS peptide attached to DNA are still open to dispute (10). Zanta et al. obtained their results using PEI-mediated transfection. However, PEI may enter the nucleus together with DNA (11).

In this study, we reexamined the effects of the NLS peptide conjugated to DNA by cytosolic and intranuclear microinjections. In addition, we compared the expression of the transgene on chemically modified and unmodified DNA molecules. Our results suggest that (i) one or two NLS peptide(s) did not dramatically improve the nuclear entry of DNA and that (ii) chemical modification of DNA reduced the transcription efficiency or stability in the nucleus.

## MATERIALS AND METHODS

**General.** COS-7 cells were from the RIKEN Cell Bank (Tsukuba, Japan). The plasmid pQBI 25–63, containing the cytomegalovirus promoter and the green fluorescent protein (GFP) gene (3), was purified with a Qiagen (Valencia, California) EndoFree Mega kit. The SV40 large T antigen NLS peptide (NH<sub>2</sub>-PKKKRKVEDPYC) with C-terminal amidation was obtained from Sigma Genosys Japan (Ishikari, Japan) in the purified form.

Physical data were measured as follows: The NMR spectra were recorded with a JEOL GX-270 spectrometer,

<sup>a</sup>X represents the modified uracil derivative conjugated or unconjugated to the NLS peptide. The italicized and underlined sequences represent sticky ends and loop-forming sites, respectively. Annealed ODN-2 and ODN-5 have an end compatible with *Hind* III, and the others have that compatible with *Bgl* II.

with CDCl<sub>3</sub> as the solvent and tetramethylsilane as the internal standard. Chemical shifts are reported in parts per million ( $\delta$ ), and signals are expressed as s (singlet), d (doublet), t (triplet), q (quartet), or m (multiplet). Mass spectra were measured on a JEOL JMS-D300 spectrometer. Matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF-MS) was conducted with Applied Biosystems Voyager System 1065 (Appera, Norwalk, CT). Edman peptide sequencing analysis was carried out with Procise 492 (Appera, Norwalk, CT). TLC was done on Merck Kieselgel F254 precoated plates. The silica gel used for column chromatography was Merck silica gel 5715.

**5-*N*-(8-Trifluoroacetylaminio-3,6-dioxaoctyl)carbamoyl-5'-*O*-dimethoxytrityl-2'-deoxyuridine (3).** To a solution of **1** (**12**) (2.1 g, 3.2 mmol) in pyridine (30 mL) was added 2,2'-(ethylenedioxy)bis(ethylamine) (1.4 mL, 9.6 mmol), and the mixture was stirred for 1 h at room temperature. The solvent was removed in vacuo, and the residue was coevaporated with toluene to give crude **2**. The resulting **2** was dissolved in MeOH (80 mL), and Et<sub>3</sub>N (2.7 mL, 19.2 mmol) and ethyl trifluoroacetate (2.3 mL, 19.2 mmol) were added to the solution. The reaction mixture was stirred at room temperature until compound **2** was consumed on TLC analysis. The solvent was removed in vacuo, and the residue was purified on a neutral silica gel column with 5–10% EtOH in CHCl<sub>3</sub> to give **3** (1.8 g, 70% as white foam): FAB-MS: *m/z* 800 (M<sup>+</sup>); FAB-HRMS: calcd for C<sub>39</sub>H<sub>43</sub>N<sub>4</sub>O<sub>11</sub>NaF<sub>3</sub> (MNa<sup>+</sup>): 823.2747. found: 823.2750; <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  9.10 (s, 1H), 8.80 (m, 1H), 8.61 (s, 1H), 7.59 (m, 1H), 7.41–6.82 (m, 13H), 6.15 (t, 1H, *J* = 6.6 Hz), 4.33 (m, 1H), 4.00 (q, 1H, *J* = 4.6 Hz), 3.78 (s, 6H), 3.62–3.52 (m, 12H), 3.47 (dd, 1H, *J* = 4.6 and 9.9 Hz), 3.37 (dd, 1H, *J* = 4.6 and 9.9 Hz), 2.45 (m, 1H), 2.45 (ddd, 1H, *J* = 6.6, 4.0, and 13.9 Hz), 2.21 (ddd, 1H, *J* = 6.6, 7.3, and 13.9 Hz).

**5-*N*-(8-Trifluoroacetylaminio-3,6-dioxaoctyl)carbamoyl-5'-*O*-dimethoxytrityl-3'-*O*-(2-cyanoethoxy-1)*N,N*-diisopropylamino)phosphoryl-2'-deoxyuridine (4).** After successive coevaporation with pyridine, **3** (80 mg, 0.1 mmol) was dissolved in CH<sub>2</sub>Cl<sub>2</sub> (5 mL) containing *N,N*-diisopropylethylamine (35  $\mu$ L, 0.2 mmol). 2-Cyanoethyl *N,N*-diisopropylphosphoramidochloride (33  $\mu$ L, 0.15 mmol) was added to the solution, and the reaction mixture was stirred for 1 h at room temperature. The mixture was diluted with CHCl<sub>3</sub> and washed with saturated aqueous NaHCO<sub>3</sub> and brine. The separated organic layer was dried (Na<sub>2</sub>SO<sub>4</sub>) and concentrated in vacuo. The residue was purified on a neutral silica gel column with 60–100% AcOEt in hexane to give **4** (61 mg, 61% as white foam): <sup>31</sup>P NMR (CDCl<sub>3</sub>)  $\delta$  149.93, 149.53.

**Oligodeoxyribonucleotides.** ODNs with the modified uracil derivative were designed to incorporate it in the loop consisting of five pyrimidine bases and to make a 5'-protruding end compatible with the *Bgl* II or *Hind* III restriction enzyme (ODN-3 to ODN-5, Table 1). These

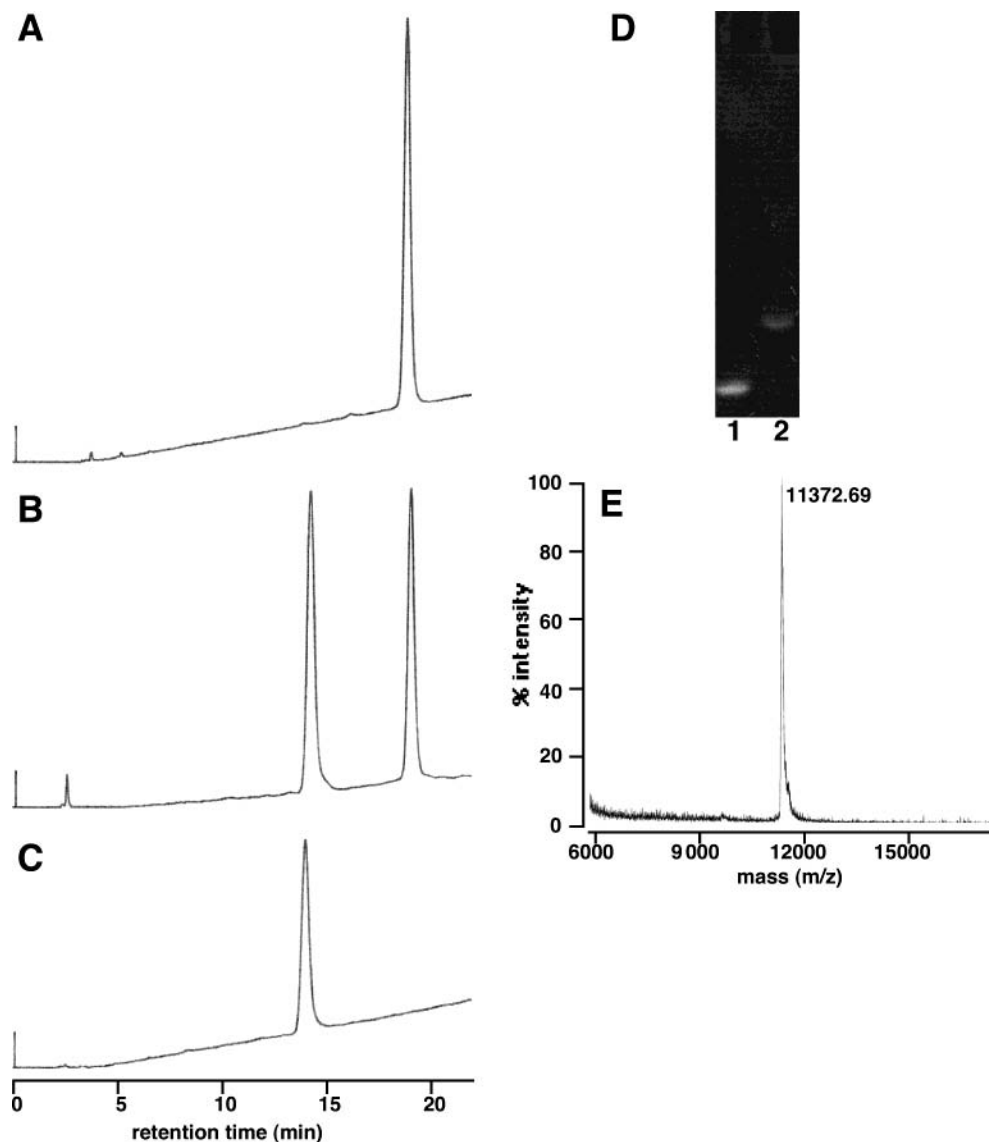

ODNs were synthesized using the phosphoramidite derivative **4** on an ABI model 381A DNA/RNA synthesizer. These ODNs were purified essentially as described (13).

The NLS peptide was conjugated to an ODN essentially as described (9), using 4-(*N*-maleimidomethyl)-cyclohexane-1-carboxylic acid *N*-hydroxysuccinimide ester (SMCC) as a bifunctional cross-linker. Namely, an ODN containing the modified uracil base(s) (16.1 nmol) was dissolved in 10 mM of sodium phosphate buffer (pH 7.5), and a 20 molar excess of SMCC (in DMF) was added. After an incubation for 1 h at room temperature, the same amount of SMCC was added, and the reaction mixture was then incubated at room temperature for another 1 h. The unreacted SMCC was removed with a NICK Column (Amersham Biosciences, Piscataway, NJ). A 20 molar excess of the NLS peptide was added, and the reaction mixture was incubated at room temperature overnight. In the case of ODN-4, containing two modified uracil bases, the amounts of SMCC and the NLS peptide were twice those described above. The conjugated ODNs were purified by anion-exchange HPLC, using a TSK-GEL DEAE-2SW column (4.6  $\times$  250 mm, Tosoh, Japan) with a linear gradient of ammonium formate (450 mM to 650 mM) in 20% aqueous acetonitrile. A new peak eluted at 15 min, faster than the unconjugated ODN (starting material, 18 min), and this peak was collected as an NLS-conjugated ODN (Figure 1). When ODN-4 containing two modified uracil bases was used, two peaks (8 and 12 min) that eluted faster than the unconjugated ODN (17 min) were observed. The 8 min peak was collected as the ODN containing two NLS peptides. The faster elution upon anion-exchange HPLC corresponded to the conjugation of the positively charged peptide. The ammonium formate was removed by gel filtration using Sephadex-G-25 (Amersham Biosciences).

The unmodified ODNs (ODN-1 and ODN-2, Table 1) were obtained from Hokkaido System Science (Sapporo, Japan) in the purified form. These ODNs were annealed and 5'-phosphorylated by T4 polynucleotide kinase and ATP.

**Preparation of Linearized DNA Dumbbells.** The plasmid pQBI 25–63 was digested with *Bgl* II and *Hind* III, according to the manufacturer's instructions. The digested DNA was loaded onto a low melting point agarose gel. The linearized DNA was recovered from the gel by visualization with UV irradiation in the presence of a thin-layer chromatography plate. The DNA was then purified as described in the literature (14). The purified 2.3-kb DNA was mixed and joined with the corresponding ODNs (DNA:ODN = 1:100), as reported previously (3). After ethanol precipitation, the ligated DNA was purified by anion-exchange HPLC using a TSK-gel DNA-NPR column ( $\phi$ 4.6  $\times$  75 mm, Tosoh, Japan), essentially as described (15).

**Microinjection.** Cells were microinjected at day 1 postplating. In this procedure, we used a semiautomatic injection system (Eppendorf transjector 5246, Hamburg, Germany) attached to the Eppendorf micromanipulator 5171. Intranuclear and cytosolic microinjections were performed with the Z (depth) limit option using a 0.2-s injection time and a 10–200 hectopascal-injection pressure. The DNA was diluted with an injection buffer solution (0.5% tetramethylrhodamine-labeled dextran in phosphate-buffered saline). At 24 h postinjection, GFP expression was monitored by fluorescence microscopy, and the ratio of cells expressing GFP to tetramethylrhodamine-positive cells was calculated.

**Figure 1.** Conjugation of the NLS peptide and ODN-3. (A–C) Behavior upon anion-exchange HPLC. Unconjugated ODN-3 (A), mixture of the conjugation reaction (B), and conjugated ODN-3 after purification (C) are shown. (D) Polyacrylamide gel electrophoresis. Lane 1, unconjugated ODN-3; lane 2, conjugated ODN-3. (E) Molecular weight analysis by MALDI-TOF-MS. The calculated molecular weight of conjugated ODN-3 is 11364.

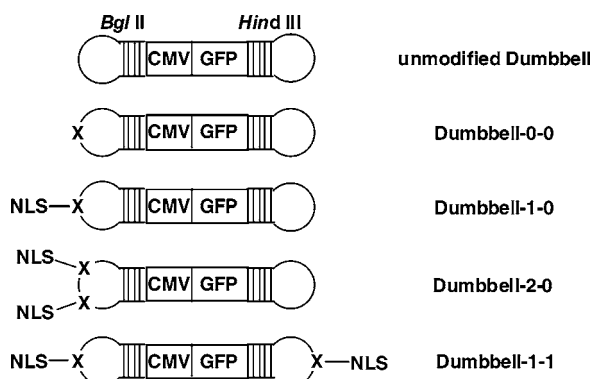

#### Scheme 1

#### RESULTS AND DISCUSSION

**Design of DNA Dumbbells.** A modified uracil base with a dioxaoctylamino linker (5), for conjugation to the NLS peptide, was incorporated into the ODNs, as shown

in Scheme 1. The conjugation of an ODN containing the modified uracil base and the NLS peptide was conducted using a bifunctional cross-linker, essentially as described (9). The conjugated ODNs were separated from the

**Figure 2.** Structures of DNA dumbbells containing the GFP gene used in this study. X, the modified uracil derivative; NLS, NLS peptide; CMV, CMV promoter. *Bgl* II and *Hind* III represent the restriction enzyme sites used for the ligation of loop-forming ODNs.

unconjugated ODNs by anion-exchange HPLC. Successful conjugation of an ODN and the positively charged peptide was indicated by chromatographic behavior upon anion-exchange HPLC (Figure 1A–C), lower mobility than the unconjugated ODN upon polyacrylamide gel electrophoresis (Figure 1D), molecular weight analysis by matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF-MS, Figure 1E), and sequencing of N-terminal 10 amino acids upon the Edman analysis (data not shown).

We prepared three DNA dumbbells with the NLS peptide (Figure 2). The NLS peptide-conjugated ODN-3 and ODN-4 (Table 1) were used to construct Dumbbell-1-0 and Dumbbell-2-0, respectively, which contain one and two peptide(s) in the loop near the *Bgl* II site. These DNA dumbbells contain the unmodified loop-forming ODN-2 near the *Hind* III site. Dumbbell-1-1 contains NLS peptides in both loops, using ODN-3 and ODN-5 conjugates. As controls, two DNA dumbbells were constructed: Dumbbell-0-0, which was capped with ODN-2 and unconjugated ODN-3, and the unmodified Dumbbell capped with ODN-1 and ODN-2. The unmodified Dumbbell was used to examine the effects of the base modification in comparison with Dumbbell-0-0. These DNA dumbbells were purified by anion-exchange HPLC to remove the unligated ODNs, which could possibly compete with the nuclear entry of NLS-conjugated DNA dumbbells via the NPC.

**Cytosolic Microinjection.** First, we microinjected various DNA dumbbells (10000 copies/cell) into the cytoplasm of simian COS-7 cells. GFP expression was monitored by fluorescence microscopy, and the ratio of cells expressing GFP to those containing the labeled dextran in their nuclei was calculated. Figure 3 shows the percentage of GFP-positive cells at 24 h postinjection.

When microinjected into the cytoplasm of simian COS-7 cells, approximately 40% of the cells expressed GFP, in the case of the unmodified Dumbbell. The GFP genes on the NLS-conjugated DNA dumbbells (Dumbbell-1-0, -1-1, and -2-0) were expressed with an efficiency similar to or slightly less than the unmodified Dumbbell (~35%, Figure 3). Thus, no dramatic increase in transgene expression was observed by the conjugation of the NLS peptide to DNA molecules, when we attached one or two peptide(s) per DNA.

Interestingly, Dumbbell-0-0 showed decreased GFP expression, as compared with that of the unmodified Dumbbell (~15%, Figure 3). This result suggests that the presence of the modified base suppressed transgene

**Figure 3.** Expression efficiencies of the GFP gene in COS-7 cells by cytoplasmic microinjection of DNAs. The DNA (10000 copies) was injected, and the expression was examined at 24 h postinjection. The data are expressed as means  $\pm$  standard deviation of two separate experiments. The datum of Dumbbell-1-1 is that obtained in a single injection experiment. cc represents closed circular plasmid DNA.

**Figure 4.** Expression efficiencies of the GFP gene in COS-7 cells by intranuclear microinjection of DNAs. The DNA (1000 copies) was injected, and the expression was examined at 24 h postinjection. The data are expressed as means  $\pm$  standard deviation of two separate experiments. cc represents closed circular plasmid DNA.

expression, for by one or two reasons: (i) the nuclear entry of the modified dumbbell (Dumbbell-0-0) occurred less efficiently than that of unmodified Dumbbell, and/or (ii) the expression of the gene on the modified Dumbbell-0-0 was reduced in the nucleus by the base modification. Moreover, the fact that the NLS-conjugated DNAs showed better expression than that of Dumbbell-0-0 (and similar expression to the unmodified Dumbbell) suggests the possibilities that the peptide improved the nuclear entry and/or the expression in the nucleus.

**Intranuclear Microinjection.** Next, we microinjected various DNAs (100 copies/nucleus) into the nuclei of simian COS-7 cells. We microinjected only Dumbbell-1-0 as the NLS-conjugated DNA, because very similar results were obtained with the three NLS-dumbbells in the cytosolic microinjection experiments described above.

As shown in Figure 4, results similar to those obtained with the cytosolic microinjection experiments were observed. Dumbbell-0-0 showed decreased GFP expression as compared with that of the unmodified Dumbbell. The transgene on the NLS-conjugated DNA dumbbell (Dumbbell-1-0) was expressed more efficiently than that on Dumbbell-0-0 (~20% and ~15%, respectively), and with less efficiency than that on the unmodified Dumbbell (~30%). Thus, the efficiencies of GFP expression by the

cytosolic microinjections, shown above, mainly depended on the event(s) in the nucleus.

**Effects of the Modified Base and the NLS Peptide.** On the basis of the results obtained with the cytosolic and intranuclear microinjections, we found that (i) one or two NLS peptide(s) did not dramatically improve the nuclear entry of DNA and that (ii) chemical modification of the DNA decreased the transgene expression. Although the actual reason(s) for the latter is unclear, the transcription efficiency or stability in the nucleus may be reduced by the introduction of the modified base. The uracil derivative used in this study was incorporated in the loop near the *Bgl*II site (Figure 2), and thereby near the promoter region. Thus, transcriptional factors may load less efficiently than on unmodified DNA. Alternatively, the modified base may be recognized by DNA repair enzyme(s) with endonuclease function(s). The NLS-conjugated DNA dumbbells, in contrast, showed GFP expression similar to that of the unmodified Dumbbell. The NLS-conjugation 'shielded' the effects of the base modification in the transcription and/or excision reactions. The peptide consists of positively charged amino acid residues and may interact with the DNA phosphate backbone. If this putative interaction occurs in the loop region, then the cellular protein(s) may hardly recognize the modification.

We showed that one or two NLS peptide(s) conjugated to DNA did not enhance transgene expression dramatically, at least when the naked DNA was microinjected into the cytoplasm. Thus, the nuclear entry of DNA appears to be similar with and without the peptide. The NLS peptide used in this study is positively charged and may interact with the DNA phosphate backbone. Thus, the NLS peptide might not act as a nuclear entry device. This interpretation is in contrast to the results of Zanta et al. (9), who reported ten- to hundreds-fold increased transgene expression by the conjugation of the NLS peptide to the loop region of dumbbell-shaped DNA. Improved transgene expression was also reported with a noncovalently bound NLS peptide. Brandén et al. combined a peptide nucleic acid (PNA) molecule to the NLS peptide, and this NLS-PNA was attached to plasmid DNA containing a sequence complementary to the PNA molecules (16). They reported that the addition of the NLS-PNA enhanced PEI-mediated transgene expression 3- to 5-fold. Interestingly, both Zanta et al. and Brandén et al. obtained their results using PEI-mediated transfection. Godbey et al. observed the intracellular trafficking of a PEI-DNA complex by confocal microscopy and found that both PEI and DNA entered the nucleus as a complex (11). Thus, PEI may alter the transcription efficiency of the delivered DNA. The NLS peptide may enhance the transcription, since the transcriptional factors may be loaded more efficiently if the interaction between the PEI and DNA is impaired. It should be emphasized that the combination of cytosolic and intranuclear microinjections enables separate considerations of the nuclear entry and the events inside the nucleus.

Recently, attachment of the NLS peptide to plasmid DNA using a triple helix-forming padlock ODN was reported (17). Upon transfection experiments, no enhancement of transgene expression was observed. Very recently, Nagasaki et al. reported the covalent conjugation of the NLS peptide to plasmid DNA, by diazo coupling through a PEG chain (18). They observed by fluorescence microscopy that the NLS peptide did not enhance the nuclear entry of the circular plasmid DNA upon cytosolic microinjection, although the conjugation of 5.1 NLS peptides per DNA increased the transgene expression

4-fold upon transfection. Their results agree with our present results, on the point that a small number of NLS peptides could not enhance the nuclear entry remarkably.

In this study, we observed that (i) one or two NLS peptide(s) did not dramatically improve the nuclear entry of a linearized DNA dumbbell and that (ii) chemical modification of the DNA reduced the transcription efficiency or stability in the nucleus. These results suggest that the NLS peptide should be attached to a DNA-carrying molecule, not to the DNA itself, to enhance the nuclear entry of DNA via the NPC.

Received May 9, 2003; Revised Manuscript Received September 3, 2003

Receptor-mediated drug targeting via nanoengineered particulate delivery systems is an emerging field. However, little is known about how such magic bullets should be assembled to yield optimal targeting efficiency. Here we investigated the influence of targeting ligand flexibility on binding of ligand-coated microparticles to cell surface receptors. Using the ganglioside G<sub>M1</sub>-binding B subunit of cholera toxin as ligand and fluorescent microparticles as a model delivery system, conjugates with different numbers of linkages between ligand and particle were prepared and tested for their efficiency to bind to live fibroblast monolayers. Our results show that multiple bonds between ligand and particle reduce the targeting rate by up to 50% compared to constructs where ligands are attached via single aliphatic chains. Thus, for maximum performance, targeted particulate drug delivery systems should be assembled such that ligands are attached via single  $\sigma$  bonds only, allowing the ligand molecules to adopt an optimal binding conformation.

## INTRODUCTION

Functional genomics, proteomics, and glycomics along with emerging technologies such as molecular breeding are expected to yield drugs with ever increasing potency and molecular specificity. Yet, except for anti-infectiva where foreign organisms are to be attacked, molecular specificity does not necessarily translate into cell type- or organ-specificity since the molecular target of the drug may be expressed at multiple locations throughout the body, exerting different functions at different sites. The predicament can be solved only when the drug is combined with a delivery technology that directs the compound exclusively to its desired site of action. This dilemma is most apparent in gene therapy and cancer medication, but also in areas less obvious such as oral vaccination where targeted delivery may be desirable.

Orally administered proteinaceous antigens rapidly fall prey to the digestive enzymes of the gastrointestinal tract and give rise to oral immune tolerance, the default reaction of the mucosal immune system (1). To overcome this, it is believed that antigens must be delivered in intact form selectively to M cells, a special epithelial cell type overlying the organized mucosa-associated lymphoid tissue (2). To meet this requirement, we devised an M

cell targeting strategy which exploits differences in cell surface receptor accessibility (3) and requires the antigen to be 30 nm in diameter and coated with a ligand directed against plasma membrane ganglioside G<sub>M1</sub>. Since we observed considerable differences in targeting efficiency in a cell culture model system depending on how the targeting ligand was attached to a particle surface (3, 4), we have chosen in this study to investigate the influence of rigidity of ligand attachment on the efficiency of ligand-mediated particle targeting.

## EXPERIMENTAL PROCEDURES

**Production of Recombinant CTB.** Recombinant cholera toxin B-subunit (rCTB) was prepared as described previously (5). Briefly, rCTB was expressed in secreted form in *Vibrio* sp. 60 containing the inducible vector pATA13 (6). rCTB was harvested from the culture supernatant by ultrafiltration and the concentrated retentate fraction subjected to hydrophobic interaction and cation exchange chromatography (5). The purified rCTB was desalted by gel permeation chromatography, equilibrated in Dulbecco's phosphate-buffered saline (D-PBS), pH 7.4, snap-frozen in liquid N<sub>2</sub> and stored at -80 °C until required.

**Biotinylation of CTB.** Mixtures of 5  $\mu$ M rCTB and either 75, 25, or 8.35  $\mu$ M NHS-LC-biotin (water soluble biotin (long arm) NHS, sulfosuccinimidyl-6-(biotinamido)-hexanoate; Vector, Burlingame, CA) in a total volume of 200  $\mu$ L of D-PBS were allowed to react for 30 min at RT on an end-to-end-mixer at 4 rpm before the reaction was quenched by adding 400  $\mu$ L of 200  $\mu$ M lysine in D-PBS to a final concentration of 133  $\mu$ M. The solution was dialyzed extensively against D-PBS at 4 °C for 48 h using Slide-A-Lyzer Dialysis Cassettes (MWCO 10 000 Da; Pierce, Bonn, Germany), snap-frozen in liquid N<sub>2</sub> and stored at -80 °C.

**Preparation of CTB-Coated Particles.** CTB-coated microparticles (CTB-P) and biocytin-quenched control particles (Control-P) were prepared by coupling biotinylated CTB or biocytin (*N*- $\epsilon$ -biotinyl-L-lysine) (Sigma, Taufkirchen, Germany) to avidin-coated, carboxy-modified, fluorescent latex particles (Molecular Probes, Eugene, OR) of 1  $\mu$ m nominal size as described earlier (3). In 500  $\mu$ L of D-PBS,  $5 \times 10^8$  or  $1 \times 10^9$  red fluorescent particles were reacted under rocking at 1.5 rpm for 72 h at 4 °C in the dark with 21  $\mu$ g (0.361 nmol) or 43  $\mu$ g (0.738 nmol) of the differently biotinylated CTBs. Thus, regardless of its degree of biotinylation, CTB was applied in a 5.5-fold molar excess over the maximally achievable CTB particle load (approximately 80 000 CTB molecules per 1- $\mu$ m particle, as calculated according to (3)). For the control particles,  $4 \times 10^9$  green fluorescent particles in 1000  $\mu$ L of D-PBS were reacted under the same conditions with 149  $\mu$ g (400 nmol) biocytin, representing a 110-fold molar excess of biocytin over biotin binding sites. Unreacted ligand was removed by centrifugation at  $1100 \times g$  and gently resuspending the particles in 1.8 mL of distilled water. Washes were repeated 10–12 times for all preparations before the particles were stored at concentrations of  $2 \times 10^8$  to  $3 \times 10^9$  particles/mL in 0.1 M HEPES–NaOH, pH 7.4, at 4 °C in the dark.

**G<sub>M1</sub> Binding Assay.** High-bind ELISA plates (Corning, Wiesbaden, Germany) coated overnight at 4 °C with 75  $\mu$ L/well of 5 ng/mL ganglioside G<sub>M1</sub> (Alexis, Grünberg, Germany) in D-PBS were washed three times with 300  $\mu$ L/well of D-PBS and blocked with 250  $\mu$ L/well of 0.1% (w/v) ovalbumin (OVA) (Sigma) in D-PBS for 6–8 h at RT. After four washes with D-PBS, plates were incubated overnight at 4 °C with 75  $\mu$ L/well of serially diluted biotinylated CTB in 0.1% (w/v) OVA/D-PBS, washed six times with PBST (D-PBS, 0.05% (v/v) Tween 20), and incubated for 90 min at RT with 75  $\mu$ L/well of 1  $\mu$ g/mL (8 pmol streptavidin/mL) peroxidase-labeled streptavidin (Vector) in 0.1% (w/v) OVA/D-PBS. After six washes with PBST, plates were developed using the 3,3',5,5'-tetramethylbenzidine substrate system of Frey et al. (7).

**Nano-Electrospray Ionization Mass Spectrometric Determination of Biotinylation.** Biotinylated CTB (5  $\mu$ g) was dialyzed extensively against 20% (v/v) acetic acid for 48 h at 4 °C in QuixSep microdialysis chambers (Roth, Karlsruhe, Germany) using Spectra/Por7 dialysis membranes (MWCO 3500; Spectrum, Rancho Dominguez, CA), lyophilized, and redissolved in 8.6  $\mu$ L of 25% (v/v) acetic acid (final concentration 10  $\mu$ M CTB) of which 5  $\mu$ L (50 pmol) was used for mass spectrometry. Measurements were carried out on a nano-electrospray Q-TOF instrument fitted with a Z-spray nano-ESI source (Micromass, Manchester, UK) using omega nanospray glass capillaries prepared from borosilicate glass (Hilgenberg, Malsfeld, Germany) on a Kopf vertical pipet puller, model 720 (David Kopf Instruments, Tujunga, CA). Electrospray potential (900–1100 V) was applied via a stainless steel wire electrode inside the nanospray source (8).

**Biochemical Determination of Biotinylation.** The differently biotinylated CTBs were serially diluted (2-fold, 6.7  $\mu$ g/mL–3.3 ng/mL) in 0.1% (w/v) BSA/PBS and 3  $\mu$ L of each dilution was pipetted onto nitrocellulose membranes (4.5  $\times$  13 cm, 0.2  $\mu$ m pore size; Schleicher & Schuell, Dassel, Germany). After being dried and washed twice with 20 mL of D-PBS and once with PBST, membranes were blocked for 5 h in 20 mL of blocking solution (1% (w/v) casein (Hammarsten grade; BDH, Poole, UK), 0.02% (w/v) thimerosal, 0.05% (v/v) Tween 20 in D-PBS) at RT. Dotted CTB labeled with a 15-, 5-, or 1.67-fold molar excess of biotinylation reagent was

then incubated in 20 mL of blocking solution for 24 h at 4 °C with 6834 ng (54.4 pmol), 2278 ng (18.1 pmol), or 759 ng (6.0 pmol) peroxidase-labeled streptavidin, each representing a 20-fold molar excess of streptavidin over the maximum amount of biotin theoretically present on the membrane. After four washes in PBST and two in D-PBS, 800  $\mu$ L of LumiLight<sup>PLUS</sup> Western blotting substrate (Roche, Mannheim, Germany) was applied, and chemiluminescence was quantitated on a Lumi-Imager-F1 (Roche). Serially diluted OVA (2-fold, 6.7  $\mu$ g/mL–3.3 ng/mL) biotinylated with a 15-fold molar excess of NHS-LC-biotin served as standard.

**Binding of Microparticles to BALB/c 3T3 Fibroblasts.** BALB/c 3T3 fibroblasts (clone A31; ATCC, Rockville, MD) were grown in high glucose (25 mM) Dulbecco's modified Eagle's medium (DMEM) (PAA Laboratories, Linz, Austria) supplemented with 10% (v/v) newborn calf serum (defined grade; Hyclone, Bonn, Germany), 2 mM glutamine, 100 U/mL penicillin/100  $\mu$ g/mL streptomycin, and 25 mM HEPES (PAA) at 37 °C in a humidified atmosphere containing 10% (v/v) CO<sub>2</sub>. For particle binding, cells (passages 70–86) were seeded onto round (13 mm diameter) glass coverslips (Bellco, Vineland, NJ) in 24-well tissue culture plates and used at 14–17 days post confluence. Monolayers were washed gently five times with 1 mL of prewarmed (37 °C) D-PBS containing 0.9 mM CaCl<sub>2</sub> and 0.5 mM MgCl<sub>2</sub> (CM-PBS) before 500  $\mu$ L of a suspension containing  $2.5 \times 10^7$  particles/mL each of CTB-P and Control-P in DMEM, 4 mM glutamine, and 25 mM HEPES were applied. For competition assays, coverslips were preincubated for 15 min with 250  $\mu$ L of 20  $\mu$ g/mL CTB in DMEM, 4 mM glutamine, and 25 mM HEPES before 250  $\mu$ L of  $5 \times 10^7$  particles/mL each of CTB-P and Control-P in the same buffer were added. After 60 min at 37 °C, coverslips were washed gently five times with 1 mL of prewarmed CM-PBS, fixed in 1 mL of 3% (w/v) paraformaldehyde in D-PBS for 90–120 min at RT in the dark, and washed three times in D-PBS and once in distilled water and mounted on glass slides with Mowiol 4–88 (Calbiochem-Novabiochem, Bad Soden, Germany) containing 2.5% (w/v) DABCO (1,4-diazabicyclo-[2.2.2]octane; Sigma). Cells were examined en face with a Zeiss Axiophot microscope equipped for epifluorescence (Zeiss, Jena, Germany) and were either photographed or recorded with a video camera.

**Statistics.** For quantitation of microparticle binding, digital images of five randomly selected nonoverlapping regions (top, bottom, center, left, and right) of each coverslip were printed and counted manually. Statistical analysis was performed using the StatView 4.51 software (Abacus Concepts, Berkeley, CA). Mixed probes of test- and control particles were considered paired samples. Results of independent experiments were treated as unpaired samples. Statistical analyses were considered significant only if  $p < 0.05$ .

## RESULTS AND DISCUSSION

When particle surfaces are to be derivatized with biomolecules, coupling is often achieved in an ill-defined manner, either by physisorption via van der Waals and electrostatic forces or by chemisorption after preactivation of the surface or in a one-pot reaction with a condensation reagent. Although macromolecules bound this way may generally retain their biological activity, it is extremely difficult to assess the degree of their functionality once the bioconjugate is formed. To tackle this problem we devised a strategy to bind a ligand to a polyvalent microparticle via a defined number of linkers.

**Figure 1.** Analysis of CTB biotinylation. A: Representative nano-ESI MS analysis in positive ion mode of CTB biotinylated with 1.67-, 5-, and 15-fold molar excess (1.67×-me, 5×-me, 15×-me) of NHS-LC-biotin. Species A: unmodified CTB; species B: phosphoric acid adduct of the CTB monomer; species C: monobiotinylated CTB; species D: CTB carrying two biotin labels. B: Regression analysis of mass spectrometric versus biochemical analysis of CTB biotinylation. Degrees of biotinylation deduced from the nano-ESI MS data closely correlate (simple regression  $R^2$ : 0.997; one-way ANOVA,  $p < 0.05$ ) with background-corrected signal intensities (mean  $\pm$  standard error) obtained from a dot-blot biotin detection assay where biotinylated ovalbumin served as standard (100%).

This enables us to deduce the rigidity of the conjugate and investigate its influence on the functionality of the probe.

As a ligand the ganglioside  $G_{M1}$ -binding B subunit of cholera toxin (CTB) was chosen. CTB (SWISS-PROT: P01556) is a torus- or donut-shaped homopentameric protein of 58222 Da bearing five identical receptor binding sites arranged in 5-fold symmetry at the bottom of the torus (9) and 10 potentially derivatizable amino functions on each subunit. While one of them (Lys-91) tolerates derivatization (10, 11), although it is directly involved in  $G_{M1}$ -binding (9), succinylation of a second lysine (Lys-34) does not impair the biological activity of its own but that of a neighboring subunit (10). Besides that, integrity of the lone tryptophan (Trp-88) is crucial for  $G_{M1}$ -binding (10).

To link CTB to the particle surface we decided to biotinylate the ligand to various degrees at its amino functions thus creating single or multiple bonds when coupling it to avidin-coated microparticles.

**Differently Biotinylated CTBs.** Recombinant CTB was produced in functional pentameric form in a *Vibrio* species and biotinylated with NHS-LC-biotin (sulfo-succinimidyl-6-(biotinamido)hexanoate), an active ester derivative of biotin, which carries a flexible 2.2 nm spacer and reacts with  $\alpha$ - and  $\epsilon$ -amino functions of proteins. Since preservation of at least about 50% of its  $G_{M1}$ -binding activity requires that no more than 30% of the amino functions of CTB be converted into amide bonds (12), a maximum of a 15-fold molar excess of NHS-LC-biotin should be used for derivatization when assuming full conversion of the active ester. We therefore carried out three different biotinylation reactions with 1.67-, 5-, and 15-fold molar excess of NHS-LC-biotin.

The actual degree of biotinylation was determined using nano-electrospray ionization mass spectrometry (nano-ESI MS). In Figure 1A the resulting spectra are shown, depicting a representative analysis of CTB, biotinylated with 1.67-, 5-, or 15-fold molar excess of NHS-LC-biotin. Several species named A, B, C, D were detected in each spectrum. The different charge states, +8 to +12, obtained for each species allowed the determination of the average molecular masses which are given in each spectrum. Species A represents the unmodified CTB-monomer (calcd average mass 11 645.36). Species B is generated by a noncovalent phosphoric acid adduct of the unmodified CTB-monomer (calcd average mass 11 743.36). Species C is assigned to a monoderivatized monomer (calcd average mass 11 984.82) and species D corresponds to a CTB monomer derivatized with 2 biotin moieties (calcd average mass 12 324.28). On the

**Table 1.** Degree of Biotinylation of CTB Depending on the Amount of Biotinylation Reagent Used

molar excess of biotinylation reagent	derivatization as determined by	
	nano-ESI-MS: no. of biotins per pentamer <sup>a</sup>	dot-blot: biotinylation as % of standard <sup>b</sup>
15-fold	2.75 $\pm$ 0.10	122.79 $\pm$ 11.61
5-fold	0.82 $\pm$ 0.06	43.39 $\pm$ 2.20
1.67-fold	0.24 $\pm$ 0.00	11.37 $\pm$ 0.85

<sup>a</sup> Data are derived from three different  $m/z$  ratios. <sup>b</sup> Data are derived from five different dot blots of each sample. Results are given as mean  $\pm$  standard error.

basis of these data the average degree of biotinylation of a CTB pentamer can be deduced by comparing the background-corrected relative signal intensities of the unmodified and differently biotinylated CTB monomers using eq 1,

$$\text{biotins per CTB pentamer} = \frac{c + 2d}{100 + c + d} \times 5 \quad (1)$$

where  $c$  is the relative signal intensity of CTB monomers carrying 1 biotin label,  $d$  the relative signal intensity of CTB monomers carrying two biotin labels, and the signal intensity of nonbiotinylated CTB monomer is set 100%. The respective degrees of biotinylation obtained with 1.67-, 5-, or 15-fold excess of NHS-LC-biotin are summarized in Table 1. They were confirmed in a quantitative dot-blot assay, which correlated strongly with the mass spectrometric data (Figure 1B). The relative differences in signal intensity between the differently biotinylated CTBs were normalized on a standard and are included in Table 1.

According to these data, the actual derivatization yield for CTB is directly correlated with the molar excess of NHS-LC-biotin applied (simple regression  $R^2$ : 1.0, one-way ANOVA,  $p < 0.025$ ) while the reaction yields for biotinylation reagent increased slightly from 14.3% for a 1.67-fold molar excess over 16.5% for a 5-fold excess to 18.3% for a 15-fold molar excess. Thus, no signs of saturation in the derivatization reactions are visible, which is to be expected when less than five amino functions are derivatized on a homopentameric protein molecule.

**Biological Activity of the Differently Biotinylated CTBs.** Due to the five equal receptor binding sites, CTB is markedly tolerant toward derivatization of its primary amino functions. Hybrid CTB pentamers renatured from equal amounts of monomers which were either formylated at Trp-88 or succinylated at Lys-34 have only 1.25

**Figure 2.** Biological activity of biotinylated CTB. ELISA-type assay with serial dilutions of CTBs derivatized with 1.67- ( $\Delta$ ), 5- ( $\bullet$ ), and 15- ( $\blacksquare$ ) fold molar excess of NHS-LC-biotin. Conjugates were captured on ganglioside  $G_{M1}$ -coated microtiter plates and visualized via streptavidin–horseradish peroxidase and a colorogenic substrate. Data represent mean  $\pm$  standard error of three independent experiments. Inset: Regression analysis of signal intensities of streptavidin-binding to  $G_{M1}$ -captured biotinylated CTB versus degree of biotinylation. Background-corrected absorbances extrapolated for saturated  $G_{M1}$ -binding (mean  $\pm$  standard error) closely correlate (simple regression  $R^2$ : 1.0; one-way ANOVA,  $p < 0.005$ ) with degrees of biotinylation determined by mass spectrometry.

functional receptor binding sites left but still retain 40% of the original affinity for  $G_{M1}$  (10). Consequently, CTB should tolerate the up to 2.75 biotins which we introduced even if labeling occurred exclusively at amino groups essential for receptor interaction. However, affinity may decrease with progressive labeling under these circumstances. Moreover, selective biotinylation of these sites will attach the CTB molecule to the avidin-coated microparticle the wrong way around with its receptor binding interface pointing toward the particle core. We therefore needed to know whether biotin was present at locations (top and/or side of the torus) which would allow CTB to conjugate to avidin-coated particles in the desired

way and whether this biotinylation pattern persists for the different degrees of biotinylation.

To address this question, soluble biotinylated CTB was first allowed to bind to a  $G_{M1}$ -coated microtiter plate before the biotin moieties were detected with a streptavidin–horseradish peroxidase conjugate. In this setup, biotinylation of amino functions located at the bottom of the torus, i.e., the  $G_{M1}$ -binding interface of CTB, cannot be detected because they are buried beneath the CTB molecule inaccessible for streptavidin–horseradish peroxidase.

Since signals were not only detectable but also increased linearly with the number of biotins per CTB pentamer (Figure 2), all three preparations did indeed carry labels at the desired part of the torus and exhibited a similar affinity for  $G_{M1}$ , although the result does not imply that some kind of site-selective labeling has occurred. Nevertheless, a substantial proportion of biotinylated CTB in each preparation can link to avidin-coated particles such that their  $G_{M1}$ -binding site points away from the particle core and all preparations are comparable in their biological activity.

#### Targeting Efficiency of Microparticles Conjugated with CTB in Mono- or Polyvalent Manner.

Since molecules biotinylated at an unfavorable position cannot be eliminated from a preparation we decided to circumvent this predicament by using rather large particles of 1  $\mu$ m diameter as an experimental delivery system. They offer a parking area for approximately 80 000 CTB molecules (3, 4), enough to generate a surface coat that is representative of the original distribution of top/side- and bottom-labeled CTB. Since the proportion of bottom-labeled CTB was shown to be constant in all preparations, its effect will then be canceled out when comparing the biological activity of different CTB-coated particles (CTB-P). As internal control for binding assays, inert microparticles of different color (Control-P) were prepared by quenching their biotin binding sites in a charge neutral manner using excess biocytin.

BALB/c 3T3 fibroblasts were chosen as an appropriate target cell since they express high levels of  $G_{M1}$  receptor (13) which is readily accessible to the 1  $\mu$ m particles used here (3, 4). To simulate a real targeting situation, cells were grown as confluent monolayers and then exposed

**Figure 3.** CTB-mediated binding of microparticles to BALB/c 3T3 fibroblasts. Cell monolayers (133 mm<sup>2</sup>) were exposed to  $2.5 \times 10^7$  particles each of CTB-P (A–C) and Control-P (D–F) for 1 h at 37 °C. Particles had been coated with CTB derivatized with 1.67-fold (A), 5-fold (B), or 15-fold (C) molar excess of biotinylation reagent. Particle binding was visualized by fluorescence microscopy and quantitated. Binding of CTB-P was significantly higher than binding of Control-P for all CTB-P preparations (two-tailed, paired  $t$ -tests,  $p < 0.0005$ ), scale bar, 200  $\mu$ m. G: In the presence of 10  $\mu$ g/mL free CTB binding of CTB-P prepared from CTB derivatized with 1.67-fold molar excess of biotinylation reagent was significantly lower (\*) than in the absence of free CTB (two-tailed, unpaired  $t$ -test,  $p < 0.0001$ ) and indistinguishable from control levels (Control-P) (two-tailed, paired  $t$ -test,  $p \approx 0.9$ ). Data given are means  $\pm$  standard error.

**Figure 4.** Influence of degree of biotinylation on the binding of CTB-particles to BALB/c 3T3 fibroblasts. A: Degree of biotinylation of CTB derivatized with 1.67-, 5- and 15-fold molar excess (1.67 $\times$ -me, 5 $\times$ -me, 15 $\times$ -me) of biotinylation reagent. The number of biotin labels per CTB pentamer (mean  $\pm$  standard error) represents the maximum number of ligand-particle bonds. B: Efficiency of CTB-mediated particle binding to apical surfaces of cultured BALB/c 3T3 fibroblasts. Data from seven independent experiments are displayed as  $n$ -fold better binding of CTB-P than Control-P (geometric mean  $\times/\div$  standard error). Particles coated with CTBs that can form no more than one single bond with avidin particles (1.67 $\times$ -me and 5 $\times$ -me) showed significantly higher binding (\*) to cell surfaces than particles coated with CTB that can form multiple bonds with a particle (15 $\times$ -me) (one-way ANOVA, Fisher's PLSD,  $p < 0.05$ ).

to a suspension of  $2 \times 10^5$  CTB-P per  $\text{mm}^2$  along with the same number of Control-P as internal standard in physiological buffer. All three CTB-P preparations showed binding to the apical plasma membranes of 3T3 fibroblasts (Figure 3A–C) which was significantly higher than that of Control-P (Figure 3D–F). Binding was exclusively mediated via the ligand since competition with soluble CTB reduced binding of CTB-P to control levels as exemplified in Figure 3G for CTB-P prepared with 1.67-fold molar excess of biotinylation reagent.

However, when comparing the targeting efficiency of the different CTB-P preparations significantly lower binding was observed for particles derived from CTB which was derivatized with a 15-fold than for particles coated with CTB derivatized with 1.67- or 5-fold molar excess of biotinylation reagent (Figure 4). Binding of the former CTB-P which may contain a mean of 2.75 bonds between ligand and particle (Figure 4A) was reduced significantly by up to 50% (one-way ANOVA, Fisher's PLSD,  $p < 0.05$ ) compared to preparations in which CTB is linked via no more than a single bond (calculated average values: 0.82 and 0.24 bonds, respectively) to the experimental particulate delivery system (Figure 4B). As chemical bonds occur in integers only, both a 0.82- and a 0.24-fold biotinylated CTB should of course behave the same in that only the biotinylated matter reacts with the particle while the nonbiotinylated CTB is lost during CTB-P preparation. As 0.24-fold biotinylated ligand still harbors less double-labels than 0.82-fold labeled CTB it should perform even better than the latter on particulate delivery systems which was indeed the case (Figure 4B). However, differences between these two CTB-P preparations were not statistically significant.

In conclusion, our results demonstrate that conjugating targeting ligands via multiple bonds to particulate delivery systems impairs the performance of the final conjugate to a significant extent. A possible reason for this adverse behavior is proposed in Figure 5. It shows that a monovalent aliphatic linker gives a ligand considerably more freedom to rotate and bend than bi- or polyvalent linkages which will tether it in a rotational

**Figure 5.** Proposed effect of ligand flexibility on targeting efficiency. Schematic diagram of ligand-particle conjugates binding to cell surfaces. Ligands conjugated to a particle surface via a single  $\sigma$  bond (A) are able to adopt an optimal position for receptor interaction. Ligands conjugated via multiple bonds to a particle surface (B) are sterically constrained which prevents them to adopt an optimal binding position.

axis tangential to the particle surface or even totally immobilize it in a position that is dictated by the location of the cross-linker on the ligand and therefore by the relative reactivities of its surface functional groups.

For optimal targeting efficiency drug targeting systems should therefore be designed such that the targeting ligand is attached via a single  $\sigma$  bond only. A powerful technology to achieve such tailored linkers on proteins may arise from current efforts to expand the genetic code in order to incorporate unnatural amino acids (14) which eventually will provide a solitary handle for attaching the ligand to the particulate drug delivery system. Alternatively, protein ligands may be substituted by chemically less complex molecules such as peptides where a single attachment handle can readily be introduced (15).

Received May 28, 2003; Revised Manuscript Received July 23, 2003

Heterobifunctional  $^{99m}\text{Tc}$  ligands are useful for antibody labeling using the precomplexation route. The aim of this work was to synthesize a ligand, which has sufficient chemical stability to be complexed with  $^{99m}\text{Tc}$  without inactivating the reactive conjugation group. Using 2,3,5,6-tetrafluorophenyl *N*-(*S*-benzoylthioacetyl)glycylglycyl-*p*-aminobenzoate (OC2) >60% of the  $^{99m}\text{Tc}$  complex was obtained at 80 °C in 20 min, which was separated from the free ligand and impurities by HPLC. After solvent evaporation,  $^{99m}\text{Tc}$ -OC2 was conjugated with the monoclonal antibody mAb425 in 50% radiochemical yield. In all, the labeling method required about 1 h preparation time. The immunoreactive fraction of the  $^{99m}\text{Tc}$ -OC2 mAb425 conjugate was 81%, indicating preserved binding capability after conjugation. Compared to recently described methods, which need in situ activation of the  $^{99m}\text{Tc}$  complex, the application of OC2 saved time and reduced the number of manipulations with radioactive material.

### INTRODUCTION

In the past, several types of heterobifunctional ligands have been presented in the literature, which were mainly designed for the labeling of antibodies with  $^{99m}\text{Tc}$ . In this context, heterobifunctionality is defined by two different molecular entities: on the one side, a chelating structure element for  $^{99m}\text{Tc}$  complexation and, on the other, a reactive structure element for covalent protein linkage. Depending on the primary reaction route for one of the two functions, the ligands have been classified as pre-conjugation (postconjugation labeling) or as precomplexation agents. Both routes are associated with advantages and disadvantages: (1) Precomplexation has the unique feature of radiolabeling antibodies with  $^{99m}\text{Tc}$  in an equimolar tracer/ligand fashion. In addition, the thermal energy supply necessary for chelate formation precedes the conjugation with thermosensitive proteins; (2) Pre-conjugation has the advantage of preparing antibody chelate conjugates in advance, which may be split into sample fractions, ready to use on demand. The amount of ligands conjugated per mole of protein are in most cases  $\gg 1$  in order to secure good labeling yields. Consequently, the resulting biological function may be impaired by the amount of added ligands.

With reference to precomplexation several types of ligands have been described, which comprise an activated

ester in the side chain. In 1987 the first heterobifunctional ligand was presented by Fritzberg et al. showing that 4,5-bis(ethylcarbonylmercaptoacetamide)pentanoic acid was capable of being activated with 2,3,5,6-tetrafluorophenol (TFP) after  $^{99m}\text{Tc}$  complexation (1, 2). Later on,  $^{99m}\text{Tc}$  complexes of  $\text{MAG}_3$  (3) and partially hydrolyzed L,L-ECD (4) were activated in a similar manner.

Cyclopentadienyltricarbonyl complexes and boronic acid adducts of  $^{99m}\text{Tc}$  dioxime complexes were also used for the precomplexation route of  $^{99m}\text{Tc}$  labeling of antibodies. The former complex was synthesized in a double ligand transfer reaction using 1,1'-bis(methoxycarbonyl)-ferrocene, [ $^{99m}\text{Tc}$ ]pertechnetate,  $\text{Cr}(\text{CO})_6$ , and  $\text{CrCl}_3$ , which was then hydrolyzed and subsequently activated using TFP (5).  $^{99m}\text{Tc}$  dioxime complexes were obtained using mixtures of dimethylglyoxime (DMG) and 3-isothiocy-anatophenylboronic acid (PICT), which was heated with [ $^{99m}\text{Tc}$ ]pertechnetate in the presence of stannous chloride, forming the reactive  $^{99m}\text{TcCl}(\text{DMG})_3\text{PICT}$  complex (6).

The syntheses of chelators exhibiting an activated ester group have been described for the preconjugation route. NHS esters of *S*-Bz-MAG<sub>3</sub> and 6-(4'-(4''-carboxyphenoxy)-butyl)-2,10-dimercapto-2,10-dimethyl-4,8-diazaundecane (NHS-BAT ester) were used for that purpose but complexation with  $^{99m}\text{Tc}$  was so far not described (7) or failed.<sup>1</sup>

The aim of this work was to synthesize a heterobifunctional ligand, which offers sufficient chemical stability for long-term storage and that could be complexed with  $^{99m}\text{Tc}$  without inactivating the reactive conjugation group. One of the ligands that fulfills these requirements was 2,3,5,6-tetrafluorophenyl *N*-(*S*-benzoylthioacetyl)glycylglycyl-*p*-aminobenzoate (OC2). The synthesis of this ligand,

the evaluation of optimal  $^{99m}\text{Tc}$  complexation conditions, and the conjugation to a monoclonal antibody are described.

#### MATERIALS AND METHODS

All commercially available chemicals were of analytical grade and used without further purification.  $^{99m}\text{Tc}$ -pertechnetate was obtained via a generator from CIS bio international (Gif/Yvette Cedex, France). HPLC was carried out on LATEK systems equipped with variable UV (Latek, Heidelberg) and  $\gamma$  radiation detectors (Berthold, Bad Wildbad, Germany). Reversed-phase HPLC columns used were Nucleosil C18 (5  $\mu\text{m}$ , 270  $\times$  4 mm or 270  $\times$  8 mm) (Macherey & Nagel, Düren, Germany). The solvents consisted of MeOH and 0.1% trifluoroacetic acid in water. Protein conjugation yields were determined by instant thin-layer chromatography using silica-coated glass fiber sheets (Pall, Ann Arbor, MI). Size exclusion chromatography (SEC) was performed with Sephadex G 25 (Pharmacia, Freiburg, Germany). The monoclonal antibody used for the conjugation experiments was the anti-EGF receptor antibody mAb425 (Merck, Darmstadt, Germany). The immunoreactive assay was performed with A431 cells, a squamous carcinoma cell line expressing the EGF receptor (Merck, Darmstadt, Germany).

Confirmation of the compounds' structure was obtained with the following analytical methods: MALDI-TOF mass spectrometry (MALDI III TOF spectrometer, Kratos/Shimadzu, Duisburg, Germany), elemental analysis (Microanalytical Laboratory, Chemistry Department, University of Heidelberg),  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectroscopy (Bruker AM-300 spectrometer, Rheinstetten, Germany), where possible assignments of the  $^1\text{H}$  and  $^{13}\text{C}$  NMR resonances are according to the numbering shown in Table 1, and IR spectra (FTIR Jasco Spectrophotometer FT/IR-460).

**S-Benzoylmercaptoactetyldiglycine (2).** Glycylglycine (5.94 g, 45 mmol) was dissolved in water (45 mL) by dropwise addition of 1 N NaOH and added in one portion to a solution of succinimidyl *S*-benzoylthioglycolate (17.58 g, 60 mmol) (**8**) in 360 mL of ethanol at 55 °C. The mixture was heated under reflux for 2.5 h and then stirred at room temperature for 12 h. After solvent evaporation, the colorless residue was extracted twice with boiling acetonitrile and recrystallized twice from 20% water in methanol. An additional recrystallization from 2-propanol resulted in 9.5 g (68%) of product, mp: 198–200 °C (lit.: 198–200 °C (**9**)).  $^1\text{H}$  NMR (DMSO- $d_6$ )

$\delta$  (ppm): 3.78 (d, 4H,  $\text{CH}_2$ -11  $\text{CH}_2$ -14); 3.89 (s, 2H,  $\text{CH}_2$ -8); 7.52–7.94 (m, 5H, *H*-Ar); 8.20 (t, 1H, *NH*-13); 8.49 (t, 1H, *NH*-10).  $^{13}\text{C}$  NMR (DMSO- $d_6$ )  $\delta$  (ppm): 32.55 ( $\text{CH}_2$ -8); 40.69 ( $\text{CH}_2$ -14); 42.32 ( $\text{CH}_2$ -11); 126.97 (*C*-3 *C*-5, Ar); 129.23 (*C*-2 *C*-6, Ar); 134.16 (*C*-1, Ar); 136.01 (*C*-4, Ar); 167.31, 169.07 (*CO*-9 *CO*-12); 171.17 (*CO*-15); 190.46 (*CO*-7). IR (KBr,  $\text{cm}^{-1}$ ): 3600–2600 (m, br,  $\nu\text{OH}$ ); 3267 (m,  $\nu\text{NH}$ ); 3100 (m,  $\nu\text{CH}$ , Ar); 1720 (m,  $\nu\text{C}=\text{O}$ , COOH); 1658 (s,  $\nu\text{C}=\text{O}$ , *S*-*C*=O); 1628 (s,  $\nu\text{C}=\text{O}$ , *N*-*C*=O, amide I); 1575 (m,  $\delta\text{NH}$ , amide II); 913 (m,  $\gamma\text{OH}$ ); 688 (m,  $\gamma\text{CH}$ , Ar).

**S-Benzoylmercaptoactetyldiglycine N-Hydroxysuccinimide Ester (3) (10).** Solid *N,N*-dicyclohexylcarbodiimide (5.15 g, 25 mmol) was added in portions to a refluxing solution of *S*-benzoylmercaptoactetyldiglycine (7.34 g, 23 mmol) and *N*-hydroxysuccinimide (2.65 g, 23 mmol) in 100 mL of acetonitrile. The mixture was stirred overnight at room temperature. The precipitate was collected by filtration and washed twice with hot acetonitrile and with hot tetrahydrofuran. The precipitate was collected by filtration and finally recrystallized from ethyl acetate to yield 2.54 g (27%) of a white solid; mp: 145–147 °C.  $^1\text{H}$  NMR (DMSO- $d_6$ )  $\delta$  (ppm): 2.80 (s, 4H,  $\text{CH}_2$ -17  $\text{CH}_2$ -18); 3.81 (d, 2H,  $\text{CH}_2$ -11); 3.88 (s, 2H,  $\text{CH}_2$ -8); 4.28 (d, 2H,  $\text{CH}_2$ -14), 7.53–7.94 (m, 5H, *H*-Ar); 8.50 (s br, 2H, *NH*-10 *NH*-13);  $^{13}\text{C}$  NMR (DMSO- $d_6$ )  $\delta$  (ppm): 25.34 ( $\text{CH}_2$ -17  $\text{CH}_2$ -18); 32.36 ( $\text{CH}_2$ -8); 38.14 ( $\text{CH}_2$ -14); 42.07 ( $\text{CH}_2$ -11); 126.79 (*C*-3 *C*-5, Ar); 126.79 (*C*-2 *C*-6, Ar); 133.95 (*C*-1, Ar); 135.90 (*C*-4, Ar); 166.11, 167.1 (*CO*-9 *CO*-12); 169.31 (*CO*-15); 169.79 (*CO*-16 *CO*-19); 190.19 (*CO*-7); IR (KBr,  $\text{cm}^{-1}$ ): 1817m, 1781m, 1753s ( $\nu\text{C}=\text{O}$ , active ester); 1659 (m,  $\nu\text{C}=\text{O}$ , *S*-*C*=O); 1628 (m,  $\nu\text{C}=\text{O}$ , *N*-*C*=O, amide I); 1217 (s,  $\nu\text{C}-\text{O}$ ). Mass spec (mw = 310.3) observed: 333.4 (*M* + *Na*) $^+$ .

**N-(S-Benzoylthioacetyl)glycylglycyl-4-aminobenzoic Acid (4).** *S*-Benzoylmercaptoactetyldiglycine *N*-hydroxysuccinimide ester (2.03 g, 5 mmol) and 4-aminobenzoic acid (0.68 g, 5 mmol) were dissolved in acetonitrile (35 mL), and the solution was heated under reflux for 5 h, during which a white precipitate formed. To the solution was added 100 mL of acetonitrile, and the mixture was heated under reflux for additional 30 min. The reaction mixture was filtered warm, and the product was washed with acetonitrile to obtain a white solid (1.56 g, 73%); mp: 266–268 °C (dec).  $^1\text{H}$  NMR (DMSO- $d_6$ )  $\delta$  (ppm): 3.80 (d, 2H,  $\text{CH}_2$ -11); 3.90 (s, 2H,  $\text{CH}_2$ -8); 3.93 (d, 2H,  $\text{CH}_2$ -14); 7.51–7.95 (m, 9H, *H*-Ar); 8.29 (t, 1H, *NH*-10); 8.57 (t, 1H, *NH*-13); 10.11 (s, 1H, *NH*-16).  $^{13}\text{C}$  NMR (DMSO- $d_6$ )  $\delta$  (ppm): 32.36 ( $\text{CH}_2$ -8); 42.58, 42.76 ( $\text{CH}_2$ -11  $\text{CH}_2$ -14); 118.34 (*C*-18 *C*-22, Ar); 125.67 (*C*-20, Ar); 126.77 (*C*-3 *C*-5, Ar); 129.02 (*C*-2 *C*-6, Ar); 130.18 (*C*-19 *C*-21, Ar); 133.95 (*C*-1, Ar); 135.88 (*C*-4, Ar); 142.51 (*C*-17, Ar); 167.04 (*CO*-23); 167.44, 167.97, 168.99 (*CO*-9 *CO*-12 *CO*-15); 190.23 (*CO*-7). IR (KBr,  $\text{cm}^{-1}$ ): 3600–2300 (m, br,  $\nu\text{OH}$ ); 3279 (s,  $\nu\text{NH}$ ); 1701 (s,  $\nu\text{C}=\text{O}$ , COOH); 1659 (s,  $\nu\text{C}=\text{O}$ , *S*-*C*=O); 1626, 1602 (s,  $\nu\text{C}=\text{O}$ , *N*-*C*=O, amide I); 1535 (s,  $\delta\text{NH}$ , amide II). Mass spec (mw = 429.4) observed: 452.4 (*M* + *Na*) $^+$ .

**2,3,5,6-Tetrafluorophenyl N-(S-Benzoylthioacetyl)glycylglycyl-4-aminobenzoate (OC2).** *N*-(*S*-Benzoylthioacetyl)glycylglycyl-4-aminobenzoic acid (1.07 g, 2.5 mmol) and 2,3,5,6-tetrafluorophenol (0.83 g, 5.0 mmol) were dissolved in dimethylformamide (20 mL) and cooled in an ice–water bath. *N,N*-Dicyclohexylcarbodiimide (1.03 g, 5 mmol) dissolved in dimethylformamide (5 mL) was added dropwise over 30 min. The reaction mixture was stirred at 0 °C for 2 h and then at room-temperature overnight. After removal of the insoluble *N,N*-dicyclohexylurea by filtration, the solvent was evaporated in

Anal. ( $\text{C}_{26}\text{H}_{19}\text{F}_4\text{N}_3\text{O}_6\text{S}$ ) C, H, N, S.

**$^{99m}\text{Tc}$  Complexation of OC2.**  $^{99m}\text{Tc}$  complexation was performed by mixing 100  $\mu\text{L}$  of 1 mM OC2 (dimethylformamide) with 10  $\mu\text{L}$  of 50 mM potassium gluconate ( $\text{H}_2\text{O}$ ), 1  $\mu\text{L}$  of acetic acid, and 300  $\mu\text{L}$  of [ $^{99m}\text{Tc}$ ]pertechnetate eluate (up to 1 GBq in 0.9% NaCl solution). After the addition of 1  $\mu\text{L}$  of 50 mM stannous chloride in 50 mM potassium gluconate, the mixture was heated for the indicated time periods at indicated temperatures (Figure 1). The resulting reaction mixture was loaded on a reversed-phase  $\text{C}_{18}$  column, and the  $^{99m}\text{Tc}$ -OC2 complex separated from the free ligand. The product eluted after 8.5 min using isocratic conditions at 80% MeOH/20% 0.1% TFA in water and after 18 min using a gradient of 60 to 100% MeOH in 30 min. Under these conditions, the ligand eluted after 4 and 17.6 min, respectively. For protein conjugation, the collected  $^{99m}\text{Tc}$ -OC2 eluate was evaporated to dryness.

**$^{99m}\text{Tc}$ -OC2 Antibody Conjugation.** For the measurements of the conjugation kinetics (Figure 2) freeze-dried monoclonal antibody mAb425 was dissolved and adjusted to pH 8, 9, and 10 at a concentration of 67  $\mu\text{M}$ . Samples of 1 mg (100  $\mu\text{L}$ ) were transferred to the dried  $^{99m}\text{Tc}$ -OC2 complex and reacted for 5, 10, 20, and 40 min at 30 °C. Two microliter aliquots were taken from the mixture and spotted on silica-coated glass fiber sheets. The sheets were developed with methanol. The  $^{99m}\text{Tc}$  complexes of OC2 and of compound 4 migrated to the front, while the labeled antibody remained at the start.

Preparation of high-dose labeled antibody was performed with size exclusion chromatography. The complete reaction mixture was transferred to an 8 mL Sephadex G25 column and eluted with PBS (pH 7.4). The

**Figure 2.** Conjugation yields of  $^{99m}\text{Tc}$ -OC2-mAb425 formation at 30 °C as a function of pH and time.

labeled antibody was recovered between 4 and 6 mL. With 67  $\mu\text{M}$  antibody concentration and at pH 10 about 50% radiochemical yield was obtained after 15 min reaction time.

**Immunoreactivity of the  $^{99m}\text{Tc}$ -OC2 Antibody Conjugate.** The immunoreactivity of the radiolabeled mAb425 was determined by a modified cell-binding assay of Lindmo et al. (17). Aliquots of the  $^{99m}\text{Tc}$ -OC2 antibody conjugate (10 ng/50  $\mu\text{L}$ ) were incubated for 1 h at 37 °C with  $6.25 \times 10^4$  to  $1 \times 10^6$  A431 cells. Cells were washed twice, and the radioactivity of the pellet was counted. The maximum cell-bound counts, corrected for nonspecific binding and expressed as a percentage of the total counts, were taken to be the immunoreactivity.

## RESULTS AND DISCUSSION

**Synthesis of 2,3,5,6-Tetrafluorophenyl *N*-(*S*-Benzoylthioacetyl)glycylglycyl-4-aminobenzoate (OC2).** Scheme 1 illustrates the course of synthesis of the heterobifunctional ligand OC2. The preparation steps are straightforward and resemble partly those which lead to *S*-Bz-MAG<sub>3</sub> (12). Starting with succinimidyl *S*-benzoylthioglycolate 1 and the sodium salt of H-Gly-Gly-OH, *S*-benzoylmercaptoacetyldiglycine 2 was formed in high yield. An excess of the NHS ester and elevated temperature was chosen to allow complete turnover of H-Gly-Gly-OH. Coprecipitation of the latter compound during the workup of compound 2 was, therefore, diminished. Because of the limited solubility of compound 2, the formation of the NHS ester 3 had to be performed in refluxing  $\text{CH}_3\text{CN}$ . Although the reaction resulted in an almost quantitative conversion into the product, losses during workup could not be avoided. The NHS ester 3 was then reacted with 4-aminobenzoic acid in refluxing  $\text{CH}_3\text{CN}$ . The triamide 4 precipitated as a white solid from the reaction solution. The purity of the precipitate was high enough to continue with the synthesis. This compound has been described before using, however, an alternative synthesis route and investigated as a renal imaging agent (13, 14). The activation of compound 4 with 2,3,5,6-tetrafluorophenol was performed using *N,N*-dicyclohexylcarbodiimide. To obtain complete turnover of compound 4, double molar excess of the latter compounds was used. Owing to the good solubility of all components, the reaction was performed at 0 °C in dimethylformamide. Pure OC2 was obtained after recrystallization from 2-propanol. The chemical stability of OC2 was not investigated in detail. However, storage of solid OC2 at ambient temperature showed no decomposition after

**Scheme 1<sup>a</sup>**

**Scheme 2 <sup>99m</sup>Tc Complexation of OC2 and Conjugation of the <sup>99m</sup>Tc-OC2 Complex with an Antibody<sup>a</sup>**

<sup>a</sup> Reagents and conditions: (a) [<sup>99m</sup>Tc]pertechnetate, potassium gluconate, AcOH, Sn<sup>2+</sup>, 80 °C/20 min; (b) mAb425, pH 9–10, 30 °C/10 min.

more than one year. On the other hand, formation of about 20% of the free acid **4** was observed after one month standing in dimethylformamide solution.

**<sup>99m</sup>Tc Complexation of OC2.** <sup>99m</sup>Tc complexation of OC2 was performed with [<sup>99m</sup>Tc]pertechnetate eluate and potassium gluconate using the stannous chloride reduction method. Heating at increasing temperatures and various time periods resulted in increased labeling yields. The results are illustrated in Figure 1. The temperature and the reaction time significantly influenced the radiochemical yield of complex formation. The optimum complexation temperature obtained from these experiments centered around 80 °C at which >60% radiochemical yield was obtained within 20 min. At higher temperatures this yield can be attained in a shorter time period, however, with the risk of hydrolysis of the TFP ester <sup>99m</sup>Tc-OC2 at later time points.

While the tracer concentration of the <sup>99m</sup>Tc complex of OC2 precludes macroscopic characterization, the structures shown in Scheme 2 are proposed to be in accordance with the <sup>99</sup>Tc-MAG<sub>3</sub> and [Ph<sub>4</sub>P][<sup>99</sup>TcO(MAG<sub>2</sub>-pABA)] complexes (12, 14). The influence of the aromatic amide nitrogen on the complex formation was, however, unknown. Therefore, competition experiments were carried out using equimolar amounts of compound **4**, the free acid of OC2, and *S*-Bz-MAG<sub>3</sub>, which were both complexed together at 80 °C for 10 and 30 min. Figure 3 presents an example of these experiments, which indicates that similar ligand reactivities lead to about the same amount of <sup>99m</sup>Tc complex formation.

**Figure 3.** HPLC of <sup>99m</sup>Tc complexes obtained with a mixture of equimolar amounts of compound **4** and *S*-Bz-MAG<sub>3</sub> after 30 min at 80 °C. Assignments of peaks: UV at 254 nm (left), 19.5 min *S*-Bz-MAG<sub>3</sub>, 22.9 min compound **4**; gamma trace (right), 16.2 min <sup>99m</sup>Tc complex of an impurity originating from compound **4**, 18.4 min <sup>99m</sup>Tc-MAG<sub>3</sub>, 21.5 min <sup>99m</sup>Tc-**4**. HPLC conditions: gradient of 0 to 100% MeOH in 30 min using 0.1% TFA in water as aqueous phase at 0.7 mL/min.

HPLC purification of the complete reaction mixture yielded <sup>99m</sup>Tc-OC2 complex in about 60% radiochemical yield and high radiochemical purity. Isocratic HPLC conditions described in the Materials and Methods section were preferred, not only because of saving time, but

**Table 2. Time Course for Precomplexation and Conjugation Using OC2**

step time	preparation step
20 min	<sup>99m</sup> Tc complexation
10 min	HPLC separation
10 min	eluate evaporation
15 min	protein conjugation
10 min	SEC and sterile filtration
65 min	total preparation time

also to ensure ligand-free <sup>99m</sup>Tc-OC2 preparations. The eluate was collected in a 10 mL glas tube and evaporated to dryness using a rotavapor run under oil pump vacuum. Both steps, HPLC and evaporation, were finished within 20 min. The <sup>99m</sup>Tc-OC2 complex was stable in solution and after evaporation for >24 h.

**<sup>99m</sup>Tc-OC2 Antibody Conjugation.** Solutions (67 μM) of monoclonal antibody mAb425 formulated at pH 8, 9, and 10 were reacted at 30 °C with the dried <sup>99m</sup>Tc-OC2 complex. The conjugation yields were monitored at the indicated reaction-time periods as shown in Figure 2. The time course of the labeling yield was clearly dominated by the pH of the reaction mixture, with the reaction time increasing for reactions performed at pH 8 and 9. The conjugation performed at pH 10 seemed to attain the endpoint just after 20 min. Raising the conjugation temperature up to 50 °C did not improve the conjugation yield at pH 10 (data not shown). Starting with 1 GBq [<sup>99m</sup>Tc]pertechnetate, specific activities of 36 ± 8 GBq/μmol (or 280 ± 53 MBq/mg) mAb425 (*n* = 3) were obtained. Owing to the high molar excess of the antibody, higher specific activities can be expected by increasing the [<sup>99m</sup>Tc]pertechnetate dose. Optimal conditions have to be evaluated for individual mAbs.

The conjugation reaction was expected to have a negligible influence on receptor binding, because <sup>99m</sup>Tc-OC2 was separated from the free ligand OC2. The immunoreactivity assay performed with A431 cells confirmed this assumption. An 81% immunoreactivity was obtained proving the binding integrity of <sup>99m</sup>Tc-OC2-mAb425.

In conclusion, OC2 represents a versatile heterobifunctional <sup>99m</sup>Tc chelating agent, which can be used as a precomplexation tool for antibody labeling. The time course of the labeling method is summarized in Table 2 indicating that about 1 h preparation time was needed for all manipulations. Compared to recently described methods, which need in situ activation of the <sup>99m</sup>Tc complex (e.g., *S*-Bz-MAG<sub>3</sub>, (3)), the application of OC2 saves time and manipulation steps with radioactive material.

#### ACKNOWLEDGMENT

We would like to thank W.E. Hull for NMR spectroscopy, W.D. Lehmann for MS measurements, and U. Bauder-Wüst as well as R. Matys (all DKFZ Heidelberg) for cell-binding experiments. Sample material of mAb425 was obtained as a gift from Merck KGaA, Darmstadt. O.C. was supported by a grant from the Deutscher Akademischer Austauschdienst (DAAD).

Interior tertiary amine groups of PAMAM-OH dendrimers (hydroxyl-terminated polyamidoamine, PAMAM) were modified by methylation to make these polymers have a more cationic character, which enabled electrostatic interaction between PAMAM-OH and plasmid DNA. A methylation reaction was dose-dependent, producing internally quaternized PAMAM-OH (QPAMAM-OH), thereby making tertiary amine/quaternary amine ratio adjustment possible. More highly condensed particles of plasmid DNA were formed as the degree of quaternization increased, whereas unmodified polymer (PAMAM-OH) could not. The location of positive charges in the internal position of QPAMAM-OH resulted in the formation of neutral polyplexes in which  $\zeta$  potential leveled off near the zero value even at high charge ratios (+/−) of 10. A light scattering experiment showed that the polyplex formed by QPAMAM-OH was very small with the size of 53.3 nm at the optimum condition. QPAMAM-OH/DNA polyplexes were round-shaped with the more compact and small particles formed as the charge ratio increased. QPAMAM-OH showed much reduced cytotoxicity compared with starburst PAMAM and branched polyethyleneimine (PEI) in which shielding of interior positive charges by surface hydroxyls might be the reason for this favorable result. These results suggest that QPAMAM-OH could be a promising tool as a nonviral vector both by itself and in conjugated form with targeting ligands.

## INTRODUCTION

Numerous gene delivery systems based on viral (1–3) and nonviral (4, 5) vectors have been developed and tried so far. Recently, several recurring issues about safety of viral vectors have led to a careful reconsideration of the use of them in human clinical trials such as in Gelsinger's case (6, 7). Moreover, they have significant limitation in large-scale production and available DNA size they can carry. In response to these problems, nonviral gene delivery systems such as cationic polymers or cationic lipids have attracted great attention to achieve a breakthrough in the development of an "ideal" gene carrier (8).

Several polymeric materials have been investigated as candidates for gene delivery; among them, cationic polymers with hydrophilic segments are gaining attention (9–14). It is because hydrophilic segments detoxify cationic polymers (11, 12), improve solubility (12, 13, 15) and prevent polycation/DNA complexes from aggregation *in vivo*.

Starburst PAMAM dendrimers are highly branched spherical polymers characterized by primary amine groups at the surface and tertiary amine groups in the interior. The polyplexes formed by PAMAM showed efficient transfection in which the primary amine groups participate in DNA binding and the tertiary amine groups exert endosome buffering effect (14, 16, 17). Biological behavior of dendrimers depends to a large extent on their surface groups. In one example, it was

reported that amine-terminated PAMAM dendrimer interacted with bovine serum albumin more strongly than carboxyl-terminated one (18). Serum albumin has been considered to cause aggregation of nonviral carriers *in vivo* (19).

PAMAM-OH dendrimers are structurally identical to PAMAM except that surface amine functions have been replaced by hydroxyl groups. Absence of surface primary amine groups in PAMAM-OH makes this polymer nearly neutral which might be advantageous in terms of cytotoxicity and an aggregation problem. However, PAMAM-OH is nearly unable to form DNA polyplex because of the low  $pK_a$  of interior tertiary amines (20).

To overcome this hurdle, we introduced internal quaternary ammonium salt to the tertiary amine of PAMAM-OH dendrimers by methylation in order to provide binding sites for negatively charged plasmid DNA. Some polymers containing quaternary ammonium groups have been known to make polyplexes with DNA more efficiently than the polymers having primary or secondary amine groups. In addition, the polyplexes of quaternary amine-based polymers were relatively smaller compared to those prepared by cationic polymers containing primary and tertiary amine groups (21). Quaternary amine-based polymers are cationic at most pHs as a strong polyelectrolyte, while the charge density in the primary amine-based polymers depend on the pH of media (22).

From such a viewpoint, here we report the synthesis and characterization of internally quaternized PAMAM-OH. We expected that interior quaternary amine groups of QPAMAM-OH would interact negatively charged DNA while preserving a neutral polymer and/or a polyplex surface, which would act affirmatively with regard to cytotoxicity and an aggregation behavior of polyplexes.

<sup>a</sup> Equiv means the equivalent moles of methyl iodide relative to interior tertiary amines in PAMAM-OH G4.

## EXPERIMENTAL PROCEDURES

**Materials.** PAMAM-OH G4, PAMAM G4 (Starburst), Methyl iodide, anhydrous *N,N*-dimethylformamide (DMF), and PEI (average molecular weight 25 kDa) were purchased from Aldrich (Milwaukee, WI). PGL3-control vector (plasmid DNA) was purchased from Promega (Madison, WI). Fetal bovine serum (FBS) and Dubecco's modified Eagle's medium (DMEM) were purchased from GIBCO (Gaithersburg, MD).

**Synthesis of Quaternized PAMAM-OH (QPAMAM-OH).** The solvent (methanol) was vacuum-evaporated and dried from manufacturer's PAMAM-OH solution prior to reaction. After redissolving PAMAM-OH (0.1 g, 7  $\mu$ mol) in DMF (0.5 mL), methyl iodide of various molar ratios diluted in DMF (0.5 mL) was added. The mixture was stirred at each optimal reaction temperature (Table 1). After 24 h, the mixture was precipitated into diethyl ether and vacuum-dried and the residue obtained was redissolved in 1 mL of water. The solution was placed into a dialysis membrane (SpectraPore, MwCO 6000–8000) and dialyzed against 2 M NaCl and pure water in succession. Freeze-drying of water resulted in a white powder of QPAMAM-OH. <sup>1</sup>H NMR (300 MHz, D<sub>2</sub>O)  $\delta$  2.47 (br m, CH<sub>2</sub>CO), 2.69 (br m, NCH<sub>2</sub>CH<sub>2</sub>NHCO), 2.88 (br m, NCH<sub>2</sub>CH<sub>2</sub>), 3.15 (s, CH<sub>3</sub>), 3.34 (br m, CH<sub>2</sub>CH<sub>2</sub>OH), 3.52 (br m, CH<sub>2</sub>N<sup>+</sup>), 3.66 (br m, CH<sub>2</sub>OH).

**Ethidium Bromide Exclusion Assay.** Ethidium bromide (1.0  $\mu$ g) in 10  $\mu$ L of water and plasmid DNA (1.0  $\mu$ g) in 10  $\mu$ L of water were mixed for 10 min at room temperature. After incubation, the plasmid DNA/ethidium bromide mixture was added to quaternized PAMAM-OH dendrimers with various charge ratios, ranging from 0.25 to 10 (+/–) and incubated further for 30 min. The charge ratio was calculated by relating the number of quaternary amine groups of QPAMAM-OH derivatives and the number of phosphate groups of DNA. The complexes were diluted to a total of 2 mL of Hepes buffered saline (HBS, 25 mM Hepes, 150 mM NaCl, pH 7.4) prior to measuring fluorescence intensity with a spectrofluorometer (JASCO FP-750). Excitation ( $\lambda_{\text{ex}}$ ) and emission ( $\lambda_{\text{em}}$ ) wavelengths were 260 and 600 nm, respectively. The fluorescence of the DNA solution in HBS with ethidium bromide was calculated as 100%. The buffer containing ethidium bromide only without DNA was used as a blank control.

**Dynamic Light Scattering (DLS) Measurement.** The size of complexes was determined using a BI-200SM Goniometer (Brookhaven Instruments Corporation, Holtsville, NY) with a Lexel laser model 95 argon laser (100 mW output power at a wavelength of 514.5 nm). Correlator, PD2000 (Precision Detectors) was used and the scattering angle was 90°. Complexes were formed at a final concentration of 5  $\mu$ g/mL plasmid DNA in water. DNA stock solution was added to QPAMAM-OH derivatives or PAMAM G4 prepared at various concentrations. DLS was performed in triplicate with the sampling time set to automatic.

**$\zeta$  Potential Measurement.** The complexes of PAMAM or 0.97 QPAMAM-OH and plasmid DNA at various charge ratios were prepared in water. Surface charges were measured using a Zetasizer (Malvern Instrument

Ltd, Malvern UK) equipped with a He–Ne laser at a wavelength of 680 nm.

**Atomic Force Microscopy (AFM).** Atomic force microscopy (Nanoscope IIIa System, Digital Instruments, Inc., Santa Barbara, CA) was used for imaging the shape of complexes at 4 (N/P or  $\pm$  ratio). Complexes were formed at a total of 1  $\mu$ g/mL of plasmid DNA concentration in water. In the case of PAMAM-OH/plasmid mixture, 2.5 mM of MgCl<sub>2</sub> was applied to the solution. Complexes containing 1 ng of plasmid DNA were applied to freshly cleaved mica and incubated on the mica for 5 min. After incubation, excess fluid was wicked off using filter paper. The solution was dried at room temperature prior to imaging. The image mode was set to tapping mode and average scan speed was 2 Hz.

**Cytotoxicity Assay in Vitro.** For the cytotoxicity assay, an MTT assay was performed (23). 293T cells were seeded at a density of  $1 \times 10^4$  cells/well in a 96-well plate and grown in 95  $\mu$ L of DMEM containing 10% FBS for 24 h, supplying 5% CO<sub>2</sub> at 37 °C. After treating cells with PEI 25 kDa, PAMAM G4, PAMAM-OH G4, and QPAMAM-OHs for 1 day, 25  $\mu$ L of MTT stock solution (5 mg/mL) was added to each well and incubated for 2 h. Then, 100  $\mu$ L of extraction buffer (20% w/v of SDS in 50% DMF, pH 4.7) was added. Absorbance was measured at 570 nm after overnight incubation.

**Transfection.** 293T cells ( $5 \times 10^4$  cells/well) were seeded in 24-well plates and grown in 600  $\mu$ L of DMEM containing 10% FBS for 1 day. Polyplexes of plasmid DNA and dendrimers were prepared by mixing 0.5 mL of plasmid DNA (4  $\mu$ g/mL) and 0.5 mL of PAMAM or QPAMAM-OHs at various N/P or charge ratios, respectively, in FBS-free DMEM, and the mixtures were incubated for 30 min at room temperature. Following 4 h treatment of polyplexes, the medium was replaced by 1 mL of DMEM containing 10% FBS. Cells were incubated further for 2 days at 37 °C. After the growth medium was removed, cells were washed with PBS and lysed for 30 min at room temperature by 100  $\mu$ L of Reporter lysis buffer (Promega, Madison, WI). The lysate was cleared by centrifugation. Luciferase activity was measured using a LB 9507 luminometer (Berthold, Germany), and the protein content was measured by Micro BCA assay reagents (Pierce, Rockford, IL).

## RESULTS AND DISCUSSION

**Synthesis of QPAMAM-OHs.** QPAMAM-OHs with various degrees of internal quaternization were synthesized by partial or near complete methylation of interior tertiary amine groups (Scheme 1). The peak area of N<sup>+</sup>-methyl group was compared to the total proton numbers of unmodified PAMAM-OH, as confirmed by empirical estimation and theoretical calculation by <sup>1</sup>H NMR (Figure 1). From the <sup>1</sup>H NMR spectra, the degree of quaternization was determined by dividing the experimental proton numbers of the N-methyl groups (3.15 ppm) with the calculated total proton numbers that were obtained by assuming that all the tertiary amines were completely methylated. Careful control over the reaction conditions, e.g., the amount of methyl iodide and reaction temperature, made it possible to produce QPAMAM-OHs with various degrees of quaternization. <sup>1</sup>H NMR spectra showed that surface hydroxyl groups were not reacted with methyl iodide. The significant chemical shift changes occurred at carbons c, d due to the chemical environment of positively charged nitrogen. Chloride salt of QPAMAM-OHs with the various quaternization degree of 27% (0.27 QPAMAM-OH), 52% (0.52 QPAMAM-OH), 78% (0.78

**Scheme 1. Synthesis of QPAMAM-OH<sup>a</sup>**

1. CH<sub>3</sub>I  
2. 2M NaCl dialysis

<sup>a</sup> Tertiary amine groups of PAMAM-OH were converted into quaternary amine groups at a degree of 27 % (0.27 QPAMAM-OH), 52 % (0.52 QPAMAM-OH), 78 % (0.78 QPAMAM-OH) and 97 % (0.97 QPAMAM-OH), respectively.

QPAMAM-OH), and 97% (0.97 QPAMAM-OH) were obtained after dialysis and lyophilization.

The PAMAM-OH dendrimers were transformed to be functional by equipping quaternary amine groups for DNA condensation, the hydroxyl groups of their surface for low cytotoxicity, and internal positively charged amines by modifying tertiary amines to quaternary ammonium salts, which screened their charges due to the exterior hydroxyl groups leading to neutral surface charges.

**Analysis of Complex Formation by Agarose Gel Electrophoresis and Ethidium Bromide Exclusion Assay.** The PAMAM-OHs having various degrees of quaternization and plasmid DNA were mixed, and the mixtures were electrophoresed in agarose gel to see if

**Figure 1.** <sup>1</sup>H NMR spectra of QPAMAM-OH derivatives. (A) PAMAM-OH G4, (B) 0.27 QPAMAM-OH, (C) 0.52 QPAMAM-OH, (D) 0.78 QPAMAM-OH, and (E) 0.97 QPAMAM-OH. c' and d' are shifted peaks from c and d after quaternization.

polyplexes could be formed by interior positive charges (Figure 2). No indication of polyplex formation between PAMAM-OH and DNA was found (Figure 2A). Low pK<sub>a</sub> values of PAMAM-OH's interior tertiary amines and ensuing low charge density should be the reason for this. Slowly migrating bands in Figure 2B might be the polyplex of 0.27 QPAMAM-OH and DNA; however, no complete retardation of DNA was observed in this polymer. It was observed that the number of charges per copolymer was an important factor in condensing DNA into small particles and in determining other physicochemical characteristics of a polymer/DNA complex (24). As the degree of quaternization increased, complete retardation of DNA was observed (Figure 2C, 2D, and 2E). More highly quaternized polymers were more efficient in polyplex formation. The polyplex formation in 0.97 QPAMAM-OH was nearly stoichiometric.

As shown in Figure 3, ethidium bromide exclusion assay was performed to quantify and confirm the complex formation ability of QPAMAM-OHs. Initial fluorescence of DNA and ethidium bromide complex decreased as dendrimers bound to DNA, releasing intercalated ethidium bromide. In 0.27 QPAMAM-OH, the relative fluorescence intensity decreased to 70% at a charge ratio of 5 and plateaued after that point. A low charge density of 0.27 QPAMAM-OH might be the reason and it is in line with the electrophoresis result (vide ante). DNA was completely retarded by 0.52 QPAMAM-OH above a charge ratio of 2 in the electrophoresis experiment; however, ethidium exclusion did not go beyond around 60% even at a charge ratio of 10. The unexpected phenomenon was revealed that interaction between 0.52 QPAMAM-OH and DNA is too weak to change DNA conformation sufficiently to exclude intercalated ethidium. 0.78 QPAMAM-OH and 0.97 QPAMAM-OH expelled ethidium from DNA, completely above a charge ratio of about 2. In summary, as the degrees of quaternization

**Figure 2.** Agarose gel band shift assay. (A) PAMAM-OH/plasmid DNA polyplexes, (B) 0.27 QPAMAM-OH/plasmid DNA polyplexes, (C) 0.52 QPAMAM-OH/plasmid DNA polyplexes, (D) 0.78 QPAMAM-OH/plasmid DNA polyplexes, and (E) 0.97 QPAMAM-OH/plasmid DNA polyplexes. Charge ratios (+/-) are indicated above each lane. In the case of PAMAM-OH/DNA, numbers of each lane are represented N/P ratios. The charge ratio was calculated by relating the number of quaternary amine groups of QPAMAM-OH derivatives and the number of phosphate groups of DNA, and the N/P ratio was calculated from the number of tertiary amines of PAMAM-OH and the number of phosphate groups of DNA. Samples were electrophoresed in 0.7% agarose gel at 100 V for 40 min in Tris-borate buffer.

**Figure 3.** Ethidium bromide exclusion assay. N/P ratio of PAMAM-OH G4 and charge ratio (+/-) of QPAMAM-OH/plasmid DNA was 0.25, 0.5, 0.75, 1, 2, 5, and 10. Data are expressed as a mean relative fluorescence intensity (%),  $n = 3$  at each ratio and the mean  $\pm$  standard deviation are shown at each data point.

**Table 2. The Complex Size of QPAMAM-OH/DNA Polyplexes and PAMAM/DNA Polyplexes As Determined by Dynamic Light Scattering**

(+/-)	PAMAM	0.52 Q	0.78 Q	0.97 Q
1	168.0	680.2	157.0	129.3
2	126.0	122.6	108.4	111.3
4	86.4	90.9	84.8	74.0
10	78.0	66.1	51.3	53.3

<sup>a</sup> Data are the mean diameter (nm) of each polyplex observed in water at 5  $\mu$ g/mL of plasmid DNA concentration. Charge ratio in PAMAM was calculated on the assumption that only primary amines are protonated in near neutral pH

(97% > 78% > 52% > 27%) in QPAMAM-OH increased, the formation of polyplexes was more efficient.

**Characterization of QPAMAM-OHs/DNA Particles.** For analysis of particle size, we performed dynamic light scattering measurements. Briefly, in the presence of quaternary amine-based PAMAM-OH, relatively smaller, compared to primary amine-based PAMAM, particles were formed (Table 2). Interestingly, in the case of 0.52 QPAMAM-OH, very large particles (680.2

**Figure 4.** Surface charge of particles measured by  $\zeta$  potential experiments. The polyplexes of 0.97 QPAMAM-OH ( $\blacklozenge$ ) or PAMAM G4 ( $\square$ ) and plasmid DNA were formed at 0.5, 1, 4, and 10 of charge ratios (+/-). Results are shown as mean  $\pm$  standard deviation ( $n = 3$ ).

nm) were detected at a charge ratio of 1 due to the poor ability of complex formation with DNA. This is also seen from the neutralization between DNA and 0.52 QPAMAM-OH, in which cancellation of net charge (25) and minimization of charge-to-charge repulsion between complex particles might cause the large particles (26). However, increasing the charge ratio up to 2, the particle size became small (122.6 nm). The size distribution of the particles of more quaternized QPAMAM-OHs with DNA was below 157 nm at all charge ratios, which means these particles were small enough to be taken up by receptor-mediated endocytosis requiring a smaller size than 150 nm (27). It can be also noted that the diameter of complex particles gradually decreased as the degree of quaternization in QPAMAM-OH increased. This result indicates that the more compact polyplexes are produced at higher degrees of QPAMAM-OHs. We believe from these results that plasmid DNA having an extended structure can contact and bind to internal positive charges.

The surface charges of particles were determined by  $\zeta$  potential measurements (Figure 4). The surface charge of PAMAM G4 particles increased as increasing charge ratios and positive  $\zeta$  potentials were observed above a charge ratio of 1. For QPAMAM-OH, although the charge ratio was increased up to 10, its surface charge never went to values beyond zero. Starburst PAMAM-OH dendrimers are highly branched macromolecules that have a specific size, spherical shape, and rigid conformation, and it seems likely that the dendrimer has enough

**Figure 5.** Particle morphology imaged by AFM at charge ratio (+/-) = 4. (A) PAMAM G4, (B) PAMAM-OH G4, (C) 0.27 QPAMAM-OH, (D) 0.52 QPAMAM-OH, (E) 0.78- QPAMAM-OH, and (F) 0.97 QPAMAM-OH.

inner space (28) to accommodate large plasmid DNA molecules. This should be the reason hydroxyl groups exposed at their surface are able to screen internal positive charges even increasing their charge ratios. Thus, the condensates are considered to be electrostatically neutralized at their surface.

The morphology and size of the complexes depending on the degree of quaternization was investigated by

atomic force microscopy (AFM) at a charge ratio of 4.0 (Figure 5). Only free plasmid DNA, or very large and loose condensates were observed for PAMAM-OH/DNA polyplexes and 0.27 QPAMAM-OH/DNA polyplexes. 0.52 QPAMAM-OH showed partially condensed structures of DNA. These results were reconfirmed by ethidium bromide exclusion assay results in which no sharp decrease of relative fluorescence was observed by 0.52

**Figure 6.** Cytotoxicity assay on 293T cell after exposing the cells with PAMAM-OH, QPAMAM-OH, PAMAM G4, and PEI 25kDa at various concentrations. Relative cell viability (RCV, %) is expressed as a percentage of viable cells divided by untreated cells.

QPAMAM-OH. The images of polyplexes composed of 0.78 QPAMAM-OH and 0.97 QPAMAM-OH were observed to be small and spherical particles.

**Cytotoxicity Issue.** Cytotoxic effects of polycations are mainly mediated by interactions of the polymers with cell membranes and/or by cellular uptake of the polymers, and subsequent activation of intracellular signal transduction pathways (29). We examined the cytotoxicity of QPAMAM-OHs with various degrees of quaternization, comparing it with PAMAM G4 and branched PEI (25 kDa) (Figure 6). The cells exposed to PAMAM G4 were more viable than that treated with PEI. In general, the relative cell viability (RCV) of both PEI and PAMAM G4 decreased significantly as the concentration increased. However, quaternized PAMAM-OHs were less toxic than PAMAM G4 and PEI 25kDa. The RCV (%) of all quaternized PAMAM-OH derivatives was over 90% throughout all the concentration levels tested.

The cytotoxicity of cationic macromolecules has been studied and reported extensively so far. One hypothesis is that their toxicity results from the interaction between positively charged polymers and negatively charged cell membranes leading to a haemolytic effect (30, 31). The presence of primary amines has a significant toxic effect on red blood cells, causing them to agglutinate (32). So, many strategies to decrease cytotoxicity of polymers were reported as follows. The cytotoxicity of polyallylamine was reported to be decreased by substituting primary amine groups with amido hydroxyl groups (11). It was also reported that the quaternization of the PEI polymer resulted in a decrease of toxicity (33). The fact that all QPAMAM-OHs were less cytotoxic than their parent dendrimer (PAMAM) should be the result of shielding interior positive charges by surface hydroxyls and of quaternization. Dendrimer-shielding of a surface charge confirmed by  $\zeta$  potential measurement might be the major reason for reduced toxicity, minimizing the direct contact of these polycations to cell membrane. In addition, an inverse correlation between cytotoxicity and degree of quaternization was observed: PAMAM-OH > 0.26 QPAMAM-OH > 0.52 QPAMAM-OH > 0.78 QPAMAM-OH  $\approx$  0.97 QPAMAM-OH with cell cytotoxicity mirroring

**Figure 7.** Transfection efficiency in 293T cell at charge ratio (+/-) = 6. Data are expressed as a RLU (Relative light unit) per  $\mu$ g protein.

the degree of quaternization. The results suggest that the cytotoxicity is a function of the nature of the polycation charged moiety (primary, secondary, tertiary, or quaternary amine group) rather than its charge density (34). The quaternary amines were always charged and strongly hydrophilic; thus, the majority of quaternary amine-containing PAMAM-OHs appeared to be less toxic than tertiary amine-containing PAMAM-OH. Moreover, the higher density of quaternary amine-containing PAMAM-OH benefited from improved hydrophilicity and showed less cytotoxicity. Therefore, the transformation of the water-soluble polymers had previously resulted in a marked reduction in toxicity (33, 35).

Introducing quaternary amines to PAMAM-OH resulted not only in less cytotoxicity, but also the ability for condensation with plasmid DNA while the parent PAMAM-OH could not. These hydroxyl group-modified dendrimer-based delivery systems are supposed to be useful for reduction of the toxicity of PAMAM dendrimers.

**Transfection Efficiency in Vitro.** The gene delivery efficiency of QPAMAM-OH/DNA polyplexes as judged by luciferase gene expression was tested on 293T cell lines. The result (Figure 7) indicated that the transfection efficiency of QPAMAM-OH was lower than that of PAMAM G4 and PEI. The neutral surface charge of QPAMAM-OH/DNA polyplexes, as shown by measurement of the  $\zeta$  potential, might decrease chances of the polyplexes to bind electrostatically to cell-matrix and cell-cell anchoring proteins, such as heparan sulfate proteoglycans (36, 37).

In principle, cellular uptake of a polycation is a nonspecific process. A positively charged complex binds to a negatively charged cell membrane with electrostatic interaction. However, anionic proteoglycans are too ubiquitous for cationic particles to reach specific targeting organs in vivo. Therefore, the introduction of a system which decreases the surface charge of particles is necessary to avoid such a nonspecific uptake into cells. QPAMAM-OHs have such a low nonspecific interaction potential due to the neutral surface of particles; however,

they should be equipped with cell-surface targeting residues that could trigger their receptor-mediated endocytosis.

Although the transfection efficiency of QPAMAM-OH derivatives was lower by 1 order of magnitude than PAMAM G4, our particles have the merit of much lower cytotoxicity and the chance to attach a ligand at the hydroxyl groups of their surface. These properties are useful for the strategy of receptor-mediated transfection by attaching a ligand as is being done in our further works.

## CONCLUSION

We introduced quaternary ammonium salts that were placed in an internal location of starburst PAMAM-OH dendrimer (generation 4) by methylation of interior tertiary amines of PAMAM-OH. Improvements were made, not only in the ability to bind to DNA, but also in the cytotoxicity. The surface hydroxyl functionalities of QPAMAM-OHs could provide low cytotoxicity, and the polyplex of the polymer exhibited a neutral surface charge. Another major advantage of QPAMAM-OH dendrimers is that unreacted hydroxyl groups can be exploited for the conjugation of targeted ligands in order to provide cell entry by receptor-mediated endocytosis, while maintaining decreased nonspecific interaction with ubiquitous cellular proteins.

## ACKNOWLEDGMENT

We acknowledge the support of this work by the Korea Research Foundation (2001-015-DP0344), the Korea Science and Engineering Foundation (R02-2002-000-00011-0), and the SRL-Molecular Therapy Research Center, in Sungkyunkwan University. We thank Prof. Doo Soo Chung for giving access to DLS.

# A Quantitative Analysis and Chemical Approach for the Reduction of Nonspecific Binding Proteins on Affinity Resins

Tsuruki Tamura, Tomohiro Terada, and Akito Tanaka\*

Chemistry Department, Reverse Proteomics Research Institute Co., Ltd. 2–6–7 Kazusa-Kamatari, Chiba 292-0818, Japan. Received June 18, 2003; Revised Manuscript Received September 2, 2003

Tubulin and actin often bind nonspecifically to affinity chromatography resins, complicating research toward identifying the cellular targets of small molecules. Reduction of nonspecific binding proteins is important for the success of such biochemical approaches. To develop strategies to circumvent this problem, we quantitatively investigated the binding of tubulin and actin to a series of affinity resins bearing 15 variant ligands on 3 commercially available polymer supports. Nonspecific protein binding was proportional to the hydrophobicity of the affinity resins and could be quantitatively correlated to the CLOGP values of the ligands, which are a measure of compound hydrophobicity. When compounds had CLOGP values greater than 1.5, (amount of tubulin) =  $0.73 \times \text{CLOGP} - 1.1$  ( $n = 7$ ,  $r = 0.97$ ), and (amount of actin) =  $0.42 \times \text{CLOGP} - 0.79$  ( $n = 7$ ,  $r = 0.99$ ). On the basis of these studies, we designed a novel hydrophilic poly(ethylene glycol) (PEG) spacer (**26**) for the conjugation of ligands to chromatography resins. As predicted by our binding algorithm, introduction of this spacer reduced the amount of nonspecific protein binding in proportion to the number of ethylene glycol units.

## INTRODUCTION

Affinity chromatography matrixes bearing bioactive compounds such as medicines, natural products, and toxins play an important role in the discovery of novel drug targets and the elucidation of drug mechanisms. Their effectiveness has been demonstrated by the discovery of FKBP12 (1), HDAC (2), and Ref-1 (3) as specific binding proteins of FK506 (1), Trapoxin, and E-3330, respectively. The successful isolation of target proteins by affinity chromatography depends on the synthesis of polymeric resins that can bind to the cellular target with maximum selectivity and efficiency. The nonspecific binding of cellular proteins to affinity matrixes is therefore a significant limitation to this biochemical approach. In particular, tubulin and actin often interfere with affinity chromatography studies, due to their high abundance and the similarity of their molecular weights (50 kDa and 42 kDa, respectively) to many putative target proteins.

Commercially available resins for the synthesis of affinity matrixes can be structurally classified as two types: one consisting of sugar derivatives such as agarose (4) or sepharose (5), and the other based upon methacrylate polymers (6). A wide variety of sugar-based resins are commonly used as bioseparators in molecular biology fields, but these supports are often irreversibly denatured in several synthetic conditions, such as organic solvents and strong acids and bases (7). These properties significantly restrict chemical approaches such as increasing the ligand density on the resin and synthesizing affinity resins bearing structurally complex compounds. In contrast, functional polymers such as poly(methacrylate) derivatives are stable under most synthetic conditions, which allow the synthesis of more effective affinity resins. This is attractive for organic chemists since the recent development of combinatorial chemistry allows us to synthesize a variety of compounds on functional polymers (8–10). However, methacrylate polymers bearing bioactive compounds often show high levels of nonspecific protein binding in comparison to agarose resins with the same ligands. Therefore, the reduction of nonspecific protein binding to methacrylate derivatives is now desired.

The phrase “nonspecific protein binding” is usually used to represent proteins that bind to affinity resins based on physical adsorption rather than specific binding such as “lock and key” interactions between ligands and receptors (11). They were usually thought to bind to the resin through hydrophobic interactions (11, 12), and indeed methacrylate resins are more hydrophobic than agarose-derived supports. As there are no systematic studies of the relationship between nonspecific protein binding and the physical and chemical characteristics of affinity resins, we quantitatively investigated these interactions using 3 kinds of polymeric supports and 15 arbitrarily selected ligands. These studies demonstrated that (1) the profile of nonspecific binding proteins is approximately constant throughout the series of affinity

resins bearing different compounds, and (2) a linear relationship exists between amount of the nonspecific protein binding and ligand hydrophobicity, as measured by CLOGP values. Moreover, we determined that introduction of a hydrophilic spacer is effective for reduction of the nonspecific binding proteins.

## EXPERIMENTAL PROCEDURES

Thin-layer chromatography (TLC) was performed on Merck silica gel 60 F-254 plates. For normal chromatography, Merck silica gel type 60 (size 70–230) was used. All evaporation was performed with a rotary evaporator under reduced atmosphere. The structures of all compounds were confirmed by a LC-MS (Agilent 1100 Series LC/MSD) and 400 MHz proton nuclear magnetic resonance spectroscopy (Bruker, Avance-series 400). The chemical shift values are reported in parts per million on the  $\delta$  scale from internal standard tetramethylsilane. No attempt was made to maximize the yields.

**Mono-TBS-Protected FK506 (2) (13).** FK506 (**1**, 1 g, 1.24 mmol) was dissolved with benzene, evaporated in vacuo, and then dried in vacuo for 1 h to remove water completely.  $\text{CH}_2\text{Cl}_2$  (20 mL) was added and cooled under ice–water conditions, lutidine (0.58 mL, 4.97 mmol) and TBS-OTf (1.15 g, 4.35 mmol) were added thereto, and the mixture was stirred for 1 h. To the reaction mixture was added MeOH (0.2 mL), and then it was poured into a mixture of  $\text{CH}_2\text{Cl}_2$  and sat.  $\text{NaHCO}_3$ . The separated organic layer was washed with water and brine and dried over  $\text{MgSO}_4$ . After filtration, the filtrate was evaporated in vacuo and then purified by chromatography on silica gel (eluted with 20% AcOEt in *n*-hexane). Fractions including the target compound were collected and evaporated in vacuo to give a 24,32-di-TBS protected FK506 derivative (0.62 g), which was used in the next reaction.

A mixture of the di-TBS protected FK506 (1.87 g, 1.81 mmol), toluenesulfonic acid monohydrate (86.1 mg, 0.453 mmol),  $\text{CH}_2\text{Cl}_2$  (20 mL), and MeOH (20 mL) was stirred at rt for 1 h. The reaction mixture was poured into a mixture of AcOEt and sat.  $\text{NaHCO}_3$ . Separated organic layer was washed with water and brine and dried over  $\text{MgSO}_4$ . After filtration, the filtrate was evaporated in vacuo and then purified by chromatography on silica gel (eluted with 15% acetone in *n*-hexane). Fractions including the target compound were collected and evaporated in vacuo to give **2** (1.33 g, 80%). MS (*m/z*): 918 ( $\text{M}^+$ ), 940 ( $\text{M} + \text{Na}$ ).

**FK506 with a Linker Moiety (3).** A mixture of **2** (138 mg, 0.15 mmol), suberic acid mono-TBDPS ester (86.7 mg, 0.218 mmol), DMAP, (16.5 mg, 0.098 mmol), EDC·HCl (69.1 mg, 0.261 mmol), and  $\text{CH}_2\text{Cl}_2$  (1 mL) was stirred at room temperature for 1.5 h. This mixture was poured into a mixture of AcOEt and an aqueous solution of ammonium chloride. The organic layer was washed with water and brine and dried over  $\text{MgSO}_4$ . After filtration, the filtrate was evaporated in vacuo and then purified by chromatography on silica gel (eluted with 20% AcOEt in *n*-hexane). Fractions including the target compound were collected and evaporated in vacuo to give a crude protected intermediate (44 mg, 24.6%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : –0.1–0.1 (6H, m), 0.70–2.65 (71H, m), 2.69–3.96 (16H, m), 3.89–5.69 (10H, m), 7.35–7.69 (10H, m).

A mixture of the protected intermediate (44 mg, 0.037 mmol), 48% HF aqueous solution (0.12 mL), and acetonitrile was stirred at room-temperature overnight. This mixture was poured into a mixture of AcOEt and an aqueous solution of ammonium chloride. The organic layer was washed with water and brine and dried over

$\text{MgSO}_4$ . After filtration, the filtrate was evaporated in vacuo and then purified by chromatography on silica gel (eluted with 5% MeOH in  $\text{CHCl}_3$ ). Fractions including the target compound were collected and evaporated in vacuo to give **3** (14.2 mg, 40%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : 0.82 and 0.85 (3H, d,  $J = 6.5$  Hz, Me), 0.91 and 0.94 (3H, d,  $J = 6.4$  Hz, Me), 0.96 and 1.00 (3H, d,  $J = 6.5$  Hz, Me), 0.8–1.2 (3H, m) 1.3–2.4 (39H, m), 2.46 (1H, m), 2.72 and 2.79 (1H, dd,  $J = 16, 2.4$  Hz), 3.02 (1H, m), 2.95–4.0 (14 H), 3.76 and 4.42 (1H, m), 4.22 and 4.86 (1H, brs, OH), 4.69 (1H, dt,  $J_t = 9.2$  Hz,  $J_d = 4.4$  Hz,  $\text{CH-OOC-linker}$ ), 4.61 and 5.02 (1H, m), 4.95–5.10 (4H, m), 5.19 and 5.32 (1H, each s,  $\text{CH}$ ), 5.71 (1H, m,  $\text{CH=CH}_2$ ). MS (*m/z*): 960 ( $\text{M}^+$ ).

**Affinity Resin Bearing FK506 on Toyopearl (4b).** A mixture of **3** (38.4 mg, 0.04 mmol), Toyopearl (Tosho, AF-Amino-650M, cat. 08002, 100  $\mu\text{L}$ , 0.01 mmol), EDC·HCl (9.2 mg, 0.048 mmol), HOBT (6.5 mg, 0.048 mmol), and DMF (1 mL) was shaken at room temperature for 6 h. After removal of solvents by filtration, the resin was washed with DMF. The reaction ratio was determined by the ninhydrin test (82%). The resin was mixed with a 20% DMF solution of acetic anhydride at rt for 1 h and was washed with DMF and 20% aqueous solution of EtOH.

The synthesis of affinity resins bearing FK506 on AffiGel (**4a**, BIO-RAD, AffiGel 102 Gel, cat. 153–2401) and TentaGel (**4c**, Fluka, TentaGel S- $\text{NH}_2$ , cat. 86364) were carried out according to a similar manner. AffiGel was used after washed with DMF five times. Other resins (**5–18**, Table 1) were prepared according to a similar manner.

**Mono-O-Trityl-Protected Pentaethylene Glycol (20).** To a mixture of pentaethylene glycol (**19**, 10 g, 42.0 mmol), DMAP (0.9 g, 7.4 mmol), and pyridine (100 mL)

was added triphenylmethyl chloride (11.6 g, 41.6 mmol) at rt, and the mixture was stirred at 35 °C overnight. After evaporation in vacuo, the resulting mixture was poured into a mixture of  $\text{CHCl}_3$  and water. The organic layer was washed with sat.  $\text{NaHCO}_3$  aq and brine and dried over  $\text{MgSO}_4$ . After filtration, the filtrate was evaporated in vacuo and then purified by chromatography on silica gel (eluted with 1.6% MeOH in  $\text{CHCl}_3$ ). Fractions including the target compound were collected and evaporated in vacuo to give **20** (10.4 g, 51.2%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : 3.16 (2H, t,  $J = 5.3$  Hz,  $\text{CH}_2\text{OTr}$ ), 3.49 (2H, m,  $\text{CH}_2\text{OH}$ ), 3.55–3.66 (16H, m), 7.14–7.41 (15H, m).

**2-(2-Tritylhydroxyethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy))))acetic Acid (21).** To a mixture of **20** (10.2 g, 21.2 mmol), THF (200 mL), and DMF (50 mL) was added 60% sodium hydride (3.1 g, 77.4 mmol) under nitrogen atmosphere over 10 min at 0 °C, and the mixture was stirred at the same temperature for 30 min. After 2-bromoacetic acid (6.5 g, 46.8 mmol) was added thereto, the mixture was stirred at rt for 1 h and then cooled at 0 °C, and sodium hydride (11.6 g, 290 mmol) was added. The mixture was stirred at rt for 1 h and was poured into a mixture of AcOEt and water. This mixture was adjusted to pH 6 by addition of 2 M potassium hydrogen sulfate. The separated organic layer was washed with brine and dried over  $\text{MgSO}_4$ . After the filtration, filtrate was evaporated in vacuo and then purified by chromatography on silica gel (eluted with 15% MeOH in  $\text{CHCl}_3$ ). Fractions including the target compound were collected and evaporated in vacuo to give crude **21** (12.4 g).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : 3.34 (2H, t,  $J = 5.2$  Hz), 3.76–3.84 (18H, m), 4.13 (2H, s,  $\text{CH}_2\text{COOH}$ ), 7.30–7.83 (15H, m).

**2-(2-Tritylhydroxyethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy))))acetic Acid Benzyl Ester (22).** A mixture of the above crude **21** (12.4 g), DMAP (0.29 g, 2.4 mmol), benzyl alcohol (3.1 mL, 30.0 mmol), EDC·HCl (4.5 g, 23.5 mmol), and  $\text{CH}_2\text{Cl}_2$  (100 mL) was stirred at rt overnight. The reaction mixture was poured into a mixture of  $\text{CHCl}_3$  and water. The separated organic layer was washed with sat.  $\text{NaHCO}_3$  aq and brine and dried over  $\text{MgSO}_4$ . After filtration, the filtrate was evaporated in vacuo and then purified by chromatography on silica gel (eluted with 50% AcOEt in *n*-hexane). Fractions including the target compound were collected and evaporated in vacuo to give crude **22** (12.0 g, 90.1%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : 3.16 (2H, t,  $J = 5.4$  Hz), 3.55–3.65 (18H, m), 4.11 (2H, s), 5.11 (2H, s,  $\text{CH}_2\text{Ph}$ ), 7.15–7.40 (20H, m).

**2-(2-Hydroxyethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy))))acetic Acid Benzyl Ester (23).** A mixture of **22** (12.0 g, 1.59 mmol), 5% TFA in  $\text{CH}_2\text{Cl}_2$  (150 mL), and water (150 mL) was stirred at 0 °C for 10 min. The reaction mixture was poured into sat.  $\text{NaHCO}_3$  aq. The separated organic layer was washed with brine and dried over  $\text{MgSO}_4$ . After filtration, the filtrate was evaporated in vacuo and then purified by chromatography on silica gel (eluted with 1.5% MeOH in  $\text{CHCl}_3$ ). Fractions including the target compound were collected and evaporated in vacuo to give crude **23** (7.0 g, 95.0%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : 3.30 (2H, t,  $J = 5.2$  Hz,  $\text{CH}_2\text{OH}$ ), 3.62–3.76 (18H, m), 4.12 (2H, s), 5.20 (2H, s), 7.36–7.41 (5H, m).

**2-(2-Azidoethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy))))acetic Acid Benzyl Ester (24).** To a mixture of **23** (7.0 g, 18.1 mmol), DMAP (0.4 g, 3.3 mmol), and pyridine (45 mL) was added *p*-toluenesulfonyl chloride (5.2 g, 27.2 mmol) at 0 °C. After the mixture was stirred at rt overnight, *p*-toluenesulfonyl chloride (5.2 g, 27.2 mmol) and DMAP (120 mg, 0.98 mol) were added

thereto at 0 °C. The reaction mixture was stirred at rt for 2 h and poured into a mixture of EA and water. The separated organic layer was washed with sat.  $\text{NaHCO}_3$  aq, water, and brine and dried over  $\text{MgSO}_4$ . After filtration, the filtrate was evaporated in vacuo to give a crude tosylate intermediate, which was used in the following reaction.

A mixture of this crude intermediate,  $\text{NaN}_3$  (11.8 g, 0.18 mol), and DMF was stirred at 60 °C for 1 h. The reaction mixture was stirred at rt for 2 h and then poured into a mixture of AcOEt and water. The separated organic layer was washed with sat.  $\text{NaHCO}_3$  aq, water, and brine and dried over  $\text{MgSO}_4$ . After filtration, the filtrate was evaporated in vacuo, and the resulting residue was purified by chromatography on silica gel (eluted with 25% AcOEt in *n*-hexane). Fractions including the target compound were collected and evaporated in vacuo to give crude **24** (3.3 g, 44.3%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : 3.31 (2H, t,  $J = 5.2$  Hz,  $\text{CH}_2\text{N}_3$ ), 3.54–3.87 (18H, m), 4.13 (2H, s), 5.12 (2H, s), 7.20–7.30 (5H, m).

**2-(2-Aminoethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy))))acetic Acid Benzyl Ester (25).** A mixture of **24** (1.94 g, 4.72 mmol), 10% Pd–C (0.5 g), and MeOH (50 mL) was stirred under hydrogen atmosphere at rt for 2.5 h. After filtration, the filtrate was evaporated in vacuo, to give crude **25** (1.4 g, 100%) which was used in the next reaction without further purifications. MS ( $m/z$ ): 296 ( $\text{M}^+$ ).

**2-(2-*N*-Fmoc-aminoethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy-(2-ethoxy))))acetic Acid Benzyl Ester (26).** To a mixture of **25** (1.25 g, 4.23 mmol) and 10% aqueous solution of  $\text{NaHCO}_3$  was added a mixture of 9-fluorenylmethoxycarbonyloxysuccinimide (2.15 g, 6.37 mmol) and dimethoxyethane (14 mL) at rt, and the mixture was stirred at rt overnight. After filtration, the filtrate was washed with 2 M  $\text{NaHSO}_4$  and brine and dried over  $\text{MgSO}_4$ . After filtration, the filtrate was evaporated in vacuo and then purified by chromatography on silica gel (eluted with 0.7% MeOH in  $\text{CHCl}_3$ ). Fractions including the target compound were collected and evaporated in vacuo to give **13** (1.38 g, 63.0%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$ : 3.34 (2H, t,  $J = 5.0$  Hz,  $\text{FmocNHCH}_2$ ), 3.50–3.71 (18H, m), 4.05 (2H, s), 4.12 (1H, t,  $J = 7.0$  Hz), 4.33 (2H, d,  $J = 7.0$  Hz), 5.57 (1H, s,  $\text{FmocNH}$ ), 7.22–7.95 (8H, m). Anal. Calcd for  $\text{C}_{27}\text{H}_{37}\text{NO}_{10}$  (monohydrate): C, 60.55; H 6.96; N 2.62. Found: C, 60.72; H 6.92; N 2.42.

**Representative Procedure for Introduction of the Hydrophilic Spacer on Resins.** A mixture of **13** (21 mg, 0.04 mmol), Toyopearl (100  $\mu\text{L}$ , 0.01 mmol), PyBOP (26 mg, 0.05 mmol), *N,N*-diisopropylethylamine (17  $\mu\text{L}$ , 0.10 mmol),  $\text{CH}_2\text{Cl}_2$  (0.4 mL), and NMP (0.1 mL) was shaken at rt for 4 h. After filtration, the resin was washed with DMF five times. The reaction ratio was determined by the ninhydrin test (81%). After the resin was washed with DMF carefully, 0.5 mL of a mixture (acetic anhydride: $\text{CH}_2\text{Cl}_2$ :NMP = 1:8:2) was added for acetyl capping of remained amines. The reaction mixture was shaken at rt for 3 h and then washed with DMF more than five times. The capping reaction was confirmed by the ninhydrin test.

This Fmoc resin was mixed with 0.5 mL of a mixture (piperidine:DMF: $\text{CH}_2\text{Cl}_2$  = 1:4:4) at rt for 3 h. After filtration, the resin was five times washed with DMF to afford the objective resins bearing the hydrophilic spacer **13**. The amount of amine was estimated by the ninhydrin (79  $\mu\text{mol/mL}$ ).

**Preparation of Rat Brain Lysate.** Preparation of tissue extracts of rat brain. Fresh rat brain were homogenized (1:10, wt/vol) in buffer A. The homogenate was

**Figure 1.** Synthesis of affinity resins bearing FK506.

centrifuged at 9500 rpm for 10 min. After supernatant was separated, it was centrifuged at 50 000 rpm for 30 min again. Obtained supernatant was used for lysate and kept at  $-80^{\circ}\text{C}$  before use.

**Binding Assay on Affinity Resins.** The lysate as crude tissue extracts were diluted by buffer A and total protein concentration was prepared about 7 mg/mL. This lysate was stirred calmly with affinity resin at  $4^{\circ}\text{C}$  for about 15 h to adsorb the nonspecific binding proteins or specific binding proteins. A typical mixture has a total volume of 1.0 mL, consisting of buffer A, 10  $\mu\text{L}$  of beads that is previously equilibrated by buffer A, and 0.5 mL of tissue extract. After incubation, the resins were precipitated by centrifugation in a microcentrifuge at 12 000 rpm for 1 min. The resins were washed five times with 1.0 mL of buffer A. The washed beads were then resuspended in 20  $\mu\text{L}$  of SDS sample buffer solution (nakalai, sample buffer solution with 2-ME(2 $\times$ ) for SDS-PAGE, cat. 30566-22, including 4% (w/v) SDS, 20% (v/v) glycerol, 0.01% (w/v) BB, 10% (v/v) 2-mercaptoethanol, 0.125 M Tris pH 6.8), shaken at  $25^{\circ}\text{C}$  for 10 min, and centrifuged for 1 min. The supernatant was subjected to SDS-PAGE followed by CBB staining.

## RESULTS AND DISCUSSION

**Nonspecific Protein Binding on Commercially Available Resins Bearing FK506.** To understand the effect of polymer structure on the amount of nonspecific protein binding, we first synthesized affinity resins bearing a common ligand, FK506 (1, Figure 1), on three types of commercially available and widely used resins, AffiGel, Toyopearl, and TentaGel. AffiGel, a polymer of sugar derivatives, is thought to have hydrophilic surface properties and is now one of the most popular resins for preparation of affinity matrixes (14). AffiGel is not suitable for organic synthesis, because it is easily denatured in organic synthesis conditions and becomes denatured even in DMF (15). Thus, chemical approaches using this resin are limited. Toyopearl consists of poly-(glycidyl methacrylate) whose epoxy moieties have been chemically converted to a hydrophilic spacer after the initial polymerization reaction (its detailed structure is

not published) (16). TentaGel is a polystyrene polymer with long PEG spacers and is often used as resin for the synthesis peptide libraries (17).

FK506 (1) is an immunosuppressive drug that targets to FKBP12 (FK506 binding protein) with a  $K_d$  of 0.4 nM (18). Structure and functions of the complex of FK506 (1) and FKBP12 have been well-characterized at molecular level by S. L. Schreiber et al. (19–21). Since the molecular weight of FKBP12 (12 kDa) differs significantly from that of actin (42 kDa) and tubulin (50 kDa), it is easy to observe and compare the amounts of specific and nonspecific protein binding. Introduction of a linker moiety onto FK506 (1) to connect it to the resins was carried out on a hydroxyl group at the 32 position of FK506 (1, Figure 1) because crystal structure studies indicate that this position is not involved in the binding of FK506 with FKBP12 (21). The synthesis of affinity resins bearing FK506 (1) is shown in Figure 1. Selective protection of a hydroxyl group at the 24 position of FK506 (1) was carried out by two steps, and the linker moiety was introduced by a standard esterification protocol, followed by deprotection of TBS and TBDPS in acidic conditions, giving the FK506 derivative (3). Conjugation of 3 to the base resins, AffiGel, Toyopearl, and TentaGel, was performed by EDC and HOBt in DMF to give the affinity resins (4a–c). Although ligand immobilization onto AffiGel is usually carried out in an aqueous solution using excess amount of ligand and condensation reagents such as EDC and HOBt, or preactivated ligand, 3 was conjugated to AffiGel in DMF to conserve compound.

We mixed the FK506 bearing resins (4a–c) with lysate prepared from rat brain using a simple buffer (buffer A; 0.25 M sucrose, 25 mM Tris-HCl, pH 7.4). Rat brain lysate was thought to be suitable since it includes both the specific binding protein, FKBP12, and the nonspecific binding proteins such as tubulin and actin. The binding proteins to each affinity resin were completely eluted by a SDS sample buffer solution, after extensive washes using buffer A. Eluted proteins were resolved by SDS-polyacrylamide gel electrophoresis, and the identification of tubulin, actin, and FKBP12 were performed by MALDI-TOF mass spectrometry peptide mass fingerprinting after

**Figure 2.** Binding proteins on the resins (A) eluted by SDS sample buffer, (B) eluted proteins by three different buffers. (A) Lane 1, molecular weight ladder; lane 2, eluted proteins from AffiGel bearing FK506; lane 3, that from Toyopearl bearing FK506, lane 4, that from TentaGel bearing FK506. (B) Lane 1, eluted proteins by 1.4 M NaCl; lane 2, that by 8 M urea; lane 3, that by the SDS sample buffer.

in-gel digestion. As determined by binding competition with soluble FK506, we confirmed that only FKBP12 specifically interacts with the FK506-bearing resins and that other proteins such as tubulin and actin are non-specific binding proteins.

A comparison of the protein binding profiles using the three affinity resins is shown in Figure 2A. AffiGel resin (**4a**, lane 2) and Toyopearl resin (**4b**, lane 3) could capture the target protein, FKBP12. However, TentaGel (**4c**, lane 4) failed to sequester significant amounts of proteins including FKBP12 even though it is often used as a resin for peptide libraries. The reason for this result with TentaGel was not clear (*22*). With respect to nonspecific protein binding, Toyopearl resin (lane 3, Figure 2A) bound several proteins with high efficiency, whereas the AffiGel support exhibited much less nonspecific binding (lane 2, Figure 2A). Nonspecifically bound tubulin and actin were observed in particularly large quantities, obscuring any specific protein binding in the 40–55 kDa molecular weight range. To understand the origins of actin and tubulin binding to the Toyopearl resin, we attempted to elute the proteins by three kinds of buffers (Figure 2B); that is, we first washed the Toyopearl resin by 1.4 M NaCl and 8 M urea, which are thought to be able to disturb ionic interaction between proteins and resins, and then washed by the SDS sample buffer solution. The SDS sample buffer is thought to disturb hydrophobic interaction as well, because it includes a high concentration (4%) of the surface-active agent, SDS. As shown in Figure 2B, the nonspecific binding proteins such as actin and tubulin were eluted only by this sample buffer, which indicated that the binding to Toyopearl resins come from hydrophobic interaction not hydrogen bonding, which coincides with Hofstee's result in which several proteins nonspecifically bind to *n*-octyl-agarose through hydrophobic interaction (*11*).

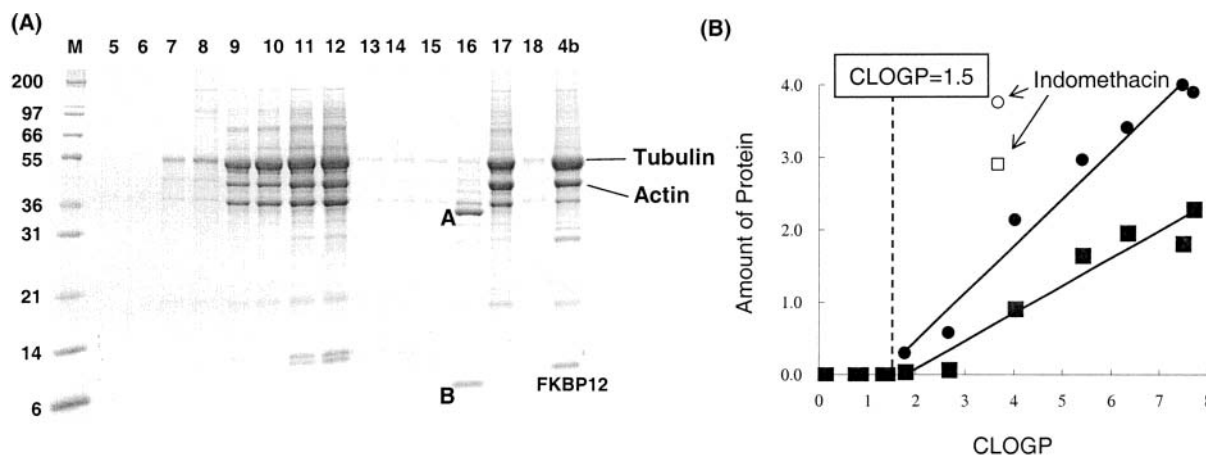

Assuming that binding of nonspecific protein binding to affinity resins is due to hydrophobic interactions, it is logical that much more nonspecific binding is observed with the Toyopearl surface than the AffiGel support, because the matrix surface of AffiGel is more hydrophilic than that of Toyopearl.

**Quantitative Study on Relationship between Nonspecific Protein Binding and Ligand Hydrophobicity.** Aiming to reduce the nonspecific binding of

proteins to the Toyopearl resins, we attempted to quantify the relationship between amount of tubulin and actin binding and hydrophobic property of affinity resins. For this purpose, we synthesized fifteen affinity resins bearing various ligands on Toyopearl and profiled the proteins bound to these resins after the supports were mixed with the rat brain lysate. These ligands were arbitrarily selected, and their structures were shown in Table 1 with their CLOGP values. CLOGP values are a representative descriptor of a compound's hydrophobicity and are often used in QSAR (quantitative structure–activity relationships) studies were calculated by CLOGP program (Version 4.72, Daylight Chemical Information Systems Inc.). All ligands have a carboxylic acid which was used to immobilize the compounds to the amino group of Toyopearl resin as shown in Table 1. Compounds **5–12**, saturated fatty acids, were selected to discuss about effect of simple hydrophobicity of ligands. We also selected some compounds to address the effects of several chemical moieties such as phenyl ring (**13**), amide bond (**14**), pyridine ring (**15**), and amino acid (**18**), which often appear in bioactive compounds and drugs. Some drugs, such as succinyl sulfathiazole (**16**) and indomethacin (**17**), were also selected with FK506 (**4b**) to investigate the effects of drug structure.

Protein binding to each affinity resin was shown in Figure 3A. Proteins binding to the resins were obtained by elution using the SDS sample buffer solution. Proteins from resins bearing hydrophilic ligands such as acetic acid (lane 5), butyric acid (lane 6), 3-phenylpropionic acid (lane 13), glutarallic acid (lane 14), 3-pyridylacetic acid (lane 15), and *N*-acetyltryptophan (lane 18) were almost undetectable. Proteins were observed from other resins while the amount was different each other. Amounts of proteins in lane 7 and 8 were very low compared with others. The large difference in amounts between lane 8 and lane 9 was particularly noteworthy because their structural difference is only three methylenes, indicating that this difference arose from nonstructural distinction. Visible protein species in Figure 3A were similar to each other and almost the same as that from the FK506 resin except for two unknown proteins (A, B) in lane 16 and FKBP12 in lane 4b, while the structures of each ligand on the resin were very diverse. Proteins at 36 kDa in lane 10, 11, 12, and 17 were identified as glyceraldehyde-3-phosphate dehydrogenase [EC 1.2.1.12] by mass spectrum analysis; however, we have not determined whether the 36 kDa bands in lane 9 and 4b are also the same enzyme or not. We also do not know the physiological relevance of the binding of this enzyme to fatty acid-containing resins. On the other hand, the total amount of nonspecific binding differed in a manner that correlated with ligand hydrophobicity. For example, resins bearing less hydrophobic ligands (CLOGP < 1.5) such as acetic acid (**5**), butyric acid (**6**), phenylpropionic acid (**13**), glutarallic acid (**14**), 3-pyridylacetic acid (**15**), and succinyl sulfathiazole (**16**) exhibited little nonspecific binding, while those bearing hydrophobic ligands (CLOGP > 1.5) sequestered much more nonspecific protein. To address this relationship quantitatively, we measured the amount of the largest proteins, tubulin and actin, and plotted them with CLOGP values of ligands (Figure 3B).

Measurement of actin and tubulin on the gel were carried out by a GS-710 Calibrated Imaging Densitometer (BIO-RAD, software; Quantity One-4.1.0). In lane 16, there were three visible and unidentified proteins (11, 34, and 36 kDa proteins); however, tubulin and actin were not detected. This plot demonstrated that the amount of nonspecific protein binding has a linear relationship with

**Figure 3.** (A) Binding proteins on resins bearing various ligands. (B) A plot of estimated amount of tubulin and actin with CLOGP values of each ligands on the resins. (A) Lanes 4b, 5–18 showed binding proteins on each resin bearing compounds **4b**, **5**–**18** (Table 1), respectively. (B) The amount of actin and tubulin was measured by a GS-710 Calibrated Imaging Densitometer (BIO-RAD, software; Quantity One-4.1.0). The linear equations were obtained by Microsoft Excel 2002. CLOGP values were calculated by CLOGP program (Version 4.72, Daylight Chemical Information Systems Inc.).

a simple descriptor for a compound's hydrophobicity, CLOGP. Indomethacin-containing resin (**17**) is the only exception for this trend, demonstrating much more nonspecific binding than would be expected for its CLOGP value. A statistical analysis of the other 14 affinity matrixes resulted in the following algorithms:

$$(\text{amount of tubulin}) = 0.73 \times \text{CLOGP} - 1.1 \quad (n = 7, r = 0.97) \quad (\text{A})$$

$$(\text{amount of actin}) = 0.42 \times \text{CLOGP} - 0.79 \quad (n = 7, r = 0.99) \quad (\text{B})$$

when CLOGP values of compounds were over 1.5, except for that bearing indomethacin (Figure 3B). The reason for the unusually high levels of nonspecific binding observed with the indomethacin-containing resin is not clear.

To our knowledge, this is the first report to quantitatively describe the relationship between nonspecific protein binding and a single descriptor of ligand character with excellent regression factors, 0.97 for tubulin (eq A) and 0.99 for actin (eq B), respectively.

Toyopearl resin bearing ligands whose CLOGP value is less than 1.5 in this work exhibit little nonspecific protein binding. In this study, we found the relationship between ligand hydrophobicity and the amount of actin and tubulin capture; however, we observed the relationship using only a series of affinity resins which consist of Toyopearl as the base resin and the 15 ligands shown in Table 1. Thus, now we actually do not have enough data to discuss whether this relationship can be generally observed in other series of affinity resins or if the 1.5 CLOGP value is universal or variable. We believe that the critical CLOGP value will be more than 1.5 when a hydrophilic basal resin such as AffiGel is used since the hydrophobicity of the resin–ligand conjugate could be a vital factor in addition to that of ligand alone.

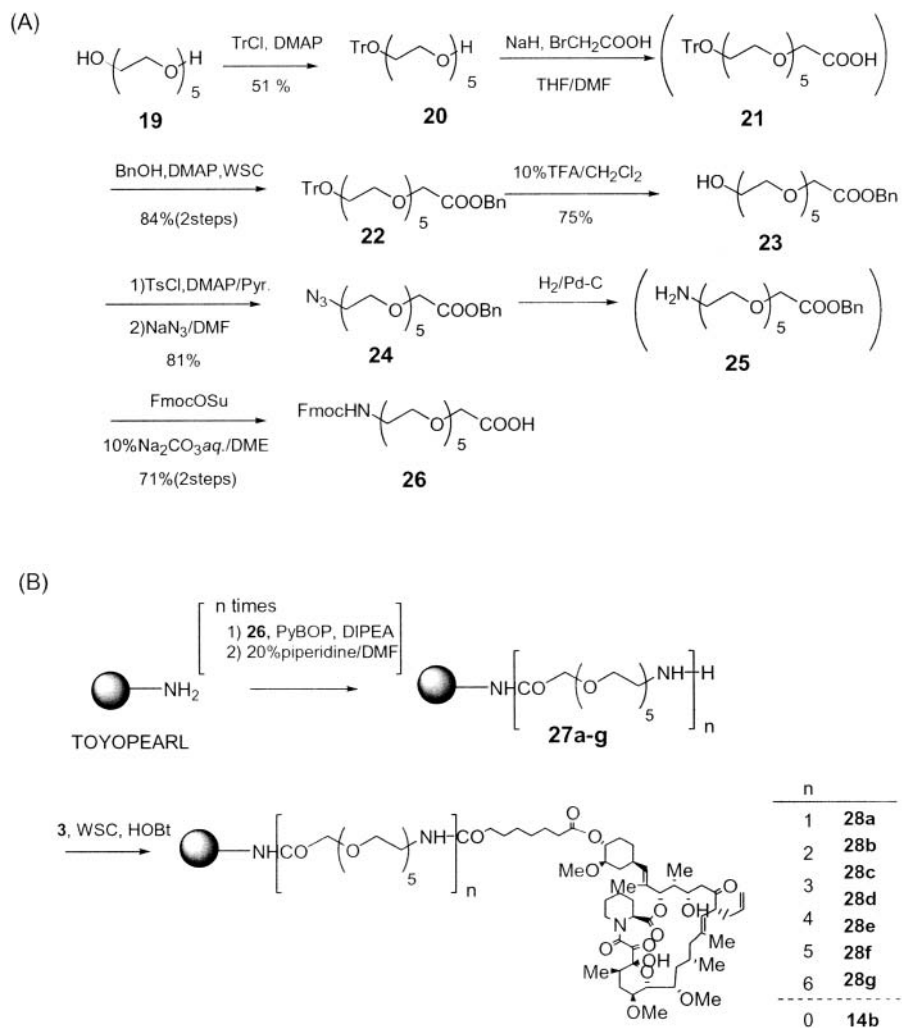

These results indicated the representative nonspecific binding proteins, actin and tubulin, bind to hydrophobic affinity resins without regard to molecular shapes of ligands. High-affinity binding to the resin was indicated because these proteins were not eluted by washing with 1.4 M NaCl and 8 M urea, as shown in Figure 2B. These results are surprising because high-affinity protein–ligand interactions are generally believed to involve a “lock and key” relationship (20). It is difficult to imagine

a common pharmacophore of stearic acid and FK506, yet their affinity resins gave very similar proteins as shown in Figure 3A. We believe that the reason for this unusual binding could be that the proteins denature to variable degrees (21) upon contact with hydrophobic ligands in an aqueous solution. Such protein denaturation would likely involve the binding of aromatic and aliphatic amino acids by the resin-bound ligands, disrupting the core hydrophobic interactions that maintain protein stability.

**Chemical Approach To Reduce Nonspecific Protein Binding.** The results in Figure 3B indicate that an increase of ligand hydrophilicity on Toyopearl resins can decrease the amount of nonspecific protein binding. Therefore, we next attempted to reduce nonspecific protein binding by introduction of a hydrophilic spacer between the base resin and ligands. We designed a hydrophilic spacer based upon poly(ethylene glycol) (PEG) (**26**, Figure 4). PEG derivatives are known to be hydrophilic and are sometimes used as hydrophilic moieties in surface-active agents (25). PEG derivatives are also known to have few unfavorable biological effects. These properties of PEG derivatives were thought to be suitable for a spacer moiety in affinity resins, as seen with TentaGel (17). The hydrophilic spacer (**26**) has an amino acid-like structure that allows study of its repetition effects while usual PEG derivatives are synthesized by the polymerization process and their exact structure is not known (26). The amino group was protected by an Fmoc (9-fluorenylmethoxycarbonyl) to facilitate the synthesis of polymer on resin by the Fmoc strategy. FK506 was also used as a ligand on the affinity resin to compare to that in Figure 1B.

The synthesis of hydrophilic spacer (**26**) is shown in Figure 4A. Single protection of a pentaethylene glycol (**19**) was carried out by using trityl chloride, followed by alkylation of the remaining hydroxyl group to introduce the acetic acid moiety, to give **21**. After introduction of a benzyl group at the carboxylic acid, the trityl group was removed under acidic conditions to afford **23**. The hydroxyl group was converted to an azide group via a *p*-toluenesulfonyl group (**24**). Both the conversion of azide group to amino group and the removal of the benzyl group were performed by hydrogenation. Finally, an Fmoc group was introduced to the amino group to give the desired Fmoc-protected hydrophilic spacer monomer (**26**). The synthesis of FK506 affinity resins bearing the

**Figure 4.** (A) Synthesis of a hydrophilic spacer (**26**). (B) Synthesis of FK506 affinity resins bearing  $n$  mers of the hydrophilic spacer between solid phase and FK506.

hydrophilic spacer between solid phase and FK506 is shown in Figure 4B. Toyopearl resin was used as basal base similar to that of Lane 3 in Figure 1B. Repetitions of the spacer monomer (**26**) on resins were carried out by the Fmoc strategy using PyBOP as a condensation reagent. Finally, introduction of FK506 derivative with the linker moiety at the end of the PEG moiety was performed by using EDC and HOBT to give the desired resin (**28a–g**).

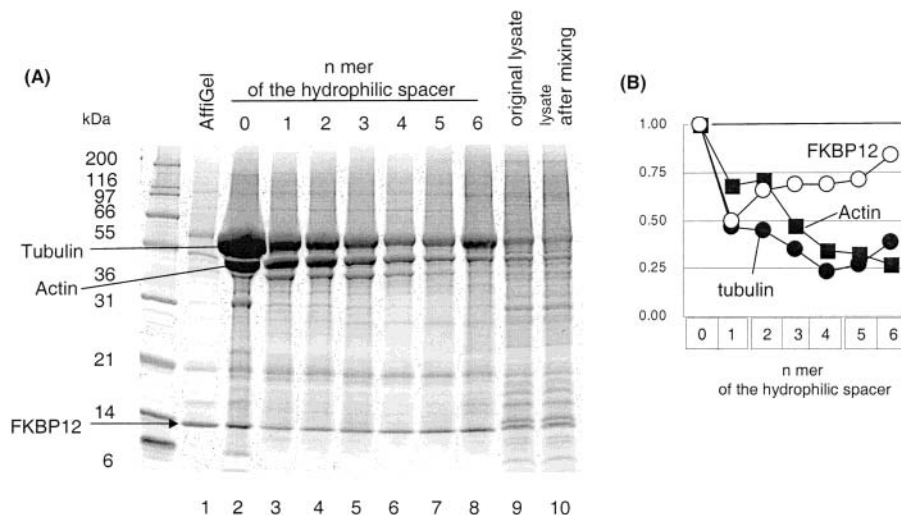

We analyzed the protein binding to each resin after mixing with rat brain lysate as shown in Figure 1B (Figure 5). As shown in Figure 5A, introduction of the hydrophilic spacer was very effective for reduction of the nonspecific protein binding, as expected, and the repetition effect is also obvious while the binding of the target protein, FKBP12, is almost constant throughout the resin series (Figure 5B). The affinity resin bearing a hexamer of the hydrophilic spacer ( $n = 6$ , lane 8 in Figure 5A) yields the same amount of FKBP12 to that without any spacer ( $n = 0$ , lane 2 in Figure 5A) while giving over four times less amount of nonspecific binding proteins. These results reinforce our observations shown in Figure 3B and demonstrate the effectiveness of the introduction of hydrophilic spacer. The effectiveness by introduction of the spacer in Figure 5A was obvious, but the estimated effect in Figure 5B did not seem to be consistent with that in Figure 5A; that is, the amount of tubulin and actin in lane 2 appear to be less. We thought the amount of protein was underestimated by the imaging densitometer

because the shape of the tubulin band was irregular due to an excessive amount on the gel.

The unfavorable proteins were still observed even in lane 8, and Figure 5B indicated that the effect appeared to reach near the maximum, but their amounts were still greater than that of the target protein, FKBP12. We thought the most important factor suggested by Figure 3A is that reduction of the hydrophobicity near the resin surface is vital to reduce the amount of proteins. Thus, the first introduction is very drastic (lane 3 compared with lane 2 in Figure 5A), because it causes introduction of hydrophilicity near the surface. However, addition of the hydrophilic spacer causes introduction of hydrophilicity at an area far from the surface because of repetition, so that the effectiveness decreased. This prompted our next project in which hydrophilicity was introduced near the surface to reduce the unfavorable proteins, which will be reported in the future.

## CONCLUSION

Tubulin and actin are often found as nonspecific binding proteins in affinity chromatography studies, interfering with research toward the identification of drug targets. Reduction of nonspecific protein binding is important for the success of such biochemical approaches. Although it is known that nonspecific binding proteins tend to stick to hydrophobic affinity resins, there is no systematic and quantitative study on the relationship

**Figure 5.** (A) Reduction effect on introduction of the hydrophilic spacer. (B) A plot of the estimated amount of nonspecific binding proteins (tubulin and actin) and the specific binding protein (FKBP12) with repetition numbers of the spacer. (A) Lane 1, molecular weight maker; lane 2, AffiGel bearing FK506 (**4a**); lane 3, Toyopearl bearing FK506 without the hydrophilic spacer ( $n = 0$ , **4b**), lane 4–9, that with  $n$  mer of the hydrophilic spacer ( $n = 1$  to 6, **28a–g**); lane 10, original lysate prepared from rat brain; lane 11, lysate after mixed with **4b**. (B) The amount of actin and tubulin was measured by a GS-710 Calibrated Imaging Densitometer (BIO-RAD, software; Quantity One-4.1.0), and all were represented as a ratio compared to the value of lane 2 ( $n = 0$ ).

between affinity resin hydrophobicity and amount of the nonspecific protein binding. We therefore first compared nonspecific binding proteins on three kinds of affinity resins, consisting of commercially available and widely used base resins AffiGel, Toyopearl, and TentaGel, with a common ligand, FK506 (Figure 2). This study showed that the hydrophilic resin, AffiGel, has low levels of nonspecific protein binding while Toyopearl exhibits much higher levels. Unfortunately, AffiGel is not chemically stable while functional polymers, Toyopearl and TentaGel, are stable in most chemical conditions, which restricts chemical modification and synthesis of desired affinity resins. Thus, the development of novel methods to reduce nonspecific protein binding to functional polymers such as Toyopearl is needed.

To reduce the unfavorable proteins, we first scrutinized the relationship between ligand hydrophobicity and the amount of the nonspecific protein binding using a series of 15 affinity resins bearing variant ligands on Toyopearl (Table 1, Figure 3A). These results showed that the amount increased in proportion to a simple descriptor of hydrophobicity of ligands, CLOGP (Figure 3B). A statistical calculation on the amount of representative nonspecific binding proteins, actin and tubulin, with CLOGP of ligands exhibited a strong correlation; that is, (amount of tubulin) =  $0.73 \times \text{CLOGP} - 1.1$  ( $n = 7$ ,  $r = 0.97$ ), (amount of actin) =  $0.42 \times \text{CLOGP} - 0.79$  ( $n = 7$ ,  $r = 0.99$ ) when CLOGP values of compounds were over 1.5, with the exception of Toyopearl conjugated to indomethacin. On the other hand, resins bearing hydrophilic ligands, whose CLOGP is less than 1.5, showed small amounts of actin and tubulin. According to our knowledge, this is the first report that shows the a quantitative relationship between the amount of nonspecific protein binding and affinity resin hydrophobicity.

Since this relationship suggested that reducing ligand hydrophobicity will be effective for the minimizing of the nonspecific protein binding to affinity matrixes, we next attempted to introduce hydrophilic spacer (**26**) between the ligand and base resin (Figure 5A and 5B). The amount of nonspecific protein binding proteins decreased in proportion to the number of spacer monomers while that of the target protein, FKBP12, is essentially constant. These results exhibited the effectiveness of the

introduction of a hydrophilic spacer to reduce the unfavorable proteins on Toyopearl resin.

It is known that the addition of surface-active agents into affinity chromatography buffers is effective for reducing nonspecific protein binding, because such reagents can noncovalently convert hydrophobic surfaces to hydrophilic ones. But the use of surface-active agents is not always useful because their addition sometimes causes the denaturation of the target proteins while the introduction of a hydrophilic spacer is not thought to affect the activities of proteins. Dextran, a sugar derivative and similar to agarose, has been used as a hydrophilic spacer to reduce nonspecific binding as well (27); however, it is chemically unstable like that of AffiGel. On the other hand, the PEG type of hydrophilic spacer (**26**) is chemically stable, making it suitable for a variety of applications. We believe that the utility of the PEG type spacer is not restricted to affinity resins but that these moieties could also have useful applications in the reduction of nonspecific protein binding on artificial materials in life science. We also apply the spacer on gold surfaces for SPR (surface plasmon resonance) chemistry to reduce noise in the BIACORE experiments and observed similar results described in this paper (data will be reported). Therefore, results described in this work could be effective for reduction of nonspecific protein binding in a wide range of experimental studies involving native proteins.

The nonspecific binding proteins were still observed even after repeated introduction of the spacer (Figure 5A), which indicated that the effect reaches a maximum and that it may be difficult to remove them completely only by introduction of the PEG spacer. We are now developing other hydrophilic and chemically stable spacers and other methods to introduce hydrophilicity on the surface of affinity resins to completely eliminate the nonspecific proteins. Their synthesis and application will be reported in the future.

#### ACKNOWLEDGMENT

We thank Dr. Isao Nakanishi (Exploratory Research Laboratories, Fujisawa Pharmaceutical Co., Ltd.) for calculation of CLOGP values. We also express our thanks

to Prof. James K. Chen (Department of Molecular Pharmacology, Stanford University School of Medicine) and Dr. Masayuki Haramura (Reverse Proteomics Research Institute Co., Ltd.) for critical reading of this manuscript.

- (15) As described in the text, AffiGel is stable in aqueous solution and usually used in aqueous solutions. However, it is impossible to use an excess amount of ligand for immobilization since we usually synthesize the compound with linker moiety via more than several synthetic steps, and only small amounts are available. Thus, the immobilization reaction, such as amide formation, needed to be carried out in organic solvent to avoid the presence of water. But AffiGel is sometimes irreversibly denatured in organic solvent and sometimes gives false-positive targets; for example, we found a novel nonspecific binding protein when we synthesized affinity material bearing FK506 in acetonitrile while it was not detected when prepared in an aqueous solution.

- (22) TentaGel is used as basal matrix in peptide library screening. We thought that proteins only bind to the very outside surface of TentaGel, so it works well only when hydrophilic ligands such as peptides are immobilized on it, and it does not work when hydrophobic ligands such as FK506 are on it because they tend to bind to the hydrophobic basal resin, which consists of polystyrene. It is usually impossible because the length of spacer moiety of the usual affinity resins is not enough while the length of TentaGel is very long; the average number of PEG polymer is ca. 66.
- (23) Dean, P. M. (1987) Molecular foundation of drug-receptor interaction. Cambridge University Press, England.
- (24) It was known that enzyme activities were still observed after absorption on *n*-octyl-agarose (11). These results indicated that the conformation of proteins was not unique; that is, some of them were completely denatured and others were partially denatured; moreover, native proteins can also bind on the surface that are occupied by various conformational states of the enzymes.
- (25) There are many surface-active agents that include PEG in their structures as a hydrophilic moiety; for examples, polyoxyethylene(23) lauryl ether ("Brij 35") and other "Brij" series, polyoxyethylene branched monocyclohexyl ether ("Triton") and other "Triton" series, and polyoxyethylene(20) sorbitan monolaurate ("Tween20") and others in the "Tween" series.
- (26) For example, the average repetition number of oxyethylene unit of TentaGel's PEG moiety is 68, and the number is not unique.
- (27) Dextran is used as hydrophilic spacer in the Biacore chips. Dextran plays as a spacer between gold foil and ligands in the Biacore system. We have observed nonspecific binding proteins after treatment of the gold foil bearing a ligand via the Dextran spacer with acetonitrile (data not shown).

ICIS, CNR Corso Stati Uniti, 4, 35020 Padova, Italy, Harvard Medical School and Brigham and Woman's Hospital, Boston, Massachusetts 02115, and Laboratory of Nuclear Medicine, Department of Clinical and Experimental Medicine, University of Ferrara, Via L. Borsari, 46, 44100 Ferrara, Italy. Received June 19, 2003; Revised Manuscript Received August 27, 2003

The incorporation of a bioactive molecule into a nitrido-containing  $^{99m}\text{Tc}$ -complex has been successfully achieved by using the [ $\text{TcN}(\text{PNP})$ ] $^{2+}$  metal fragment. In this strategy, the strong electrophilic [ $\text{TcN}(\text{PNP})$ ] $^{2+}$  metal fragment efficiently reacts with bifunctional chelating ligands having a  $\pi$ -donor atom set, such as *N*-functionalized *O,S*-cysteine. The 2-methoxyphenylpiperazine (2-MPP) pharmacophore, which displays preferential affinity for 5HT<sub>1A</sub> receptors, was conjugated to the amino group of cysteine to obtain 2-MPPP-cys-OS, where 2-MPPP is 3-[4-(2-methoxyphenyl)piperazin-1-yl]propionate. The asymmetric Tc(V)-nitrido complexes, [ $^{99g/99m}\text{Tc}(\text{N})(\text{PNP})(2\text{-MPPP-cys-OS})$ ] (PNP = PNP3, PNP4), were obtained in high yield (95%), by simultaneous addition of PNP and 2-MPPP-cys-OS ligand to a solution containing a starting  $^{99g/99m}\text{Tc}$ -nitrido precursor. A mixture of syn and anti isomers was observed, the latter being the thermodynamically favored species. In vitro challenge experiments using the anti isomers with glutathione and cysteine indicated that no transchelation reaction occurs. Assessment of the in vitro 5HT<sub>1A</sub> receptor-affinity of the technetium complexes revealed that only the *anti*-PNP4 complex possesses some affinity for the receptor, but displayed negligible brain uptake in biodistribution studies in rats in vivo.

## INTRODUCTION

One aspect of radiopharmaceutical development focuses on the design and synthesis of imaging agents that target specific receptors and transporters involved in certain pathological conditions. In vivo imaging via positron emission tomography (PET) provides the means to visualize receptor and transporter densities in living subjects and to estimate the inhibition of receptor, transporter density, and binding of endogenous (neurotransmitter) or exogenous (e.g. neuroleptic drug) ligands. This methodology is of general importance in elucidating how various neuropsychiatric conditions unfold in human subjects and for establishing the mechanism and efficacy of drug-treatment strategies. In this regard, investigation of the serotonergic system, which is implicated in several neuropsychiatric disorders including anxiety, depression, schizophrenia, and Alzheimer's disease, has been a subject of particular interest. Recent reports have described [ $^{11}\text{C}$ ]WAY-100635 as a  $^{11}\text{C}$ -labeled radioligand that may provide a means to noninvasively image the 5HT<sub>1A</sub> receptors with PET (1, 2). While this agent is a potent and selective 5HT<sub>1A</sub> receptor antagonist, its initial high signal-to-noise ratio is compromised by the in vivo formation of small amounts of labeled metabolites that bind nonspecifically in various brain regions, thereby reducing image contrast. Thus the search for and devel-

opment of new 5HT<sub>1A</sub> radioligands is under active investigation (3, 4).

Given the general availability in most nuclear medicine facilities of single-photon-emission tomography (SPECT) instrumentation compared with that for PET, the widespread availability of  $^{99}\text{Mo}$ – $^{99m}\text{Tc}$  generators, and the near ideal imaging characteristics of  $^{99m}\text{Tc}$  via SPECT, the potential utility of a technetium-99m-labeled receptor-specific agent for 5HT<sub>1A</sub> would be of interest. Thus, over the past few years various approaches have been proposed for synthesizing  $^{99m}\text{Tc}$ -complexes capable of selectively binding central nervous system (CNS) 5HT<sub>1A</sub> receptors. Most of the reported complexes are based on the monooxo-Tc(V) core (5–11), with one utilizing the organometallic [ $^{99m}\text{Tc}(\text{CO})_3$ ] $^{+}$  metal fragment (12). Among all these strategies, however, the  $\text{Tc}\equiv\text{N}$  core has yet to be developed for synthesizing  $^{99m}\text{Tc}$ -labeled, receptor-targeting radiopharmaceuticals. To explore the utility of the  $\text{Tc}\equiv\text{N}$  core, we have developed a simplified route to incorporate biologically active molecules into stable  $^{99m}\text{Tc}$ -nitrido complexes. The strategy relies on the presence of asymmetric complexes containing two different polydentate ligands bound to the [ $\text{Tc}\equiv\text{N}$ ] $^{2+}$  core (13). The synthesis entails the initial preparation of the substitution inert [ $\text{Tc}(\text{N})(\text{PXP})$ ] $^{2+}$  moiety, a strongly electrophilic fragment, that selectively reacts with bidentate chelating ligands (YZ) possessing  $\pi$ -donors as coordinating atoms, to form heterocomplexes of the type [ $\text{Tc}(\text{N})(\text{YZ})(\text{PXP})$ ] $^{0/+}$  (14, 15); thus, for example, cysteine readily reacts as a bidentate ligand with the precursor complex [ $^{99m}\text{Tc}(\text{N})(\text{PXP})\text{Cl}_2$ ] via [O-, S-] or [NH<sub>2</sub>, S-] coordination in a nearly stoichiometric ratio, demonstrating that a terminal cys-

**Figure 1.** Diphosphine (PNP) and bifunctional ligands utilized in this study.

teine group can act as an efficient chelating system for this metal fragment.

The general requirements for a compound to cross the blood–brain barrier (BBB) in appreciable amounts must be met when designing complexes to target CNS receptors. These include that the complex be neutral in charge, lipophilic in character, and possess a molecular weight lower than 700 Da. Considering these criteria, we focused on di-negative [O-,S-], N-functionalized, cysteine-containing ligands, with the cysteine N-terminus conjugated via a propionate link to the biological molecule of interest, the arylpiperazine [(2-methoxyphenyl)piperazine], known to be active toward the 5HT<sub>1A</sub> subclass of serotonergic receptors. The final bidentate ligand (2-MPPP-cys-OS), when reacted with the [<sup>99m</sup>Tc(N)(PXP)Cl<sub>2</sub>] fragment would thus provide Tc≡N-based neutral, lipophilic complexes and a means of assessing the feasibility of this approach.

Herein we report the application of this labeling procedure to the preparation of asymmetrical <sup>99g</sup>/<sup>99m</sup>Tc-nitrido complexes with the diphosphine ligands PNP3 and PNP4 and the bidentate chelating ligand 2-MPPP-cys-OS (Figure 1).

#### EXPERIMENTAL PROCEDURES

**Caution!** <sup>99g</sup>Tc is a weak β<sup>-</sup>-emitter ( $E_{\beta^-} = 0.292$  MeV,  $t_{1/2} = 1.12 \times 10^5$  years). All manipulations were carried out in laboratories approved for low-level radioactivity use. Handling milligram amounts of <sup>99g</sup>Tc does not present a serious health hazard since common laboratory glassware provides adequate shielding and all work is performed in approved and monitored hoods and glove-boxes. Bremsstrahlung is not a significant problem due to the low energy of the β-particles; however, proper radiation safety procedures must be followed at all times, and particular care should be taken when handling solid samples.

**General.** All chemicals and reagents were purchased from Aldrich Chemicals. All solvents were reagent grade and were used without further purification. Due to the tendency of the diphosphine ligands to oxidize, all the solvents used in reactions with PNP3 and PNP4 were previously degassed to remove dissolved trace oxygen.

Commercially available NH<sub>4</sub>[<sup>99g</sup>TcO<sub>4</sub>] (Oak Ridge National Laboratories) was purified from a black contaminant (<sup>99g</sup>TcO<sub>2</sub> × *n*H<sub>2</sub>O) by addition of H<sub>2</sub>O<sub>2</sub> and NH<sub>4</sub>OH solutions followed by recrystallization as NH<sub>4</sub>[<sup>99g</sup>TcO<sub>4</sub>] from hot water. Technetium-99m as Na[<sup>99m</sup>TcO<sub>4</sub>] was eluted from a <sup>99</sup>Mo–<sup>99m</sup>Tc generator provided by Nymed Amersham-Sorin (Saluggia, Italy). [<sup>99g</sup>Tc(N)Cl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] was prepared as previously described (16). The diphosphine ligands bis(dimethoxypropylphosphinoethyl)methoxyethylamine, [PNP3 = (CH<sub>3</sub>OC<sub>3</sub>H<sub>6</sub>)<sub>2</sub>P(CH<sub>2</sub>)<sub>2</sub>N(C<sub>2</sub>H<sub>4</sub>OCH<sub>3</sub>)(CH<sub>2</sub>)<sub>2</sub>P(C<sub>3</sub>H<sub>6</sub>OCH<sub>3</sub>)<sub>2</sub>] and bis(dimethylphosphinoethyl)methylamine [PNP4 = (CH<sub>3</sub>)<sub>2</sub>P(CH<sub>2</sub>)<sub>2</sub>N(CH<sub>3</sub>)(CH<sub>2</sub>)<sub>2</sub>P(CH<sub>3</sub>)<sub>2</sub>] were purchased from Argus Chemicals (Prato, Italy). [<sup>3</sup>H]-8-Hydroxy-*N,N*-dipropyl-2-amino-

tetralin ([<sup>3</sup>H]-8-OH-DPAT, specific activity = 147.2 Ci/mmol) and Aquasure were purchased from New England Nuclear Research Products (NEN, Boston, MA). Female Sprague–Dawley rats were acquired from Morini (Reggio Emilia, Italy).

Elemental analyses (C, H, N, S) were performed on a Carlo Erba 1106 elemental analyzer. FT IR spectra were recorded on a Nicolet 510P Fourier transform spectrometer, in the range 4000–200 cm<sup>-1</sup> and in KBr mixture using a Spectra-Tec diffuse-reflectance collector accessory. <sup>1</sup>H, <sup>13</sup>C, and <sup>31</sup>P NMR spectra were collected on a Bruker 300 instrument, using SiMe<sub>4</sub> as internal reference (<sup>1</sup>H and <sup>13</sup>C) and 85% aqueous H<sub>3</sub>PO<sub>4</sub> as external reference (<sup>31</sup>P).

Chromatographic purification of the compounds was accomplished on silica gel columns: for the bifunctional ligand, 120 × 5 cm, 70–230 mesh (Aldrich) and for the asymmetrical <sup>99g</sup>Tc-complexes, 30 × 2 cm, 70–230 mesh (Merck). Thin-layer chromatography (TLC) (SiO<sub>2</sub> F<sub>254</sub>S, Merck) and high performance liquid chromatography (HPLC) analyses were used to evaluate the radiochemical purity (RCP) and stability of the compounds. Radioactivity on TLC plates was detected and measured using a Cyclone instrument equipped with a phosphorus imaging screen and OptiQuant image analysis software (Packard, Meridian, CT). HPLC was performed on a Beckman System Gold instrument equipped with a programmable solvent Model 126, a sample injection valve 210A, a scanning detector Module 166, and a radioisotope detector Model 170. HPLC analysis was carried out on a reversed-phase Hamilton PRP-1 precolumn (45 × 4.1 mm), and a reversed-phase Hamilton PRP-1 column (250 × 4.1 mm, Ø = 10 μm) using the chromatographic condition reported in Table 1; flow rate: 1 mL/min. Log *k'*<sub>0</sub> of the complexes was determined by HPLC chromatography as reported previously (17). The results are summarized in Table 1.

**3-[4-(2-Methoxyphenyl)piperazin-1-yl]propionic Acid Methyl Ester (1).** 1-(2-Methoxyphenyl)piperazine hydrochloride (2-MPP) (4 g, 0.017 mol) and *N,N*-diisopropylethylamine (4.49 g, 0.035 mol) were dissolved in CH<sub>2</sub>Cl<sub>2</sub> (150 mL). To this solution was added methyl 3-bromopropionate (1.947 g, 0.012 mol), and the reaction mixture was stirred at room-temperature overnight. The solvent was evaporated, and the residual oil was suspended in water (50 mL) and extracted with CH<sub>2</sub>Cl<sub>2</sub> (50 mL × 3). The combined CH<sub>2</sub>Cl<sub>2</sub> layers were reduced in volume, and the resulting pale yellow oil was purified by silica gel chromatography eluting with CH<sub>2</sub>Cl<sub>2</sub> followed by a 3% MeOH/CH<sub>2</sub>Cl<sub>2</sub> solution (3.51 g, 72%). <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ: 6.97–6.82 (4H, Ar), 3.82 (s, 3H, OCH<sub>3</sub>), 3.66 (s, 3H, CH<sub>3</sub>), 3.06 (m, 4H, CH<sub>2</sub>), 2.76 (t, 2H, CH<sub>2</sub>CO), 2.65 (m, 4H, CH<sub>2</sub>), 2.54 (t, 2H, CH<sub>2</sub>). Anal. Calcd for C<sub>15</sub>H<sub>22</sub>N<sub>2</sub>O<sub>3</sub>: C, 64.73; H, 7.97; N 10.06; O, 17.24; found: C, 64.72; H, 7.79; N, 10.06; O, 17.02.

**3-[4-(2-Methoxyphenyl)piperazin-1-yl]propionate (2).** Compound 1 (3.42 g, 12.3 mmol) was dissolved in MeOH (30 mL), and 10 mL of an aqueous solution containing KOH (1.034 g, 18.4 mmol) was added. The reaction mixture was stirred at room temperature for 1 h. The solvent was evaporated, and the residue, dissolved in the minimum amount of CH<sub>2</sub>Cl<sub>2</sub>, was purified by chromatography using a short silica gel column eluted with 20% MeOH/CH<sub>2</sub>Cl<sub>2</sub> solution (3.01 g, 81%). <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ: 7.08–6.89 (4H, Ar), 3.89 (s, 3H, OCH<sub>3</sub>), 3.24 (m, 4H, CH<sub>2</sub>), 3.02 (m, 4H, CH<sub>2</sub>), 2.96 (t, 2H, CH<sub>2</sub>CO), 2.63 (t, 2H, CH<sub>2</sub>). Anal. Calcd for C<sub>14</sub>H<sub>19</sub>KN<sub>2</sub>O<sub>3</sub>: C, 55.60; H, 6.33; N, 9.26; O, 15.87; found: C, 55.02; H, 6.55; N, 9.31; O, 15.8.

**2-Amino-3-tritylsulfanyl-propionic Acid Ethyl Ester (3).** A suspension of (S)-trityl-L-cysteine (1.125 g, 3.1 mmol) and ethyl *p*-toluenesulfonate (2.250 g, 6.2 mmol) in dry ethanol was refluxed under an argon atmosphere for 48 h, during which time dissolution occurred. After evaporation of the solvent, the residue was dissolved in 30 mL of an aqueous solution of KHCO<sub>3</sub> (pH 8) and extracted three times with an equal volume of CH<sub>2</sub>Cl<sub>2</sub>. The combined organic phases were evaporated, and the pale yellow oil was redissolved in the minimum amount of CH<sub>2</sub>Cl<sub>2</sub>. Finally, Et<sub>2</sub>O was added to precipitate a white powder. The precipitate was separated by filtration, and the ether filtrate was evaporated to obtain the crude ester. Purification was achieved by SiO<sub>2</sub> chromatography, eluting with a 2% MeOH/CH<sub>2</sub>Cl<sub>2</sub> solution (0.97 g, 80%) <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ: 7.46–7.23 (15H, Ar), 4.14 (q, 2H, CH<sub>2</sub>O), 3.22 (m, 1H, CHNH<sub>2</sub>), 2.59 (q, 1H, CH<sub>2</sub>S), 2.50 (q, 1H, CH<sub>2</sub>S), 1.25 (t, 3H, CH<sub>3</sub>). Anal. Calcd for C<sub>24</sub>H<sub>25</sub>N<sub>2</sub>O<sub>2</sub>S: C, 73.62; H, 6.44; N, 3.58; S, 8.19; found: C, 73.02; H, 6.96; N, 3.66; S, 8.06.

**2-{3-[4-(2-Methoxyphenyl)piperazin-1-yl]propionylamino}-3-trityl-sulfanylpropionic Acid Ethyl Ester (4).** Compounds **2** (0.310 g, 1.15 mmol) and **3** (0.45 g, 1.15 mmol) were dissolved in CH<sub>2</sub>Cl<sub>2</sub> (30 mL). The solution was cooled at –78 °C in a dry ice acetone bath, and 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide (EDC) (0.330 g, 1.73 mmol), previously dissolved in the minimum amount of DMF, was added. The reaction mixture was stirred at –78 °C, under argon atmosphere for 1 h, allowed to reach room temperature, and stirred overnight. The solvent was removed, and the residue was subjected to H<sub>2</sub>O/CH<sub>2</sub>Cl<sub>2</sub> extraction. The combined CH<sub>2</sub>Cl<sub>2</sub> layers were dried with anhydrous Na<sub>2</sub>SO<sub>4</sub>, evaporated to minimum volume, and purified by SiO<sub>2</sub> chromatography eluting with 3% MeOH/CH<sub>2</sub>Cl<sub>2</sub> solution (0.70 g, 96%). <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ: 9.53 (d, 1H, NH), 7.36–7.18 (15H, Ar), 7.03–6.80 (4H, Ar), 4.73 (m, 1H, CHNH), 4.15 (t, 2H, CH<sub>2</sub>N<sub>pip</sub>), 3.87 (s, 3H, OCH<sub>3</sub>), 3.14 (m, 4H, CH<sub>2</sub>N<sub>pip</sub>), 2.93 (m, 2H, CH<sub>2</sub>CO), 2.79 (m, 4H, CH<sub>2</sub>N<sub>pip</sub>), 2.64 (q, 1H, CH<sub>2</sub>OC(O)), 2.53 (q, 1H, CH<sub>2</sub>OC(O)), 2.45 (d, 2H, CH<sub>2</sub>S), 1.25 (t, 3H, CH<sub>3</sub>). Anal. Calcd for C<sub>38</sub>H<sub>43</sub>N<sub>3</sub>O<sub>4</sub>S: C, 71.56; H, 6.79; N, 5.58; S, 5.03; found: C, 70.18; H, 6.80; N, 6.59; S, 5.03.

**2-{3-[4-(2-Methoxyphenyl)piperazin-1-yl]propionylamino}-3-trityl-sulfanylpropionic Acid (5).** Compound **4** (2.027 g, 0.0032 mol) was dissolved in MeOH (30 mL), and 5 mL of an aqueous solution containing KOH (0.267 g, 0.005 mol) was added. The reaction mixture was stirred at room temperature for 1 h. After the solvent was evaporated, the residue was redissolved in water, the pH was adjusted to 3 with HCl (2 M), and

the ligand was extracted with CH<sub>2</sub>Cl<sub>2</sub> (30 mL × 3). The combined CH<sub>2</sub>Cl<sub>2</sub> layers were reduced to a minimum volume with the pure hydrochloride salt precipitating as a white powder with the addition of anhydrous Et<sub>2</sub>O (1.61 g, 83%). The powder was dissolved in methanol and treated with KHCO<sub>3</sub> to obtain the free base. <sup>1</sup>H NMR (CD<sub>3</sub>COOD) δ: 7.85 (s, 1H, NH), 7.42–7.21 (15H, Ar), 7.10–6.93 (4H, Ar), 4.44 (t, 1H, CHNH), 3.89 (s, 3H, OCH<sub>3</sub>), 3.37–3.26 (m, 12H, alkyl), 2.73–2.66 (m, 4H, alkyl). FT IR (cm<sup>–1</sup>): [3258 ν (NH)], [2930–2835 ν (CH<sub>2</sub>–CH<sub>2</sub>)], [1750 ν (COOH)], [1683 ν (CONH)], [1240 ν (OCH<sub>3</sub>)], [743, 701 ν (CH=CH)]. Anal. Calcd for C<sub>36</sub>H<sub>39</sub>N<sub>3</sub>O<sub>4</sub>S·2HCl: C, 63.38; H, 6.05; N, 6.15; S, 4.7; found: C, 63.46; H, 6.85; N, 6.31; S, 4.59.

**2-{3-[4-(2-Methoxyphenyl)piperazin-1-yl]propionylamino}-3-sulfhydryl-propionic Acid (2-MPPP-cys-OS) (6).** Trityl deprotection of the thiol was performed by dissolving **5** (0.2 g, 0.293 mmol) in trifluoroacetic acid (TFA) (5 mL). The resulting yellow solution was stirred for 5 min, and then triethylsilyl hydride was added by drops until the solution became colorless. The solution was evaporated to dryness to remove TFA and subsequently dried under vacuum and used without further purification.

**Synthesis of [<sup>99g</sup>Tc(N)Cl<sub>2</sub>(PNP3)] (7).** To [Tc(N)Cl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] (118 mg, 0.166 mmol) suspended in CH<sub>2</sub>Cl<sub>2</sub> (10 mL) was added PNP3 (120 mg, 0.248 mmol) dissolved in CH<sub>2</sub>Cl<sub>2</sub> (5 mL). The solution was stirred at reflux for 30 min. The initial orange-pink solution changed color to yellow. After the solution was cooled, the solvent was removed by a gentle stream of nitrogen and the oily residue was washed with Et<sub>2</sub>O, dissolved in the minimum amount of EtOH, and precipitated with *n*-hexane. The yellow powder was collected by filtration, washed with Et<sub>2</sub>O and *n*-hexane again, and dried under vacuum (94.04 mg, 85%). <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ: 3.44–1.63 (H, alkyl). <sup>31</sup>P NMR (CDCl<sub>3</sub>) δ: 31.0 (broad singlet). FT IR (cm<sup>–1</sup>): [1054 ν (Tc≡N)], [2979–2817 ν (C–H)]. Anal. Calcd for C<sub>23</sub>H<sub>51</sub>N<sub>2</sub>O<sub>5</sub>P<sub>2</sub>Cl<sub>2</sub>Tc: C, 41.38; H, 7.71; N, 4.21; found: C, 40.57; H, 7.87; N, 4.51.

**Synthesis of [<sup>99g</sup>Tc(N)Cl<sub>2</sub>(PNP4)] (8).** To [Tc(N)Cl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] (90 mg, 0.130 mmol) suspended in CH<sub>2</sub>Cl<sub>2</sub> (10 mL) was added PNP4 (30 mg, 0.145 mmol) dissolved in EtOH (5 mL). The solution was stirred at room temperature for 30 min during which time the initial orange-pink solution changed color to yellow. The solvent was removed by a gentle stream of nitrogen, and the residue was washed with Et<sub>2</sub>O and treated with *n*-hexane. The precipitated yellow residue was redissolved in methanol, and a residual white powder was separated by filtration. The yellow filtrate was evaporated, and the residue was

treated with Et<sub>2</sub>O to provide a yellow precipitate, which was collected by filtration, washed with Et<sub>2</sub>O and *n*-hexane, and dried under vacuum (40.67 mg, 80%). <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ: 2.47 (m, 4H, NCH<sub>2</sub>), 2.26 (m, 2H, PCH<sub>2endo</sub>), 2.11 (s, 3H, NCH<sub>3</sub>), 1.92 (m, 2H, PCH<sub>2exo</sub>), 2.02, 1.99, 1.78, 1.76 (4s, 12H, PCH<sub>3</sub>). <sup>13</sup>C NMR (CDCl<sub>3</sub>) δ: 51.88 (NCH<sub>2</sub>), 46.20 (NCH<sub>3</sub>), 27.65, 27.45 (PCH<sub>2</sub>), 17.96, 17.76, 14.98, 14.76 (PCH<sub>3</sub>). <sup>31</sup>P NMR (CDCl<sub>3</sub>) δ: 23.1 (bs). FT IR (cm<sup>-1</sup>): [1045 ν (Tc≡N)], [2971–2804 ν (C–H)]. Anal. **Synthesis of [<sup>99g</sup>Tc(N)(2-MPPP-cys-OS)(PNP3)] Anti (9a) and Syn (9b).** *Method A:* Compound **7** (57.3 mg, 0.086 mmol) was dissolved in EtOH (5 mL) along with five drops of neat Et<sub>3</sub>N. To this solution was added 2-MPPP-cys-OS ligand (41 mg, 0.108 mmol) dissolved in CH<sub>2</sub>Cl<sub>2</sub> (5 mL). The reaction mixture was stirred at reflux for 60 min. No apparent color change from yellow was observed during the reaction. After the solution was cooled, the solvent was removed, and the residue was washed with Et<sub>2</sub>O. The yellow oily residue was dissolved in the minimum amount of CHCl<sub>3</sub> and chromatographed on a silica column, preconditioned with CHCl<sub>3</sub>, and eluted with a mixture of CHCl<sub>3</sub>/MeOH/NH<sub>4</sub>OH (20%) (95/5/3). Two yellow bands were separated and collected; the first fraction was identified (vide infra) as the pure anti isomer **9a** (35%, based on Tc) and the second fraction as the pure syn isomer **9b** (29%, based on Tc).

*Method B:* To [<sup>99g</sup>Tc(N)Cl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] (29.32 mg, 0.041 mmol) suspended in CH<sub>2</sub>Cl<sub>2</sub> (5 mL) were added PNP3 (20 mg, 0.043 mmol) dissolved in CH<sub>2</sub>Cl<sub>2</sub> (5 mL), 2-MPPP-cys-OS ligand (37.08 mg, 0.060 mmol) dissolved in CH<sub>2</sub>Cl<sub>2</sub> (5 mL), and neat Et<sub>3</sub>N (five drops). Within 10 min the initial orange-pink solution turned yellow. The reaction mixture was further stirred at room temperature under a nitrogen atmosphere, for 1 h. The solvent was evaporated, and the crude yellow residue was dissolved in CHCl<sub>3</sub> (1 mL) and chromatographed on silica. After the column was eluted with the mobile phase described above, two yellow bands were separated and isolated as yellow oily residues. The first fraction was identified as the anti isomer **9a** (48.5%, based on Tc) and the second fraction as the syn isomer **9b** (43.6%, based on Tc). These two isomers were identical to those prepared by method A, as confirmed by TLC, HPLC, and NMR data.

Complex **9a** was soluble in chlorinate solvents and in alcohols, and insoluble in diethyl ether and *n*-hexane. <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ: 8.04 (d, 1H, NHC(O)), 7.00–6.82 (4H, C<sub>6</sub>H<sub>4</sub>OCH<sub>3</sub>), 4.83 (m, 1H, CHNHC(O)), 3.85 (s, 3H, C<sub>6</sub>H<sub>4</sub>OCH<sub>3</sub>), 3.36–3.19 (5s, 15H, aliphatic OCH<sub>3</sub>), 3.32 and 2.41 (m, 2H, S–CH<sub>2exo</sub> and S–CH<sub>2endo</sub>), 3.16 and 2.74 (bs, 4H+4H, CH<sub>2pip</sub>), 3.55–1.55 (36H+4H, CH<sub>2</sub> groups). <sup>13</sup>C NMR (CDCl<sub>3</sub>) δ: 177.65, 170.75 (C=O), 152.28, 141.42, 122.75, 120.96, 118.39, 111.21 (C<sub>6</sub>H<sub>4</sub>OCH<sub>3</sub>), 73.14, 72.93, 72.63, 72.48, 68.34 (CH<sub>2</sub>O), 58.67, 58.57 (OCH<sub>3</sub>), 56.63 (SCH<sub>2</sub>CH), 55.37 (C<sub>6</sub>H<sub>4</sub>OCH<sub>3</sub>), 54.13 (CH<sub>2</sub>N<sub>pip</sub>), 53.03 (CH<sub>2pip</sub>), 51.54 (NCH<sub>2</sub>CH<sub>2</sub>OCH<sub>3</sub>), 50.48 (CH<sub>2pip</sub>), 47.27, 46.13 (NCH<sub>2</sub>CH<sub>2</sub>P), 33.47, 29.70 (SCH<sub>2</sub>CH), 25.77, 24.77, 23.85, 22.80, 18.20, 16.27 (PCH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OCH<sub>3</sub>). <sup>31</sup>P NMR (CDCl<sub>3</sub>) δ: 32.8 (broad s), 25.4 (broad s). FT IR (cm<sup>-1</sup>): [1050 ν (Tc≡N)], [3300 ν (NH)], [2933–2817 ν (C–H)], [1732 ν (CO)O], [1636 ν NH(CO)], [1240 ν (OCH<sub>3</sub>)], [749 ν (b, CH=CH)]. Anal. **Synthesis of [<sup>99g</sup>Tc(N)(2-MPPP-cys-OS)(PNP4)] Anti (10a) and Syn (10b).** *Method A:* To compound **8** (33.56 mg, 0.086 mmol) dissolved in EtOH (5 mL) were added neat Et<sub>3</sub>N (five drops) and 2-MPPP-cys-OS ligand (39 mg, 0.103 mmol) dissolved in CH<sub>2</sub>Cl<sub>2</sub> (5 mL). The mixture was stirred at reflux for 60 min. No color change from the initial yellow was observed throughout the reaction. After the solution was cooled, the solvent was removed by a gentle stream of nitrogen and the residue was washed with Et<sub>2</sub>O followed by *n*-hexane. The yellow oil was dissolved in the minimum amount of CH<sub>2</sub>Cl<sub>2</sub> and loaded onto a silica column conditioned with CH<sub>2</sub>Cl<sub>2</sub>. The column was eluted with a mixture of CH<sub>2</sub>Cl<sub>2</sub>/MeOH/NH<sub>4</sub>OH (20%) (89/10/1), and two yellow bands were separated and collected. The eluate was evaporated, and the residues were treated with Et<sub>2</sub>O to precipitate the complexes. The first pale yellow product was identified as the pure anti isomer **10a** (35%, based on Tc) and the second lemon-yellow complex as the pure syn isomer **10b** (19%, based on Tc).

*Method B:* To [<sup>99g</sup>Tc(N)Cl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] (30.6 mg, 0.043 mmol) suspended in CH<sub>2</sub>Cl<sub>2</sub> (5 mL) were added PNP4 (10 mg, 0.048 mmol) dissolved in CH<sub>2</sub>Cl<sub>2</sub> (5 mL), 2-MPPP-cys-OS ligand (38 mg, 0.062 mmol) dissolved in CH<sub>2</sub>Cl<sub>2</sub> (5 mL), and an excess of Et<sub>3</sub>N (five drops). The reaction mixture was stirred at reflux for 1 h under nitrogen atmosphere. The initial orange-pink solution turned yellow. After the solution was cooled, the solvent was evaporated, and the resulting oily residue was dissolved in CH<sub>2</sub>Cl<sub>2</sub> (1 mL) and chromatographed on a silica column using the conditions described above. Two fractions were collected, **10a** (48.5%, based on Tc) and **10b** (19.5%, based on Tc). These two isomers were identical to those prepared by method A, as confirmed by TLC, HPLC, and NMR data.

Complex **10a** was soluble in chlorinate solvents and alcohols and insoluble in diethyl ether. <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ: 8.33 (d, 1H, NHC(O)), 6.98–6.83 (4H, C<sub>6</sub>H<sub>4</sub>OCH<sub>3</sub>), 4.89 (m, 1H, CHNHC(O)), 3.86 (s, 3H, C<sub>6</sub>H<sub>4</sub>OCH<sub>3</sub>), 3.34 (dd, 1H, SCH<sub>2exo</sub>), 2.47 (m, 1H; SCH<sub>2endo</sub>), 3.17 (bs, 4H, CH<sub>2pip</sub>), 2.78 (m 6H; CH<sub>2pip</sub>, CH<sub>2zen</sub>), 2.47 (m, 2H, CH<sub>2zen</sub>), 2.6–1.9 (8H, PCH<sub>2</sub>CH<sub>2</sub>N), 2.0 (s, 3H, NCH<sub>3</sub>), 1.78, 1.75, 1.72, 1.69 (4s, 12H, P–CH<sub>3</sub>). <sup>13</sup>C NMR (CDCl<sub>3</sub>) δ: 177.95–170.67 (C=O), 152.19, 141.29, 122.70, 120.88, 118.39, 111.10 (C<sub>6</sub>H<sub>4</sub>OCH<sub>3</sub>), 56.92 (SCH<sub>2</sub>CH), 55.32 (OCH<sub>3</sub>), 54.13 (CH<sub>2</sub>N), 52.97, 50.36 (CH<sub>2pip</sub>); 51.80, 51.19 (PCH<sub>2</sub>CH<sub>2</sub>N), 45.05 (NCH<sub>3</sub>), 33.28 (C(O)CH<sub>2</sub>CH<sub>2</sub>N), 30.13 (SCH<sub>2</sub>CH), 28.27 (d), 26.19 (d, P–CH<sub>2</sub>), 19.13 (d), 15.46 (d), 13.55 (d), 11.75 (d, P–CH<sub>3</sub>). <sup>31</sup>P NMR (CDCl<sub>3</sub>) δ: 20.0 (broad s), 14.0 (broad s). **Syn → Anti Isomerization of [<sup>99m</sup>Tc(N)(2-MPPP-cys-OS)(PNP3/4)].** *Effect of pH:* In a propylene test tube containing EtOH (0.250 mL) and an alcoholic solution of the selected <sup>99m</sup>Tc-complex (10 mM, 0.050 mL) was added the appropriate buffer solution at pH 5–9 (0.250 mL). The mixture was vortexed and incubated at various temperatures (4 °C, 25 °C, 37 °C) for one week. A control reaction containing an equal volume of water, instead of buffer solution, was maintained in parallel. Aliquots of the reaction mixtures were withdrawn and analyzed by TLC and HPLC chromatography at appropriate time intervals (0 h, 12 h, 24 h, 3 d, 5 d, 7 d). The results are summarized in Table 2.

*Effect of Temperature:* In a propylene test tube containing EtOH (0.250 mL) and an alcoholic solution of the selected <sup>99m</sup>Tc-complex (10 mM, 0.050 mL), H<sub>2</sub>O (0.250 mL) was added. The mixture was vortexed and kept at 50 °C or 100 °C for various times (0, 15 min, 60 min, 120 min, 6 and 24 h). Aliquots of the reaction mixtures were withdrawn at the appropriate time and analyzed immediately by TLC and HPLC chromatography (Table 2).

*Challenge Reaction with Thioacetate:* In a propylene test tube containing EtOH (0.250 mL) and an alcoholic solution of **10b** (10 mM, 0.050 mL) was added an aliquot of an aqueous solution of sodium *O,S*-thioacetate (OS-TA) (20.0 mM). The volume of the resulting solutions, having final **10b**/thioacetate molar ratios of 1/1, 1/5, and 1/10, were adjusted to 0.5 mL with water. The mixtures were vortexed and heated at 50 °C or 100 °C for 24 h. A control reaction containing an equal volume of water without thioacetate was run in parallel. At 15 min, 4 h, and 24 h, aliquots of the reaction mixtures were withdrawn and analyzed by TLC and HPLC chromatography. The results are summarized in Table 3.

**Preparation of [<sup>99m</sup>Tc(N)(2-MPPP-cys-OS)(PNP3/4)] Anti (11a, 12a) and Syn (11b, 12b).** *Method A:* Na[<sup>99m</sup>TcO<sub>4</sub>] (0.250 mL, 50.0 MBq/3.0 GBq) was added to a

**Table 3. Incubation of *syn*-[<sup>99m</sup>Tc(N)(2-MPPP-cys-OS)(PNP4)] (10b) with Sodium *O,S*-Thioacetate (OS-ta)**

vial containing succinic dihydrazide (SDH) (5.0 mg) and SnCl<sub>2</sub> (0.1 mg) suspended in saline (0.1 mL) and ethanol (1.0 mL). The vial was kept at room temperature for 15 min giving a mixture of <sup>99m</sup>Tc-nitrido precursors [<sup>99m</sup>Tc≡N]<sub>mix</sub><sup>2+</sup>. The appropriate diphosphine ligand (PNP3 or PNP4) (1.0 mg), dissolved in EtOH (0.1 mL), was then added, and the reaction mixture was left standing for 30 min at room temperature. To the resulting intermediate complex [<sup>99m</sup>Tc(N)(PNP3/4)]<sup>2+</sup> was added an ethanolic solution (0.1 mL) containing the 2-MPPP-cys-OS ligand (1 mg, 1.6 × 10<sup>-3</sup> mmol), and the solution was heated at 100 °C for 30 min. TLC and HPLC characterization showed the presence of two separate radioactive spots, which resulted from the formation of two distinct isomeric forms (**a** and **b**) of the complex [<sup>99m</sup>Tc(N)(2-MPPP-cys-OS)(PNP3/4)]. Total radiochemical purity (RCP) as determined by TLC and HPLC chromatography for the two isomers was 90.4% for [<sup>99m</sup>Tc(N)(2-MPPP-cys-OS)(PNP3)] (**11a**, 78.3%; **11b**, 12.1%) and 80.7% for [<sup>99m</sup>Tc(N)(2-MPPP-cys-OS)(PNP4)] (**12a**, 65.7%; **12b**, 15%).

*Method B:* To a mixture of [Tc≡N]<sub>mix</sub><sup>2+</sup> prepared as above, an ethanolic solution (0.1 mL) containing 2-MPPP-Cys-OS (1 mg, 1.6 × 10<sup>-3</sup> mmol) was added, and the reaction vial was left to stand at room temperature for 30 min. The reaction mixture was then treated with PNP3 or PNP4 (1.0 mg) dissolved in EtOH (0.1 mL) and heated at 100 °C for 30 min. Total RCP determined by TLC and HPLC chromatography for the two isomers was 42% for [<sup>99m</sup>Tc(N)(2-MPPP-cys-OS)(PNP3)] (**11a**, 35.9%; **11b**, 6.1%) and 45% for [<sup>99m</sup>Tc(N)(2-MPPP-cys-OS)(PNP4)] (**12a**, 40.5%; **12b**, 4.5%). These products exhibited the same chromatographic profiles as those obtained by method A.

*Method C:* To [Tc≡N]<sub>mix</sub><sup>2+</sup> prepared as above, the appropriate diphosphine (PNP3 or PNP4) (1.0 mg) dissolved in EtOH (0.1 mL) and 2-MPPP-Cys-OS (0.1 mg, 0.16 × 10<sup>-3</sup> mmol) dissolved in EtOH (0.1 mL) were added simultaneously, and the reaction mixture was

heated at 100 °C for 30 min. Total RCP determined by TLC and HPLC chromatography was 98% for [<sup>99m</sup>Tc(N)-(2-MPPP-cys-OS)(PNP3)] (**11a**, 85%; **11b**, 13%) and 85.4% for [<sup>99m</sup>Tc(N)-(2-MPPP-cys-OS)(PNP4)] (**12a**, 76.9%; **12b**, 8.5%). In both cases, the major compound, **11a** or **12a**, isolated by HPLC (*t<sub>R</sub>* **11a** = 23.4 min, *t<sub>R</sub>* **12a** = 27.8 min), was concentrated on a Sep pack C18 column rinsed with H<sub>2</sub>O and eluted using EtOH (3 × 0.5 mL). The second fraction containing all the activity was diluted with saline (1/10 EtOH/saline) and utilized for in vitro stability studies and in vivo biodistribution studies. After this purification the RCP's of both complexes, evaluated by TLC and HPLC chromatography, was >95%. In all cases the pH of the reaction mixture, measured at the end of the reaction, was 7.5.

**Preparation of [<sup>99m</sup>Tc(N)(OS-ta)(PNP4)] (OS-ta = Thioacetate) (**13**).** This complex was synthesized as reported earlier (*14*).

**Determination of Partition Coefficients (Log *P*).** After HPLC purification, Log *P* values of the thermodynamically stable *anti*-Tc-99m complexes (**11a**, **12a**) were determined by measuring the activity that partitioned between *n*-octanol (3.0 mL) and aqueous phosphate buffer (3.0 mL, 0.1 M, pH 7.4) under strict equilibrium conditions. Results are presented in Table 1. The syn to anti conversion of **11b** and **12b** complexes precluded the measurements of their Log *P*, and these were therefore not determined by this method.

**Stability Studies.** Compound **11a** or **12a** (100 μL) was added to a 5-mL propylene test tube containing rat serum (900 μL) or saline (900 μL). The resulting mixture was incubated at 37 °C for 2 h and assayed at 15, 30, 60, and 120 min by TLC for any changes in radiochemical purity. The complexes were found to be stable.

**Glutathione (GSH) and Cysteine Challenge.** To a 5-mL propylene test tube containing phosphate buffer (250.0 μL, 0.2 M, pH 7.4) were added water (100.0 μL), **11a** or **12a** (100.0 μL), and an aliquot (50.0 μL) of an aqueous stock solution of GSH (10.0 mM). The mixture was vortexed and incubated at 37 °C for 2 h. A control reaction containing an equal volume of H<sub>2</sub>O instead of GSH was studied in parallel. At 15, 30, 60, and 120 min, aliquots of the reaction mixture were withdrawn and analyzed by TLC and HPLC chromatography. The complexes were found to be inert toward substitution by GSH. A study using cysteine hydrochloride (10.0 mM and 1.0 mM) as the challenge ligand demonstrated a similar stability toward cysteine transchelation.

**Receptor-Binding Assays and Calculations.** The 5-HT<sub>1A</sub>-radioligand-binding assay was performed with rat (Sprague Dawley) cerebral cortex membrane prepared according to published procedures (*19, 20*). The net content of protein was determined via the Bradford method (Comassie Brilliant Blue, Biorad) using human serum albumin as a standard (*21*).

Competitive binding assays were performed in triplicate using [<sup>3</sup>H]-8-OH-DPAT as the radioligand, in a final volume of 0.250 mL. Briefly, aliquots (0.1 mL) corresponding to 0.15 mg of membrane protein were mixed with Tris-HCl buffer (50 mM, pH 7.7), [<sup>3</sup>H]-8-OH-DPAT (0.025 mL, 1 nM final concentration), and increasing concentrations (0.125 mL, 1 nM–10 μM) of the competing <sup>99m</sup>Tc-complex (**9a**, **9b**, **10a**, and **10b**). Incubations were carried out at 25 °C for 30 min. The reaction was terminated by the addition of ice-cold assay buffer (3 mL) followed by separation of bound from free radioligand by rapid filtration of the reaction mixture through Whatman GF/B glass-fiber filters. The filters were rinsed three times with ice-cold Tris-HCl buffer (3 × 3 mL). Filter-

bound radioactivity (<sup>99m</sup>Tc) was measured by liquid scintillation counting using a beta counter (LS 5081, Beckman) with a window set to exclude the interference from the tritium channel. IC<sub>50</sub> values were obtained graphically and the inhibition constant (*K<sub>i</sub>*) was calculated according to the Cheng and Prusoff equation (*22*) (Table 4).

**Animal Studies.** Female Sprague–Dawley rats weighing 200–250 g were anesthetized with an intramuscular injection of a mixture of ketamine (80 mg kg<sup>-1</sup>) and xylazine (19 mg kg<sup>-1</sup>). Compound **12a** (100 μL, 300–370 kBq) was injected via the jugular vein. The animals (*n* = 3) were sacrificed by cervical dislocation at 0, 2, 10, 20, and 60 min postinjection. Immediately after sacrifice of the rats, blood was withdrawn from the heart through a syringe and counted. Organs were excised, rinsed with saline, weighed, and counted in a gamma counter. The results are expressed as percentage injected dose per gram (% ID g<sup>-1</sup>) for each organ and blood (Table 5).

## RESULTS

**Preparation of the Bifunctional Ligand.** As outlined in Scheme 1, 2-{3-[4-(2-methoxyphenyl)piperazin-1-yl]propionylamino}-3-tritylsulfanypropionic acid (**5**) was obtained by coupling the amino group of the *S*-trityl-cysteine ethyl ester (**3**) to the carboxylic group of 3-[4-(2-methoxyphenyl)piperazin-1-yl]propionate (**2**) in CH<sub>2</sub>-Cl<sub>2</sub> in the presence of EDC, followed by base hydrolysis of the ester group. Compound **2** was obtained by a two-step reaction through N-alkylation of 1-(2-methoxyphenyl)piperazine hydrochloride (2-MPP) with methyl 3-bromopropionate, and subsequent hydrolysis to the corresponding acid under basic conditions. The final product 2-MPPP-cys-OS (**6**) was activated by removing the *S*-trityl protecting group from cysteine thiolate with TFA in the presence of triethylsilyl hydride to produce the free thiol ligand. The resulting bifunctional ligand is composed of a potentially bioactive moiety with affinity for 5HT<sub>1A</sub> receptors tethered to a bidentate chelating system having the thiol and carboxyl oxygen atoms of the cysteine as π-donor coordinating atoms.

**Preparation and Characterization of <sup>99m</sup>Tc-labeled Compounds.** The intermediate compounds [<sup>99m</sup>Tc(N)Cl<sub>2</sub>(PNP3/4)] (**7**, **8**) have been prepared, in high yield, via ligand-exchange reaction of the labile precursor [<sup>99m</sup>Tc(N)Cl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] with the appropriate diphosphine ligand in CH<sub>2</sub>Cl<sub>2</sub> solution (Scheme 2). IR absorption spectra exhibit typical medium intense bands at 1054 (**7**) and 1045 (**8**) cm<sup>-1</sup>, attributable to ν[Tc≡N] along with characteristic absorptions of coordinated alkylidiphosphine ligand in the 2979–2808 cm<sup>-1</sup> region. Elemental analyses, as reported in the Experimental Section, are also in good agreement with the proposed formulation.

Magnetic equivalence of the diphosphine phosphorus, results in <sup>31</sup>P NMR spectra of the intermediate complexes **7** and **8** exhibiting a broad singlet at room-temperature centered at δ = 31.0 and 23.1, respectively. Similar signal broadening is found in diamagnetic d<sup>2</sup> Tc-complexes and is attributed to the quadrupole relaxation induced by the

**Scheme 1**

$^{99}\text{Tc}$  nucleus ( $I = 9/2$ ) on the neighboring P atoms (16).  $^1\text{H}$  and  $^{13}\text{C}$  spectra show relatively complex patterns consistent with the molecular structure depicted in Scheme 2, in which the asymmetry introduced by the terminal nitrido group removes the equivalence of the substituents on P (syn and anti oriented) and makes the methylene protons of the diphosphine chain diastereotopic. The molecular structure of an isostructural Re complex,  $[\text{Re}(\text{N})\text{Cl}_2(\text{PNP}2)]$  ( $\text{PNP}2 = \text{bis}[(2\text{-diphenylphosphino)ethyl]methoxyethylamine}$ ), has recently been solved by X-ray diffraction analysis (15), and the spectroscopic properties exhibited by this Re complex compared well with the complexes depicted in Scheme 2.

As detailed in Scheme 2, these intermediate compounds react with the bidentate dinegative ligand 2-MPPP-cys-OS resulting in stable neutral asymmetrical compounds of the type  $[\text{M}(\text{N}(\text{2-MPPP-cys-OS})(\text{PNP}3/4)]$

(9, 10). The same heterocomplexes are formed with the simultaneous addition of the two polydentate ligands ( $\text{PNP}3/4$  and 2-MPPP-cys-OS) to the labile precursor  $[\text{M}(\text{N})\text{Cl}_2(\text{PPh}_3)_2]$  in  $\text{CH}_2\text{Cl}_2$  solution in the presence of an excess of  $\text{Et}_3\text{N}$ . Under the synthetic conditions reported, no symmetric disubstituted compounds of the type  $[\text{M}(\text{N})(\text{PNP}3/4)_2]$  and  $[\text{M}(\text{N})(\text{2-MPPP-cys-OS})_2]$  have been detected.

For  $[\text{M}(\text{N})(\text{2-MPPP-cys-OS})(\text{PNP}3/4)]$ , two distinct isomeric forms have been isolated and identified as syn or anti isomers depending on the orientation of the N-substituted cysteine pendant group with respect to the central  $\text{Tc} \equiv \text{N}$  terminal core. The final isomeric ratio, evaluated by TLC and HPLC chromatography, is approximately 50/50 for 9a and 9b and 70/30 for 10a and 10b. In both cases, the two isomers were separated by silica column chromatography and were relatively stable

## Scheme 2

on this time scale. IR spectra of these asymmetric Tc(V)-nitrido complexes show typical absorptions of the intermediate compounds with two additional vibrations at 1732–1638 and 1240  $\text{cm}^{-1}$ , characteristic of 2-MPPP-cys-OS, indicating that the bifunctional chelating ligand is coordinated to the metal fragment  $[\text{}^{99\text{g}}\text{TcN}(\text{PNP3/4})]^{2+}$ . The expected bands of the technetium nitrogen multiple bond, appear in the region 1050–1047  $\text{cm}^{-1}$ , but no significant difference in the Tc $\equiv$ N stretch between syn and anti species has been observed.

The complete characterization of two isomeric forms was obtained by multinuclear NMR spectroscopy. Coordination of the asymmetric S,O-cysteine fragment on the equatorial plane removes the magnetic equivalence of the facing diphosphine phosphorus. Consequently, the  $^{31}\text{P}$  NMR spectrum of each nitrido heterocomplex has two distinct broad signals. Syn and anti isomers are distinguished by the different proton patterns of the coordinated cysteine framework, as previously determined in similar isomeric pairs,  $[\text{}^{99\text{g}}\text{Tc}(\text{O})(\text{RP294})]$  (RP294 = dimethylglycyl-L-seryl-L-cysteinylglycinamide) (23) and  $[\text{Re}(\text{N})(\text{PNP2})(\text{N-ac-cys})]$  (PNP2 = aryldiphosphine and N-ac-cys = N-acetyl-L-cysteine) (24), containing N,S-carboxylic-substituted cysteine and O,S-amine-substituted cysteine, respectively. The assignment of the anti isomer in complexes **9** and **10** is based on the assumption that the pertinent NH and methyne protons of cysteine are shifted upfield and downfield, respectively, relative to the corresponding proton resonances in the syn isomer (Figure 2).

The syn  $\rightarrow$  anti isomerization of **9b** and **10b** was found to occur relatively slowly and to be an irreversible and temperature-dependent process. In fact, by monitoring the conversion by TLC or HPLC for **10b** (see Table 2), we observed that the isomerization reached the final 90/10 anti/syn ratio only after one week at 37  $^\circ\text{C}$ , and after only 15 min at 100  $^\circ\text{C}$ . A faster syn  $\rightarrow$  anti conversion was observed for the syn-PNP3 complex. On the other hand, no variation of the reverse anti  $\rightarrow$  syn conversion was observed by either varying the pH of the mixture from 5 to 9 or the temperature.

**Figure 2.** Proton NMR spectra in the 8.4–3.5 ppm region of *anti*- $[\text{}^{99\text{g}}\text{Tc}(\text{N})(2\text{-MPPP-cys-OS})(\text{PNP4})]$  **10a** (top), of *syn*- $[\text{}^{99\text{g}}\text{Tc}(\text{N})(2\text{-MPPP-cys-OS})(\text{PNP4})]$  **10b** (bottom), and mixture of **10a** and **10b** (middle).

## Scheme 3

To clarify the mechanism of isomer conversion, *syn*- $[^{99g}\text{TcN}(2\text{-MPPP-cys-OS})(\text{PNP4})]$  (**10b**) was incubated with an equimolar or excess amount of the less hindered cysteine-mimicking molecule *O,S*-thioacetate sodium salt at 50 °C and 100 °C. As reported in Table 3, in addition to the expected *syn* → *anti* conversion, the chromatographic profile reveals the presence of a more hydrophilic peak (see Scheme 4) identified as  $[^{99g}\text{TcN}(\text{O,S-thioacetate})(\text{PNP4})]$  (**13**) by comparison with an authentic sample prepared in earlier studies (17). The production of **13** is increased with time by using an excess of *O,S*-thioacetate or by raising the temperature.

**Preparation of  $^{99m}\text{Tc}$ -Labeled Compounds.** Methods employed for preparing neutral tracer asymmetric  $^{99m}\text{Tc}$ -nitrido complexes of the type  $[^{99m}\text{Tc}(\text{N})(\text{PNP3/4})-(2\text{-MPPP-cys-OS})]$  are outlined in Scheme 3. The labeling procedures have been carried out using either a two- or a three-step approach.

In all preparations the first step is to generate a mixture of  $^{99m}\text{Tc}$ -nitrido precursors, all containing the  $[\text{Tc}\equiv\text{N}]^{2+}$  core, through the reduction of pertechnetate with tin(II) chloride in the presence of SDH as donor of the nitrido nitrogen atom. The three-step procedure (method A) entails formation of the strongly electrophilic  $[^{99m}\text{Tc}(\text{N})(\text{PNP})]^{2+}$  intermediate fragment by addition of the appropriate diphosphine ligand (PNP3/4) to the starting  $^{99m}\text{Tc}$ -nitrido mixture. The preparation is then completed by addition of 2-MPPP-cys-OS, which selectively reacts with the intermediate fragment to yield the

final asymmetric complexes. An analogous three-step procedure (method B) reverses the order of addition of the reagents. The yield, however, is somewhat reduced. The optimal labeling procedure involves only two separate steps (method C). After production of the mixture  $[^{99m}\text{Tc}\equiv\text{N}]_{\text{mix}}^{2+}$ , the appropriate diphosphine and bidentate 2-MPPP-cys-OS ligand are simultaneously added to the reaction vial to afford the final product in high yield, after 30 min at 100 °C. Chromatographic characterization indicates that the chemical nature of the final complexes is independent of the preparation method utilized.

The chemical identity of the  $^{99m}\text{Tc}$ -complexes were established by comparison of their chromatographic properties with those of the corresponding complexes obtained at the macroscopic level with the long-lived  $^{99g}\text{Tc}$  isotope (see Table 1 and Figure 3). The  $\log k'_0$  values were determined for each compound by reversed-phase HPLC using various mixtures of methanol/buffer (pH 7.4) as eluant, these served as a measure of the relative lipophilicity of the complexes particularly when traditional octanol/water ( $\log P$ ) ratios (Table 1) could not be determined due to *syn* → *anti* isomer conversion.

All  $^{99m}\text{Tc}$ -complexes exist in two distinct isomeric forms (see  $^{99g}\text{Tc}$ ) but with an *anti*/*syn* isomeric ratio of 90/10 irrespective of the diphosphine utilized. This difference in the tracer  $^{99m}\text{Tc}$  synthesis, compared with the macroscopic  $^{99g}\text{Tc}$  synthesis is attributed to the higher temperature employed in the *nca*  $^{99m}\text{Tc}$  synthesis which accel-

**Figure 3.** RP-HPLC comparison of  $[^{99m}\text{Tc}(\text{N})(2\text{-MPPP-cys-OS})(\text{PNP4})]$  (**12**) complexes with  $[^{99g}\text{Tc}(\text{N})(2\text{-MPPP-cys-OS})(\text{PNP4})]$  (**10**) analogue.

erates the syn to anti conversion observed at room temperature with the  $^{99g}\text{Tc}$ -complexes.

Consequently, only the anti  $^{99m}\text{Tc}$  isomers were isolated by HPLC (RCP > 95%) and utilized for both in vitro stability and in vivo biodistribution studies after appropriate dilution with saline.

**Stability.** Complexes **11a** and **12a** exhibit a good in vitro stability and no significant change in radiochemical purity after 2 h of incubation at 37 °C, thus indicating the high stability and substitution inertness of these compounds.

**Biological Studies.** The in vitro affinity for the 5HT<sub>1A</sub> receptors of the underivatized 2-MPP compound and of the technetium complexes (**9a**, **9b**, **10a**, **10b**) was assessed by measuring the ability of the compounds to compete with [ $^3\text{H}$ ]-8-OH-DPAT binding in isolated membranes from rat cerebral cortex. The inhibition binding-constant ( $K_i$ ) values, measured at 25 °C (Table 4), show that only complex **10a** (*anti*-PNP4) possesses some affinity compared with that observed for the free 2-MPP ligand, while a complete absence of receptor affinity is observed for the other complexes.

For biodistribution studies of the  $^{99m}\text{Tc}$ -compound **12a** in female Sprague–Dawley rats, the radiolabeled compound was purified before injection to remove excess unlabeled cold ligand. The radiochemical purity of the purified compound was verified prior to in vivo administration and the tissue distribution of the complexes is summarized as % ID/g tissue in Table 5.

The complex exhibits rapid blood clearance with the activity mainly eliminating through both the hepatobiliary system and the urinary tract. Only a small fraction of the injected activity ( $\approx 0.14\%$  ID at 2 min) crosses the BBB, followed by a rapid wash out. A very high intestinal uptake is observed at 2 min postinjection.

## DISCUSSION

In this study a new route for incorporating a bioactive molecule into stable  $^{99m}\text{Tc}$ -nitrido compounds is reported. The method is based on the chemical properties of the electrophilic nitrido metal fragment [ $^{99g/99m}\text{Tc}(\text{PNP})$ ] $^{2+}$ . The structural framework of these moieties contains a pseudo tridentate diphosphine ligand (PNP) coordinated to the technetium-nitrido group and two labile sites usually filled by halogens which complete the pseudo-octahedral environment. The [ $^{99g/99m}\text{Tc}(\text{PNP})$ ] $^{2+}$  metal fragment is an activated intermediate which selectively reacts with bidentate chelating ligands carrying  $\pi$ -donor atoms (YZ) to form the final complex [ $\text{Tc}(\text{N})(\text{YZ})(\text{PXP})$ ] $^{0/+}$  which is characterized by an asymmetric arrangement of two polydentate ligands around the metal center.

Neutral asymmetric complexes [ $^{99g}\text{Tc}(\text{N})(2\text{-MPPP-cys-OS})(\text{PNP})$ ] are prepared in high yield by ligand-exchange reactions of [ $^{99g}\text{Tc}(\text{N})\text{Cl}_2(\text{PNP})$ ] with the bifunctional ligand 2-MPP-cy-OS, or, alternatively, by direct reaction of the relevant diphosphine (PNP3 or PNP4) and 2-MPPP-cys-OS with the labile precursor [ $^{99g}\text{Tc}(\text{N})\text{Cl}_2(\text{PPh}_3)_2$ ]. As indicated in Scheme 2, the heterocomplexes display a metal fragment, composed of a terminal  $\text{Tc}\equiv\text{N}$  multiple bond with an ancillary diphosphine ligand, and are coordinated to the thiolate sulfur and carboxylate oxygen of the 2-MPPP-cys-OS ligand. Upon coordination to the metal fragment, 2-MPPP-cys-OS adopts two distinct isomeric forms depending on the relative syn or anti orientation of the *O,S*-cys-piperazinyl group with respect to the  $\text{Tc}\equiv\text{N}$  terminal group. The isolated syn isomer slowly and irreversibly converts to the anti isomer in a temperature-dependent process.

pH does not modify the course of this syn  $\rightarrow$  anti conversion (Table 2). This lack of acid–base sensitivity is likely due to the pseudo-octahedral geometry of the nitrido heterocomplex, where the position trans to the nitrido group is already occupied by the PNP tertiary amine nitrogen, thus preventing the insertion of additional molecules (e.g., water). A dissociative mechanism for this syn  $\rightarrow$  anti conversion is proposed based on the temperature dependence of the conversion process and the formation, in addition to syn  $\rightarrow$  anti transformed complex, of a more hydrophilic [ $\text{Tc}(\text{N})(\text{OS-ta})(\text{PNP})$ ] species when the syn complex is incubated with equimolar or excess amounts of a less hindered cysteine-mimicking *S,O*-thioacetate (Scheme 4). These observations support a mechanism which requires the dissociation of the carboxylate oxygen of 2-MPPP-cys-OS and the insertion of the thioacetate thiolate, resulting in production of the hydrophilic [ $\text{Tc}(\text{N})(\text{OS-ta})(\text{PNP})$ ] species together with isomerization of the syn to anti [ $\text{Tc}(\text{N})(2\text{-MPPP-cys-OS})(\text{PNP})$ ]. This behavior also suggests that the anti isomer is the sterically and thermodynamically favored conformation of these heterocomplexes.

The chromatographic profile (Figure 3) shows that the complexes synthesized at the millimolar level are identical to those prepared at n.c.a. level, the only difference being the increased anti/syn isomeric ratio, which is attributed to the higher temperature employed in the former  $^{99m}\text{Tc}$  synthesis. At the n.c.a. level asymmetric  $^{99m}\text{Tc}$ -nitrido complexes are efficiently prepared through three alternative routes as indicated in Scheme 3. The most efficient labeling procedure involves only two steps, mixing in the same reaction vial both the PNP and 2-MPPP-cys-OS ligand with the starting mixture of [ $^{99m}\text{Tc}\equiv\text{N}$ ] $^{2+}_{\text{mix}}$  nitrido precursor. Alternatively, intermediate Tc-nitrido diphosphine complex can also be formed prior to reacting with the  $\pi$ -donor 2-MPPP-cys-OS ligand present in the same reaction vial to give the desired nitrido heterocomplex in high yield. The most salient feature of these reactions is that no formation of the symmetric complexes [ $^{99m}\text{Tc}(\text{N})(\text{PNP})_2$ ] $^{2+}$  and [ $^{99m}\text{Tc}(\text{N})(2\text{-MPPP-cys-OS})_2$ ] are detected under a broad range of experimental conditions.

In vitro stability studies carried out on the anti isomers show that these compounds are stable in aqueous solutions and serum and are inert toward transchelation with free glutathione and cysteine, suggesting that the arrangement of two  $\pi$ -acceptor phosphorus and two  $\pi$ -donor atoms around the [ $\text{Tc}\equiv\text{N}$ ] $^{2+}$  core possess a high thermodynamic stability and kinetic inertness.

Despite these promising physicochemical properties, in vitro binding studies of the technetium complexes (**9a**, **9b**, **10a**, **10b**) with the 5HT<sub>1A</sub> receptors show that only complex **10a** (*anti*-PNP4) retains some affinity for the 5HT<sub>1A</sub> receptors. The complete loss of receptor affinity observed for complexes containing the PNP3 phosphine could be attributed to the larger steric hindrance imparted to the metal fragment by this phosphine. The relatively smaller complex formed with PNP4 displayed  $K_i$  values of the same order of magnitude as the underivatized 2-MPP ligand (**22**). For PNP4 complexes, the partial loss of affinity may be attributed to the interaction of the piperazinyl fragment with the aminomethyl PNP pendant group. This suggests that affinity could be improved by further manipulating the structure, e.g., by increasing the length of the spacer between the piperazine moiety and the cysteine fragment, eliminating the amide link in the linker arm, or using an alkyl link between the MPP and the bidentate coordinating groups. Studies with this focus are in progress.

## Scheme 4

Although both the molecular weight and the lipophilicity of the *anti*-PNP4 complex are in the appropriate range required for crossing the BBB, in vivo biodistribution data displayed negligible brain uptake. This low affinity toward the receptor along with the rapid blood clearance of the complex may reduce the bioavailability of the tracer thus limiting the brain uptake. In non-CNS peripheral sites, such as the intestine, in our opinion, the accumulation may reflect an excretory pathway via the hepatobiliary system for these molecule rather than binding to peripheral 5HT<sub>1A</sub> receptors, particularly since the complex displays only low affinity toward the receptor in vitro.

## CONCLUSIONS

This work describes application of a new labeling procedure for incorporating a bioactive molecule into a stable asymmetric  $^{99m}\text{Tc}$ -nitrido complex. The chemistry is based on the use of the  $[\text{Tc}(\text{N})(\text{PNP})]^{2+}$  metal fragment which, once formed, selectively reacts with bidentate ligands, such as bifunctional N-derivatized cysteine ligand carrying the bioactive 2-MPP fragment. The resulting neutral species are easily prepared both at macroscopic and n.c.a. levels and exhibit remarkable stability toward glutathione or cysteine challenge. Despite these promising properties, the lack of BBB penetration indicates that these particular complexes may not be useful for CNS-receptor mapping. However, the

experimental evidence that the incorporation of the  $[\text{Tc}(\text{N})(\text{PNP})]^{2+}$  molecular fragment with a bioactive molecule (2-MPP) maintains its affinity for 5HT<sub>1A</sub> receptors suggests that this class of complexes might be useful for peripheral applications (25) and that this strategy may be applied to other receptor-targeting molecules with appropriately modified bidentate chelates.

## ACKNOWLEDGMENT

The authors are indebted to Nihon Medi-Physic, Tokyo, Japan, for financial support of this work. The authors wish to thank Anna Rosa Moresco for her work on the elemental analysis.

# Oligomeric Assembly and Ligand Binding of the Members of Protein Family YER057c/YIL051c/YJGF

Edita Mistiniene,<sup>\*,†</sup> Virginijus Lukša,<sup>‡</sup> Jolanta Sereikaite,<sup>§</sup> and Vytautas Naktinis<sup>‡</sup>

Institute of Biotechnology, V. Graičiūno 8, Vilnius 2028, Lithuania, SICOR Biotech UAB, V. Graičiūno 8, Vilnius 2028, Lithuania, and Vilnius Gediminas Technical University, Sauletekio al. 11, Vilnius 2040, Lithuania. Received June 23, 2003; Revised Manuscript Received September 24, 2003

Proteins UK114 and p14.5 are both members of the putative family of small proteins YER057c/YIL051c/YjgF. The biological role of these proteins is not understood very well, and in addition, their oligomeric structure in solution remains controversial. We therefore investigated the oligomeric structure of UK114 and p14.5 using a number of methods. Both proteins have exhibited a homotrimeric structure in solution. Indeed the trimeric structure of the two proteins appeared to be so similar that when protein subunits derived from different species were mixed, stable heterotrimeric complexes (monomer ratio of 1:2 and 2:1 of UK114 and p14.5, respectively) could be formed in vitro. Furthermore, the trimeric structure of both UK114 and p14.5 proved essential for the stoichiometric hydrophobic ligand, such as fatty acid binding activity of the two proteins.

## INTRODUCTION

Perchloric acid- or trifluoroacetic acid-soluble extracts from liver or kidney of mammals have been shown to contain regularly identifiable proteins of currently unknown function. UK114 is one of the three proteins found in perchloric acid-soluble extract of goat liver (1, 2). UK114 is located in the cytoplasm of normal cells, while in a wide variety of tumors it is also expressed on the cell surface (3), to suggest that tumors, which express UK114 on the cell membrane, could be subjected to antibody-mediated cytotoxicity. Indeed, administration of the UK-specific antibodies in vivo specifically suppresses growth of human colon cancer HT29 cells xenografted into *nu/nu* mice (4, 5). Preliminary evidence on an anticancer efficacy of UK114-containing preparations in humans has also been reported (3, 6).

The mode of biological action of these proteins however remains undefined. Melloni et al. demonstrated that UK114 activated the protease  $\mu$ -calpain and showed its similarity to other activators, such as long chain acyl-coAs-binding proteins or activators from bovine brain (7, 8). PSP (perchloric acid-soluble protein), a homologue of UK114, from rat liver and kidney, on the other hand, has been shown to inhibit a cell-free protein synthesis in a rabbit reticulocyte lysate system (9, 10). PSP may also be involved in fatty acid binding and in intracellular metabolism of fatty acids (11). A 14.5 kDa trichloroacetic acid-soluble p14.5 protein from human mononuclear monocytes has also been isolated and characterized. Human recombinant p14.5 appears similar to PSP in its ability to inhibit protein synthesis in vitro (12). Hrp12, a homologue from mouse, described by Samuel et al., has specifically been assigned the function of a translation inhibitor, though it also exhibited features of a heat shock protein (13).

All these proteins were identified as constituting a new hypothetical family of small proteins, the YER057c/YIL051c/YjgF family (12). The amino acid sequences of the members of this family are highly conserved throughout the evolutionary tree, from prokaryotes to eukaryotes. Approximately 30 proteins sharing sequence similarity of 32–93% have currently been assigned to this family.

3-D structures in crystal are currently available for two bacterial member proteins of the family, a purine regulatory protein from *Bacillus subtilis* (14) and YjgF from *E. coli* (15). In both cases, data obtained was consistent with the proteins forming symmetric trimers in crystals. Recently, the crystal structure of the first mammalian protein UK114 from this family has also revealed the trimeric organization (16). Information about oligomeric structure in solution for members of the YER057c/YIL051c/YjgF family is controversial. Preliminary X-ray data on PSP was indicative of two molecules being present per asymmetric unit (17), a conclusion supported with size exclusion chromatographic data, which was consistent with the dimeric structure of the protein in solution (9). A monomeric structure of a homologue protein from human mononuclear monocytes, p14.5, has been reported (12). Recently, the first NMR study of the member of YjgF/YER057c/UK114 family HI0719 from *Haemophilus influenzae* in solution showed trimeric structure (18). There is no clear evidence of oligomeric structures for mammalian members of this family in solution.

Such controversy over the oligomeric structure of these very similar and evolutionarily well preserved proteins in solution generates a significant hurdle for efforts made to understand the biological role of these proteins. We therefore made our own routine gel filtration chromatographic measurements and then applied a carefully designed gentle chemical cross-linking method to two proteins of the YER057c/YIL051c/YjgF family, namely, UK114 and p14.5, in solution. We supported this approach by characterizing the conditions of ESI-MS<sup>1</sup> (electrospray ionization mass spectrometry) analysis required for identification of the oligomeric state of the

<sup>§</sup> Vilnius Gediminas Technical University.

proteins. In the present study the first homotrimeric solution structure was confirmed for two mammalian members of the YER057c/YIL051c/YjgF family. Furthermore, the trimeric structure in solution was demonstrated to be so similar for the two proteins that stable heterotrimeric complexes could be formed in vitro. Indeed, our evidence indicates that the maintenance of the trimeric structure of these proteins in solution may be critical to their ability to bind hydrophobic ligands, such as free fatty acids, one possible mode of action of these proteins.

## EXPERIMENTAL PROCEDURES

**Materials.** Recombinant UK114 and p14.5 expressed in *Escherichia coli* were a kind gift from SICOR Biotech UAB (Lithuania). Protein molecular weight markers for SDS-PAGE were obtained from MBI Fermentas (Lithuania). Lipidex 1000 was obtained from Packard Instrument Company. <sup>3</sup>H-labeled fatty acids were obtained from Amersham Pharmacia Biotech, England. Scintillation cocktail Rotiszint Eco Plus was obtained from ROTH. 1,3,5-Triacryloyl-hexahydro-*s*-triazine (TAT) was prepared as described by T. L. Gresham and T. R. Steadman (19) and recrystallized from water. Ethylene glycol bis-(succinimidylsuccinate) (EGS) and 8-anilino-1-naphthalenesulfonic acid (ANS) were obtained from Sigma.

**Cross-Linking by TAT.** The solution containing 0.025 mM of UK114 or p14.5 in 0.05 M borate buffer pH 9.2 was incubated for 5 min at 30 °C, and then TAT was added to a concentration of 2.8 mM. The reaction mixture was incubated at 30 °C; samples were withdrawn after 5, 15, 30, 60, 120, 180, and 300 min, and the reaction was stopped by acidification to pH 5.0. The samples were analyzed by SDS-PAGE to identify cross-linked protein forms.

**SDS-PAGE.** SDS-PAGE was carried out on the Mighty Small electrophoresis unit (Hoefer Scientific Instruments, San Francisco, CA) according to the method of Laemmli (20). The acrylamide concentration used in the gel was 15%. Proteins were stained with Coomassie Brilliant Blue R-250 or silver.

**Kinetic Measurements.** Kinetics of TAT reaction with glycine amino groups were measured spectrophotometrically in a thermostated cell at 275 nm, under pseudo-first-order conditions. Five kinetic runs were carried out for each experiment. Pseudo-first-order rate constants were calculated with eq 1, using linear-regression program GraphPad:

$$k = \frac{1}{t} \ln \frac{A_0 - A_{\text{inf}}}{A_t - A_{\text{inf}}} \quad (1)$$

where  $A_0$  is the initial absorbance,  $A_t$  is the absorbance at the time  $t$ , and  $A_{\text{inf}}$  is the final absorbance, after completion of the reaction. Light absorbance of glycine at 275 nm is negligible.

**Size Exclusion Chromatography.** (a) *Nondenaturing Conditions.* Size exclusion chromatography was performed on Superdex200 HR 300×10 mm column

(Amersham Pharmacia, Sweden), equilibrated with 10mM potassium phosphate buffer, pH 7.0, 0.3 M NaCl using FPLC Akta-explorer 100 (Amersham Pharmacia, Sweden). Protein samples were applied, and isocratic elution was carried out at a flow rate of 0.5 mL/min.

(b) *Denaturing Conditions.* The column, as described above, was equilibrated with 10 mM potassium phosphate buffer, pH 7.0, 0.3 M NaCl, 7 M GdnHCl. Protein samples were incubated in 7 M GdnHCl for 24 h at ambient temperature and applied on the column, and isocratic elution was carried out at a flow rate of 0.5 mL/min.

**Separation of Heterotrimers by Anion Exchange Chromatography.** The mixture of 100 μL of UK114 solution (1 mg/mL) in 10 mM phosphate buffer pH 7.4 and 100 μL of p14.5 solution (1 mg/mL) in the same buffer and 200 μL of 3 M urea water solution was incubated for 2.5 h at 30 °C. Then the mixture was diluted to 2 mL with 10 mM glycine-NaOH buffer, pH 9.0, and chromatographed on Mono Q HR 5/5 in a gradient of 30 column volumes in the same buffer, containing 0.1 M NaCl at flow rate of 1 mL/min using FPLC Akta-explorer 100 (Amersham Pharmacia, Sweden). Collected peaks were analyzed using isoelectric focusing.

**Electrospray Ionization Mass Spectrometry.** The method was developed according to the published procedure (21).

(a) *Mild Conditions.* All samples prior to mass spectrometry were dialyzed against 0.1% acetic acid in water. The HP 1100 MSD (mass selective detector) was used for the acquisition of the electrospray ionization mass spectra. Mass spectra were in positive ion mode, over mass range 500–2900  $m/z$ . The samples (protein concentration 0.5 mg/mL) were delivered to the analyzer using a 30 mL/min flow of 1.0% acetic acid. The temperature of drying gas was 150 °C. Nitrogen was used for drying and nebulizing.

(b) *Denaturing Conditions.* All samples prior to mass spectrometry were purified by RP-HPLC using reversed phase column Hi-Pore RP-304 (250 × 4.6 mm, Bio-Rad); solvent A: 0.1% trifluoroacetic acid in water, solvent B: 0.1% trifluoroacetic acid in acetonitrile/water (90/10, v/v). The column was initially equilibrated with solvent A at flow rate of 1 mL/min. After the injection, the column was eluted with a 4 min linear gradient to 50% B followed by a 64 min linear gradient to 70% B and 65 min to 90% B. Chromatographic analysis was performed on a HP 1100 Series HPLC system. Collected peaks were lyophilized and dissolved in acetonitrile/water/acetic acid (49.5/49.5/1, v/v/v).

Mass spectra were in positive ion mode, over mass range 500–2900  $m/z$ . The samples (protein concentration 0.05 mg/mL) were delivered to the analyzer using a 50 mL/min flow of acetonitrile/water/acetic acid (49.5/49.5/1, v/v/v). The temperature of drying gas was 350 °C. Nitrogen was used for drying and nebulizing.

**Delipidation by Lipidex Chromatography.** Delipidation by Lipidex chromatography was carried out according to the method described by J. F. Glatz (22). Lipidex 1000 was washed free of methanol in a column by elution with 10 bed volumes of 10 mM potassium phosphate buffer (pH 7.4), containing 0.01% NaN<sub>3</sub>. The gel was transferred to a glass vial and stored at 4 °C as Lipidex-buffer suspension (1/1, v/v).

The lipid components in the protein samples were recovered by chromatography on a column (10'×60 mm) of Lipidex1000 equilibrated with 10 mM potassium

<sup>1</sup> Abbreviations: AEC, anion exchange chromatography; ANS, 8-anilino-1-naphthalenesulfonic acid; DMSO, dimethyl sulfoxide; ESI-MS, electrospray ionization mass spectrometry; GdnHCl, guanidine hydrochloride; I-FABP, intestinal fatty acid binding protein; RP-HPLC, reversed phase high performance liquid chromatography; SDS-PAGE, sodium dodecyl sulfate polyacrylamide gel electrophoresis; SEC, size exclusion chromatography; TAT, 1,3,5-triacryloyl-hexahydro-*s*-triazine; TNF-α, tumor necrosis factor.

phosphate buffer pH 7.4 at room temperature. All proteins were eluted in a void volume.

**Free Fatty Acid Binding Assay.** For the assay of fatty acid binding activity, protein samples (2 mM) were incubated in 1.5 mL polyethylene test tubes in 10 mM potassium phosphate buffer pH 7.4 with various concentrations of  $^3\text{H}$ -fatty acid. The final volume was 0.45 mL. After incubation for 10 min at 37 °C, the test tubes were cooled in ice water. Unbound fatty acid was removed from the solution by adding of 0.05 mL of ice cold Lipidex1000/water suspension, incubated for 10 min at 0 °C, and centrifuged for 2 min at 20000*g* and 4 °C. An aliquot of supernatant was assayed for radioactivity by liquid scintillation counting. Fatty acid binding was calculated from the amount of radioactivity present in the supernatant and was expressed as mol of fatty acid per mol of monomeric protein.

**ANS Binding Assay.** All fluorescence experiments were performed on a Perkin-Elmer Luminescence Spectrometer LS50B. For the ANS binding assay, protein samples (9.1  $\mu\text{M}$ ) in 2 mL 10 mM potassium phosphate buffer pH 7.4 were titrated with increasing ANS concentration. ANS emission spectra (excitation  $\lambda_{\text{max}}$  365 nm) were recorded in the range of 350–650 nm, slit widths 5 nm.

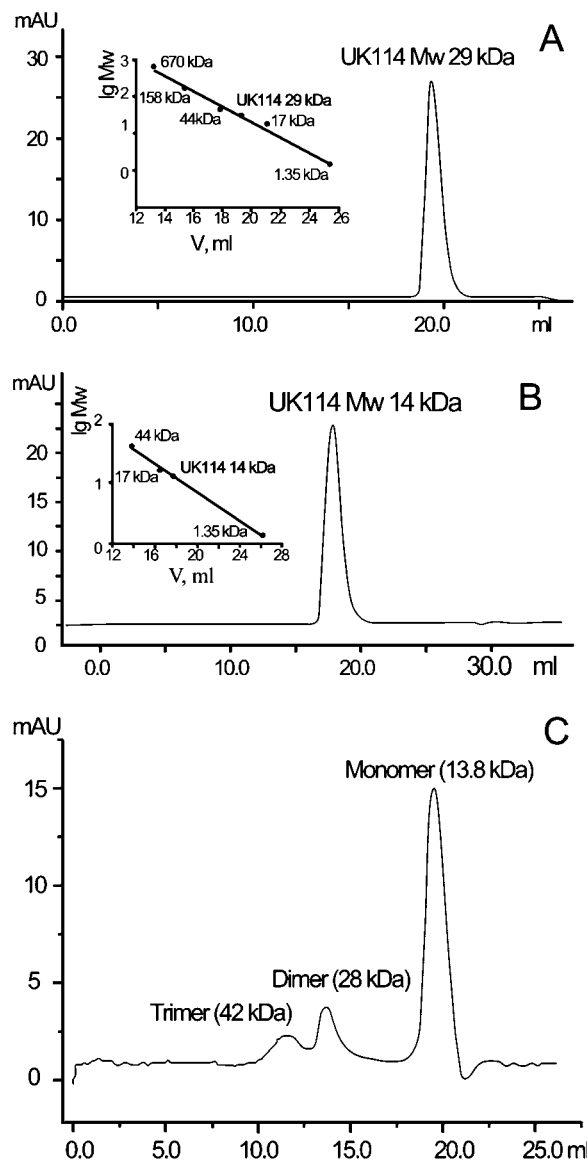

## RESULTS

**Size Exclusion Chromatography.** Size exclusion chromatography provides means by which the state of aggregation of proteins can be effectively determined, provided that the subunit–subunit interaction forces are sufficiently strong to withstand such a nonequilibrium analysis. As it is shown in Figure 1A, the UK114 protein behavior on Superdex200 was consistent with the molecular mass of 29 kDa. These experiments were performed at an initial protein concentration of  $\sim 70 \mu\text{M}$ . Reductions of protein concentration to 1.4  $\mu\text{M}$  did not affect the gel-filtration behavior of the protein, to indicate that the oligomeric state of the protein was stable through the range of the concentrations tested. The gel-filtration behavior of the p14.5 human analogue of UK114 was exactly the same as that of UK114.

The molecular mass of UK114 derived from the gene sequence has been reported to be 14166 Da (23), to suggest that UK114 may exist in a dimeric state under the experimental conditions described above. Indeed, when UK114 was subjected to gel-filtration using 6 M guanidine hydrochloride (Gdn·HCl) in a mobile phase, the elution volume was consistent with molecular weight of 14.0 kDa (Figure 1B), a number in good agreement with the expected molecular mass of monomeric subunit.

**Electrospray Ionization Mass Spectrometry.** Significant evidence has now been reported to suggest that proper adjustment of experimental conditions used in the performance of ESI-MS experiments is required to provide insight into oligomeric structure. Without such precisely defined conditions, quaternary structure can be easily disrupted by low pH, high organic solvent content, high temperature of drying gases, and high flow rate of mobile phase (24). When these disruptive forces are not controlled, only covalent protein interactions usually survive, and a precise molecular mass of the protein monomeric subunits is obtained. Quaternary structure of the protein, however, can be maintained throughout the course of analysis by careful adjustment of these disruptive factors, such that the molecular mass of the complex can be established.

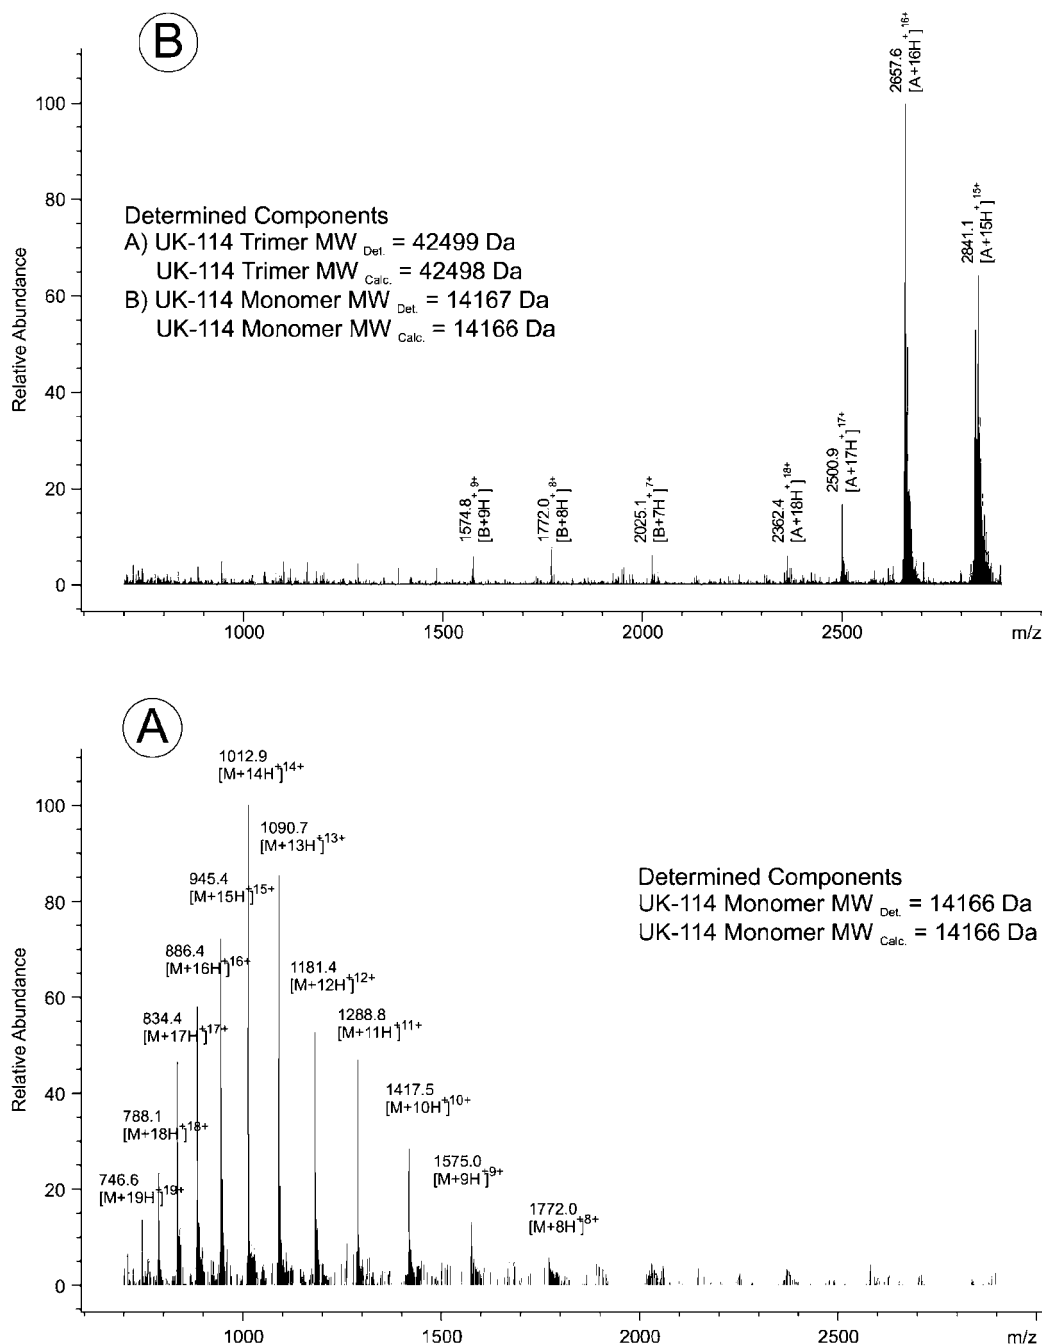

Initially, we subjected UK114 to ESI-MS analysis under denaturing conditions where disruption of oligo-

**Figure 1.** Size exclusion chromatography of UK114 on Superdex200 HR 300 $\times$ 10 mm using FPLC Akta-explorer100 (Amersham Pharmacia, Sweden). The column was equilibrated with 10 mM potassium phosphate buffer, pH 7.0, 0.3 M NaCl (A), buffer A also containing 6 M Gdn HCl (B) and buffer A with 0.1% SDS (C). UK114 samples of 200  $\mu\text{L}$  (1 mg/mL) in the A buffer (A), in the B buffer (B) and UK114 3 h cross-linked with TAT in 0.1% SDS (C) were applied and isocratic elution was carried out at flow rate of 0.5 mL/min.

meric state of the protein was expected. Denaturing ESI-MS conditions include RP-HPLC with high organic solvent concentration for sample preparation and rigorous ionization parameters (high temperature, high concentration of organic solvent in mobile phase, and high flow rate of mobile phase) for ESI-MS. The data (Figure 2A) demonstrated a typical ESI-MS spectrum of the protein, consisting of multiply charged  $[\text{M} + n\text{H}]^{n+}$  ions, with charges ranging from +8 to +19. The set of ions detected corresponded to the protein average mass of  $14166 \pm 1$  (mean  $\pm$  SD) Da. This value was in excellent agreement with the theoretically calculated mass of 14.166 kDa for the monomeric form of UK114. Using denaturing conditions, i.e., RP-HPLC for sample preparation and rigorous conditions for ESI-MS ionization, it is not clear enough which of the factors are mainly responsible for destruction of trimeric structure.

**Figure 2.** Mass spectrum of UK114 under denaturing (A) and mild conditions (B).

To preserve noncovalent protein complexes, we used mild sample preparation conditions, i.e., dialysis against 0.1% acetic acid in water, and milder ionization parameters for ESI-MS. Organic solvent was not used in the mobile phase for ESI-MS; lower temperature and lower flow rate of mobile phase were applied. After using mild sample preparation conditions together with mild ionization parameters, a significant change in the overall spectrum was observed (Figure 2B). Two protein components were detected on the spectrum, a major component of  $42499 \pm 3$  kDa which corresponded with the trimeric form of UK114, and a minor component of  $14166 \pm 1$  kDa, which was clearly reflective of monomeric form of the protein. At the same time no dimeric form was detected.

**Chemical Cross-Linking.** The formation of protein oligomers in solution is commonly investigated by cross-linking studies in which closely associated subunits are

cross-linked in such a manner that the so-formed quaternary structure can be subsequently isolated and analyzed. Two cross-linking agents, 1,3,5-triacryloyl-hexahydro-*s*-triazine (TAT) (25, 26) and ethylene glycol bis(succinimidylsuccinate) (EGS) (27), were therefore used to probe the quaternary structure of UK114.

TAT is a trifunctional chemical cross-linking agent, previously demonstrated to be extremely stable, simple and convenient to use in the generation of cross-linking patterns, which are characteristic of the native structure of the proteins (25, 26, 28). We have previously described its use in concentrations of 4.5–30-fold molar excess of TAT active groups over the concentrations of amino groups in the protein, defining the oligomeric state of such well-characterized monomeric, dimeric, or trimeric proteins, such as human growth hormone, interferon- $\gamma$ , and tumor necrosis factor alpha (TNF- $\alpha$ ), respectively (25, 28).

**Figure 3.** SDS-PAGE (15%) of UK114 (A) and TNF- $\alpha$  (B) cross-linked by TAT. A. Lane 1, protein markers; lane 2, unmodified UK114; lane 3–9, samples taken at 5, 15, 30, 60, 120, 180, and 300 min. B. Lane 1, protein markers; lane 2, unmodified TNF- $\alpha$ ; lane 3–6, samples taken at 30, 60, 120, and 300 min.

Every attempt was made to ensure that the experimental conditions, adjusted to specific characteristics of UK114, exclusively promoted the cross-linking of true molecular contacts rather than accidental protein molecular collisions. First, UK114 was incubated with TAT at a molar ratio of 30:1 of TAT acrylic groups:UK114 amino groups, at pH 9.2. Next, the aliquots of the reaction mixture were withdrawn at increasing time intervals and subjected to denaturing SDS–PAGE analysis. The profile obtained by applying this experimental approach to the well-known trimeric protein, tumor necrosis factor  $\alpha$ , is indicated in Figure 3B. Characteristically, the TAT interaction with the trimeric protein resulted in an early intermediate of dimeric form. The presence of cross-linked dimers on PAGE gels does not mean that they actually exist in the solution. Cross-linked dimers may be not yet completely cross-linked trimers. If trimer is the main form of a protein in solution, cross-linked trimers become dominant on PAGE at the completion of cross-linking process, as is shown on the Figure 3 for TNF and UK114. Then trimeric structures appeared gradually, and no higher oligomers were detected after long time incubation. A detailed explanation of the kinetics of the cross-linking profile of TNF- $\alpha$  has previously been reported (26, 28).

<sup>a</sup> UK114 cross-linked with TAT pH 9.2, 3 h at 30 °C.

As it is demonstrated in Figure 3A, the cross-linking profile obtained with UK114 was the same as that of TNF- $\alpha$ . Two predominant species with apparent molecular mass in a range of 48–54 kDa were observed as the ultimate products of cross-linking reaction. It has previously been demonstrated that these two molecular species resemble two different steric isoforms of the cross-linked trimer, the linear and ring-shape isoforms (29). Therefore, the similarity of cross-linking profiles of UK114 with those of the trimeric TNF- $\alpha$  protein was consistent with the trimeric structure of UK114 in solution.

Since the most favorable TAT cross-linking conditions included a pH of 9.2, we questioned whether the reaction kinetics and the end product profile were similar under physiological conditions. We reproduced the cross-linking reaction results using ethylene glycol bis(succinimidylsuccinate) at pH 7.2.

To further support the observation that UK114 formed trimers in solution, we subjected the products of the TAT 3 h (Figure 3A, lane 8) cross-linking reaction to more detailed characterization. Size exclusion chromatography under mild denaturing conditions (in the presence of 0.1% SDS) revealed that the 3 h reaction mixture was composed of three principal components, with their molecular masses being consistent with monomeric, dimeric, and trimeric forms of UK114 (Figure 1C). The behavior of UK114 in the presence of SDS is no more exceptional: experimental molecular mass of the cross-linked trimer is near the calculated one (42 and 43.2 kDa, respectively).

Extending this analysis of the TAT reaction products, we used ESI-MS. Main components of a complex mixture of monomeric, dimeric, and trimeric structures of UK114 3 h cross-linked with TAT (Figure 3A, lane 8) were identified. They are listed in Table 1. Up to seven TAT moieties were attached to the monomeric UK114 form, a number in good agreement with the fact that the UK114 monomer contains seven lysine residues in polypeptide chain. Two principal forms of trimeric UK114 were confirmed in the reaction mixture, with 14 and 15 covalently attached TAT moieties, respectively.

All the methods used for probing the quaternary structure led us to conclude that two mammalian proteins from the YjgF/YER057c/UK114 family UK114 and p14.5 exist as homotrimers in solution, like their bacterial homologue HI0719 (18).

**The Interaction between Subunits in the Trimeric Structure.** Having established the TAT cross-linking technique as a reliable tool for probing quaternary structure of UK114, we addressed the issue of the nature of interaction between monomeric subunits in the tri-

1	$4.62 \pm 0.08$
2	$4.75 \pm 0.07$
3	$4.85 \pm 0.05$

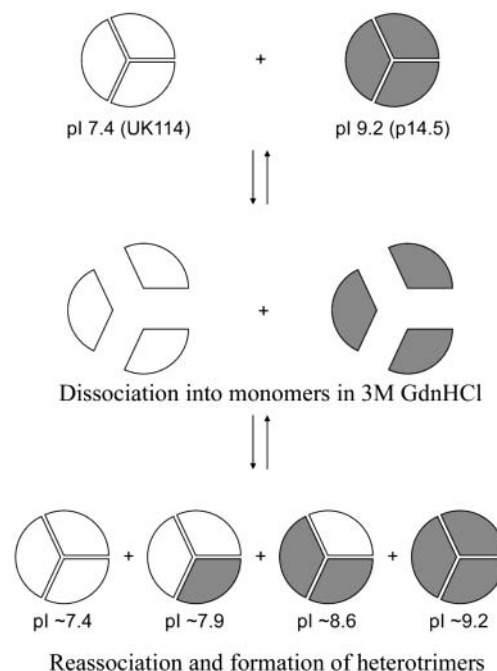

<sup>a</sup> Initial concentrations: TAT,  $6.9 \times 10^{-4}$  M; glycine, 0.07 M; 30 °C and pH 9.0. <sup>b</sup> Standard deviations are given.

meric structure. It was expected that if electrostatic interactions were predominant in forming trimers, then the disruption of such interactions by increasing ionic strength would preclude the formation of trimers in the cross-linking reaction. We added KCl to the cross-linking reaction mixture and monitored UK114 trimer formation by SDS–PAGE analysis. Our results indicated that the elevation of KCl concentration to 0.5 M considerably reduced the formation of the trimeric structure. The further elevation of salt concentration to 2.5 M completely abolishes recovery of the trimeric form.

To eliminate the possibility that the inhibitory effect of high salt concentration on the formation of the UK114 trimeric structure was due to the inhibition of the TAT reaction with amino groups, we performed a study where kinetic parameters of the TAT reaction with amino group of model compound, glycine, were measured. As shown in Table 2, pseudo-first-order rate constant of the reaction remained unchanged through the range of KCl concentrations from 0 to 3 M, to suggest that we could exclude the possibility that observed inhibiting effect of elevated salt concentrations on the formation of the trimeric structure of UK114 was due to the inability of TAT to react under these conditions.

To explore the possible contribution of hydrophobic interactions in UK114 trimer formation, we added dimethyl sulfoxide (DMSO) to the cross-linking reaction mixture and monitored trimer formation by SDS–PAGE analysis. This chaotropic reagent, when present in concentrations of up to 10%, is known to disrupt hydrophobic interactions of proteins (30). DMSO in concentrations up to 15% had no effect on trimerization, to suggest that the role of hydrophobic interactions in the association of monomeric subunits was insignificant.

**Heterotrimer Formation.** Alignment of the sequence of UK114 with that of p14.5 revealed a striking 86% similarity in primary structure. The cross-linking experiments described above, then repeated using p14.5, generated results very similar to those described for UK114. It was therefore interesting to explore the possibility of creating chimeric structures in vitro. To do so, we exploited the fact that the two proteins, despite significant overall similarity, had very different isoelectric points, pI 7.4 and pI 9.2, for UK114 and p14.5, respectively. We also exploited the fact that we could reversibly dissociate UK114 into subunits and reassociate the trimer structure afterward. If one mixed the two proteins, then subjected the mixture to mild denaturation, to cause the break down of trimers into monomers, and then removed denaturant, monomeric subunits would reassociate into the trimers. Under such conditions, four species of trimers theoretically should form (Figure 4). Two species would resemble the original UK114 and p14.5 trimers, while two would be chimeric structures with monomer ratios of 1:2 and 2:1, UK114 and p14.5, respectively. All four trimeric species would be characterized by different pI values, to allow their separation in a properly selected chromatographic system.

**Figure 4.** Hypothetical scheme for the formation of hetero-trimers of UK114 and p14.5 subunits.**Figure 5.** The chromatographic separation of the dissociated–associated mixture of UK114 and p14.5. Solution of UK114 and p14.5 (1 mg/mL of each) in 3 M Gdn–HCl was incubated for 2.5 h at 30 °C and diluted with 3 volumes of 10 mM glycine–NaOH, pH 9.0. Samples of reaction mixture (2 mL) were chromatographed on Mono Q HR5/5 in a gradient of 30 column volumes in the same buffer, containing 0.1 M NaCl at flow rate of 1 mL/min using FPLC Akta-explorer100 (Amersham Pharmacia, Sweden).

As indicated in Figure 5, heterotrimer formation was achieved using the scheme described above, and the heterotrimers formed were separable. The nature of all the species formed was confirmed by isoelectrofocusing analysis.

**Free Fatty Acid Binding.** PSP, a protein from rat liver, also a homologue of both UK114 and p14.5, is known as a fatty acid binding protein (11). Because of the significant homologies between these proteins, UK114 and p14.5 may also bind free fatty acids, the possibility we investigated. The principle of the method we exploited involved the incubation of the protein with varying amounts of <sup>3</sup>H-labeled fatty acid, removal of unbound free fatty acid on Lipidex1000, and measurement of the remaining labeled complex. Two known proteins were used for comparison: I-FABP, which has previously been demonstrated to stoichiometrically bind 1 mol of fatty acid per mol of protein (31, 32), and TNF- $\alpha$ , a cytokine, whose biological function is apparently not related to fatty acid metabolism (33, 34) and which therefore served as a negative control. The data generated for binding of oleic acid are presented in Table 3. The same results were

**Table 3. Binding Activity of  $^3\text{H}$ -Labeled Oleic Acid**

protein	$B_{\text{max}}$ , mol/mol monomeric protein
I-FABP	$1.10 \pm 0.20$
UK114	$0.90 \pm 0.15$
p14.5	$0.70 \pm 0.17$
TNF- $\alpha$	$0.09 \pm 0.04$

obtained in palmitic acid binding experiments. Both fatty acids bind to UK114 (or p14.5) in a saturable manner. This indicates the specific nature of the binding. The stoichiometry of both complexes was very close 1:1 (mol fatty acid per mol monomer protein). As it was expected, the protein known to bind fatty acids specifically (I-FABP) manifested 1:1 stoichiometric binding activity, while the binding activity of TNF- $\alpha$ , the negative control, barely exceeded the background level.

These results suggest that UK114 maintains three fatty acid binding sites per trimeric molecule. Further, the apparent dissociation constant of the complex UK114-fatty acid decreased while increasing the saturation of the protein with ligand, to suggest cooperative character of the fatty acid binding.

To exclude the possibility that the free fatty acid binding observed was a random event, we addressed the correlation between structural integrity of the protein and its binding ability. Specifically we evaluated binding at various stages of thermal inactivation. Samples of UK114 were incubated at 37, 60, and 80 °C for 20 min, and at 100 °C for 1 min, and their ability to bind fatty acid was measured as described above. The results of this study revealed that the UK114 gradually lost binding activity with thermal inactivation, starting from 60 °C with only minor activity remaining after heating for 1 min at 100 °C. These data confirmed the specific nature of the binding observed.

**ANS Binding.** Stoichiometric binding activity of fatty acid suggests the presence of three binding sites per trimeric protein. We found that UK114 and p14.5 are able to bind the hydrophobic fluorescent dye ANS in their native state. The fluorescent probe ANS is traditionally used to detect molten globules, i.e. partly folded proteins that accumulate under mild conditions (35). ANS fluorescence is sensitive to the polarity of its microenvironment; upon binding to the apolar surfaces, its emission maximum is shifted to shorter wavelengths and the emission intensity is enhanced. ANS is believed to bind to molten globules due to the presence of solvent-exposed hydrophobic patches, which are a particular characteristic of this protein state (36). Certain proteins also bind ANS in the native state, however, provided this conformation displays exposed hydrophobic sites (37). Fluorescence emission spectra of ANS in the presence or absence of UK114 (or p14.5) are shown in Figure 6A. In water, ANS fluoresce is negligible and exhibits a maximum emission wavelength ( $\lambda_{\text{max}}$ ) of  $\sim 515$  nm. In the presence of UK114 (or p14.5) under native conditions (pH 7.4), ANS fluorescence displays a pronounced increase in intensity with a concomitant shift of  $\lambda_{\text{max}}$  to 465 nm, both of which indicate transfer of ANS to a less polar environment. These data show that UK114 and p14.5 bind ANS in the native state.

The affinity of the interaction between ANS and UK114 (or p14.5) was examined by titration of UK114 (or p14.5) with ANS while following the ANS emission at 465 nm. The resulting binding curves, displayed in Figure 6B, show that ANS binds to UK114 (or p14.5) in a saturable manner.  $K_d$  values for UK114 and p14.5 are 2.2 and 2.4  $\mu\text{M}$ , respectively. These experiments yield a binding stoichiometry of  $1.1 \pm 0.2$  mol ANS/mol mono-

**Figure 6.** A. ANS binding to native UK114. Fluorescence of 9.1  $\mu\text{M}$  ANS in the absence and presence of 9.1  $\mu\text{M}$  UK114 at 25 °C in 10 mM potassium phosphate buffer pH 7.4. ANS fluorescence is a very weak exhibiting a  $\lambda_{\text{max}}$  of  $\sim 515$  nm (I). Upon addition of UK114 the fluorescence of ANS increase with a concomitant shift of  $\lambda_{\text{max}}$  to 465 nm (II). ANS was excited at 365 nm. B. Affinity of ANS to UK114 interaction. Titration of 9.1  $\mu\text{M}$  UK114 with ANS in 10 mM potassium phosphate buffer pH 7.4. ANS was excited at 365 nm. C. ANS binding to UK114 with increasing concentration of Gdn-HCl. 9.1  $\mu\text{M}$  UK114 was preincubated 5h at 25 °C in 10 mM potassium phosphate buffer pH 7.4 with increasing Gdn-HCl concentration. ANS binding was monitored by 365 nm excitation and 465 nm emission.

meric protein and support the presumption that proteins UK114 and p14.5 exhibit three ligand binding sites per trimeric molecule.

To prove the importance of quaternary structure for ligand binding, we investigated the ANS binding under denaturation of UK114 with GdnHCl. The profile of ANS emission intensity with increasing GdnHCl concentration shows two maxima (Figure 6C). The ANS fluorescence intensity decreases and reaches minimum at 0.25 M GdnHCl. It may be explained by disruption of trimeric structure and intersubunit binding sites. Further increase of emission intensity at GdnHCl concentration above 2.75 M is related with unfolding of UK114 to molten globule, when hydrophobic surfaces of protein are exposed to a greater extent compared with a native state.

To confirm disruption of quaternary structure we performed size-exclusion chromatography of UK114 in

the presence of GdnHCl. UK114 was incubated in various concentrations of GdnHCl and applied to a TSK G2000SW FPLC size-exclusion column equilibrated with buffer containing an identical concentration of GdnHCl. In the absence of GdnHCl UK114 eluted as a single peak, corresponding to native trimeric protein, increasing of GdnHCl concentration up to 0.25 M UK114 also eluted as a single peak, but with elution volume, corresponding with monomeric form. This transition from trimer to monomer occurred having the same GdnHCl concentration as the losing of specific binding of ANS (Figure 6C). With further increase of GdnHCl concentration, the peak, corresponding to monomeric UK114, gradually shifted to earlier elution times, suggesting that monomer of UK114 was unfolded and a molecule with increased apparent volume produced. The midpoint of the unfolding curve was 2.5 M.

## DISCUSSION

The highly conserved protein family YER057c/YIL051c/YjgF is comprised of ~30 homologues exhibiting varying degrees of sequence homology from 32 to 93%. Some of them have been identified as proteins soluble in strong acids, but most sequences from this protein's group were hypothetical and identified by genome projects. Despite the sequence conservation through evolution and the high degree of homology between members of the YER057c/YIL051c/YjgF family, no common biological function has been allocated to it yet. With the mounting evidence as to the potentially high clinical value of the biotherapeutics being developed on the basis of proteins of this family (6), the deciphering of biochemical mechanisms underlying their clinical actions becomes increasingly urgent.

In this paper we describe the oligomeric structures and ligand binding properties of two recombinant DNA-derived members of the YER057c/YIL051c/YjgF family: perchloric acid-soluble protein from goat liver, UK114, and its analogue from human monocytes, p14.5, proteins that manifest 86% sequence similarity.

Indications as to biological function of these proteins could potentially be derived from the details of their structural organization. However, in the case of the YER057c/YIL051c/YjgF family evidence on oligomeric state in solution has supported conclusions of monomeric to trimeric forms. Gel-filtration data used to demonstrate the native state of the protein yielded results interpreted to be consistent with the dimeric form (9, 12). Indeed, we also initially produced gel-filtration data indicative of the dimeric form for both UK114 and p14.5 in solution. However, we extended our study of the oligomeric state of these proteins by applying a carefully designed cross-linking technique. The formation of UK114 (and p14.5) trimers was observed under a variety of conditions in water solution. Direct evidence of trimeric structure was obtained by using nondisrupting ESI-MS analysis. In fact, our results as well as crystallographic data (16) indicate that these proteins are trimeric under physiological conditions.

The apparent conflict between cross-linking, ESI-MS and gel-filtration data may be explained by the UK114 (and p14.5) protein assuming an extremely compact structure in solution, such that effective hydrodynamic radii of the proteins were substantially smaller than the radii of reference proteins used for gel-filtration column calibration. Support of this explanation has now been provided by X-ray study data (16) of the crystal form of UK114, which revealed the dimensions of highly sym-

metric homotrimeric UK114 of  $\sim 48 \times 45 \times 43$  Å. The apparently more compact spatial organization of UK114 could provide a clue into the misleading gel-filtrational behavior of this protein, compared with conventional reference proteins.

To delineate the character of the interaction forces, which keep separate subunits in trimeric form, we exploited cross-linking methodology, where reaction conditions were altered to limit either hydrophobic or electrostatic protein interactions. The overall electrostatic interaction was demonstrated to be the major factor in the trimerization of the protein. Information on monomer: monomer surface interactions retrieved from recent crystal data (16) was consistent with our observation. The UK114 molecule possesses an extensive network of hydrogen bonds and electrostatic interactions throughout the subunits contact surface. The number of complementary interactions between oppositely charged ionizable groups on the contact surfaces between monomers was sufficient to confirm that electrostatic interaction played the major role in the stabilization of UK114 trimer. The critical putative interaction points identified from the 3-D structure now provide a basis for future site-specific mutagenesis studies directed at further biochemical confirmation of the role of these putative contacts in maintaining trimeric organization of the protein.

Further, the high degree of sequence similarity between UK114 and p14.5, together with the proven trimeric structure of the two proteins, led us to hypothesize that there could be a high similarity in tertiary structure such that the monomeric subunits from one protein could be interchangeable with the monomeric subunits from the other in their respective trimeric states. We successfully demonstrated that such a possibility could be implemented *in vitro* by exploring the finding that each of the proteins could be dissociated into monomers under mild conditions and then reassembled into functional trimers by removing the denaturing agent. By mixing the two original proteins, dissociating them into monomers, and later reassociating them, we produced chimeric trimers containing two subunits from one protein and one subunit from another. The heterotrimers formed were sufficiently stable to withstand anionic exchange chromatographic separation, and isoelectric focusing in a way analogous to that of the original homotrimers, to indicate an extremely close if not identical spatial organization of monomers in these two proteins. We plan to explore this observation further in future eukaryote genetic knock-out models (38).

Stable trimeric organization could potentially play an important role in the biological function of the protein, specifically its ability to bind hydrophobic ligands, such as free fatty acids. We confirmed that these two proteins bind fatty acid with  $K_d \sim 2.0$   $\mu$ M, forming one to one stoichiometric complex (mol of fatty acid per mol of monomeric protein), a finding similar to that of PSP from rat (11). The ability of these proteins to bind hydrophobic ligands in their native state was also demonstrated with fluorescent dye ANS. The binding isotherm is rectangular hyperbolic and reaches saturation, suggesting that binding is specific, i.e. a well-defined number of binding sites exist. Indeed, titrating of UK114 (or p14.5) with ANS at concentrations well above  $K_d$  indicates a 1:1 (mol of dye per mol of monomeric protein) binding stoichiometry. Stoichiometric ligand binding activities suggest the presence of three binding sites per trimeric protein. Indeed, trimeric UK114 in a crystalline state contains three hydrophobic solvent-exposed cavities, created between

interacting subunits (16), as it was shown previously for some members of the YER057c/YIL051c/YjgF family (14, 15, 18).

It was found that oleic acid displaces ANS bound to UK114, i.e. the two substances compete for the same binding sites. We also demonstrated that ligand binding activity exhibits only trimeric protein. UK114 lost ANS binding ability when trimer was disrupted to monomer under unfolding, induced by GdnHCl.

In conclusion, these findings may have important biological implications. Despite the mentioned above multifunctionality of the proteins from YER057c/YIL051c/YjgF family, high similarity in quaternary structures suggest that these proteins use the same biochemical way for the manifestation of their biological function. Trimeric organization of the two proteins of the YER057c/YIL051c/YjgF family has been shown to be a critical structural feature in ligand binding, one potential mode of action of these proteins. The structural elements, which direct formation of the trimeric state of the protein, are apparently preserved throughout the evolutionary tree to support a correlation between structural organization and function of these proteins. The data presented therefore could target further studies of the structure–function relationship of these proteins, to elucidate their respective mechanisms of action.

#### ACKNOWLEDGMENT

We thank prof. G. Dienys for helpful comments and discussion, Barbara Richmond-Smith for critical reading of the manuscript and L. Noreika for technical assistance. This work was supported by Lithuanian State Science and Studies Foundation, grant no. G-053.

# Synthesis of a New Heterobifunctional Linker, *N*-[4-(Aminooxy)butyl]maleimide, for Facile Access to a Thiol-Reactive $^{18}\text{F}$ -Labeling Agent

Tatsushi Toyokuni,\* Joseph C. Walsh, Alan Dominguez, Michael E. Phelps, Jorge R. Barrio, Sanjiv S. Gambhir, and Nagichettiar Satyamurthy

Crump Institute for Molecular Imaging, Department of Molecular & Medical Pharmacology, David Geffen School of Medicine at UCLA, Los Angeles, California 90095-1770. Received June 25, 2003; Revised Manuscript Received August 25, 2003

A new heterobifunctional linker containing an aldehyde-reactive aminooxy group and a thiol-reactive maleimide group, namely *N*-[4-(aminooxy)butyl]maleimide, was synthesized as a stable HCl salt by *O*-alkylation of either *N*-hydroxyphthalimide or *N*-(4-monomethoxytrityl)hydroxylamine, followed by *N*-alkylation of maleimide, in an overall yield of 18% (seven steps) or 29% (five steps), respectively. This heterobifunctional linker allowed a simple and efficient synthesis of a maleimide-containing thiol-reactive  $^{18}\text{F}$ -labeling agent. Thus, *N*-{4-[(4- $^{18}\text{F}$ ]fluorobenzylidene)aminooxy]butyl}maleimide (specific activity:  $\sim 3000$  Ci/mmol at end of synthesis) was synthesized in two steps involving the preparation of 4- $^{18}\text{F}$ fluorobenzaldehyde, followed by its aminooxy-aldehyde coupling reaction to the heterobifunctional linker, with an overall radiochemical yield of  $\sim 35\%$  (decay corrected) within  $\sim 60$  min from end of bombardment. Initial  $^{18}\text{F}$ -labeling experiments were carried out using a thiol-containing tripeptide glutathione (GSH) and a 5'-thiol-functionalized oligodeoxynucleotide (5'-*S*-ODN) in phosphate-buffered saline (PBS, pH 7.5). After standing at room temperature for 10 min, the  $^{18}\text{F}$ -labeled GSH and 5'-*S*-ODN were obtained in  $^{18}\text{F}$ -labeling yields of  $\sim 70\%$  and  $\sim 5\%$  (decay-corrected), respectively. The heterobifunctional linker is easy to synthesize and provides a facile access to the maleimide-containing thiol-reactive  $^{18}\text{F}$ -labeling agent, which could be advantageously employed in the development of  $^{18}\text{F}$ -labeled biomolecules for use with positron emission tomography.

## INTRODUCTION

As medicine moves toward treatment at the molecular level, complementary molecular diagnostic tools will be of vital importance. In this regard, molecular imaging techniques, namely positron emission tomography (PET) (1, 2) and single photon emission computed tomography (SPECT) (3), are of particular interest due to their ability to noninvasively and repeatedly track radiolabeled probes in living subjects. Advances in basic medical sciences have led to an appreciation of biomolecules that selectively target a particular disease at the cellular level. Examples for this approach include peptide (4) and nucleic acid probes (aptamers) (5), monoclonal antibodies (6), and antisense oligodeoxynucleotides (ODNs) (7). Synthetic and engineered variants of these biomolecules are also being developed to improve their native chemical and biological characteristics. Such variants of biomolecules can be potential target-specific imaging probes for PET and SPECT when they are labeled with appropriate radioisotopes (8–11). PET in general is superior to SPECT in terms of sensitivity and spatial resolution. Among the routinely available positron-emitting isotopes,  $^{18}\text{F}$  is the most attractive isotope due to its relatively long half-life (110 min) which permits multistep radiosyntheses. Furthermore, better quality PET images can be

obtained from  $^{18}\text{F}$ -labeled radiotracers due to the short range of positrons emitted by the radioisotope. Accordingly, recent years have seen a growing interest in the development of  $^{18}\text{F}$ -labeled biomolecules for target-specific PET imaging probes (12, 13).

Radiofluorination of biomolecules generally utilizes  $^{18}\text{F}$ -labeled intermediates which are synthesized by nucleophilic [ $^{18}\text{F}$ ]fluorination of precursor compounds. These  $^{18}\text{F}$ -labeled intermediates are subsequently converted into amine-reactive (14–18) or thiol-reactive (14, 19, 20) functional groups. Such indirect approaches are required since nucleophilic radiofluorination reactions are carried out with anhydrous [ $^{18}\text{F}$ ]fluoride ion in polar aprotic solvents under strong basic conditions, which are frequently detrimental to sensitive functional groups. Nonetheless, a few direct [ $^{18}\text{F}$ ]fluorinations of preformed active esters have been reported. However, these direct methods are not selective and suffer from either the need of an extensive HPLC purification (21) or low specific activity of the final product (22). The amine-reactive  $^{18}\text{F}$ -labeling agent *N*-succinimidyl 4- $^{18}\text{F}$ fluorobenzoate has currently found considerable applications in  $^{18}\text{F}$ -labeling of peptides (23–25), proteins (16, 26), and ODNs (27). Nevertheless, the preparation of this agent requires at least three major synthetic steps: (1) [ $^{18}\text{F}$ ]fluorination of an aromatic aldehyde/ester precursor, (2) a functional group transformation to the corresponding carboxylic acid, and (3) formation of its *N*-succinimidyl ester. In order for  $^{18}\text{F}$ -labeling of biomolecules to be a routine procedure, there is a need for simpler and more efficient  $^{18}\text{F}$ -labeling methods.

We herein report that a novel heterobifunctional linker containing an aldehyde-reactive aminoxy group and a thiol-reactive maleimide group facilitates a facile access to a maleimide-containing thiol-reactive  $^{18}\text{F}$ -labeling agent obtainable via readily available 4- $^{18}\text{F}$ fluorobenzaldehyde (28–32).

## EXPERIMENTAL METHODS

**General.** All reagents and solvents were purchased from commercial suppliers and used without further purification, except for THF and MeCN which were distilled under  $\text{N}_2$  from sodium benzophenone ketyl and  $\text{CaH}_2$ , respectively. The 5'-thiol functionalized 15-mer ODN,  $\text{HS}-(\text{CH}_2)_6\text{OPO}_3\text{-AACGTTGAGGGGCAT}$ , was purchased from Genset (Paris, France) as the *S*-trityl protected form, which was deprotected according to the manufacture's protocol just before use. Reactions were monitored by TLC on 0.25-mm thickness silica gel plates containing  $\text{UV}_{254}$  indicator. Flash column chromatography was performed on silica gel 60 (0.032–0.063 mm). Melting points were determined with a Fisher-Johns melting point apparatus and are uncorrected. Elemental analyses were done by Galbraith Laboratories in Knoxville, TN.

$^1\text{H}$  and  $^{13}\text{C}$  NMR spectra were recorded using either a Bruker AM360, Bruker ARX400, or Bruker Avance 500 spectrometer using TMS as the internal standard. High-resolution mass spectra were recorded on an IonSpec HiResMALDI spectrometer (MALDI) or a VG Analytical 70VSE spectrometer (FAB). MALDI-TOF MS was obtained at The Scripps Research Institute, La Jolla, CA.

No-carrier-added  $^{18}\text{F}$ fluoride ( $\sim 600$  mCi; specific activity:  $> 10\,000$  Ci/mmol) was produced by 11 MeV proton bombardment of 95%  $^{18}\text{O}$ -enriched  $\text{H}_2\text{O}$  via  $^{18}\text{O}(\text{p},\text{n})^{18}\text{F}$  nuclear reaction using a RDS-112 cyclotron. HPLC was performed with a Rainin-HP system equipped with a UV detector (250 nm) and a Bioscan  $\gamma$  detector. Semi-preparative HPLC was carried out using a C-18 column (Phenomenex Aqua, 5  $\mu\text{m}$ ,  $250 \times 10$  mm) with MeCN–water (1:1 v/v for 8 min followed by 7:3 v/v) at 5 mL/min. For analytical HPLC, a C-18 column (Phenomenex Aqua, 5  $\mu\text{m}$ ,  $250 \times 4.6$  mm) was used with a linear gradient elution of 5–80% solvent B in solvent A over 20 min at 1 mL/min, where solvent A: 0.1 M triethylammonium acetate (TEAA) (pH 7) containing 5% MeCN; solvent B: 0.1 M TEAA (pH 7) containing 70% MeCN. The specific activity was determined by on-line measurements of radioactivity and UV absorption.

***N*-[4-(*tert*-Butyldimethylsiloxy)butoxy]phthalimide (3).** DEAD (1.10 mL, 7.07 mmol) was added dropwise over a period of 1 h to a solution of 4-(*tert*-butyldimethylsiloxy)butanol (33) (2) (1.20 g, 5.87 mmol), *N*-hydroxyphthalimide (1.13 g, 6.93 mmol) and  $\text{Ph}_3\text{P}$  (1.83 g, 6.80 mmol) in THF (15 mL) at 0 °C. The mixture was then stirred at room-temperature overnight. The reaction mixture was poured into water and extracted with  $\text{Et}_2\text{O}$ . The  $\text{Et}_2\text{O}$  extract was washed with water and dried ( $\text{MgSO}_4$ ). After concentration of the ethereal solution, the residue was purified by flash column chromatography with hexanes– $\text{Et}_2\text{O}$  (3:2 v/v) to give **3** (1.74 g, 85%) as a clear colorless oil. The  $^1\text{H}$  NMR data were in agreement with the literature values (34).

***N*-(4-Hydroxybutoxy)phthalimide (4).** The reaction was carried out in a neoprene flask. A mixture of **3** (1.70 g, 4.87 mmol), 48% aqueous HF (0.79 mL, 19.5 mmol), and MeCN (20 mL) was stirred at room temperature for 30 min. The reaction mixture was poured into water and extracted with  $\text{Et}_2\text{O}$ . The  $\text{Et}_2\text{O}$  extract was dried ( $\text{MgSO}_4$ )

and concentrated. The residue was purified by flash column chromatography with  $\text{Et}_2\text{O}$  to give **4** (0.98 g, 85%) as a clear colorless oil. The  $^1\text{H}$  NMR data were in agreement with the reported values (34).

**4-(Aminoxy)butanol (5).** A solution of **4** (0.98 g, 4.16 mmol) and hydrazine (0.62 mL, 19.4 mmol) in EtOH (20 mL) was refluxed for 2.5 h. A white precipitate that formed was removed by filtration, and the filtrate was concentrated to dryness. The residue was purified by flash column chromatography with  $\text{CHCl}_3$ –MeOH (17:3 v/v) containing 1%  $\text{Et}_3\text{N}$  to give **5** (0.35 g, 80%) as a pale yellow oil. Vanillin was used to visualize spots on TLC plates. The  $^1\text{H}$  NMR data were in agreement with the literature values (35).

**4-[(4-Monomethoxytrityl)aminoxy]butanol (6).** From **5**. 4-Methoxytrityl chloride (0.96 g, 3.11 mmol) was added dropwise over a period of 15 min to a solution of **5** (0.34 g, 3.23 mmol) and  $\text{Et}_3\text{N}$  (0.45 mL, 3.23 mmol) in  $\text{CH}_2\text{Cl}_2$  (7 mL) at 0 °C. The mixture was stirred at room temperature for 90 min. After concentration of the mixture, the residue was purified by flash column chromatography with  $\text{CH}_2\text{Cl}_2$ –MeOH (95:1 v/v) to give **6** (0.85 g, 70%) as a clear colorless oil.  $^1\text{H}$  NMR (360 MHz,  $\text{CDCl}_3$ )  $\delta$  1.44 (br quint,  $J = 6$  Hz, 2H) and 1.54 (br quint,  $J = 6$  Hz, 2H) ( $\text{CCH}_2\text{CH}_2\text{C}$ ), 3.47 (t,  $J = 6.1$  Hz, 2H,  $\text{CH}_2\text{OH}$ ), 3.71 (t,  $J = 6.1$  Hz, 2H,  $\text{CH}_2\text{ON}$ ), 3.79 (s, 3H, *OMe*), 6.29 (br s, 1H, *NH*), 6.82 (br d,  $J = 9$  Hz, 2H) and 7.22–7.35 (m, 12H) (*Ar*).  $^{13}\text{C}$  NMR (90 MHz,  $\text{CDCl}_3$ )  $\delta$  24.77, 29.56, 55.08, 62.41, 73.34, 73.76, 112.86, 126.68, 127.57, 128.90, 130.16, 136.52, 144.57, 158.20. HRMS (FAB) calcd for  $\text{C}_{24}\text{H}_{28}\text{NO}_3$  [ $\text{M} + \text{H}$ ] $^+$  378.2069, found 378.2063.

From **13** (for preparation of **13**, see below). A 1 M solution of  $\text{Bu}_4\text{NF}$  in THF (17.8 mL, 17.8 mmol) was added to a solution of **13** (4.38 g, 8.92 mmol) in THF (20 mL). The mixture was stirred at room temperature for 3 h. The reaction mixture was poured into water and extracted with  $\text{Et}_2\text{O}$ . The  $\text{Et}_2\text{O}$  extract was dried ( $\text{MgSO}_4$ ) and concentrated. The residue was purified by flash column chromatography with  $\text{CH}_2\text{Cl}_2$ –MeOH (95:1 v/v) to give **6** (3.36 g, quantitative) as a clear colorless oil.

***N*-[4-[(4-Monomethoxytrityl)aminoxy]butyl]-maleimide (7).** DEAD (0.19 mL, 1.22 mmol) was added dropwise over a period of 1 h to a solution of **6** (0.38 g, 1.00 mmol),  $\text{Ph}_3\text{P}$  (0.31 g, 1.18 mmol), and maleimide (0.12 g, 1.23 mmol) in THF (15 mL) at 0 °C. The mixture was then stirred at room-temperature overnight. The reaction mixture was poured into water and extracted with  $\text{Et}_2\text{O}$ . The  $\text{Et}_2\text{O}$  extract was dried ( $\text{MgSO}_4$ ) and concentrated. The residue was purified by flash column chromatography with hexanes– $\text{Et}_2\text{O}$  (3:2 v/v) to give **7** (0.25 g, 55%) as a clear colorless oil.  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  1.44–1.48 (m, 4H,  $\text{CCH}_2\text{CH}_2\text{C}$ ), 3.41 (t,  $J = 6.7$  Hz, 2H,  $\text{CH}_2\text{N}$ ), 3.66 (t,  $J = 5.8$  Hz, 2H,  $\text{CH}_2\text{ON}$ ), 3.79 (s, 3H, *OMe*), 6.30 (br s, 1H, *NH*), 6.64 (s, 2H, maleimide), 6.82 (br d,  $J = 9$  Hz, 2H) and 7.21–7.35 (m, 12H) (*Ar*).  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  25.34, 25.71, 37.66, 55.20, 73.34, 73.48, 112.96, 126.76, 127.68, 129.06, 130.37, 134.02, 136.66, 144.73, 158.29, 170.84. HRMS (MALDI) calcd for  $\text{C}_{28}\text{H}_{28}\text{N}_2\text{O}_4\text{Na}$  [ $\text{M} + \text{Na}$ ] $^+$  479.1947, found 479.1937.

***N*-[4-(Aminoxy)butyl]maleimide (8).** HCl gas was bubbled into a solution of **7** (0.12 g, 0.27 mmol) in  $\text{Et}_2\text{O}$  (15 mL) at 0 °C for 1 min. The mixture was stirred at the same temperature for an additional 5 min. The resulting white precipitate was collected by filtration. Recrystallization from MeCN afforded **8** (0.058 g, quantitative) as the HCl salt: mp 131–132 °C.  $^1\text{H}$  NMR (400 MHz,  $\text{CD}_3\text{OD}$ )  $\delta$  1.60–1.70 (m, 4H,  $\text{CCH}_2\text{CH}_2\text{C}$ ), 3.53 (t,  $J = 6.2$  Hz, 2H,  $\text{CH}_2\text{N}$ ), 4.02 (t,  $J = 5.8$  Hz, 2H,  $\text{CH}_2\text{ON}$ ),

6.81 (br s, 2H, *maleimide*). Anal. Calcd for  $\text{C}_8\text{H}_{13}\text{ClN}_2\text{O}_3$ : C, 43.55; H, 5.94; Cl, 16.07; N, 12.70. Found: C, 43.45; H, 6.20; Cl, 16.14; N, 12.71.

**N-(4-Monomethoxytrityl)hydroxylamine (10).** 4-Monomethoxytrityl chloride (50.0 g, 162 mmol) was added to a solution of  $\text{NH}_2\text{OH}\cdot\text{HCl}$  (10.4 g, 162 mmol) and  $\text{Et}_3\text{N}$  (35.3 mL, 324 mmol) in DMF (450 mL). The resulting cloudy mixture was stirred at room-temperature overnight. The mixture was poured into water and extracted with  $\text{Et}_2\text{O}$ . The  $\text{Et}_2\text{O}$ -extract was washed with water and dried ( $\text{MgSO}_4$ ). After concentration, the residue was triturated with hexanes to afford a yellow solid. Recrystallization from EtOH gave **10** (35.3 g, 72%) as white crystals: mp 112–113 °C. The  $^1\text{H}$  and  $^{13}\text{C}$  NMR data were in agreement with the values reported in the literature (36).

**1-(tert-Butyldimethylsiloxy)-4-[(4-monomethoxytrityl)aminooxy]butane (13).** 1-(tert-Butyldimethylsiloxy)-4-iodobutane (**37**) (5.60 g, 17.8 mmol) was added to a solution of **10** (4.53 g, 14.9 mmol) and NaH (60% dispersion in mineral oil, 0.54 g, 17.8 mmol) in DMF (50 mL). The mixture was stirred at room-temperature overnight. The reaction mixture was poured into water and extracted with  $\text{Et}_2\text{O}$ . The  $\text{Et}_2\text{O}$  extract was washed with water and dried ( $\text{MgSO}_4$ ). After concentration, the residue was purified by flash column chromatography with hexanes– $\text{Et}_2\text{O}$  (9:1 v/v) to give **13** (4.38 g, 60%) as a clear colorless oil.  $^1\text{H}$  NMR (360 MHz,  $\text{CDCl}_3$ )  $\delta$  0.03 (s, 6H,  $\text{SiMe}_2$ ), 0.87 (s, 9H, *t*-Bu), 1.40 (br quint,  $J = 6$  Hz, 2H) and 1.52 (br quint,  $J = 6$  Hz, 2H) ( $\text{CCH}_2\text{CH}_2\text{C}$ ), 3.52 (t,  $J = 6.5$  Hz, 2H,  $\text{CH}_2\text{OTBDMS}$ ), 3.67 (t,  $J = 6.4$  Hz, 2H,  $\text{CH}_2\text{ON}$ ), 3.80 (s, 3H, *OMe*), 6.25 (s, 1H, *NH*), 6.82 (br d,  $J = 9$  Hz, 2H) and 7.21–7.31 (m, 12H) (*Ar*).  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  –5.40, 14.01, 25.84, 29.37, 31.47, 55.01, 62.80, 73.28, 73.75, 112.78, 126.59, 127.49, 128.94, 130.23, 136.65, 144.69, 158.15. **N-{4-[(4-Fluorobenzylidene)aminooxy]butyl}-maleimide (16- $^{19}\text{F}$ ).** 4-Fluorobenzaldehyde (**15- $^{19}\text{F}$** ) (27.0  $\mu\text{L}$ , 0.25 mmol) was added to a solution of **8**·HCl (36.6 mg, 0.17 mmol) in DMF (2 mL). The mixture was stirred at room temperature for 30 min. The reaction mixture was poured into water and extracted with  $\text{Et}_2\text{O}$ . The  $\text{Et}_2\text{O}$  extract was washed with water and dried ( $\text{MgSO}_4$ ). After concentration, the residue was purified by flash column chromatography with hexanes– $\text{Et}_2\text{O}$  (3:2 v/v) to give **16- $^{19}\text{F}$**  (44 mg, 91%) as a white powder: mp 79–81 °C.  $^1\text{H}$  NMR (360 MHz,  $\text{CD}_3\text{OD}$ )  $\delta$  1.65–1.75 (m, 4H,  $\text{CCH}_2\text{CH}_2\text{C}$ ), 3.57 (t,  $J = 6.7$  Hz, 2H,  $\text{CH}_2\text{N}$ ), 4.15 (t,  $J = 6.0$  Hz, 2H,  $\text{CH}_2\text{ON}$ ), 6.68 (s, 2H, *maleimide*), 7.07 (br t,  $J = 9$  Hz, 2H) and 7.54 (br dd,  $J = 9, 6$  Hz, 2H) (*Ar*), 8.02 (s, 1H,  $\text{CH}=\text{NOR}$ ). HRMS (FAB) calcd for  $\text{C}_{15}\text{H}_{16}\text{FN}_2\text{O}_3$  [ $\text{M} + \text{H}$ ] $^+$  291.1145, found 291.1142. Anal. Calcd for  $\text{C}_{15}\text{H}_{15}\text{FN}_2\text{O}_3$ : C, 62.06; H, 5.21; F, 6.54; N, 9.65. Found: C, 62.37; H, 5.50; F, 6.60; N, 9.32.

**N-{4-[(4- $^{18}\text{F}$ )Fluorobenzylidene)aminooxy]butyl}-maleimide (16- $^{18}\text{F}$ ).** *Step 1: Preparation of 4- $^{18}\text{F}$ -Fluorobenzaldehyde (15- $^{18}\text{F}$ ).* Cyclotron-produced [ $^{18}\text{F}$ ]-fluoride (~600 mCi; specific activity: >10000 Ci/mmol) was transferred to a reaction vessel containing Kryptofix 222 (7 mg) and  $\text{K}_2\text{CO}_3$  (0.7 mg) in MeCN–water (25:1 v/v, 0.7 mL). After water was evaporated at 110 °C with a stream of nitrogen gas, the residue was dried further by the azeotropic distillation with MeCN (3  $\times$  0.2 mL). A solution of (4-formylphenyl)trimethylammonium triflate (**28**) (**14**) (8 mg, 0.026 mmol) in DMSO (0.7 mL) was added and the mixture was heated at 120 °C for 10 min. After dilution with water (7 mL), the mixture was passed

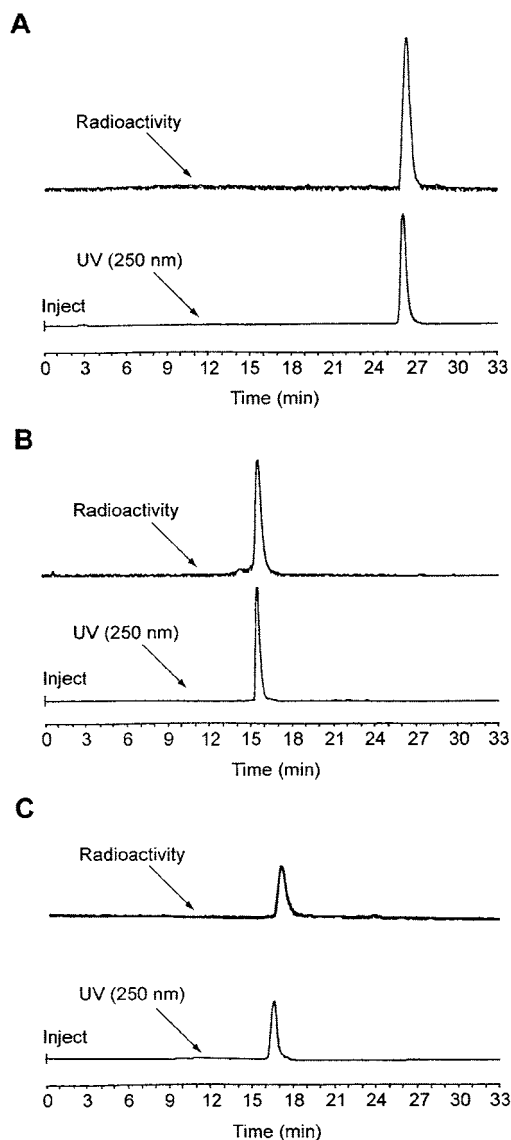

through a Waters Sep-Pak C-18 cartridge (1 mL). The cartridge was washed with water (2  $\times$  5 mL), and the product **15- $^{18}\text{F}$**  was eluted with MeOH (1.5 mL) into a vial containing **8**·HCl (8.00 mg, 0.036 mmol). The yield of **15- $^{18}\text{F}$**  was ~250 mCi (~50% decay-corrected) at ~20 min after end of bombardment (EOB).

*Step 2: Aminooxy-Aldehyde Coupling Reaction.* The mixture was gently agitated with a stream of nitrogen gas for 15 s and allowed to stand at room temperature for 15 min. The reaction mixture (~1.5 mL) was purified by semipreparative HPLC. The chemically and radiochemically pure fraction (~5 mL;  $t_R$  ~16 min) was collected, diluted with water (25 mL), and passed through a Waters Sep-Pak C-18 cartridge (1 mL). The cartridge was washed with  $\text{H}_2\text{O}$  (2  $\times$  5 mL), and the product was eluted with MeCN (1 mL) to afford **16- $^{18}\text{F}$**  (~140 mCi; ~70% decay corrected). The overall radiochemical yield was ~35% (decay corrected) at ~60 min after EOB. The chemical and radiochemical purities as well as chemical identity were confirmed by analytical HPLC by reference to **15- $^{19}\text{F}$**  ( $t_R$  ~26.5 min) (Figure 1A). The specific activity was found to be ~3000 Ci/mmol at end of synthesis (EOS).

**Coupling of 16- $^{19}\text{F}$  with Glutathione (GSH) (17).** A solution of **16- $^{19}\text{F}$**  (16 mg, 0.055 mmol) in DMF (0.5 mL) was added dropwise to a solution of GSH (**17**) (17 mg, 0.055 mmol) in phosphate-buffered saline (PBS, pH 7.5) (1 mL). The mixture was stirred at room temperature for 10 min. At this time TLC indicated the disappearance of **16- $^{19}\text{F}$**  ( $R_f$  0.3; hexanes– $\text{Et}_2\text{O}$  3:2) and the appearance of one major product ( $R_f$  0.6; *n*-BuOH–EtOH– $\text{H}_2\text{O}$ –AcOH 4:2:2:1). After dilution with water (5 mL), the mixture was passed through a Waters Sep-Pak C-18 cartridge (1 mL). The cartridge was washed with water (2  $\times$  5 mL), and the product was eluted with MeOH (5 mL). Evaporation of the MeOH eluate afforded  $^{19}\text{F}$ -GSH **19- $^{19}\text{F}$**  (26 mg, 79%) as a pale yellow solid.  $^1\text{H}$  NMR (400 MHz,  $\text{CD}_3\text{OD}$ )  $\delta$  1.50 (br s, 4H,  $\text{NOCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 1.98–2.03 (m, 2H) and 2.37–2.40 (m, 2H) (Glu  $\text{C}_\beta\text{H}_2\text{C}_\gamma\text{H}_2$ ), 2.41–3.20 (m, 4H, Cys  $\text{C}_\beta\text{H}_2$ , succinimide  $\text{CH}_2$ ), 3.38 (br s, 2H,  $\text{NOCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 3.56–3.69 (m, 3H, Glu  $\text{C}_\alpha\text{H}$ ,  $\text{NOCH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 3.83–3.89 (m, 1H, succinimide  $\text{CH}$ ), 3.98 (br s, 2H, Gly  $\text{C}_\alpha\text{H}_2$ ), 4.51 (m, 1H, Cys  $\text{C}_\alpha\text{H}$ ), 6.98 (br t,  $J = 9$  Hz, 2H, *Ar*), 7.40–7.44 (m, 2H, *Ar*), 7.98 (d,  $J = 2.8$  Hz, 1H,  $\text{CH}=\text{NOR}$ ). HRMS (FAB) calcd for  $\text{C}_{25}\text{H}_{33}\text{FN}_5\text{O}_9\text{S}$  [ $\text{M} + \text{H}$ ] $^+$  597.1905, found 597.1904.

**$^{18}\text{F}$ -Labeling of GSH 17.** A portion (~20 mCi, ~140  $\mu\text{L}$ ) of the MeCN eluate containing **16- $^{18}\text{F}$**  (see above) was added to a solution of **17** (4 mg) in PBS (pH 7.5) (1 mL). The mixture was gently agitated and left at room temperature for 10 min. Analytical HPLC indicated the total consumption of **16- $^{18}\text{F}$**  ( $t_R$  ~26.5 min) and the appearance of a new radioactive peak ( $t_R$  ~15.5 min). After dilution with water (5 mL), the mixture was passed through a Waters Sep-Pak C-18 cartridge (1 mL). The cartridge was washed with water (2  $\times$  5 mL), and the activity was eluted with MeOH (1 mL) to yield  $^{18}\text{F}$ -GSH **19- $^{18}\text{F}$**  (~12 mCi, ~70% decay corrected). The labeling time was ~30 min. The chemical and radiochemical purities as well as chemical identity were confirmed by analytical HPLC by reference to **19- $^{19}\text{F}$**  ( $t_R$  ~15.5 min) (Figure 1B).

**Coupling of 16- $^{18}\text{F}$  with 5'-Thiol-Functionalized Oligodeoxynucleotide (5'-S-ODN) 18.** A solution of **16- $^{18}\text{F}$**  (150  $\mu\text{g}$ ) in MeCN (20  $\mu\text{L}$ ) was added to a solution of 5'-S-ODN **18** (~100  $\mu\text{g}$ ) in PBS (pH 7.5) (0.2 mL). After gentle agitation, the mixture was left at room temperature for 40 min. The mixture was purified by analytical HPLC and the peak at  $t_R$  ~16.5 min was collected (20

**Figure 1.** Analytical HPLC profiles of (A) the maleimide-containing  $^{18}\text{F}$ -labeling agent **16- $^{18}\text{F}$**  coinjected with the standard **16- $^{18}\text{F}$** , (B) the  $^{18}\text{F}$ -labeled glutathione **19- $^{18}\text{F}$**  coinjected with the standard **19- $^{18}\text{F}$** , and (C) the  $^{18}\text{F}$ -labeled 5'-thiol-functionalized oligodeoxynucleotide **20- $^{18}\text{F}$**  coinjected with the standard **20- $^{18}\text{F}$** . Column: Phenomenex Aqua (C-18, 5  $\mu\text{m}$ , 250  $\times$  4.6 mm); elution protocol: a linear gradient elution of 5–80% solvent B (0.1 M TEAA, pH 7, 70% MeCN) in solvent A (0.1 M TEAA, pH 7, 5% MeCN) over 20 min; flow rate: 1 mL/min.

$\mu\text{L}$  each injection). After lyophilization, the product  $^{19}\text{F}$ -5'-S-ODN **20- $^{18}\text{F}$**  was characterized by MALDI-TOF MS: calcd for  $\text{C}_{169}\text{H}_{213}\text{FN}_{64}\text{O}_{93}\text{P}_{15}\text{S}$  [ $\text{M} + \text{H}$ ] $^{+}$  5141, found 5138.

**$^{18}\text{F}$ -Labeling of 5'-S-ODN **18**.** A portion ( $\sim 30$  mCi,  $\sim 160$   $\mu\text{L}$ ) of the MeCN eluate containing **16- $^{18}\text{F}$**  (see above) was added to a solution of **18** ( $\sim 400$   $\mu\text{g}$ ) in PBS (pH 7.5) (160  $\mu\text{L}$ ). The mixture was gently agitated and left at room temperature for 10 min. After dilution with water (5 mL), the mixture was passed through a Waters Sep-Pak C-18 cartridge (1 mL). The cartridge was washed with water ( $2 \times 5$  mL), and the activity was eluted with EtOH (1 mL). The EtOH eluate was concentrated to  $\sim 200$   $\mu\text{L}$  and diluted with PBS (pH 7.5) (800  $\mu\text{L}$ ). The mixture was applied to a NAP-10 gel-filtration cartridge with PBS (pH 7.5) as an eluting solvent. The eluate was fractionated ( $\sim 1$  mL each) and analyzed by analytical HPLC. The second fraction was found to contain chemically and

radiochemically pure  $^{18}\text{F}$ -5'-S-ODN **20- $^{18}\text{F}$**  ( $t_{\text{R}} \sim 16.5$  min) (Figure 1C). The radioactivity was  $\sim 1$  mCi ( $\sim 5\%$  decay-corrected) and the labeling time was  $\sim 60$  min.

## RESULTS AND DISCUSSION

Thiol-reactive agents have been widely used to modify peptides and proteins at specific sites (38–40). This is because under physiological conditions a thiol group is more nucleophilic than amines. The thiol-reactive agents include maleimides, vinyl sulfones, haloacetyl derivatives, bromomethyl derivatives, and pyridyl disulfides, among which maleimides are the most preferable due to their highest selectivity toward the thiol group. Therefore, maleimide-containing thiol-reactive  $^{18}\text{F}$ -labeling agents are of particular interest for the selective introduction of  $^{18}\text{F}$  at a predetermined site. In 1988 Shiue et al. reported a multistep preparation of two maleimide-containing  $^{18}\text{F}$ -labeling agents starting from 1- $^{18}\text{F}$ fluoro-4-nitrobenzene or 4- $^{18}\text{F}$ fluorobenzonitrile (19). They also reported unsuccessful direct  $^{18}\text{F}$ fluorination of pre-formed maleimides. The likely reason for their failure is that the strongly basic conditions required for radiofluorination with  $^{18}\text{F}$ fluoride are not compatible with base-labile maleimides. Since then little efforts have been made on the development of maleimide-containing thiol-reactive  $^{18}\text{F}$ -labeling agents (41–43).

We therefore envisioned the thiol-reactive maleimide **16** (Scheme 3) as a potential precursor for modifying peptides and proteins. Condensation of the readily available 4- $^{18}\text{F}$ fluorobenzaldehyde (28–32) with the aminoxy maleimide **8** was a key step in the preparation of **16**. The choice of the aminoxy derivative **8** instead of the corresponding amine was based on the enhanced reactivity of the aminoxy group toward carbonyl groups and the greater stability of the oxime ethers formed (44). The hydrazide maleimide derivatives, such as BMPH, EMCH, and KMH (45), are commercially available as aldehyde- and thiol-reactive heterobifunctional linkers, in which the hydrazide group reacts with carbonyl groups forming stable hydrazones. However, the aminoxy group is more attractive for time-restricted PET radiochemistry (46) because of its greater nucleophilicity than the hydrazide group (47–49). Although a number of examples are described in bioconjugate chemistry (50–55), aminoxy chemistry has not been previously utilized in PET radiochemistry.

**Synthesis of the Heterobifunctional Linker **8** (Scheme 1).** The conventional route to aminoxy ethers involves an *O*-alkylation of *N*-hydroxyphthalimide (PhthNOH) with alkylating agents (56). The Mitsunobu reaction has also been shown effective for this transformation with alcohols (57). We employed the Mitsunobu reaction for the preparation of the *N,O*-protected aminoxy alcohol **3**. The monosilyl ether **2**, prepared from 1,4-butanediol (**1**) as reported (33), was subjected to the Mitsunobu reaction condition using PhthNOH as a nucleophile and DEAD and  $\text{PPh}_3$  as activators. The desired compound **3** was obtained in 85% yield from **2**. This product was previously prepared from the tosylate of the monosilyl ether **2** in 60% yield (2 steps) (34). Removal of the phthalimido group requires strong basic/nucleophilic conditions, under which decomposition of the maleimide group can occur. Accordingly, the phthalimide group was replaced with an acid-labile 4-monomethoxytrityl (MMTr) group before the introduction of the maleimide group. Desilylation of **3** and subsequent hydrazinolysis of **4** afforded the aminoxy alcohol **5**, which upon treatment with MMTrCl gave rise to the *N*-tritylaminoxy alcohol

Scheme 1<sup>a</sup>

<sup>a</sup> Reagents and conditions (yield): (a) ref 34 (81%); (b) PhthNOH, Ph<sub>3</sub>P, DEAD, THF, 0 °C→rt, overnight (85%); (c) 48% aq HF, MeOH, 30 min (85%); (d) NH<sub>2</sub>NH<sub>2</sub>, EtOH, reflux, 2.5 h (80%); (e) MMTTrCl, Et<sub>3</sub>N, CH<sub>2</sub>Cl<sub>2</sub>, 0 °C→rt, 90 min (70%); (f) maleimide, Ph<sub>3</sub>P, DEAD, THF, 0 °C→rt, overnight (55%); (g) HCl(g), Et<sub>2</sub>O, 0 °C, 5 min (quantitative).

Scheme 2<sup>a</sup>

<sup>a</sup> Reagents and conditions (yield): (a) MMTTrCl, Et<sub>3</sub>N, DMF, overnight (72%); (b) ref 37 (89%); (c) NaH, DMF, overnight (60%); (d) Bu<sub>4</sub>NF, THF, 3 h (quantitative).

**6.** An alternative synthesis of **5** was reported in the literature involving *O*-alkylation of PhthNOH with 4-bromobutyl acetate (35).

*N*-Alkylmaleimides are in general prepared by reaction of alkylamines with maleic anhydride, followed by cyclization of the maleamic acid intermediates (58). Direct *N*-alkylation of maleimide with alkyl halides is reported to be unsuccessful, except for the use of the heavy metal salts of maleimide (59, 60). Once again the Mitsunobu reaction proved to be effective for the direct *N*-alkylation of maleimide (61). Thus, treatment of **6** with maleimide under the Mitsunobu condition furnished the desired *N*-tritylaminoxy maleimide **7** in good yields. Detritylation of **7** by bubbling HCl gas through the Et<sub>2</sub>O solution rapidly precipitated the heterobifunctional linker **8** as a stable HCl salt in quantitative yield. The overall yield of **8** was 18% (seven steps from **1**).

**An Improved Synthesis of the Key Intermediate 6 (Scheme 2).** To eliminate the undesirable protecting group manipulation (*N*Phth → *N*MMTr), *O*-alkylation of the *N*-tritylhydroxylamine **10** was investigated. *N*-Tritylation of hydroxylamine (**9**) with MMTTrCl in pyridine was reported to be problematic necessitating two consecutive chromatographic purifications of **10** (52% yield) (36). In our hands the reaction was straightforward in DMF containing Et<sub>3</sub>N and simple recrystallization was enough to provide pure **10** in a 72% yield without column chromatography. The siloxyiodobutane **12** was prepared from THF (**11**) using TBDMSI as reported (37). *O*-Alkylation of **10** was successful by reaction with NaH and **12** in DMF to furnish the desired protected aminoxy alcohol **13**, the desilylation of which afforded the key intermediate **6**. Thus, the overall yield of **8** was improved to 29% (five steps from **11**).

Scheme 3<sup>a</sup>

<sup>a</sup> Reagents and conditions (yield): (a) K<sup>18</sup>F, Kryptofix 222, DMSO, 120 °C, 10 min (~50% decay corrected); (b) DMF, 30 min (91%); (c) MeOH, 15 min (~70% decay corrected).

**Synthesis of the Maleimide-Containing Thiol-Reactive  $^{18}\text{F}$ -Labeling Agent **16- $^{18}\text{F}$**  (Scheme 3).** The efficiency of the aminoxy-aldehyde coupling reaction was first evaluated by reaction of **8**·HCl with commercially available 4-fluorobenzaldehyde (**15- $^{19}\text{F}$** ). The coupling reaction proceeded essentially to completion within 30 min at room temperature affording the nonradioactive standard **16- $^{19}\text{F}$**  in a 91% yield. The aminoxy group proved to be highly chemoselective toward the aldehyde group over the maleimide group. Although **16- $^{19}\text{F}$**  could exist as *E*- and *Z*-isomers, the <sup>1</sup>H NMR spectrum revealed only one isomer evidenced by a single oxime proton (*CH*=NOR) at  $\delta$  8.02. It is reported that the chemical shifts of the oxime protons are characteristic of the *E*- and *Z*-isomers, e.g.,  $\delta$  7.56 for *E* and  $\delta$  6.95 for *Z* (62). Accordingly, **16- $^{19}\text{F}$**  was tentatively assigned to possess the *E*-configuration.

Synthesis of the maleimide-containing thiol-reactive  $^{18}\text{F}$ -labeling agent **16- $^{18}\text{F}$**  began with the radiochemical synthesis of 4-[ $^{18}\text{F}$ ]fluorobenzaldehyde (**15- $^{18}\text{F}$** ) by [ $^{18}\text{F}$ ]-fluoride-for-trimethylammonium substitution on 4-(formylphenyl)trimethylammonium triflate (**14**) at 120 °C for 10 min (28). After rapid Sep-Pak (C-18) purification, **15- $^{18}\text{F}$**  was subjected to the aminoxy-aldehyde coupling reaction with the linker **8**·HCl. The coupling reaction proceeded efficiently in ~70% coupling yield (decay corrected) within 15 min at room temperature. After HPLC purification, the radioactive fraction (5 mL) was reconstituted in acetonitrile (1 mL) using the solid-phase extraction technique (63). Acetonitrile is the choice of cosolvent particularly for modification of peptides due to its preventive effect against peptide aggregation (64). The chemical and radiochemical purity of **16- $^{18}\text{F}$**  was verified by analytical HPLC (Figure 1A). Coelution of the radioactive peak with the UV peak of the **16- $^{19}\text{F}$**  confirmed the identity. The overall radiochemical yield was ~35% (decay corrected) and the total reaction time was ~60 min from EOB. The specific activity was determined to be ~3000 Ci/mmol at EOS.

**Model  $^{18}\text{F}$ -Labelings of Glutathione (GSH) (**17**) and 5'-Thiol-Functionalized ODN (5'-S-ODN) **18** (Scheme 4).** The  $^{18}\text{F}$ -labeling ability of **16- $^{18}\text{F}$**  was preliminarily assessed by using a tripeptide GSH (**17**) and a 5'-S-ODN **18** as model thiol-containing/functionalyzed biomolecules. Both  $^{18}\text{F}$ -labelings were performed in PBS (pH 7.5) at room temperature for 10 min. The  $^{18}\text{F}$ -labeled GSH **19- $^{18}\text{F}$**  (Figure 1B) and 5'-S-ODN **20- $^{18}\text{F}$**  (Figure 1C) were obtained in over 95% purities after Sep-Pak (C-18) purification and sequential Sep-Pak (C-18) and NAP-10 purification, respectively, without the use of HPLC. The  $^{18}\text{F}$ -labeling yields (unoptimized) were ~70% and ~5% (decay corrected) for **19- $^{18}\text{F}$**  and **20- $^{18}\text{F}$** , respectively. The isolated yields of **19- $^{18}\text{F}$**  (~12 mCi) and

Received July 2, 2003; Revised Manuscript Received September 23, 2003

Synthetic oligopeptides comprising linear or continuous topographic B-cell epitope sequences of proteins might be considered as specific and small size antigens. It has been demonstrated that the strength and specificity of antibody binding could be altered by conjugation to macromolecules or by modification in the flanking regions. However, no systematic studies have been reported to describe the effect of different carrier macromolecules in epitope conjugates. To this end, the influence of carrier structure and topology on antibody recognition of attached epitope has been studied by comparing the antibody binding properties of a new set of conjugates with tetratuftsin analogue (H-[Thr-Lys-Pro-Lys-Gly]<sub>4</sub>-NH<sub>2</sub>, T20) sequential oligopeptide carrier (SOC<sub>n</sub>), branched chain polypeptide, poly[Lys(Ser<sub>i</sub>-DL-Ala<sub>m</sub>)] (SAK), multiple antigenic peptide (MAP), and keyhole limpet hemocyanine (KLH). In these novel constructs, peptide <sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup> ([Nle<sup>11</sup>]-9–22) representing an immunodominant B cell epitope of herpes simplex virus type 1 glycoprotein D (HSV-1 gD) was conjugated to polypeptides through a thioether or amide bond. Here we report on the preparation of sequential and polymeric polypeptides possessing chloroacetyl groups in multiple copies at the α- and/or ε-amino group of the polypeptides and its use for the conjugation of epitope peptides possessing Cys at C-terminal position. We have performed binding studies (direct and competitive ELISA) with monoclonal antibody (Mab) A16, recognizing the HSV gD-related epitope, [Nle<sup>11</sup>]-9–22, and conjugates containing identical and uniformly oriented epitope peptide in multiple copies attached to five different macromolecules as carrier. Data suggest that the chemical nature of the carrier and the degree of substitution have marked influence on the strength of antibody binding.

## INTRODUCTION

Synthetic oligopeptides comprising linear or continuous topographic B-cell epitope peptides corresponding to sequences of proteins might be considered as specific and small size antigens. It has been demonstrated that the strength and specificity of antibody binding could be altered by conjugation of peptide epitopes to macromolecules or by the substitution of amino acids in the flanking regions of the epitope (1). Such constructs are frequently applied to induce specific immune responses against the covalently attached peptide epitopes for antibody production to identify gene products or for

synthetic vaccine construction (2, 3). An additional application of synthetic oligopeptides and their conjugates is the use in diagnostic microbiologic assays to determine the presence of antibodies against particular microorganisms in patients' sera (4, 5). So far, branched chain polypeptide epitope conjugates have been analyzed with respect to the effect of the carrier macromolecule on immune recognition (6). Here we extend these studies to analyze the effect of the structure and topology of the carrier macromolecule on antibody recognition of epitope. For this we have included sequential oligopeptide carriers (tetratuftsin analogue (H-[Thr-Lys-Pro-Lys-Gly]<sub>4</sub>-NH<sub>2</sub>, T20) (7), and Ac-[Lys-Aib-Gly]<sub>4</sub>-NH<sub>2</sub>, SOC<sub>4</sub> (8)),<sup>2</sup> polymeric branched chain polypeptide, poly[Lys(Ser<sub>i</sub>-DL-Ala<sub>m</sub>)] (SAK) (9, 10), Lys-dendrimer construct (multiple antigenic peptide (MAP) (11) (Figure 1), and the widely used keyhole limpet hemocyanin (KLH) (12) as carrier.

In these novel constructs our model peptide <sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup> ([Nle<sup>11</sup>]-9–22) representing an immunodominant B cell epitope from herpes simplex virus type 1 glycoprotein D (HSV gD-1) was conjugated to synthetic polypeptides mentioned above through a thioether or amide bond (Figure 1). HSV, with its two closely related serotypes (HSV-1 and HSV-2), is one of the most common infectious agents in man. Glycoprotein D of HSV

**Figure 1.** Schematic structure of conjugates in which a peptide epitope corresponding to the 9–22 region of glycoprotein D of HSV-1 is connected with multivalent synthetic sequential (SOC<sub>4</sub>, tetratuftsin analogue), polymeric (SAK), or dendrimeric (MAP) peptide carrier.

is a highly conserved glycoprotein and is >98% similar among HSV strains. It is a major target of both humoral and cellular immune responses of the human host (13). Mature gD-1 is a glycoprotein consisting of 369 amino acids with an *N*-terminal ectodomain of 316 residues and with three *N*-linked oligosaccharide attachment sites. The X-ray crystal structure, comprising residues 1–254, of a soluble ectodomain of gD was published (14).

There are many well-defined coupling methods for the attachment of biologically active peptides to carriers through amide bonds (water-soluble carbodiimide (15), active ester (16), BOP (17)), or via disulfide bridge (heterobifunctional reagents such as SPDP (18) or Cys-(Npys) (19)). An alternative strategy for thiol-based conjugation is the introduction of a thioether bond. This can be achieved by heterobifunctional reagents with a maleimido (MBS (20), SMCC (21)), or iodoacetyl (SIAB (22)) moiety. The simplest way to incorporate an  $\alpha$ -haloacetyl group is to use a corresponding activated ester derivative such as a *p*-nitrophenyl ester of iodoacetic acid

(23). For conjugation, usually small peptides with terminal (24, 25) or internal (24)  $\alpha$ -bromo- or chloroacetyl groups are prepared, and the partner protein or polymer possesses the SH function. Peptides with a chloro- or bromoacetyl group were used for repetitive ligation of  $\alpha$ -helical peptide segments (26), assembly of peptide vaccines composed of T helper and B cell epitopes (27), or for attachment of peptides to antibodies (28). Sporadic reports are available in the literature on the reverse strategy. Jones et al. (29) reported on the synthesis and favorable tolerogenic activity of a peptide–PEG conjugate in which four copies of cyclic mimotope peptides containing an SH group were attached with iodo- or bromoacetylated PEG derivatives. During the preparation of a three-component conjugate, Grandjean et al. (30) have conjugated 2-thioethyl- $\alpha$ -D-mannopyranoside with a construct containing a single copy of a toxoid-derived epitope TT(830–846) peptide and glyoxylyl-*N*-chloroacetylated-L-lysine dendrimers. In this conjugate, four copies of the SH-carbohydrate component were attached to a tetrameric chloroacetylated Lys dendrimer.

Here we report on the preparation of sequential and polymeric polypeptides possessing chloroacetyl groups in multiple copies at the  $\alpha$ - and/or  $\epsilon$ -amino group of the polypeptides and its use for the conjugation of epitope peptides possessing a Cys at C-terminal position. With these constructs, we have performed a comparative study to understand of the effect of carrier structure on antibody recognition. Five conjugates containing different macromolecules as carrier, but identical and uniformly oriented epitope peptide from gD of herpes simplex virus (<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>, [Nle<sup>11</sup>]-9–22), were prepared. Binding studies with monoclonal antibody (Mab) A16, recognizing the HSV gD-related epitope, [Nle<sup>11</sup>]-9–22 (31), were performed by direct and competitive ELISA. Data suggest that the chemical nature of the carrier and the degree of substitution have marked influence on the strength of antibody binding.

## EXPERIMENTAL PROCEDURES

Abbreviations used in this paper follow the rules of the IUPAC–IUB Commission of Biochemical Nomenclature (32) in accordance with the recommended nomenclature of graft polymers (32).

<sup>2</sup> Abbreviation: Ac, acetyl; Aib, aminoisobutyric acid, Boc, *tert*-butoxycarbonyl; BOP, benzotriazol-1-yloxytris(dimethylamino)phosphonium hexafluorophosphate; Bzl, benzyl; cHex, cyclohexyl; ClZ, 2-chlorobenzoyloxycarbonyl; DCC, *N,N*-dicyclohexylcarbodiimide; DCM, dichloromethane; DCU, *N,N*-dicyclohexylurea; DIEA, *N,N*-diisopropylethylamine; DMF, *N,N*-dimethylformamide; *DP<sub>n</sub>*, average ratio of polymerization; DTT, dithiothreitol; ESI, electrospray ionisation; FAB-MS, fast atom bombardment mass spectrometry; HATU, 2-(7-aza-1*H*-benzotriazol-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate; HOBt, 1-hydroxybenzotriazole; HPLC, high performance liquid chromatography; HSV gD, Herpes simplex virus glycoprotein D; KLH, keyhole limpet hemocyanin; MALDI, matrix-assisted laser desorption; MAP, multiple antigenic peptide; MBHA, 4-methylbenzhydrylamine; MBS, *N*-(3-maleimidobenzoyloxy)succinimide; Mab, monoclonal antibody; Meb, 4-methylbenzyl; MeOH, methanol; MS, mass spectrometry; Npys, 3-nitro-2-pyridinesulfenyl; PEG, poly(ethylene glycol); SAK, poly[Lys(Ser<sub>0.9</sub>-DL-Ala<sub>3.5</sub>)]<sub>4</sub>; SIAB, *N*-succinimidyl 4-(iodoacetyl)-aminobenzoate; SMCC, succinimidyl 4-(*N*-maleimidomethyl)-cyclohexane-1-carboxylate; SOC, sequential oligopeptide carrier; SPDP, *N*-succinimidyl 3-(2-pyridyldithio)propionate; TBTU, 2-(1*H*-benzotriazol-1-yl)-1,1,3,3-tetramethyluronium tetrafluoroborate; TFA, trifluoroacetic acid; TLC, thin-layer chromatography; Tos, tosyl; UV, ultraviolet.

<sup>a</sup> Molar ratio calculated from the amino acid composition. <sup>b</sup> ESI-MS. <sup>c</sup> Not tested. <sup>d</sup> Four conjugates were X = 4.4, 5.4, 13.2, or 26.4. <sup>e</sup> Chloroacetyl groups at all four (α- and ε-) amino ends. <sup>f</sup> MALDI. <sup>g</sup> Na<sup>+</sup> adduct, MALDI.

**Synthesis of Epitope Peptides H-<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>-NH<sub>2</sub> ([Nle<sup>11</sup>]-9–22) and H-<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>C-NH<sub>2</sub> ([Nle<sup>11</sup>]-9–22-Cys).** The HSV gD-1 epitope peptide, H-<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>-NH<sub>2</sub> ([Nle<sup>11</sup>]-9–22) and its elongated derivative with C-terminal Cys (H-<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>C-NH<sub>2</sub>) ([Nle<sup>11</sup>]-9–22-Cys), were synthesized manually by solid-phase synthesis using an MBHA resin (0.5 g, 1.1 mmol/g capacity) and the Boc/Bzl strategy. The following *N*<sup>t</sup>-Boc-protected amino acids were used: Asp(OcHex), Lys(CIZ), Arg(Tos), and Cys(Meb). The protocol of the synthesis was the following: (i) deprotection with 33% TFA/DCM (2+20 min); (ii) DCM washing (5 × 0.5 min); (iii) neutralization with 10% DIEA/DCM (3 × 1 min); (iv) DCM washing (4 × 0.5 min); (v) coupling with three equivalent amino acid derivatives—DCC—HOBT in DCM—DMF 4:1 or 1:4 (v/v) mixture depending on the solubility of Boc-amino acid derivatives (60 min); (vi) DMF washing (1 × 0.5 min); (vii) DCM washing (2 × 0.5 min); (viii) ninhydrin (34) or isatin (35) assay. The peptides were cleaved from the resin by the aid of liquid HF in the presence of *p*-cresol and DTT (HF—*p*-cresol—DTT = 10 mL:1 g:0.1 g) for 1.5 h at 0 °C. The crude products were purified by RP-HPLC using a Delta Pak C<sub>18</sub> semipreparative column (300 × 19 mm, 10 μm, 300 Å). The purified peptides were analyzed by RP-HPLC (*t*<sub>R</sub> = 30.9 min for [Nle<sup>11</sup>]-9–22, and *t*<sub>R</sub> = 31.4 min for [Nle<sup>11</sup>]-9–22-Cys), amino acid analysis (data not shown) and ESI-MS (Table 1).

**Synthesis of Chloroacetylated Tetrafluorotyrosine Analogue (H-[Thr-Lys-Pro-Lys(ClAc)-Gly]<sub>4</sub>-NH<sub>2</sub>, T20-(ClAc)<sub>4</sub>).** Chloroacetylated tetrafluorotyrosine analogue (H-[Thr-Lys-Pro-Lys(ClAc)-Gly]<sub>4</sub>-NH<sub>2</sub>, T20(ClAc)<sub>4</sub>) was synthesized using MBHA resin (0.5 g, 1.1 mmol/g capacity) and the Boc/Bzl strategy. The following *N*<sup>t</sup>-Boc-protected amino acids were used: Lys(CIZ), Lys(Fmoc), and Thr(Bzl). The protocol described above for the epitope peptide was used. Chloroacetyl groups were introduced at the *N*<sup>t</sup>-amino group of Lys residues using chloroacetic acid pentachlorophenyl ester in 5 equiv excess in DMF after removal of *N*<sup>t</sup>-Fmoc groups by 20% piperidine/DMF. The chloroacetylated peptides were cleaved from the resin by the aid of anhydrous HF—*m*-cresol—*p*-thiocresol (10 mL:0.5 mL:0.5 g) for 1.5 h at 0 °C (36). The crude product was purified by RP-HPLC using a Delta Pak C<sub>18</sub> semipreparative column (300 × 19 mm, 10 μm, 300 Å). The purified peptides were analyzed by RP-HPLC (*t*<sub>R</sub> = 23.7 min), amino acid analysis and ESI-MS (Table 1). The yield was 65%.

**Synthesis of Chloroacetylated Sequential Oligopeptide (Ac-[Lys(ClAc)-Aib-Gly]<sub>4</sub>-OH, Ac-[SOC<sub>4</sub>(ClAc)<sub>4</sub>].** Chloroacetylated sequential oligopeptide carrier (Ac-[Lys(ClAc)-Aib-Gly]<sub>4</sub>-OH, Ac-[SOC<sub>4</sub>(ClAc)<sub>4</sub>]) was synthesized using a PAM resin and the Boc/Bzl strategy.

Boc-Lys(Fmoc) as side chain protected amino acid derivative was used. The protocol for the synthesis was as follows: (i) deprotection with 40% TFA/DCM (1 × 2 min, 1 × 13 min); (ii) washing DCM (3 × 1 min), MeOH (3 × 1 min), DCM (3 × 1 min); (iii) neutralization with 10% DIEA/DCM (2 × 2 min); (iv) washing DCM (3 × 1 min), MeOH (3 × 1 min), DCM (3 × 1 min); (v) coupling of three equivalent amino acid derivatives—TBTU—HOBT in DCM/DMF 1:1 (60 min); (vi) washing DCM (3 × 1 min), MeOH (3 × 1 min), DCM (3 × 1 min) vii) ninhydrin assay. Chloroacetyl groups were introduced at the *N*<sup>t</sup>-amino group of Lys residue by chloroacetic acid pentachlorophenyl ester as described above after removal of *N*<sup>t</sup>-Fmoc groups by 40% piperidine/DMF. The product was cleaved from the resin with anhydrous HF in the presence of anisole and phenol (10% v/v) as scavengers at –8 °C for 30 min and 0 °C for 1 h. The crude product was purified by RP-HPLC using a Supelco Discovery C<sub>18</sub> semipreparative column (250 mm × 10 mm, 5 μm). The purified peptides were analyzed by RP-HPLC (*t*<sub>R</sub> = 40.5 min) and ESI-MS (Table 1). The yield was 42%.

**Conjugation of Peptide H-<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>C-NH<sub>2</sub> ([Nle<sup>11</sup>]-9–22-Cys) with Sequential Oligopeptides Using Thioether Linkage.** 40 mg of sequential glycopeptides Ac-(Lys(ClAc)-Aib-Gly)<sub>4</sub>-OH (Ac-[SOC<sub>4</sub>(ClAc)<sub>4</sub>]) or H-[Thr-Lys-Pro-Lys(ClAc)-Gly]<sub>4</sub>-NH<sub>2</sub> (T20(ClAc)<sub>4</sub>) containing four chloroacetyl groups was dissolved in 40 mL of 0.1 M Tris-HCl (pH 8.0) .1.2–1.4 equiv (calculated for the chloroacetyl content of the oligopeptides) of epitope peptide ([Nle<sup>11</sup>]-9–22-Cys) was added to the solution of chloroacetylated oligopeptides over a period of time in solid form. The mixtures were stirred at RT. The reaction was monitored by RP-HPLC and proceeded for 24–72 h. The conjugates were purified by RP-HPLC and were characterized by *t*<sub>R</sub> values (*t*<sub>R</sub> = 31.8 min for Ac-[SOC<sub>4</sub>(ClAc)<sub>4</sub>], *t*<sub>R</sub> = 31.0 min for T20-(ClAc)<sub>4</sub>), the amino acid compositions, and mass value presented in Table 1. The yields of purified conjugates were over 60% in all cases. The conjugates were designated as Ac-[SOC<sub>4</sub>([Nle<sup>11</sup>]-9–22-C)<sub>4</sub>] and T20([Nle<sup>11</sup>]-9–22-C)<sub>4</sub>, respectively.

**Synthesis of Chloroacetylated Multiple Antigenic Peptide (ClAc-Lys(ClAc)-Lys(ClAc-Lys(ClAc))-Arg-Arg-βAla-NH<sub>2</sub>, MAP(ClAc)<sub>4</sub>).** The lysine dendrimer (ClAc-Lys(ClAc)-Lys(ClAc-Lys(ClAc))-Arg-Arg-βAla-NH<sub>2</sub>, MAP(ClAc)<sub>4</sub>), was synthesized stepwise using MBHA resin (0.7 mmol/g, 145 mg) of. The side chains of Arg and Lys were protected with Tos and Boc groups, respectively, the latter to allow creation of the dendrimeric structure. The synthesis protocol was as follows: (i) deprotection with 30% TFA/DCM (2+20 min); (ii) DCM washing (6 × 1 min); (iii) neutralization with 5% DIEA/DCM (3 × 1 min); (iv) DCM washing (4 × 0.5 min); (v) DMF washing

(3 × 0.5 min); (vi) coupling with 3 equiv of Boc-amino acid, in the presence of an equimolar amount of TBTU and 2-fold molar excess DIEA in DMF for 1 h; (vii) DMF washing (3 × 0.5 min); (viii) DCM washing (3 × 0.5 min); (ix) ninhydrin test. After assembly of the peptide chain was completed, the Boc protecting groups of the two outlying Lys residues were removed as above, and the resulting  $\alpha$ - and  $\epsilon$ -amino groups were acylated with chloroacetyl chloride (3 equiv) in the presence of DIEA (3 equiv) in DCM. The peptide was deprotected and cleaved off the resin by treatment with HF/*p*-cresol (9:1; v/v) for 1 h at 0 °C. The product was purified by semipreparative RP-HPLC and resulted in homogeneous material ( $t_R$  = 22.4) characterized by amino acid analysis and MALDI-TOF mass spectrometry (Table 1). The yield was 50%.

**Conjugation of the peptide H-<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>C-NH<sub>2</sub> ([Nle<sup>11</sup>]-9-22-Cys) with Chloroacetylated Multiple Antigenic Peptide (ClAc-Lys(ClAc)-Lys(ClAc-Lys(ClAc))-Arg-Arg- $\beta$ -Ala-NH<sub>2</sub>, MAP(ClAc)<sub>4</sub>) Using a Thioether Linkage.** Conjugation was performed by reacting 14 mg (8  $\mu$ mol) of [Nle<sup>11</sup>]-9-22-Cys peptide with 1.1 mg (1  $\mu$ mol) of MAP(ClAc)<sub>4</sub> in 0.1 M Tris-HCl buffer, pH 8, under N<sub>2</sub> atmosphere. The reaction was monitored by RP-HPLC. After 24 h the expected tetravalent MAP([Nle<sup>11</sup>]-9-22-C)<sub>4</sub> was found by MALDI-TOF mass spectrometry as a minor component of the main peak. Preparative HPLC purification resulted in a homogeneous fraction, that was characterized by RP-HPLC ( $t_R$  = 19.3 min) and MALDI-TOF MS (linear mode). The yield was 55%. The conjugate was designated as MAP-[Nle<sup>11</sup>]-9-22-C)<sub>4</sub>.

**Tandem Synthesis of Conjugate (Ac-SOC<sub>4</sub>([Nle<sup>11</sup>]-9-22)<sub>4</sub>) Composed of Sequential Oligopeptide Carrier (SOC<sub>4</sub>) and H-<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>-NH<sub>2</sub> ([Nle<sup>11</sup>]-9-22) with an Amide Linkage.** The conjugate was prepared by tandem synthesis on a PAM resin using the Boc/Bzl strategy. The following side chain protected *N*<sup>t</sup>-Boc amino acids were used: Asp(OBzl), Lys(Fmoc) and Arg(Tos). First the carrier Ac-[Lys(Fmoc)-Aib-Gly]<sub>4</sub>-OH was synthesized. After completion and *N*<sup>t</sup>-acetylation by acetic anhydride, the *N*<sup>t</sup>-Fmoc-group was removed and the epitope peptide was built up on the  $\epsilon$ -amino groups of lysines according to the Ac-[SOC<sub>4</sub>(ClAc)]<sub>4</sub> protocol described above. The conjugate was cleaved from the resin with HF in the presence of anisole and phenol (10% v/v) as scavengers at -8 °C for 30 min and 0 °C for 1 h. The crude product was purified by RP-HPLC using a Supelco Discovery C<sub>18</sub> semipreparative column (250 mm × 10 mm, 5  $\mu$ m). The purified conjugate was analyzed by RP-HPLC and ESI-MS (Table 1). The yield was 20%. The conjugates were designated as Ac-[SOC<sub>4</sub>([Nle<sup>11</sup>]-9-22)<sub>4</sub>].

**Synthesis of Chloroacetylated Branched Polypeptide Poly[Lys(ClAc-Ser<sub>1</sub>-DL-Ala<sub>m</sub>)] (SAK(ClAc)<sub>j</sub>).** Branched chain polymer polypeptide poly[Lys(Ser<sub>0.9</sub>-DL-Ala<sub>3.5</sub>)] (SAK) with polylysine backbone was produced as described earlier (9). Briefly, poly[Lys] was synthesized by polymerization of *N*<sup>t</sup>-carboxy-*N*<sup>t</sup>-benzyloxycarbonyl-lysine anhydride (average degree of polymerization: 60). After cleavage of the protecting groups, poly[Lys(DL-Ala<sub>3.5</sub>)] (AK) was prepared by grafting of short oligomeric DL-Ala side chains using the respective *N*<sup>t</sup>-carboxy-alanine anhydride onto the  $\epsilon$ -amino groups of poly[Lys]. Benzyloxycarbonyl-protected amino acid derivative (Z-Ser-OPcp) was coupled to the end of the side chains of AK by the HOBt-catalyzed active ester method (37). Blocking groups were removed completely with HBr in

glacial acetic acid. The composition of SAK was determined by amino acid analysis. The size and molecular weight of polymer was calculated from the amino acid composition and the sedimentation analysis of polylysine (38).

Chloroacetylation of SAK was carried out as follows: 80 mg (0.145 mmol) SAK-HBr salt ( $\overline{DP}_n$  = 60,  $M_{w,monomer}$  = 550) was dissolved in 1 mL water, and the solution was diluted with 4 mL of DMF. Chloroacetyl groups were introduced at the *N*<sup>t</sup>-amino group of Ser residues by chloroacetic acid pentachlorophenyl ester. Six different SAK-ClAc-OPcp ratios were used (1:1, 1:0.8, 1:0.6, 1:0.5, 1:0.4, and 1:0.3 mol/mol; 50 mg, 40 mg, 30 mg, 25 mg, 20 mg, 15 mg of ClAc-OPcp, respectively), and the active ester was added to the polymer-containing solution dissolved in 5 mL of DMF. The reaction mixtures were stirred overnight at room temperature. The solution was dialyzed for 2 days in Visking tubes (cut-off 8000–12000) against 0.1% acetic acid and freeze-dried. According to the Cl analysis of six SAK derivatives: 46.5%, 45.9%, 48.5%, 41.3%, 30.1%, and 21.7% of the side chains were blocked by ClAc groups, respectively.

**Conjugation of the Peptide H-<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>C-NH<sub>2</sub> ([Nle<sup>11</sup>]-9-22-Cys) with Chloroacetylated Branched Polypeptide Poly[Lys(ClAc-Ser<sub>1</sub>-DL-Ala<sub>m</sub>)] (SAK(ClAc)<sub>j</sub>) Using a Thioether Linkage.** For conjugation of epitope peptide to chloroacetylated SAK, four differently substituted carriers were applied. Fifteen milligrams of SAK(ClAc)<sub>48.5</sub>, SAK(ClAc)<sub>41.3</sub>, SAK(ClAc)<sub>30.1</sub>, or SAK(ClAc)<sub>21.7</sub> (acetate salt form) was dissolved in 100 mL of 0.1 M Tris-HCl (pH 8.2). A 1.2 equiv (calculated for the chloroacetyl content of the polymers) amount of epitope peptide (23.4 mg, 20 mg, 14.8 mg, and 10.6 mg, respectively) were added in two portions to the solution. The conjugations proceeded for 24 h, and then they were terminated by addition of an excess of Cys to block the unreacted chloroacetyl groups. The solutions were dialyzed in Visking tubes (cut-off 8000–12000) for 2 days against water. The average degree of substitution was calculated from the amino acid analysis. Depending on the input molar ratio, 44%, 22%, 9%, and 7% of the side chains were substituted by epitope peptide, respectively. The conjugates were designated as SAK([Nle<sup>11</sup>]-9-22-C)<sub>x</sub>.

**Conjugation of the Peptide H-<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>C-NH<sub>2</sub> ([Nle<sup>11</sup>]-9-22-Cys) with Keyhole Limpet Hemocyanin (KLH) Using a Thioether Linkage.** The conjugation involved three steps: (i) KLH activation with *m*-maleimidobenzoic acid *N*-hydroxysuccinimido ester (MBS), (ii) Sephadex G25 purification, and (iii) coupling of the peptide epitope to the purified, activated protein (19). Briefly, to 3.75 mg of KLH in 0.01 M PBS was added dropwise 112  $\mu$ L of a 20 mg/mL solution of MBS in DMF. After 30 min the reaction mixture was loaded onto a Sephadex G-25 column (16 × 1 cm) eluted with 0.05 M PBS, pH 6, at a flow rate of 20 mL/h, to separate the KLH-MBS adduct from excess MBS and nonactivated KLH. One milliliter fractions were collected and monitored at  $\lambda$  = 280 nm. The KLH-MBS adduct usually was eluted in fractions 5–10. To the pooled, KLH-MBS-containing fractions was slowly added 3.75 mg of freeze-dried peptide. The pH was adjusted to 7.5 with 0.1 M NaOH, and the reaction was allowed to proceed for 3 h and then dialyzed in Visking tube (MW cut-off 8000–12000 Da) against 4 × 1 L of 10 mM PBS, pH 8. An aliquot of the peptide-KLH conjugate solution was hydrolyzed and subjected to amino acid analysis (see below) to determine the molar peptide/KLH ratio. The conjugate was designated as MAP([Nle<sup>11</sup>]-9-22-C)<sub>4</sub>.

**RP-HPLC.** RP-HPLC analysis of peptides [Nle<sup>11</sup>]-9–22, [Nle<sup>11</sup>]-9–22-C, T20(CIAC)<sub>4</sub>, and conjugates Ac-[SOC<sub>4</sub>([Nle<sup>11</sup>]-9–22-C)<sub>4</sub>], T20 ([Nle<sup>11</sup>]-9–22-C)<sub>4</sub>, was performed using a Phenomenex Jupiter C<sub>18</sub> (250 × 4.6 mm, 5 μm, 300 Å) reverse phase column with Knauer apparatus (H. Knauer, Bad Homburg, Germany). The instrument was assembled from two HPLC Pumps 64, a variable wavelength monitor, and functionalized by HPLC Software/Hardware Package Version 2.21 A. The type of columns, gradients, and solvents are summarized below. Eluent A was 0.1% TFA in water, and eluent B was 0.1% TFA in acetonitrile–water (80:20 V/V). A linear gradient (0 min 0% B; 5 min 0% B; 50 min 90% B) at a flow rate of 1 mL/min was used as mobile phase. Detection was performed at λ = 220 nm. Purification was carried out on a Phenomenex Jupiter C<sub>18</sub> (250 × 10 mm, 10 μm, 300 Å) semipreparative column using the same eluents at a flow rate of 5 mL/min. The gradient was 0 min 10% B; 5 min 10% B; 50 min: 50% B. Detection was carried out at λ = 220 nm.

HPLC analysis of Ac-[Lys([Nle<sup>11</sup>]-9–22)-Aib-Gly]<sub>4</sub>-OH was performed using a Supelco Discovery C<sub>18</sub> (250 mm × 4.6 mm, 5 μm, 300 Å) reverse phase column with a Waters instrument equipped with a Waters 616 pump and a Waters 996 photodiode array detector. Eluent A was 0.1% TFA in water, and eluent B was 0.1% TFA in acetonitrile. A linear gradient 15% to 35% acetonitrile in 0.1% TFA at a flow rate of 1 mL/min. Purification was carried out on a Waters 4000 semipreparative instrument using a Supelco Discovery C<sub>18</sub> (250 mm × 10 mm, 5 μm, 300 Å) column with the same linear gradient at a flow rate of 4.7 mL/min. Detection was carried out at λ = 214 nm.

HPLC analysis of ClAc-Lys(CIAC)-Lys(CIAC-Lys(CIAC))-Arg-Arg-β-Ala-NH<sub>2</sub> (MAP(CIAC)<sub>4</sub>) and its epitope conjugate was performed on a Shimadzu (Japan) HPLC system using a Vydac C<sub>18</sub> column, linear 10–40% gradient of acetonitrile (0.036% TFA) into water (0.045% TFA) over 30 min at 1 mL/min. Purification was carried out on a Vydac C<sub>18</sub> column (200 mm × 25 mm, 20 μm) in a Waters Delta Prep 4000 system using a linear 10 to 30% gradient of acetonitrile (0.1% TFA) into water (0.1% TFA) over 60 min at 3 mL/min flow rate. Detection was performed at λ = 214 nm.

**Amino Acid Analysis.** The amino acid composition of sequential oligopeptides (SOC<sub>n</sub>, tetratuftsin analogue), branched polypeptide (SAK), keyhole limpet hemocyanin (KLH), epitope peptide, and their conjugates was determined by amino acid analysis using a Beckman (Fullerton, CA) model 6300 amino acid analyzer. Prior to the analysis, samples were hydrolyzed in 6 M HCl in sealed and evacuated tubes at 110 °C for 24 h.

**Mass Spectrometry.** Positive ion electrospray ionization mass spectrometric (ESI-MS) analyses of peptides [Nle<sup>11</sup>]-9–22, [Nle<sup>11</sup>]-9–22-C, T20(CIAC)<sub>4</sub>, and conjugates Ac-[SOC<sub>4</sub>([Nle<sup>11</sup>]-9–22-C)<sub>4</sub>], T20 ([Nle<sup>11</sup>]-9–22-C)<sub>4</sub>, were performed on a PE API 2000 triple quadrupole mass spectrometer (Sciex, Toronto, Canada). Spray voltage was set to 4.8 kV, and 30 V orifice voltage was applied. Samples were dissolved in methanol–water (1:1 V/V) mixture containing 0.1% acetic acid, and 5 μL of sample was injected at a flow rate of 100 μL/min. The instrument was used in Q<sub>1</sub> scan mode in the range of *m/z* 400–1700, with a step size of 0.3 amu and a dwell time of 0.5 ms.

Positive and negative ion electrospray ionization mass spectrometric (ESI-MS) analyses of Ac-[Lys([Nle<sup>11</sup>]-9–22)-Aib-Gly]<sub>4</sub>-OH and Ac-[Lys(CIAC)-Aib-Gly]<sub>4</sub>-OH were performed on a Micromass Platform LC-MS. Capillary and cone voltages were set to 3 kV and 40 V, respectively.

Samples were dissolved in water/acetonitrile/trifluoroacetic acid (1/1/0.05 V/V/V).

MALDI-TOF mass spectra of ClAc-Lys(CIAC)-Lys(CIAC-Lys(CIAC))-Arg-Arg-β-Ala-NH<sub>2</sub> (MAP(CIAC)<sub>4</sub>) and its epitope conjugate were recorded in a Voyager DE-STR instrument (Applied Biosystems, Foster City, CA) operating routinely in the linear mode and using α-cyano-4'-hydroxycinnamic acid as matrix.

**Enzyme-Linked Immunosorbent Assay (ELISA).** Throughout the ELISA studies culture medium of the hybridoma cell line Mab A16 was used. The preparation of Mab A16 has been described earlier (31, 39, 40). Briefly, Mab A16 was isolated after immunization of mice with extracts of HSV-1 infected cells. Hybridomas reactive with HSV were isolated. The isolated hybridomas were screened for reactivity with HSV specific proteins. Mab A16, isotype IgG2a, is reactive with HSV glycoprotein D. The Mab A16 is a conformation-independent monoclonal antibody and is classified together with Mabs LP14, ID3 as a group VII monoclonal antibody of gD (39, 41). The epitope of group VII Mabs is located within residues 9–19 of mature gD (39, 42).

In the direct ELISA, a standard dilution, containing an excess Mab A16, was used in combination with serial dilutions of the conjugates, used as coating antigen. For the direct ELISA, 96-well ELISA plates (Greiner Labortechnik, Germany) were coated with serial dilutions of peptide 9–22 and the conjugates (dilutions started at 100 ng/well). The dilutions were made in coating buffer (0.05 M sodium carbonate-bicarbonate buffer, pH 9.6). Plates were incubated overnight 4 °C or 2 h at 37 °C. After coating, the plates were washed three times with washing buffer (0.3% Tween-20, 1.0 M NaCl, in phosphate-buffered saline, pH 7.2 (PBS)). The monoclonal antibody A16 was diluted in dilution buffer (0.3% Tween-20, 0.2 M NaCl, in PBS), and 100 μL of the standard dilution Mab A16 was added to each well. Thereafter, the plates were incubated at room temperature for 1 h and subsequently washed three times with washing buffer. Then 100 μL of peroxidase-conjugated goat anti-mouse IgG (Dako, Denmark) diluted 1000 times in dilution buffer was added to each well, and the plates were incubated at 37 °C for 1 h. After incubation, the plates were washed three times with washing buffer and 100 μL of *o*-phenylenediamine dihydrochloride (0.5 mg/mL) in substrate buffer (0.05 M sodium phosphate-citrate buffer, pH 5.0) with 100 μL of 30% hydrogen peroxide per 100 mL of substrate buffer was added. After 30 min, the reaction was stopped by adding 50 μL of 2 M H<sub>2</sub>SO<sub>4</sub> and the absorbance at λ = 490 nm was measured. The concentration of the peptide/conjugate construct which gave an OD<sub>490</sub> of 1.0 by a standard dilution of Mab A16 was calculated.

The competition ELISA was performed as described earlier (31, 39). Briefly, 2-fold dilution series of peptide LKNleADPNRFRGKDL ([Nle<sup>11</sup>]-9–22) of gD and the conjugates containing peptide ([Nle<sup>11</sup>]-9–22) were preincubated for 2 h at room temperature with optimal concentrations (dilution 800×) of Mab A16 (38). After preincubation, the residual binding capacity of Mab A16 in the preincubation mixture was determined by ELISA in microtiter wells coated with peptide ([Nle<sup>11</sup>]-9–22 (0.5 μg/well)). As standard, a serial dilution of peptide ([Nle<sup>11</sup>]-9–22 with a fixed dilution of Mab A16 was always included: approximately 3 pmol of peptide ([Nle<sup>11</sup>]-9–22 present per 100 μL resulted in an OD<sub>490</sub> of 1.0. The relative amount of peptide ([Nle<sup>11</sup>]-9–22 present in the conjugates giving a residual OD<sub>490</sub> of 1.0 was estimated graphically from plots of OD vs peptide concentrations.

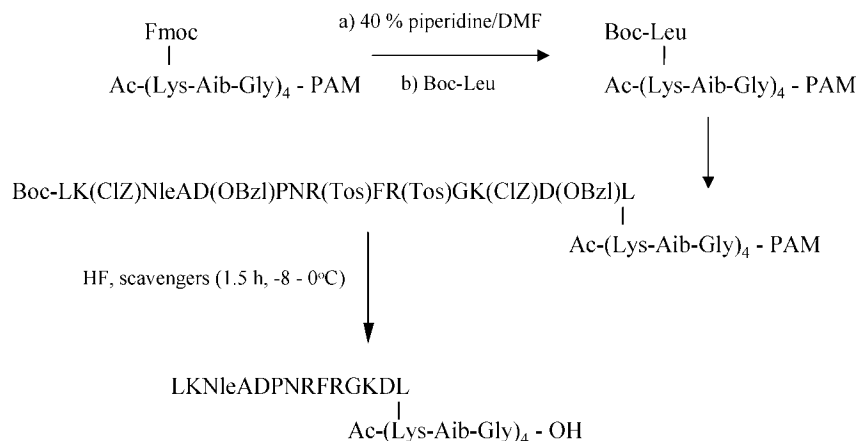

**Figure 2.** Outline of the synthesis of ([Nle<sup>11</sup>]-9-22-Cys) conjugate with chloroacetylated tetratuftsin analogue T20(ClAc)<sub>4</sub> by introduction of a thioether bond.

## RESULTS AND DISCUSSION

**Synthesis and Chemical Characterization of [Nle<sup>11</sup>]-9-22-polypeptide Conjugates.** The coupling of epitope peptide with the sequence according to herpes simplex virus type 1 glycoprotein D (HSV gD-1) was coupled to sequential polypeptide carriers (SOC<sub>4</sub> (8), tetratuftsin analogue T20 (7), to branched chain polymeric polypeptide SAK (10, 43), and to Lys-dendrimer (11) (Figure 1) by the introduction of thioether linkage. For this, thiol group was incorporated by elongation the peptide with a Cys residue at its C-terminal, H-<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>C-NH<sub>2</sub>. Simultaneously, sequential oligopeptides and Lys-dendrimers were assembled by solid-phase synthesis using the Boc/Bzl strategy and MBHA or PAM resins. Chloroacetyl groups were introduced into the polypeptides by chloroacetic acid pentachlorophenyl ester after removal of Fmoc groups (tetratuftsin analogue, SOC<sub>n</sub>) or Boc-groups (Lys-dendrimer). It should be noted that the chloroacetylated derivative of the SOC<sub>4</sub> oligopeptide (Ac-[Lys(ClAc)-Aib-Gly]<sub>4</sub>-OH), the tetratuftsin analogue (H-[Thr-Lys-Pro-Lys(ClAc)-Gly]<sub>4</sub>-NH<sub>2</sub>), and the Lys-dendrimer (ClAc-Lys(ClAc)-Lys(ClAc-Lys(ClAc))-Arg-Arg-β-Ala-NH<sub>2</sub>) were tetravalent, e.g., contained four ClAc groups. The synthesis of the chloroacetylated tetratuftsin derivative is outlined in Figure 2. The scheme indicates that selective side chain protection strategy was used to provide access only to every second Lys residues in the sequence. After removal of Fmoc blocking groups, the chloroacetyl moiety was introduced. This strategy allowed us to design the number and position of epitopes after conjugation. In the case of SOC<sub>4</sub> oligopeptide (Ac-[Lys(ClAc)-Aib-Gly]<sub>4</sub>-OH) and Lys-dendrimer, all four ε- and α- plus ε-amino groups were chloroacetylated. The synthetic peptides containing chloroacetyl moiety at their N<sup>ε</sup>- and/or N<sup>α</sup>-Lys amino groups were cleaved from the resins by HF in the presence of appropriate scavengers by the simultaneous liberation of the peptide and cleavage of Bzl, Tos, and ClZ protections (an example of the strategy is shown in Figure 2). Compounds were purified on RP-HPLC prior to the conjugation. Conjugation reactions were carried out in solution using 0.1 M Tris-HCl (pH 8.0). To avoid dimerization, the cysteine containing epitope peptide ([Nle<sup>11</sup>]-9-22-Cys) was added in solid form to the solution of chloroacetylated polypeptides (1 mg/mL) over a period

of time. The reaction was monitored by HPLC and mass spectrometric analysis of samples and proceeded for 2–3 days. For conjugation of peptide H-<sup>9</sup>LKNleADPNRFRGKDL<sup>22</sup>C-NH<sub>2</sub> ([Nle<sup>11</sup>]-9-22-Cys) with tetratuftsin analogue (H-[Thr-Lys-Pro-Lys(ClAc)-Gly]<sub>4</sub>-NH<sub>2</sub>), the formation of thioether linkage is a stepwise and time-consuming process. First, we observed the appearance of the monosubstituted compound. After 3.5 h, two additional peaks were present: the conjugate with two copies of the epitope peptide and also the dimeric form of the peptide. At 29 h no unsubstituted chloroacetyl tuftsin analogue was present in the reaction mixture which was predominated by conjugates containing three or four copies of the epitope peptides. After reduction with DTT, at the end of the reaction (72 h) mainly the tetravalent target compound and peptide [Nle<sup>11</sup>]-9-22-Cys applied in excess were present. It should be noted that the excess of the Cys-peptide was recovered. Conjugates were purified by RP-HPLC and characterized by *t<sub>R</sub>* values, amino acid compositions from amino acid analysis, and relative molar mass. Even the Lys-dendrimer conjugation reaction resulted in a satisfactory end product. The yields of purified conjugates were over 60%.

For the preparation of multivalent epitope conjugates, branched chain polymeric polypeptide (SAK) was reacted with chloroacetic acid pentachlorophenyl ester in DMF–water (9:1, v/v) solution. The conjugation with peptide [Nle<sup>11</sup>]-9-22-Cys resulting in a thioether linkage between the carrier and epitope peptide was performed similarly to the MAP, SOC<sub>4</sub>, and tetratuftsin analogue constructs. The conjugation reaction was terminated after 24 h by addition of an excess of Cys to block the unreacted chloroacetyl groups. The crude product was dialyzed against water to remove of uncoupled peptide and Cys. By using various input peptide/polymer molar ratios, we have prepared conjugates in which 7–44% of the side chains were substituted by the epitope peptide, as determined from amino acid analysis. The KLH conjugate of peptide [Nle<sup>11</sup>]-9-22-Cys was prepared by using *N*-succinimidyl *m*-maleimidobenzoate activated protein as described in the literature (20). For comparison, we have produced a conjugate of the SOC<sub>4</sub> oligopeptide. In this tetravalent construct—instead of a thioether bond—an amide linkage connected the epitope and to the carrier (Figure 3). For this, a tandem solid-phase synthesis

**Figure 3.** Outline of the tandem synthesis of  $[(\text{Nle}^{11})\text{-9-22}]$  conjugate with sequential oligopeptide carrier (Ac-(SOC<sub>4</sub>)) using an amide bond.

<sup>a</sup> Molar ratio calculated from the amino acid composition. <sup>b</sup> The lowest amount in ng peptide per 100  $\mu\text{L}$  to obtain an OD = 1.0. <sup>c</sup> pmol peptide per 100  $\mu\text{L}$  needed to obtain a residual OD = 1.0. Values are based on the amounts of epitope peptide present in the conjugate. <sup>d</sup> Not interpretable.

strategy was used. After completion of the assembly of the 68-mer conjugate, the compound was cleaved from the resin by HF in the presence of appropriate scavengers.

**Comparison of the Reactivity of the Peptide  $[(\text{Nle}^{11})\text{-9-22}]$  Conjugates against Mab A16.** The peptide conjugates were compared for reactivity against Mab A16 in the direct and competition ELISA. In direct ELISA, two different properties of the conjugates are measured: the reactivity of the conjugates against Mab A16, and the coating properties of the conjugates to the polystyrene of the ELISA plates. Coating of the conjugates to the polystyrene may affect the accessibility of the epitope by the Mab and makes interpretation of the results difficult. Differences in reactivity could be due either to the nature of the conjugates or to the binding properties of the conjugates to the polystyrene. Therefore, the reactivity of the conjugates and the Mab in solution were determined as well in the competition ELISA.

In the direct ELISA peptide conjugates, peptide  $[(\text{Nle}^{11})\text{-9-22}]$  and the conjugates were coated to ELISA plates. Subsequently Mab A16 and peroxidase-conjugated anti-monoclonal antibody was added. The results are summarized in Table 2. For peptide  $[(\text{Nle}^{11})\text{-9-22}]$ , 51.2 ng per 100  $\mu\text{L}$  was required for coating to obtain an OD<sub>490</sub> of 1.0. Substantially less of the conjugated peptide was needed. It should be noted that the comparison was made based on the amount of the epitope peptide present in the conjugates and not on the total amount of conjugate. For the conjugates of Ac-[SOC<sub>4</sub>[(Nle<sup>11</sup>)-9-22-C]<sub>4</sub>], T20-[(Nle<sup>11</sup>)-9-22-C]<sub>4</sub>, and SAK[(Nle<sup>11</sup>)-9-22-C]<sub>x</sub> roughly the same amount, approximately 3–4 ng of peptide, present in the conjugates was required, while for Ac-[SOC<sub>4</sub>-

**Figure 4.** Reactivity of HSV glycoprotein D type 1 specific monoclonal antibody A16 to  $[(\text{Nle}^{11})\text{-9-22}]$  epitope conjugates in competition ELISA. The effect of the carrier on the binding. Peptide 9-22 ( $\square$ ), T20  $[(\text{Nle}^{11})\text{-9-22-C}]_4$  ( $\bullet$ ), Ac-[SOC<sub>4</sub>[(Nle<sup>11</sup>)-9-22-C]<sub>4</sub>] ( $\circ$ ), Ac-[SOC<sub>4</sub>[(Nle<sup>11</sup>)-9-22-C]<sub>x</sub>] ( $\triangle$ ), KLH  $[(\text{Nle}^{11})\text{-9-22-C}]_x$  ( $\blacktriangle$ ).

$[(\text{Nle}^{11})\text{-9-22}]_4$  and KLH  $[(\text{Nle}^{11})\text{-9-22-C}]_x$  conjugates, slightly more (9.3 and 13.6 ng, respectively) conjugated peptide was needed. The carriers without peptide  $[(\text{Nle}^{11})\text{-9-22}]$  did not show any reactivity with Mab A16 (data not shown).

To compare the binding properties of the different conjugates to Mab A16, competition ELISAs were performed (Figure 4). Serial dilutions of peptide  $[(\text{Nle}^{11})\text{-9-22}]$ , the conjugates, and the carriers were preincubated with optimal concentrations of Mab A16. The residual binding capacity of Mab A16 in the mixtures was

determined in microtiter wells coated with peptide [Nle<sup>11</sup>]-9-22. The relative amount of peptide in the conjugates giving an OD<sub>490</sub> of 1.0 was estimated graphically from plots of OD vs peptide concentrations. We found that the chemical nature of the carrier has marked effects on the antibody binding (Table 2).

Conjugates Ac-[SOC<sub>4</sub>([Nle<sup>11</sup>]-9-22-C)<sub>4</sub>], T20([Nle<sup>11</sup>]-9-22-C)<sub>4</sub>, and Ac-[SOC<sub>4</sub> ([Nle<sup>11</sup>]-9-22)<sub>4</sub>] all required similar amounts of peptide, which was approximately five times less than that needed of the nonconjugated peptide [Nle<sup>11</sup>]-9-22, to inhibit the binding of peptide [Nle<sup>11</sup>]-9-22 and Mab A16. Of the SAK conjugate (SAK([Nle<sup>11</sup>]-9-22-C)<sub>x</sub>), slightly more was required than of the Ac-[SOC<sub>4</sub>([Nle<sup>11</sup>]-9-22-C)<sub>4</sub>], T20([Nle<sup>11</sup>]-9-22-C)<sub>4</sub>, and Ac-[SOC<sub>4</sub> ([Nle<sup>11</sup>]-9-22)<sub>4</sub>], conjugates, but still less than the amount of the nonconjugated peptide. Of the KLH-([Nle<sup>11</sup>]-9-22-C)<sub>x</sub> conjugate, approximately 50-fold excess peptide was required than of the nonconjugated peptide [Nle<sup>11</sup>]-9-22, to obtain the same level of inhibition. None of the carriers without peptide [Nle<sup>11</sup>]-9-22 could inhibit the reactivity between peptide [Nle<sup>11</sup>]-9-22 and Mab A16. A possible explanation for the higher reactivity of the conjugates Ac-[SOC<sub>4</sub>([Nle<sup>11</sup>]-9-22-C)<sub>4</sub>], T20([Nle<sup>11</sup>]-9-22-C)<sub>4</sub>, Ac-[SOC<sub>4</sub> ([Nle<sup>11</sup>]-9-22)<sub>4</sub>], and SAK([Nle<sup>11</sup>]-9-22-C)<sub>x</sub> in comparison to KLH([Nle<sup>11</sup>]-9-22-C)<sub>x</sub> conjugate could be that in the conjugates with the higher reactivity, the distances between the [Nle<sup>11</sup>]-9-22 peptide molecules are smaller than in KLH([Nle<sup>11</sup>]-9-22-C)<sub>x</sub> conjugate. As a consequence, the [Nle<sup>11</sup>]-9-22 peptide molecules in close vicinity of each other could possibly cooperate with the IgG combining sites of the Mab in the formation of di- or multivalent immune complexes. In agreement with this explanation are earlier results, in which we found that dimers of peptide [Nle<sup>11</sup>]-9-21 of gD have approximately a 5–10-fold higher binding to Mabs than the monomer of peptide [Nle<sup>11</sup>]-9-21.

Combining the results of the direct and competition ELISA indicates that the differences in binding of Mab A16 as observed for the KLH([Nle<sup>11</sup>]-9-22-C)<sub>x</sub> versus the other conjugates in the competition ELISA is partly overridden by the coating properties of these conjugates, as shown by less pronounced differences in the direct ELISA.

Next, we studied whether the amount of peptide [Nle<sup>11</sup>]-9-22 coupled to the carrier molecule had effect on the reactivity of the conjugate and Mab A16. Therefore, three conjugates of the SAK carrier were synthesized in which 9%, 22%, and 44% of the reactive groups were replaced by peptide [Nle<sup>11</sup>]-9-22-C. These SAK conjugates with a different average degree of substitution were studied in the direct and competition ELISA, and the results are summarized in Figure 5 and Table 2. The direct ELISA results show that the different average degree of substitution of peptide [Nle<sup>11</sup>]-9-22-C in the SAK([Nle<sup>11</sup>]-9-22-C)<sub>x</sub> conjugate has only a small effect on the reactivity, when the conjugate is coated. The conjugate with 22% average degree of substitution proved to be the most efficient. The results of the competition ELISA (Figure 5) show that the SAK([Nle<sup>11</sup>]-9-22-C)<sub>x</sub> conjugate with 22% substitution rate of peptide [Nle<sup>11</sup>]-9-22 are slightly more effective in the binding of Mab A16 in solution than the SAK([Nle<sup>11</sup>]-9-22-C)<sub>x</sub> conjugates with the 9% and 44% substitution rates. The results of the direct and competition ELISA combined give the impression that the SAK([Nle<sup>11</sup>]-9-22-C)<sub>x</sub> conjugate with 9% substitution rate of peptide [Nle<sup>11</sup>]-9-22 is slightly less efficiently coated than those with substitution rates of 22% and 44%. The reactivity of the SAK([Nle<sup>11</sup>]-9-22-C)<sub>x</sub> conjugate with 22% substitution rate of peptide

**Figure 5.** Reactivity of HSV glycoprotein D type 1 specific monoclonal antibody A16 to [Nle<sup>11</sup>]-9-22 epitope-SAK conjugates in competition ELISA. The effect of the degree of epitope substitution. Peptide 9-22 (□), SAK([Nle<sup>11</sup>]-9-22-C)<sub>9</sub> (△), SAK([Nle<sup>11</sup>]-9-22-C)<sub>22</sub> (●), SAK([Nle<sup>11</sup>]-9-22-C)<sub>44</sub> (▲).

[Nle<sup>11</sup>]-9-22 was comparable to the Ac-[SOC<sub>4</sub>([Nle<sup>11</sup>]-9-22-C)<sub>4</sub>], T20([Nle<sup>11</sup>]-9-22-C)<sub>4</sub>, and Ac-[SOC<sub>4</sub> ([Nle<sup>11</sup>]-9-22)<sub>4</sub>] conjugates.

## CONCLUSION

In this paper we described a conjugation method for linking Cys-peptides with sequential, dendrimeric, or polymeric polypeptide possessing chloroacetyl groups by formation of a stable (44) thioether linkage. We found that the incorporation of ClAc moiety with a chloroacetic acid pentachlorophenyl ester or chloroacetyl chloride is simple and results in the desired product. The coupling of peptide [Nle<sup>11</sup>]-9-22-Cys to the macromolecules under mild conditions (0.1 M Tris-HCl, pH 8.0) produced tetra- and multivalent conjugates with uniformly oriented epitope peptides. The results of the monoclonal antibody binding experiments with the various conjugates clearly indicated that the carrier bound peptide epitopes are recognized more efficiently than free peptides in all multivalent peptide conjugates except in the dendrimeric and KLH conjugate. We found that the binding properties of conjugates could differ 2.5–50-fold depending on the carrier, the average degree of substitution, and the experimental system used. In conclusion, our results indicate that well-characterized synthetic carriers with well-defined substitution degree of epitopes may open new possibilities not only in their use as target antigen in diagnostic assays, but also when applied as tools in molecular biology to prepare antisera with desired specificity.

## ACKNOWLEDGMENT

Synthesis of an organomercury hapten and conjugation of the hapten to proteins and peptides is described. Starting with allylamine, synthesis of the organomercury hapten was completed in five steps using readily available and inexpensive reagents. The key transformation in the synthesis, intramolecular oxymercuration, was achieved in good yield and under mild conditions. Hapten conjugation was afforded via disuccinimide active ester coupling chemistry, and the resulting conjugates were analyzed by matrix-assisted laser desorption ionization mass spectrometry (MALDI-MS). To exploit the accurate mass measuring capabilities of MALDI-MS, the conjugates were digested with trypsin prior to analysis. The masses of the peptides resulting from tryptic digestion of the organomercury conjugates were accurately measured, and five hapten attachments were identified in the mass range of 1000–2200 *m/z*. The organomercury bioconjugate synthesized in this study was designed to contain a stable carbon–metal bond, constituting an underutilized approach for preparing protein–metal complexes and may result in mAbs consisting of unique recognition capabilities.

## INTRODUCTION

Mercury has played a rich role and has made diverse contributions to the field of bioconjugate chemistry. For example, mercury's unique electronic properties have proved useful in designing electrochemical-based thiol assay methods (1). Mercury metal has aided electron microscopy characterization of proteins (2) and has been incorporated into fluorescent peptide and protein tags (3). More recently, there has been interest in developing anti-mercury mAbs for their potential use as diagnostic tools capable of providing highly specific, inexpensive, easy to use mercury detection assays (4, 5). Our interest in this area prompted us to design and prepare a synthetic organomercury hapten that is amenable to protein conjugation methods. Mercury metal, mercury salts, and organomercury compounds are ubiquitous and persistent environmental toxins, and the associated health hazards to humans, mammals, and aquatic systems are of keen interest (6).

The preparation of metal containing bioconjugates for the purpose of generating mAbs capable of binding metals and metal ions has been the focus of numerous research efforts over the last 20 years (7–12). Generally, the approach taken to generate metal-based bioconjugates has been to chemically modify carriers by covalently attaching EDTA<sup>1</sup> or other structurally similar metal chelating agents (7–11). The chelating species facilitates encapsulation of a metal in a cagelike structure on the carrier's surface via formation of coordination bonds between the electron rich atoms of the chelate and the electron deficient metal atom. The earliest examples of bioconjugates prepared with the metal chelation methodology have resulted in several useful substrates. These substrates have found practical applications as metal-labeled therapeutic antibodies (8, 13), magnetic reso-

nance imaging substrates (14, 15), and radioimaging techniques (16). One recent extension of the EDTA chelation methodology has been the synthesis of a fluorescent optical sensor designed to detect Hg<sup>2+</sup> ions (17). In this work, Hg<sup>2+</sup> is trapped in a cagelike structure arising from a porphyrin dimer. Preliminary work has shown that the chemical sensor is capable of detecting Hg<sup>2+</sup> at concentrations of 10<sup>−4</sup> to 10<sup>−7</sup> M with high degrees of specificity preferentially over other divalent metal ions.

One shortcoming of the chelation methodology is that EDTA is known to form stable coordination complexes with virtually all of the transition metals (8). Because of the nonselective nature of EDTA–metal complexes, efforts to develop immunoassays based on mAbs elicited from EDTA–metal bioconjugates have been thwarted by poor sensitivity and lack of metal specificity (10). Additionally, mAbs generated via EDTA-encapsulated metal bioconjugates often display poor selectivity between the metal–chelate analyte and metal-free chelate (18).

Currently, there are only a few examples of protocols that have yielded metal binding antibodies from methodologies other than chelate complexation. Benkovic and co-workers have chemically modified the binding site of a specific antibody to accommodate complexation of Zn<sup>2+</sup> ion (19). The catalytic hydrolysis rate of the resulting Ab–Zn<sup>2+</sup> substrate was observed to increase relative to the native enzyme. In another approach, Wylie and co-workers covalently attached glutathione, a tripeptide of glutamic acid, cysteine, and glycine, to KLH via carbodiimide chemistry (20). Mercuric chloride (HgCl<sub>2</sub>) was then attached to the glutathione-modified carrier by sulfur-mediated ligand exchange. Mercury ions have a particularly high affinity for thiols; the binding constant between cysteine and mercury is on the order of 10<sup>14</sup> (21).

Our overall strategy was to synthesize a structurally simple, but chemically robust, organomercury hapten, which was obtained via an intramolecular oxymercuration reaction. The synthetic hapten was covalently bonded

to BSA and a model peptide through an amine positioned at a site removed from the carbon–mercury bond. MALDI/FT-ICR MS<sup>1</sup> was used to unequivocally characterize the resulting bioconjugates. The short-term goals of this project have been completed, and we are currently preparing to initiate a mAb development program with the organomercury bioconjugate resulting from this work. In this paper we describe the complete synthesis of the organomercury hapten, conjugation of the hapten, and the results obtained from MALDI-MS characterization of the bioconjugates.

## EXPERIMENTAL PROCEDURES

**Materials and Methods.** All reagents were purchased from Sigma-Aldrich at the highest purity available and used without further purification, except where noted. Allylamine, di-*tert*-butyl dicarbonate, *m*CPBA, and benzyl bromide were purchased from Acros. BS<sup>3</sup> was purchased from Pierce and C-18 Zip Tips were purchased from Millipore.

<sup>1</sup>H NMR and <sup>13</sup>C NMR were recorded on a Bruker Avance 400 Fourier transform spectrometer at 400 MHz for hydrogen and 100 MHz for carbon using tetramethylsilane (TMS) as an internal standard. HiResMALDI-FTMS (IonSpec, Irvine, CA) equipped with a 4.7 T actively shielded superconducting magnet was used to record all MALDI-MS. The MALDI source uses a 337-nm nitrogen laser and a 10-faceted sample probe. Flash chromatography was carried out on a SiO<sub>2</sub> column (32–63 μm particle size) at an elution rate of 2 in./min. GC/MS was done on a Hewlett-Packard Series 5988A equipped with an EC-1 column, 30 m, 0.25 mm i.d., 0.25 μm film thickness (Alltech, Deerfield, IL), injector 250 °C, detector 280 °C, oven 40 °C, programmed at a rate of 10 °C/min to 280 °C. EI, CI (CH<sub>4</sub>), and CI (NO/CH<sub>4</sub>) MS were collected. Infrared spectroscopy was carried out on a Nicolet 210 FTIR. Melting points were determined in open glass capillary tubes with a Mel-Temp II Melting Point Apparatus and were not corrected.

The toxicological properties of the organomercury compounds prepared in this study have not been characterized. All mercury-containing compounds were handled using standard safety guidelines, which included protective clothing, safety goggles, and doubled gloves. Whenever possible, substrates were reduced in situ with NaBH<sub>4</sub> to avoid excessive handling of mercury containing substrates.

**Organomercury Hapten Synthesis.** *tert*-Butyl Allylcarbamate. To a solution of allylamine (**1**) (4.87 mL, 65 mmol) in 80 mL of double-distilled H<sub>2</sub>O was added 40 mL of 1.5 M Na<sub>2</sub>CO<sub>3</sub>, followed by 13.9 mL of di-*tert*-butyl carbonate (63.7 mmol), and the solution was stirred overnight at room temperature. The desired product, a white precipitate, was filtered and recrystallized from water. If precipitate did not form, the reaction mixture was extracted with CH<sub>2</sub>Cl<sub>2</sub>, and the combined extracts were washed with HCl (1 M) and brine, dried over Na<sub>2</sub>SO<sub>4</sub>, and concentrated in vacuo. Regardless of purification method, the product was obtained in 85% as a white solid: mp 30–32 °C; <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ 1.40 (s, 9H, CH<sub>3</sub>), 3.75 (m, 2H, CH<sub>2</sub>), 4.65 (br s, 1H, NH), 5.13 (m, 2H, =CH<sub>2</sub>), 5.85 (m, 1H, =CH); <sup>13</sup>C NMR (CDCl<sub>3</sub>) δ 28.6 (CH<sub>3</sub>), 43.3 (CH<sub>2</sub>), 79.6 (quaternary C), 115.9 (=CH<sub>2</sub>), 135.1 (CH=), 156.0 (C=O); FTIR cm<sup>-1</sup> 3450 (νNH), 3056 (ν=CH<sub>2</sub>), 2976 (νCH), 1710 (νC=O), 1502 (νC–N), 1272 (νC–O); GC/MS CI (CH<sub>4</sub>) *m/z* 142 [(M + 41) – 56]<sup>+</sup>, 130 [(M + 29) – 56]<sup>+</sup>, 102 [(M + 1) – 56]<sup>+</sup>.

*tert*-Butyl (Oxiran-2-ylmethyl)carbamate (**2**). To a solution of the protected amine (5 g, 31.9 mmol) in 60 mL of

CH<sub>2</sub>Cl<sub>2</sub> was slowly added excess dry *m*CPBA (8.77 g, 51 mmol), allowing the *m*CPBA to dissolve between additions. The reaction was stirred with a magnetic stir bar overnight at room temperature. To precipitate unreacted *m*CPBA and byproduct *m*-chlorobenzoic acid, the reaction mixture was placed in the refrigerator overnight, filtered, and washed with cold CH<sub>2</sub>Cl<sub>2</sub>. The filtrate was stirred magnetically for 1 h in 1 M Na<sub>2</sub>CO<sub>3</sub>, and the aqueous layer was extracted with CH<sub>2</sub>Cl<sub>2</sub>. The pooled CH<sub>2</sub>Cl<sub>2</sub> layers were washed with brine, dried over Na<sub>2</sub>SO<sub>4</sub>, and concentrated in vacuo, to obtain a clear, colorless slightly viscous oil (84%): <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ 1.45 (s, 9H, CH<sub>3</sub>), 2.59 (dd, 1H, CH<sub>2</sub>O), 2.78 (dd, 1H, CH<sub>2</sub>O), 3.08 (m, 1H, NHCH<sub>2</sub>), 3.20 (m, 1H, ring CH), 3.51 (m, 1H, NHCH<sub>2</sub>), 4.89 (br s, 1H, NH); <sup>13</sup>C NMR (CDCl<sub>3</sub>) δ 28.7 (CH<sub>3</sub>), 42.0 (CH), 45.4 (CH<sub>2</sub>O), 51.2 (NHCH<sub>2</sub>), 80.0 (quaternary C), 156.3 (C=O); IR cm<sup>-1</sup> 3438 (νNH), 3046 (νCH<sub>2</sub> ring), 2978 (νsp<sup>3</sup>CH), 1707 (νC=O), 1509 (νC–N), 1263 and 1168 (νC–O–C); GC/MS CI (CH<sub>4</sub>) *m/z* 202 [M + 29]<sup>+</sup>, 174 [M + 1]<sup>+</sup>, 158 [(M + 41) – 56]<sup>+</sup>, 146 [(M + 29) – 56]<sup>+</sup>, 118 [(M + 1) – 56]<sup>+</sup>.

*tert*-Butyl (2-Hydroxy-5-hexen-1-yl)carbamate (**3**). Allylmagnesium bromide (1 M in ether, 57 mL, 57.8 mmol) was transferred via a cannula to a round-bottom flask equipped with reflux condenser, magnetic stir bar, and nitrogen inlet. The ether was evaporated under nitrogen flow to yield a white solid paste. Dry dioxane (100 mL) was added via cannula to the dried allylmagnesium bromide, and the mixture was stirred magnetically under nitrogen for 2.5 h to precipitate MgBr<sub>2</sub>. A solution of **2** (2 g, 11.6 mmol) in 5 mL of dioxane was added, and the reaction was refluxed for 2 h. A slight excess of 1 M NH<sub>4</sub>Cl(aq) was added, and the reaction was stirred magnetically overnight at room temperature. Dioxane and H<sub>2</sub>O were removed in vacuo to yield a yellow oil (**3**) and white solid. The product was extracted with CH<sub>2</sub>Cl<sub>2</sub> and diH<sub>2</sub>O. The combined organic layers were washed with brine, dried over Na<sub>2</sub>SO<sub>4</sub>, and concentrated in vacuo to yield a yellow viscous oil (80%). GC analysis of the crude product indicates a 20:1 ratio of regioisomers. The crude product was purified by flash chromatography (10% acetone:CH<sub>2</sub>Cl<sub>2</sub>) to yield a pale yellow viscous oil (65%): <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ 1.45 (s, 9H, CH<sub>3</sub>), 1.55 (q, 2H, HOCHCH<sub>2</sub>), 2.16 (m, 2H, allylic CH<sub>2</sub>), 2.72 (br s, 1H, OH), 3.04 (m, 1H, NHCH<sub>2</sub>), 3.30 (m, 1H, NHCH<sub>2</sub>), 3.71 (br s, 1H, NH), 4.98 (m, 2H, =CH<sub>2</sub>), 5.06 (m, 1H, CHOH), 5.84 (m, 1H, CH=); <sup>13</sup>C NMR (CDCl<sub>3</sub>) δ 28.8 (CH<sub>3</sub>), 30.2 (allylic CH<sub>2</sub>), 34.2 (HOCHCH<sub>2</sub>), 47.0 (NHCH<sub>2</sub>), 71.5 (CHOH), 80.0 (quaternary C), 115.5 (=CH<sub>2</sub>), 138.6 (=CH), 157.2 (C=O); FTIR cm<sup>-1</sup> 3339 (δOH), 3069 (ν=CH), 2978 (νsp<sup>3</sup>CH), 2923 (νsp<sup>3</sup>CH), 1687 (νC=O), 1513 (νC–N), 1362 (νOH), 1255 and 1160 (νC–O); GC/MS CI *m/z* 216 [M + 1]<sup>+</sup>, 200 [(M + 41) – 56]<sup>+</sup>, 188 [(M + 29) – 56]<sup>+</sup>, 170 [(M + 29) – 56]<sup>+</sup>, 160 [(M + 1) – 56]<sup>+</sup>, 142 [(M + 1) – 56 – H<sub>2</sub>O]<sup>+</sup>, 116 [(M + 1) – 56 – CO<sub>2</sub>]<sup>+</sup>; CI(NO/CH<sub>4</sub>) *m/z* 214 [M – 1]<sup>+</sup>, 158 [(M – 1) – 56]<sup>+</sup>, 140 [(M – 1) – 56 – H<sub>2</sub>O]<sup>+</sup>.

*tert*-Butyl [(5-Methyl mercuric chloride tetrahydrofuran-2-yl)methyl]carbamate (**4**). Grignard product **3** (200 mg, 0.93 mmol) was dissolved in 5 mL of freshly distilled CH<sub>3</sub>CN in a round-bottom flask equipped with magnetic stir bar and argon gas inlet/outlet. Mercuric acetate (0.591 g, 1.9 mmol) was dissolved in 10 mL of CH<sub>3</sub>CN and added to the solution of **3**. The mixture was stirred overnight at room temperature under argon gas, after which time the reaction mixture became clear and colorless. Brine was added and the resulting mixture was stirred 3 h at room temperature. Excess NaHCO<sub>3</sub> (250 mg, 3.0 mmol) was added to the crude mixture to

neutralize the acetic acid formed. Acetonitrile was removed in vacuo, and the remaining mixture was extracted with  $\text{CH}_2\text{Cl}_2$ . The organic layers were combined, washed with brine, dried over  $\text{Na}_2\text{SO}_4$ , and concentrated in vacuo. The desired product was purified by flash chromatography (2:1 hexane:ethyl acetate) to yield a viscous, yellow oil (270 mg, 65%):  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  1.47 (s, 9H,  $\text{CH}_3$ ), 1.65 (m, 2H, ring  $\text{CH}_2$ ), 2.15 (m, 2H, ring  $\text{CH}_2$ ), 2.19 (m, 1H,  $\text{CH}_2\text{Hg}$ ), 2.32 (m, 1H,  $\text{CH}_2\text{Hg}$ ), 3.06 (m, 1H,  $\text{NHCH}_2$ ), 3.35 (m, 1H,  $\text{NHCH}_2$ ), 4.15 (m, 1H,  $\text{CHCH}_2\text{Hg}$ ), 4.23 (m, 1H,  $\text{OCHCH}_2$ ), 5.08 (br s, 1H, NH);  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ )  $\delta$  28.8 ( $\text{CH}_3$ ), 30.0 (ring  $\text{CH}_2$ ), 36.8 ( $\text{CH}_2\text{Hg}$ ), 38.6 (ring  $\text{CH}_2$ ), 45.0 ( $\text{NHCH}_2$ ), 77.9 ( $\text{OCHCH}_2$ ), 78.7 ( $\text{CHCH}_2\text{Hg}$ ), 78.8 (quaternary C), 156.1 ( $\text{C}=\text{O}$ ); FTIR  $\text{cm}^{-1}$  3384 (br,  $\nu\text{NH}$ ), 2975 ( $\nu\text{sp}^3\text{CH}$ ), 2928 ( $\nu\text{sp}^3\text{CH}$ ), 1752 ( $\nu\text{C}=\text{O}$ ), 1703 ( $\nu\text{C}=\text{O}$ ), 1505 ( $\nu\text{C}-\text{N}$ ), 1265 and 1170 ( $\nu\text{C}-\text{O}-\text{C}$ ); HRMS calcd for  $\text{C}_{11}\text{H}_{20}\text{NO}_3\text{HgClNa}$  474.0729, found 474.0730.

*tert*-Butyl [(5-Methyltetrahydrofuran-2-yl)methyl]carbamate (**6**). To crude **4** (60 mg, 0.113 mmol) dissolved in 2 mL of  $\text{CH}_2\text{Cl}_2$  was added 7.56 mg of  $\text{NaBH}_4$  (0.2 mmol) dissolved in 1 mL of 10 M NaOH and stirred magnetically for 2 h. The resulting mixture was filtered through Celite with  $\text{CH}_2\text{Cl}_2$  to remove the mercury metal formed. The filtrate was extracted with double-distilled  $\text{H}_2\text{O}$ , and the organic layer was washed with brine, dried over  $\text{Na}_2\text{SO}_4$ , and concentrated in vacuo to yield a viscous yellow oil:  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  1.19 (d, 3H,  $\text{CH}_3$ ), 1.42 (s, 9H,  $\text{CH}_3$ ), 1.52 (m, 2H, ring  $\text{CH}_2$ ), 2.01 (m, 2H, ring  $\text{CH}_2$ ), 3.12 (m, 1H,  $\text{NHCH}_2$ ), 3.36 (m, 1H,  $\text{NHCH}_2$ ), 4.05 (m, 1H,  $\text{OCHCH}_2$ ), 4.07 (m, 1H,  $\text{CHCH}_3$ ), 5.04 (br s, 1H, NH);  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ )  $\delta$  21.4 ( $\text{CH}_3$ ), 28.8 ( $\text{CH}_3$  tBOC), 29.6 (ring  $\text{CH}_2$ ), 34.2 (ring  $\text{CH}_2$ ), 45.1 ( $\text{NHCH}_2$ ), 76.2 ( $\text{CHCH}_3$ ), 77.9 ( $\text{OCHCH}_3$ ), 79.5 (quaternary C), 156.5 ( $\text{C}=\text{O}$ ); GC/MS EI (diastereomer ratio 1:1.7; identical fragmentation patterns were seen for both diastereomers)  $m/z$  159 [ $\text{M} - 56$ ] $^+$ , 142 [ $\text{M} - 56 - \text{H}_2\text{O}$ ] $^+$ , 98 [ $\text{M} - 117$ ] $^+$  (117 = tBOCOC(O)NHCH), 85 [ $\text{M} - 130$ ] $^+$  (130 = tBOCOC(O)NHCH<sub>2</sub>), 57 [*tert*-butyl fragment] $^+$ .

(5-Methylmercuric chloride tetrahydrofuran-2-yl)-methylamine (**5**). A large excess of TFA (1.0 mL, 12.9 mmol) was added to **4** (100 mg, 0.22 mmol) in 1.0 mL of  $\text{CH}_2\text{Cl}_2$ , and the mixture was stirred magnetically overnight at room temperature. TFA and  $\text{CH}_2\text{Cl}_2$  were removed in vacuo to yield a pale yellow viscous oil, which was extracted with  $\text{CH}_2\text{Cl}_2$  and double-distilled  $\text{H}_2\text{O}$ . The aqueous layer was basified with NaOH (12.9 mmol), and  $\text{CH}_2\text{Cl}_2$  was added to precipitate any remaining salts. The mixture was filtered, and the filtrate was concentrated in vacuo to yield a viscous yellow oil (65%), which was used in the conjugation protocols without further purification.

**Conjugation of Organomercury Hapten 5 and MALDI-MS Characterization.** Prior to MALDI-MS analysis samples were purified using a C-18 zip tip and were eluted with 50%  $\text{CH}_3\text{CN}$  in 0.1% TFA. The purified samples (0.5  $\mu\text{L}$ ) were added to the matrix (0.5  $\mu\text{L}$  of 40 mg DHB in 250  $\mu\text{L}$  of  $\text{CH}_3\text{CN}$  and 250  $\mu\text{L}$  of 0.1% TFA/ $\text{H}_2\text{O}$  stock solution), and the 1  $\mu\text{L}$  mixture was placed on the MALDI probe. Protein concentrations were typically 120  $\mu\text{g}/\text{mL}$ .

**BSA–Benzylamine Model Conjugates.** A 5 mg/mL stock solution of BSA was prepared in 20 mM phosphate buffer, pH 7.5. Just prior to use, 15 mg of  $\text{BS}^3$  ( $2.62 \times 10^{-2}$  mmol) was dissolved in 5 mL of 20 mM phosphate buffer, pH 7.5. To the  $\text{BS}^3$  solution, 2.28  $\mu\text{L}$  of benzylamine ( $2.08 \times 10^{-2}$  mmol) was added, and 1.7 mL aliquots of this solution were removed at time 0, 1, and 5 min and added to 200  $\mu\text{L}$  aliquots of the BSA solution.

The three reactions were stirred for 45 min at room temperature, quenched with benzylamine (1  $\mu\text{L}$ ,  $9.15 \times 10^{-3}$  mmol), and stirred for an additional 1.0 h. Each conjugate was dialyzed exhaustively (dialysis membrane tubing MWCO 10 000) against 20 mM phosphate buffer, pH 7.5.

**Tryptic Digestion of BSA–Benzylamine Model Conjugates.** Each of the above conjugates (60  $\mu\text{g}$ ) was dissolved in 100  $\mu\text{L}$  of urea (6 M in 25 mM  $\text{NH}_4\text{HCO}_3$ ). To each mixture was added 5 mL of DTT (200 mM in 25 mM  $\text{NH}_4\text{HCO}_3$ ), and the reactions were vortexed and then gently rotated for 1 h at room temperature. After adding 20  $\mu\text{L}$  of iodoacetamide (200 mM in 25 mM  $\text{NH}_4\text{HCO}_3$ ), the reactions proceeded for 1 h at room temperature in the dark. To consume unreacted iodoacetamide, 20  $\mu\text{L}$  of DTT (200 mM in 25 mM  $\text{NH}_4\text{HCO}_3$ ) was added, followed by 900  $\mu\text{L}$  of 25 mM  $\text{NH}_4\text{HCO}_3$ . The resulting mixtures were enzymatically digested with 20  $\mu\text{L}$  of trypsin (0.1  $\mu\text{g}/\mu\text{L}$  in 25 mM  $\text{NH}_4\text{HCO}_3$ ) and incubated overnight at 37  $^\circ\text{C}$ . Each sample was concentrated to approximately 0.5 mL. Identical fragmentation patterns were observed in the MALDI-MS for all three conjugates. MALDI/FT-ICR MS: Unconjugated BSA peptides were observed at  $m/z$  1283.725, 1439.835, 1479.805, and 1567.716. These unconjugated peptides were also identified in the digested sample of conjugate **9** (corresponding to residues 361–371, 360–371, 421–433, and 347–359, respectively). Peptides coupled to 1 equiv of benzylamine were observed at  $m/z$  1062.638 (452–459), 1092.654 (242–248), 1236.758 (210–218), 1246.735 (233–218), and 1886.138 (437–451). Numbers in parentheses indicate the tryptic peptide residue that is coupled to benzylamine. Residues 452–459, 242–248, and 437–451 were also observed as hapten attachment points in the MALDI-MS of digested conjugate **9**.

**Model Peptide and Organomercury Hapten 5 Conjugations.** A 5 mg/100  $\mu\text{L}$  stock solution of hapten **5** was prepared in 20 mM phosphate buffer at pH 7.5. Just prior to use,  $\text{BS}^3$  was dissolved in 20 mM phosphate buffer at pH 7.5 to yield a 0.3 mg/100  $\mu\text{L}$  solution. To 400  $\mu\text{L}$  of the  $\text{BS}^3$  solution ( $2.02 \times 10^{-3}$  mmol) was added 7.0  $\mu\text{L}$  of hapten stock solution (5:BS<sup>3</sup> 0.5:1 molar ratio), and the solution was mixed for 5 min. A 0.5 mg/100  $\mu\text{L}$  peptide solution was prepared in 20 mM phosphate buffer at pH 7.5, and 200  $\mu\text{L}$  was added to the 5/BS<sup>3</sup> solution. The reaction was magnetically stirred for 1 h at room temperature, quenched with a 0.5 mol equiv of the hapten **5** stock solution, and stirred another 1 h at room temperature. The sample volume was reduced to approximately 0.5 mL in vacuo. MALDI/FT-ICR MS  $m/z$ : 1440.740 [ $\text{MH} - \text{HCl}$ ] $^+$ , 987.616 (uncoupled peptide), 1143.698 (peptide and  $\text{BS}^3$  only); with CsI added to the matrix  $m/z$  1568.604 [ $\text{M} + \text{H}$ ] $^+$  of peptide–mercuric iodide conjugate, 1440.740 [ $\text{MH} - \text{HI}$ ] $^+$ .

**BSA–Organomercury Hapten Conjugation (9).** To 100  $\mu\text{L}$  ( $1.42 \times 10^{-2}$  mmol) of a 50 mg/mL hapten **5** stock solution in double-distilled water was added 400  $\mu\text{L}$  ( $2.99 \times 10^{-5}$  mmol) of a 5 mg/mL BSA solution in 20 mM phosphate buffer at pH 7.5. The pH of this solution was adjusted to 7.5. Immediately after preparation, 340  $\mu\text{L}$  ( $1.75 \times 10^{-2}$  mmol) of a 30 mg/mL  $\text{BS}^3$  stock solution in 20 mM phosphate buffer at pH 7.5 was added to the hapten **5**/BSA mixture, and the reaction was stirred magnetically for 1 h at room temperature. The reaction was quenched with 0.5 equiv of the hapten stock solution (50  $\mu\text{L}$ ,  $7.14 \times 10^{-3}$  mmol) and stirred magnetically for 30 min.

**Tryptic Digestion of Conjugate 9.** The protocol previously described for the digestion of the BSA–

## Scheme 1

## Scheme 2

benzylamine conjugate was not suitable because of potential coupling between DTT and the mercury. Consequently, the digest of the BSA-hapten conjugate **9** was done without DTT. The conjugate was purified on a Sephadex G-25 column (20 mM phosphate buffer, pH 7.2) and was concentrated in vacuo. A 0.125 mg/mL solution was prepared by adding 0.5 mL of 100 mM  $\text{NH}_4\text{HCO}_3$  to the purified conjugate. To 100  $\mu\text{L}$  of the conjugate solution was added 100  $\mu\text{L}$  of trypsin (10  $\mu\text{g}/\text{mL}$  in 25 mM  $\text{NH}_4\text{HCO}_3$ ), and the mixture was reacted overnight at 37  $^\circ\text{C}$ . The sample was concentrated to dryness in vacuo, and the resulting fragmented conjugate was taken up in 5  $\mu\text{L}$  of 0.1% TFA. MALDI-MS unconjugated BSA peptides were observed at  $m/z$  847.5 (161–167), 1283.7 (361–371), 1439.8 (360–371), 1479.8 (421–433), 1567.7 (347–359), 1639.9 (437–451), and 2045.1 (168–183). Peaks at  $m/z$  1283.7, 1439.8, 1479.8, and 1567.7 were also observed in the digested benzylamine conjugate. BSA-hapten conjugate peptides were observed at  $m/z$  1270.6 (452–459), 1300.6 (242–248), 1646.7 (25–34), 1702.7 (35–44), 1802.6 (24–34), and 2093.2 (437–451) all corresponding to  $[\text{MH} - \text{HCl}]^+$ . Loss of water  $[\text{MH} - \text{HCl} - \text{H}_2\text{O}]^+$  from peaks at  $m/z$  1646.7, 1702.7, and 2093.2 lead to peaks at  $m/z$  1628.7, 1684.7, and 2075.2, respectively.

## RESULTS AND DISCUSSION

**Organomercury Hapten Synthesis.** Synthesis of the organomercury hapten **5** (Scheme 1) was initiated by protecting allylamine with *tert*-butyl carbamate (*t*-Boc). Using standard protocols, the protection proceeded cleanly at room temperature in  $\text{CH}_2\text{Cl}_2$  (22). Recrystallization of the crude reaction mixture provided *t*-Boc-allylamine, which was converted directly to epoxide **2** by reaction with *m*CPBA in  $\text{CH}_2\text{Cl}_2$  under standard conditions (23). The desired epoxide was routinely prepared in greater than 80% yield and was used without further purification. GC data of the crude reaction mixture indicated pure product, as did the sharp melting point of the crystalline solid. Both the amine protection reaction and the epoxidation reaction were readily amenable to scale-up (>5 g batch size) without further optimization.

Initially the nucleophilic ring opening reaction of epoxide **2** in the presence of allylmagnesium bromide in THF appeared to provide the desired hydroxy alkene **3**, albeit in poor yield. Upon further characterization, it was found that the desired product was contaminated by a significant amount of bromohydrin byproduct **7** (Scheme 2). Several purification methods were attempted in order to isolate the desired hydroxy alkene (**3**) from the crude reaction mixture, but under all conditions investigated, bromohydrin contamination remained unacceptable.

Etheral solutions of Grignard reagents tend to exist as equilibrium mixtures of alkylmagnesium bromide, magnesium bromide, and dialkylmagnesium (24). When magnesium bromide is present in solution, epoxide **2** is susceptible to bromide ion-mediated nucleophilic ring opening reactions, thus forming the bromohydrin as a byproduct. Hydroxy alkene **3** was prepared successfully upon addition of anhydrous dioxane to allylmagnesium bromide prior to reacting with epoxide **2**. Dioxane promotes precipitation of magnesium bromide, shifting the equilibrium toward higher concentrations of dialkylmagnesium (25, 26). When the resulting enriched solution of dialkylmagnesium was reacted with epoxide **2**, the desired hydroxy alkene (**3**) was formed without the problematic bromohydrin present. GC analysis of the crude reaction mixture indicated that the product consisted of a 20:1 mixture of regioisomeric ring-opened products (**3** and **8**).

With hydroxy alkene **3** in hand, optimization of the intramolecular oxymercuration cyclization, the key synthetic transformation in the synthesis, was explored. The organomercury precursor (**3**) was designed to readily accommodate intramolecular mercury-mediated cyclization to generate a mercurio cyclic ether. Oxymercuration reactions have been extensively studied and the intramolecular reaction of  $\gamma$ -hydroxy alkenes was well suited for preparing the target organomercury hapten (27–30) because these reactions are fast, high yielding, and occur under extremely mild conditions (28). The reaction is also highly versatile, accommodating numerous alkene structures, and tolerant of many organic functional groups (29,

**Scheme 3**

30). The resulting carbon–mercury bond is especially chemically and thermally stable (28). Additionally, organomercury compounds are air stable and therefore amenable to routine purification and characterization techniques.

The oxymercuration reaction proceeded smoothly upon addition of mercuric acetate to a solution of hydroxy alkene **3** in acetonitrile. The organomercury compounds prepared in this study were not amenable to routine GC-MS analysis, presumably due to their low volatility; therefore, the course of the cyclization reaction was followed via TLC. When starting material was no longer observed, the reaction mixture was quenched with NaCl to facilitate mercury ligand exchange, yielding cyclic mercuric chloride **4** (Scheme 1). The organomercury substrate was purified via column chromatography and was isolated in good yield. The exact mass of mercuric chloride **4** was determined by high-resolution MALDI/FT-ICR MS. The experimental exact mass found for the sodiated parent ion of **4** ( $[M + Na]^+$ ) was 474.0730 *m/z* and the calculated mass was 474.0729 *m/z*. The isotopic distribution of Hg was observed in the MS and proved to be a very useful diagnostic tool in characterizing the organomercury hapten and the bioconjugates coupled with the hapten.

A small sample of the crude oxymercuration reaction mixture was reduced with  $\text{NaBH}_4$  to generate cyclic ether **6** (Scheme 1). GC analysis of the reaction mixture after reduction revealed a 1:1.7 mixture of cyclic diastereomers. In the proton NMR of a purified sample of the reduced product, two methyl doublets were observed, providing additional evidence that the mercuric chloride (**4**) was formed as a pair of diastereomers.

The final step in the synthesis of organomercury hapten **5**, deprotection of cyclic mercuric chloride **4** was carried out in excess TFA, which was removed in vacuo prior to quenching the crude reaction mixture with 1 equiv of NaOH. The free amine organomercury hapten **5** was coupled directly to BSA without further purification (Scheme 3). In designing the organomercury hapten, we had intended to prepare a water-soluble substrate to facilitate protein conjugation protocols. Hapten **5** was moderately water soluble upon deprotection and basification to the free amine.

**Conjugation of Organomercury Hapten.** Prior to conjugating organomercury hapten **5** to BSA, hapten carrier coupling conditions were optimized with benzylamine serving as a model hapten. Benzylamine was selected as a suitable model hapten because it is an inexpensive, water-soluble aliphatic amine, and has a  $pK_a$  similar to hapten **5**. Additionally, benzylamine would be a useful analyte for testing the feasibility of MALDI/FT-ICR MS as a viable method for characterizing the resulting bioconjugates.

The bioconjugate prepared in this work constitutes a novel approach to achieving an organometallic–protein complex, in which the metal is covalently bound to the

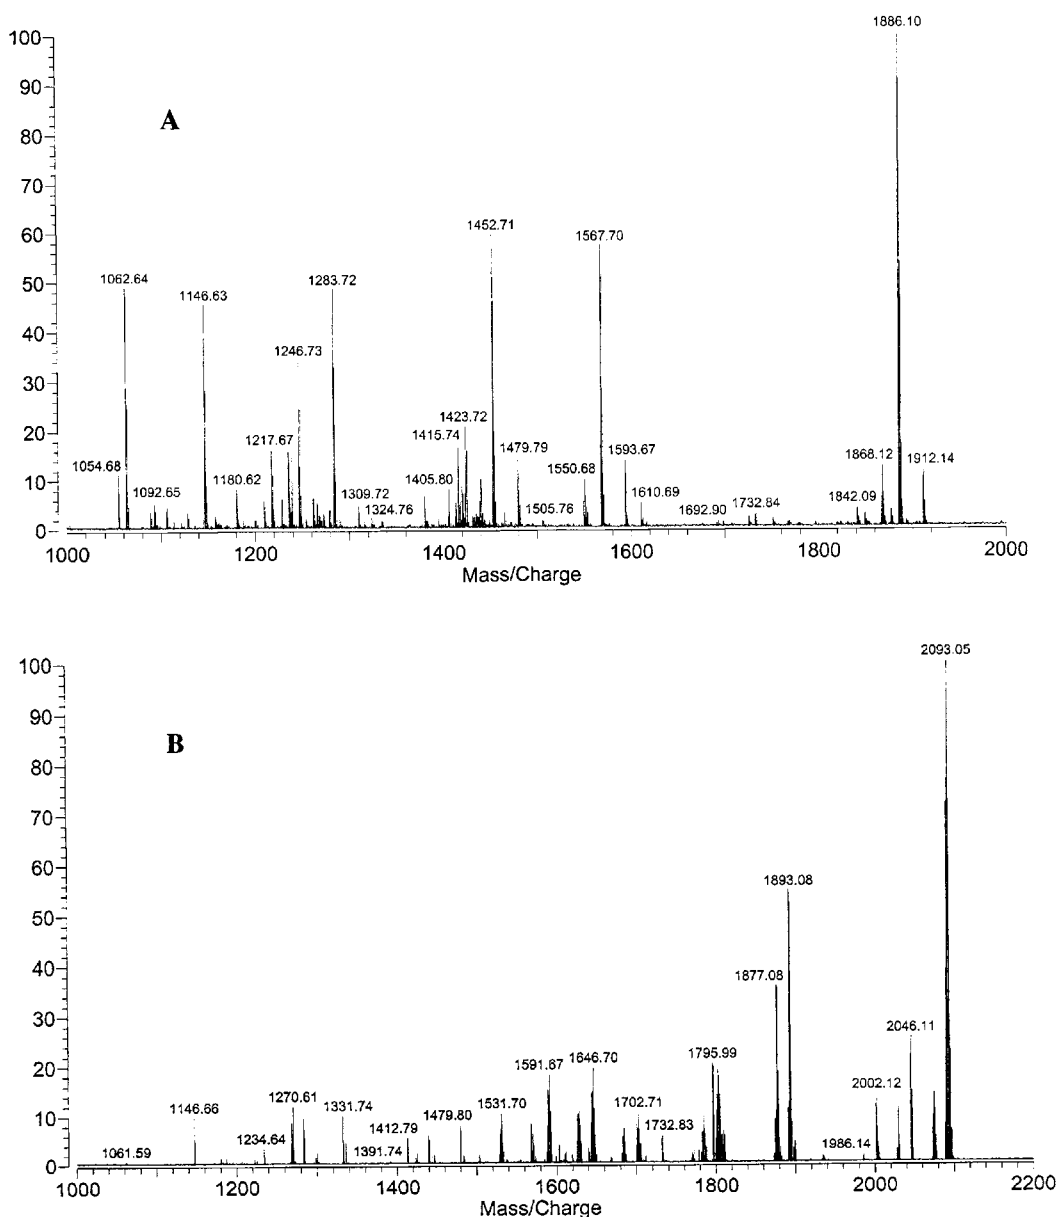

protein.  $\text{BS}^3$ , a commercially available homobifunctional (disuccinimide ester) cross-linking reagent that targets amine functional groups and forms stable amide linkages (31, 32), was utilized to covalently couple organomercury hapten **5** to BSA and in all the model conjugates prepared in this study. Upon coupling, a linker arm distance of 14 atoms separates the mercury atom from the protein in bioconjugate **9** (Scheme 3). We propose that the hydrophobic, nonpeptide character of the linker arm will provide more optimal immunological response and result in mAbs consisting of unique recognition capabilities, compared to the anti-mercury Ab previously prepared (20).

Succinimide esters are commonly used amine reactive cross-linking reagents, but can be problematic because undesirable ester hydrolysis becomes favorable at pH levels most suited for promoting nucleophilic substitution by unprotonated amines. Active ester coupling reactions are typically preformed in pH ranges of 7.0–7.5 (33). In this pH range the concentration of unprotonated amine is low, but the rate of the nucleophilic substitution reaction is sufficiently fast (10 min) relative to the succinimide ester hydrolysis rate, which is on the order of hours. The reaction conditions examined for the model coupling consisted of incubating a 1:2 molar ratio of benzylamine and  $\text{BS}^3$  for varying times (0, 1, and 5 min) in pH 7.5 phosphate buffer prior to coupling with BSA. The preincubation was intended to maximize monosubstitution of  $\text{BS}^3$  with benzylamine and limit protein cross coupling. BSA–phosphate buffer solution was added to each reaction mixture after the  $\text{BS}^3$ –benzylamine preincubation, and the solutions were allowed to react an additional 45 min at room temperature. The conjugates were dialyzed and enzymatically digested with trypsin. MALDI/FT-ICR MS analysis of the model conjugates revealed that preincubating  $\text{BS}^3$  with benzylamine at different time intervals did not significantly affect the molar ratio of benzylamine to protein in the bioconjugates.

Since the model conjugation reactions with benzylamine indicated that the extent of hapten coupling was not sensitive to incubation times, organomercury hapten **5** was covalently coupled to BSA via  $\text{BS}^3$  cross-linking reagent under slightly modified reaction conditions. BSA and hapten **5** were dissolved initially in pH 7.5 phosphate buffer. A concentrated stock solution of  $\text{BS}^3$  was prepared in pH 7.5 phosphate buffer and immediately added to the hapten–carrier solutions. After incubating for 1 h, each reaction was quenched with an additional aliquot of hapten and stirred for 30 more minutes at room temperature.

**MALDI Characterization of Conjugates.** The techniques suitable for characterizing the bioconjugates prepared in this study were limited. UV spectroscopy, a very common bioconjugate characterization method, was not possible because hapten **5** does not contain any UV detectable chromophores. Another example of a routine method for characterizing carrier:hapten ratios is TNBS colorimetric assays (34), which quantify the number of lysine residues that have been modified upon conjugation of a hapten to a protein carrier. Hampered by competitive hydrolysis of  $\text{BS}^3$ , there is the possibility that the hydrolyzed linker alone occupies some of the lysine sites. Consequently, the results of a TNBS assay would not distinguish between lysine residues that had been modified by covalent attachment of hapten- $\text{BS}^3$  linker from those that had been modified only by the addition of hydrolyzed linker.

MALDI-MS techniques have been shown to be very powerful and accurate tools for analyzing complex bio-

**Figure 1.** MALDI MS of trypsin digested conjugates. A. Benzylamine-BSA conjugate. B. Organomercury hapten-BSA conjugate **9**.

conjugate structures (35–40). For example, in a comparative study, Adamczyk and co-workers demonstrated that MALDI-MS is a significantly more accurate analytical tool than either UV spectroscopy or TNBS colorimetric assays for determining the extent of coupling of low molecular weight haptens to protein carriers (37). MALDI-MS is a sensitive ionization technique (detection limits in the low attomole range have been demonstrated) that generates primarily singly charged  $[M + H]^+$  ions for peptides and proteins (35, 40). These ions undergo limited subsequent fragmentation and are ideally suited for characterization of mixtures of structurally complex substrates (39). MALDI is most commonly used in combination with TOF mass analyzers; however, the MALDI/FT-MS used in this study has ultrahigh mass resolution, coupled with ppm mass accuracy. In addition, MS/MS techniques can be used for structural characterization (40, 41).

The mass range of the MALDI/FT-MS is lower than that of a MALDI/TOF and analysis of the intact BSA conjugates was not possible (41–43). Consequently, the

conjugates were digested with trypsin to produce peptides of an appropriate mass for MALDI/FT-MS analysis (39). With this approach, modifications to specific regions of BSA can be identified through the accurate measurement of the masses of the tryptic peptides. As a test of this approach, a sample of unmodified BSA and the benzylamine model bioconjugates were enzymatically digested with trypsin (39, 44). The monoisotopic masses of the peptides resulting from tryptic digestion of the benzylamine bioconjugates were compared to native BSA's tryptic peptides. A MALDI/FT-MS (mass range 1000–2000  $m/z$ ) spectrum of a digested benzylamine-BSA conjugate is shown in Figure 1A. The spectrum shows that five benzylamine-coupled peptides are detected along with four peptides without the amine attached. Unconjugated BSA peptides are observed at  $m/z$  1283.7, 1439.8, 1479.8, and 1567.7. Peptides coupled to 1 equiv of benzylamine are observed at  $m/z$  1062.6, 1092.7, 1236.8, 1246.7, and 1886.1 (Figure 1A). This experiment revealed that the BS<sup>3</sup> coupling protocol was effective in covalently attaching the aliphatic amine model hapten to BSA, and

**Figure 2.** MALDI-MS of hapten **5** coupled to model peptide (KKRAARATS-amide), base peak ( $[MH - HCl]^+$ ) observed at  $m/z$  1440.74.

that tryptic digestion coupled with MALDI-MS would provide a convenient method for accurately measuring hapten attachment sites in the bioconjugates.

To investigate the behavior of peptides containing organomercury moieties under MALDI-MS conditions, the synthetic hapten (**5**) was coupled via BS<sup>3</sup> to a commercially available peptide, nine amino acids in length and containing a terminal lysine (KKRAARATS-amide). Upon examination of the MS data, the  $[M + H]^+$  peak ( $m/z$  1476.7) was not detected; however, several peaks containing mercury were apparent. The base peak in the spectrum, containing one mercury, corresponds to  $[MH - HCl]^+$  at  $m/z$  1440.7. The mass spectra of organomercury halides are often dominated by loss of the halide, and the facile loss of HCl in this case may prevent detection of the intact  $[M + H]^+$  peak. When cesium iodide was added to the matrix/peptide–conjugate mixture, iodine-mediated ligand exchange with the mercuric chloride hapten was favorable, and a peak at  $m/z$  1568.6 corresponding to the  $[M + H]^+$  parent ion of the peptide–mercuric iodide conjugate was observed (Figure 2). A distinct peak, clearly containing mercury, at  $m/z$  1440.7 was also observed in this spectrum. This peak arises from the parent ion minus HCl or HI ( $[MH - HCl]^+$ ,  $[MH - HI]^+$ ), respectively. MS/MS of the  $m/z$  1568.6  $[M + H]^+$  ion showed a peak at  $m/z$  1440 resulting from loss of HI, demonstrating that the  $m/z$  1440 peak results from an

ionization-induced fragmentation of the protonated parent ion. The  $[MH - HCl]^+$  ion was found to be characteristic of the other peptide–organomercury conjugates. Other peaks observed in the spectrum included the unreacted peptide ( $m/z$  987.6) and peptide coupled to hydrolyzed BS<sup>3</sup> ( $m/z$  1143.7) and a peak at  $m/z$  1240.8 arising from loss of HgCl from the  $[M + H]^+$  parent ion. (Figure 2). The MS/MS experiment indicated that  $m/z$  1240.8 is also an ionization-induced fragment.

Confident that MALDI-MS was a viable tool for analyzing peptides covalently bound to mercury, BSA–organomercury bioconjugate **9** was digested with trypsin, and the resulting peptide fragments were analyzed by MALDI-MS. Analysis of the model peptide–organomercury conjugates had revealed that the peak of key diagnostic value arises from loss of HCl from the parent ion ( $[MH - HCl]^+$ ). There are five hapten attachment sites apparent in the MS of the tryptic fragments of conjugate **9** in the range of 1000–2200  $m/z$ .

The exact mass of all the peptide fragments expected upon tryptic digestion of BSA and of each peptide coupled to the organomercury hapten through a BS<sup>3</sup> linker were calculated by the Web version of Protein Prospector (45) and compared to the experimental masses measured in the digested sample of **9**. Several tryptic peptide fragments without any hapten attachment are observed at  $m/z$  847.5, 1283.7, 1439.8, 1479.8, 1567.7, 1639.9, and

**Figure 3.** Expansion of  $m/z$  2093.0579 peak arising from hapten **5** coupled to tryptic peptide composed of amino acid sequence KVPQVSTPTLVEVSR (437–451). A. Experimentally measured peak, including isotopic distribution of mercury. B. Calculated monoisotopic mass and isotope distribution.

2045.1. Four of these peptides are consistent with the peptides identified in the MS of the digested benzylamine model conjugate. The calculated monoisotopic masses of each of these hapten free peptide fragments were compared to the experimentally measured mass values and are shown in Table 1. The peaks at  $m/z$  1270.6, 1300.6, 1646.7, 1702.7, and 2093.1 all correspond to a BSA tryptic peptide coupled to organomercury hapten **5** ( $[MH - HCl]^+$ ). The calculated monoisotopic mass of these peptides compared to the measured mass is also presented in Table 1. Fragmentation of water from peaks at  $m/z$  1646.7, 1702.7, and 2093.1 gives rise to the peaks observed at  $m/z$  1628.7, 1684.7, and 2075.2, respectively. The peak at  $m/z$  1802.6 was initially interpreted as a sixth hapten attachment site, as it clearly displays the mercury isotopic pattern evident in other peaks and matched the calculated mass (1802.8266  $m/z$ ) for hapten **5** coupled to lysine 28 in the peptide containing amino acids 24–34 (RDTHKSEIAHR). This peak, however, is a result of BSA's multiple possible tryptic cleavage points, which can generate peptide fragments containing overlapping amino acid sequences. The peak at  $m/z$  1646.7, which arises from hapten **5** coupled to the peptide composed of amino acids 25–34 (DTHKSEIAHR), already accounts for coupling between the hapten and lysine 28. The  $m/z$  1893.1 peak is consistent with the loss

of Hg from the  $m/z$  2093.5 peak, but in this case a MS/MS experiment did not identify this peak as arising from ionization-induced fragmentation. Surprisingly, there were no peaks corresponding to peptides coupled to hydrolyzed BS<sup>3</sup> in the mass range investigated.

The expanded spectrum of the peak measured at  $m/z$  2093.2 is compared to the theoretical isotopic distribution and the calculated monoisotopic mass for hapten **5** coupled to the tryptic peptide fragment containing amino acids 437–451 in Figure 3A and 3B, respectively. The experimentally measured mass, 2093.0579  $m/z$ , has a mass accuracy of  $-2.1$  ppm relative to the calculated mass value (2093.0623  $m/z$ ). The symmetrical nature observed in the peaks shown in Figure 3 was a reoccurring pattern found in all the peptide fragments containing an organomercury moiety. The peaks at  $m/z$  2089.1–2093.1 and 2095.1 arise from the mercuric isotopes of mass 198–202 and 204, respectively.

Aided by MALDI-MS, we were able to validate our conjugation protocol through the examination of model conjugates, and specifically identify sites containing covalently linked organomercury hapten **5** by accurate mass measurements. It was also demonstrated that our approach to preparing a metal–protein complex via formation of a stable organometallic bond was successful. As MALDI-MS analysis of conjugates becomes a more widely exploited technique, it may provide the opportunity to correlate epitope density, hapten conformation and linker arm length and structure to immune response.

#### ACKNOWLEDGMENT

This work was supported by CIB (Center for Innovation in Biotechnology) in Augusta, ME, and by the University of Southern Maine Faculty Senate. The MALDI instrumentation used in this study was supported by the National Science Foundation under Grant No. CHE-0116416. The NMR (400 MHz) instrumentation was supported by the National Science Foundation under Grant No. 9724321. The authors thank Professor Elizabeth Stemmler at Bowdoin College for her assistance in collecting and analyzing MALDI-MS data.

Received July 17, 2003; Revised Manuscript Received August 21, 2003

The design, synthesis, and biological evaluation of nitrido technetium-99m complexes for imaging benzodiazepine receptors are described. The design was performed by selecting the precursor biologically active substrate desmethyldiazepam, and the reactive metal-containing fragment  $[^{99m}\text{Tc}(\text{N})(\text{PXP})]^{2+}$  (PXP = diphosphine ligand) as molecular building-blocks for assembling the structure of the final radiopharmaceuticals through the application of the so-called 'bifunctional' and 'integrated' approaches. This required the synthesis of the ligands  $\text{H}_2\text{BZ1}$ ,  $\text{H}_2\text{C1}$ , and  $\text{H}_2\text{C2}$  (Figures 1 and 2) derived from desmethyldiazepam. In turn, these ligands were reacted with  $[^{99m}\text{Tc}(\text{N})(\text{PXP})]^{2+}$  to afford the complexes  $[^{99m}\text{Tc}(\text{N})(\text{PXP})(\text{L})]$  ( $\text{L} = \text{BZ1}, \text{C1}, \text{C2}$ ). The chemical nature of the resulting Tc-99m radiopharmaceuticals was investigated using chromatographic methods, and by comparison with the analogous complexes prepared with the long-lived isotope Tc-99g and characterized by spectroscopic and analytical methods. Results showed that the complexes  $[^{99m}\text{Tc}(\text{N})(\text{PXP})(\text{L})]$  are neutral and possess an asymmetrical five-coordinated structure in which two different bidentate ligands, PXP and L, are coordinated to the same  $\text{Tc}\equiv\text{N}$  core. With the ligand  $\text{H}_2\text{BZ1}$ , two isomers were obtained depending on the syn or anti orientation of the pendant benzodiazepine group relative to the  $\text{Tc}\equiv\text{N}$  multiple bond. Biodistribution studies of Tc-99m complexes were carried out in rats, and affinity for benzodiazepine receptors was assessed through in vitro binding experiments on isolated rat's cerebral membranes using the corresponding Tc-99g complexes.

## INTRODUCTION

Benzodiazepine receptors are ubiquitously involved in the GABA postsynaptic receptor complex. In particular, the biochemical evidence indicates that benzodiazepine receptors are part of the  $\text{GABA}_A$  receptor chloride ion channel complex. Alterations of benzodiazepine receptor distribution are involved in many pathological states of the central nervous system (1–4). Positron emission tomography (PET) and single photon emission tomography (SPET) are unique technologies for the noninvasive monitoring of receptor patterns in integrated organisms without affecting their in vivo stability. Various radiopharmaceuticals have been proposed as suitable candidates for the application of these imaging procedures to the evaluation of benzodiazepine receptor distribution (5, 6). It has been showed previously that the derivative Iomazenil labeled with the  $\gamma$ -emitting radionuclide I-123 possesses useful biological characteristics, and it is currently employed as imaging agent for the diagnosis of various brain diseases related to alterations of benzodiazepine receptors (7). Nonetheless, since production of I-123 is performed through a neutron reactor, its routine clinical use is strongly limited. Analogous compounds labeled with the short-lived, positron-emitting nuclides C-11 and F-18 have been also described (8–13). However,

the main limitation with this type of radionuclides comes from the fact that their production requires the use of an on-site cyclotron, an apparatus that is not widely accessible in all nuclear medicine centers.

The  $\gamma$ -emitting nuclide technetium-99m possesses almost ideal nuclear properties for SPET imaging and is readily available in all nuclear medicine centers through the use of a transportable  $^{99}\text{Mo}/^{99m}\text{Tc}$  generator (14). These advantages account for the widespread use of Tc-99m radiopharmaceuticals in routine clinical practice. They further suggest that the search for a useful Tc-99m tracer for imaging benzodiazepine receptor distribution would be highly desirable. However, the preparation of a diagnostic agent of this type would appear immediately as a rather difficult task due to the strict, structural requirements that should be attained by such a compound in order to penetrate the intact blood–brain barrier (BBB) and localize selectively into the target receptor. For instance, a first prerequisite indicates that diffusion through BBB can be achieved only for complexes having a neutral charge and a suitable lipophilic character. Moreover, the molecular shape of the potential Tc-99m receptor imaging agent has to fit correctly the target receptor site to allow the setting up of a selective interaction (15–17).

The above considerations clearly point out the need for a preliminary design of the structure of a Tc-99m complex before coming to its actual synthesis. In the last years, two main approaches to the design of Tc-99m receptor imaging agents have been proposed. Both strategies start initially with the selection of a convenient biologically

<sup>§</sup> Department of Pharmaceutical Sciences.

active molecule or drug know to have affinity for a specific receptor. After this common input, the two methods diverge. The so-called 'bifunctional' or 'pendant' approach literally suggests to append the bioactive group to a metal complex through a suitable linkage. This can be conveniently accomplished using a 'bifunctional ligand' that could be viewed as a composite molecule combining a strong chelating group for the radiometal with the biomolecule by means of a suitable linker connecting these two moieties. After the radiometal has been engaged by the chelating system, the resulting 'conjugate' complex retains the bioactive group into its structure as an appended side chain. Instead, the other procedure, called 'integrated approach', puts its focus on the selected biomolecule itself that may serve as a mold for assembling the structure of the final Tc-99m receptor radiopharmaceutical. The key step is to identify a region in its structure that is not essential for preserving its biological properties. The final radiopharmaceutical, therefore, is assembled by replacing this nonessential part with a metal-containing fragment having a molecular shape and dimension similar to the substituted portion of the original biomolecule in order to fit almost exactly into the same position. Obviously, the ultimate success of both design strategies lies in their ability to keep unaltered the intrinsic biological behavior of the starting biomolecule (17, 14, 18–20).

A key, theoretical advantage of the two approaches outlined above originates from their representation of the molecular structure of a radioactive tracer as consisting of different 'pieces' or 'fragments', which can be, at least in principle, conveniently assembled to build up the final radiopharmaceutical. However, the merging of the various fragments to yield a stable product is not always simple to accomplish and, for practical purposes, this has been obtained only through the application of the bifunctional approach.

In recent years, an alternative approach to the problem of assembling the various parts of a receptor-specific Tc-99m radiopharmaceutical has emerged. This method is based on the chemical properties of certain types of substitution-labile technetium complexes showing a marked reactivity only toward ligands having some specific set of coordinating atoms. In these complexes, a few coordination positions are occupied by a set of ligands that are tightly bound to the metal center. The resulting strong ligand field allows a significant stabilization of the metal oxidation state preventing the complex to undergo oxidation–reduction reactions. The remaining positions of the coordination arrangement are usually spanned by weakly bound ligands that could be easily replaced by some other incoming ligand carrying a specific set of donor atoms. As a consequence, the reaction between the precursor complex and the hypothetical incoming ligand is expected to be kinetically favored and should produce the final substituted complex in very high yield. Such a behavior can be efficiently exploited for assembling a 'robust' Tc-99m fragment with a biomolecule including the appropriate set of coordinating atoms. The high affinity of the precursor metal fragment for the specific donor set on the bioactive ligand would ensure the perfect fitting of these two molecular building blocks to form the final, combined complex (21).

The first example of the application of the above 'metal fragment' approach have been reported, a few years ago, by Alberto and co-workers. This is based on the chemical properties of the precursor, aquo-carbonyl, metal complex  $[^{99m}\text{Tc}(\text{CO})_3(\text{H}_2\text{O})_3]^+$ . In this species, the fragment  $[^{99m}\text{Tc}(\text{CO})_3]^+$  constitutes the chemically inert portion of

**Figure 1.** Chemical structure of complexes **1–3**.

the complex. On the contrary, the three water molecules are weakly coordinated and, thus, can be easily replaced by some substituting ligand having the appropriate set of donor atoms. Under these conditions, the reaction between the metal fragment  $[^{99m}\text{Tc}(\text{CO})_3]^+$  and the incoming ligand becomes highly selective allowing the efficient assemblage of these two pieces to afford the final complex. Therefore, the precursor complex  $[^{99m}\text{Tc}(\text{CO})_3(\text{H}_2\text{O})_3]^+$  can be conveniently used as a synthon for the synthesis of a variety of Tc-99m carbonyl derivatives (22–24).

Very recently, we described the second definite example of the 'metal fragment' approach by studying the synthesis of a novel class of asymmetrical nitrido heterocomplexes characterized by the presence of two different bidentate ligands bound to the same Tc<sup>5+</sup> center. It was found that this novel type of mixed-ligand complexes was efficiently prepared by reacting the precursor complex  $[^{99m}\text{Tc}(\text{N})(\text{PXP})\text{Cl}_2]$  (PXP = diphosphine ligand) with bidentate chelating ligands carrying  $\pi$ -donors as coordinating atoms. In these reactions, the arrangement of atoms  $[^{99m}\text{Tc}(\text{N})(\text{PXP})]^{2+}$ , composed by a Tc≡N group coordinated to a chelating diphosphine ligand PXP, behaves as 'robust' metal fragment, and the two chlorine atoms can be easily displaced by the incoming  $\pi$ -donor ligand to afford the asymmetrical complex  $[^{99m}\text{Tc}(\text{N})(\text{PXP})(\text{L})]^{0/+}$ . Thus, the metal synthon  $[^{99m}\text{Tc}(\text{N})(\text{PXP})]^{2+}$  could be conveniently utilized to obtain a very broad class of asymmetrical nitrido Tc(V) complexes with a variety of bidentate ligands (25–27).

In this paper, we describe the application of the labeling method based on the metal fragment  $[^{99m}\text{Tc}(\text{N})(\text{PXP})]^{2+}$  to the preparation of a series of Tc-99m complexes with bidentate ligands derived from the benzodiazepine receptor drug desmethyldiazepam showed in Figure 1. This latter compound has been modified in two different ways to allow the application of both the bifunctional and integrated approaches as described in the following sections. The resulting ligands H<sub>2</sub>BZ1, H<sub>2</sub>-C1, and H<sub>2</sub>C2 were then reacted with  $[^{99m}\text{Tc}(\text{N})(\text{PXP})]^{2+}$  to afford asymmetrical Tc-99m complexes, which have been characterized by chromatographic methods and their biological properties evaluated both in vitro and in vivo. A drawing of the structure of the new complexes and the corresponding numbering scheme are illustrated in Figures 1 and 2 for the ligands H<sub>2</sub>BZ1, and H<sub>2</sub>C1 and H<sub>2</sub>C2, respectively.

## EXPERIMENTAL SECTION

All reactions were carried out under an inert atmosphere of dry nitrogen, unless otherwise described. Organic solutions were dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>. Dry DMF was distilled from calcium chloride and stored over molecular sieves (3 Å).

**Figure 2.** Chemical structure of the ligands **H<sub>2</sub>C1** and **H<sub>2</sub>C2**, and of complexes **3** and **5**.

**Figure 3.** The PNP-type diphosphine ligands.

The diphosphine ligands **PNP2**, **PNP3**, and **PNP4**, shown in Figure 3, were prepared as reported elsewhere or obtained from Argus Chemicals (Florence, Italy). The ligand **H<sub>2</sub>BZ1** was obtained using a procedure detailed below and illustrated in Scheme 1. The ligands (L)-*N*-thiobenzoyl glycine (**H<sub>2</sub>C1**) (**28**) and (L)-*N*-thiobenzoyl leucine (**H<sub>2</sub>C2**) (**29**) (Figure 2) have been synthesized following literature procedures. Succinic dihydrazide [SDH =  $H_2NNH(OC)CH_2CH_2(CO)NHNH_2$ ] and  $SnCl_2 \cdot 2H_2O$  were purchased from Aldrich Chimica (Milan, Italy). A generous supply of the compound 7-chloro-1,3-

**Scheme 1.** Schematic Drawing of the Preparation of the Ligand **H<sub>2</sub>BZ1**<sup>a</sup>

<sup>a</sup> Reagents and conditions: (a) NaH,  $BrCH_2CO_2Et$ ; (b) LiOH, THF/MeOH/ $H_2O$  (3:1:1); (c) EDCI, HOBT, *S*-trityl cysteine *tert*-butyl ester, DMF, rt, 18 h; (d)  $Et_3SiH$ , TFA, DCM, rt.

dihydro-5-phenyl-2*H*-1,4-benzodiazepin-2-one (desmethyldiazepam or nordazepam) was obtained as a gift from FIS S.p.A. (Vicenza, Italy). [ $^3H$ ]-Ro151788 (85.0 Ci/mmol) and [ $^3H$ ]-flunitrazepam (85.0 Ci/mmol) were provided by New England Nuclear.

Tc-99g as  $[NH_4][^{99g}TcO_4]$  was obtained from Oak Ridge National Laboratory. Samples were dissolved in water and treated with excess aqueous ammonia and 30% hydrogen peroxide at 80 °C prior to use to eliminate residual  $TcO_2$ . Solid samples of purified ammonium pertechnetate were obtained by slow evaporation of the solvent by heating at 40 °C. *Caution!* Tc-99g is a weak  $\beta$ -emitter ( $E_{\beta max} = 0.292$  MeV,  $t_{1/2} = 2.12 \times 10^5$  years). When handled in milligram amounts, it does not present a serious health hazard as normal laboratory glassware provides adequate shielding. Bremstrahlung is not a significant problem due to the low energy of the  $\beta$ -particle. However, a laboratory approved for low-level radiation equipped with gloves-boxes and monitored hoods, and normal radiation safety procedures should be used to prevent contamination and inhalation. The complex  $[^{99g}Tc(N)Cl_2(PPh_3)_2]$  was prepared as described previously (30).

TLC chromatography was performed on Merck silica gel plates. TLC chromatograms were analyzed with a Packard Cyclone instrument equipped with a phosphor imaging screen and OptiQuant image analysis software. HPLC was performed on a Beckman System Gold Instrument equipped with a programmable solvent Module 126, a scanning detector Module 166, and a radioisotope detector Module 170. Chromatographic runs were performed on a reversed-phase C18 column (Beckman Ultrasphere,  $4.6 \times 250$  mm) with a reversed-phase C18 precolumn (Beckman Ultrasphere,  $4.6 \times 45$  mm) or, alternatively, on a semipreparative reversed-phase C18 column (Beckman Ultrasphere,  $10.0 \times 250$  mm). The radiochemical purity (RCP) of Tc-99m complexes was expressed as the ratio between the activity associated with a single radiocompound, revealed as a single spot on a TLC strip, and the total activity on the strip or, alternatively, as the percent of the area under the corresponding HPLC peak.

Positive ion fast atom bombardment mass spectra (FAB+) of selected complexes in an NBA matrix were

recorded on a VG 30–250 spectrometer (VG Instrument) at the probe temperature. Xe was used as the primary beam gas and the ion gun was operated at 8 keV (ca.  $1.28 \times 10^{-15}$  J) and 100  $\mu$ A. Elemental analyses (C, H, N, S) were carried out on a Carlo Erba 1106 Elemental Analyzer. FT IR spectra were recorded on a Nicolet 510P Fourier transform spectrometer in the range 4000–200  $\text{cm}^{-1}$  in KBr mixtures using a Spectra-Tech diffuse-reflectance collector accessory. IR spectra of the ligands  $\text{H}_2\text{BZ1}$ ,  $\text{H}_2\text{C1}$ , and  $\text{H}_2\text{C2}$  were recorded on a Perkin-Elmer 781 IR spectrophotometer. Proton and  $^{31}\text{P}$  NMR spectra were collected in  $\text{CDCl}_3$  and  $d_6$ -DMSO solutions on a Bruker AC-200 instrument using  $\text{SiMe}_4$  as internal reference ( $^1\text{H}$ ) and 85% aqueous  $\text{H}_3\text{PO}_4$  as external reference ( $^{31}\text{P}$ ).

**Preparation of (7-Chloro-2-oxo-5-phenyl-2,3-dihydro-benzo[*e*][1,4]diazepin-1-yl)acetic Acid Ethyl Ester (II).** A mixture of sodium hydride (50% dispersion in mineral oil, 288 mg, 6 mmol) and desmethyldiazepam (I) (1.35 g, 5 mmol) in DMF (5 mL) was stirred at room temperature for 0.5 h. Ethyl bromoacetate (1 g., 6 mmol) in DMF (2 mL) was then added, and the reaction mixture was stirred further for 18 h at room temperature and decomposed with ice. The resulting mixture was extracted with EtOAc ( $2 \times 15$  mL) and the organic phase washed with water (10 mL), brine (5 mL) and finally dried over  $\text{Na}_2\text{SO}_4$ . After evaporation under vacuum, the residue was purified by flash-chromatography (EtOAc/petroleum ether, 7:3, v/v) to give **II** (1.48 g, yield = 81%) as a white solid.

**Preparation of (7-Chloro-2-oxo-5-phenyl-2,3-dihydro-benzo[*e*][1,4]diazepin-1-yl)acetic Acid (III).** Lithium hydroxide monohydrate (252 mg, 6 mmol) was added to a solution of **II** (732 mg, 2 mmol) in 15 mL of THF/MeOH/ $\text{H}_2\text{O}$  (3:1:1) at room temperature. The reaction mixture was stirred for 3 h, concentrated under vacuum, and then diluted with water (10 mL) and extracted with EtOAc ( $3 \times 10$  mL). The combined organic extracts were washed with brine (5 mL), dried over  $\text{Na}_2\text{SO}_4$ , and concentrated under vacuum. Flash chromatography (EtOAc) afforded **III** (494 mg, yield = 75%) as a white solid.

**Preparation of (S)-2-[2-(7-Chloro-2-oxo-5-phenyl-2,3-dihydro-benzo[*e*][1,4]diazepin-1-yl)acetylaminol]-3-tritylsulfanylpropionic Acid *tert*-Butyl Ester (IV).** EDC (960 mg, 5 mmol, 1.25 equiv), HOBt (675 mg, 5 mmol), and *S*-trityl cysteine *tert*-butyl ester (1.68 g., 4 mmol) were added to a solution of **III** (1.31 g, 4 mmol) in dry DMF (10 mL) cooled at 0 °C (29). This mixture was stirred for 24 h and then concentrated in vacuo. The residue was dissolved in EtOAc (10 mL) and washed with water (5 mL) and brine (5 mL). The organic layer was dried over  $\text{Na}_2\text{SO}_4$  and concentrated in vacuo. The resulting residue, purified by column chromatography using EtOAc/ $\text{CH}_2\text{Cl}_2$  (2:8, v/v), furnished the derivatives **IV** (1.82 g, yield = 62%) as a white solid.

**Preparation of (S)-2-[2-(7-Chloro-2-oxo-5-phenyl-2,3-dihydro-benzo[*e*][1,4]diazepin-1-yl)acetylaminol]-3-mercaptopropionic Acid (V).** The compound **IV** (730 mg, 1 mmol) was stirred for 3 h, at room temperature, in a mixture of TFA/ $\text{CH}_2\text{Cl}_2$  (1:1, 5 mL) containing  $\text{Et}_3\text{SiH}$  (0.8 mL, 582 mg, 5 equiv). The volatiles were removed in vacuo, and the residue was diluted with 5% aqueous  $\text{NaHCO}_3$  (5 mL). The aqueous mixture was extracted with  $\text{CH}_2\text{Cl}_2$  ( $3 \times 5$  mL), and the combined organic extracts were dried over  $\text{Na}_2\text{SO}_4$  and concentrated in vacuo. The resulting pale-yellow solid was used for the next reactions without any further purification.

(V)  $\text{C}_{20}\text{H}_{18}\text{N}_3\text{O}_4\text{SCL}$ . Calcd (%): C, 55.62; H, 4.20; N, 9.73; S, 7.41. Found (%): 55.68; H, 4.25; N, 9.69; S, 7.20.

**Synthesis of the Intermediate Complexes [ $^{99\text{g}}\text{Tc}(\text{N})(\text{PXP})\text{Cl}_2$ ] (PXP = PNP2, PNP3, PNP4).** The dichloride derivatives of the metal synthon [ $^{99\text{g}}\text{Tc}(\text{N})(\text{PXP})\text{Cl}_2$ ] $^{2+}$  were obtained starting from the precursor nitrido complex [ $^{99\text{g}}\text{Tc}(\text{N})\text{Cl}_2(\text{PPh}_3)_2$ ]. A representative procedure is given below for the ligand PNP3.

[ $^{99\text{g}}\text{Tc}(\text{N})\text{Cl}_2(\text{PPh}_3)_2$ ] (94 mg, 0.132 mmol) was suspended in dichloromethane (10 mL) and then reacted with PNP3 (73 mg, 0.145 mmol) at reflux temperature, for 30 min. The starting pink-orange solution turned to yellow. The solvent was removed by passing a weak stream of nitrogen, and a yellow solid was collected, which was washed with isopropyl alcohol, diethyl ether, and *n*-hexane. The yellow compound was dissolved in the minimum amount of chloroform, and the resulting solution was treated with diethyl ether. The precipitation of yellow microcrystalline powder was observed, which was then dried by overnight high-vacuum suction.

Yields expressed as (number of moles of the final complex/number of moles of the starting complex)  $\times 100$  were in the range 75–80%.

**Synthesis of the Complexes [ $^{99\text{g}}\text{Tc}(\text{N})(\text{L})(\text{PXP})$ ] ( $\text{H}_2\text{L} = \text{H}_2\text{BZ1}$ ,  $\text{H}_2\text{C1}$ ,  $\text{H}_2\text{C2}$ ; PXP = PNP2, PNP3, PNP4) (1–5).** The asymmetrical heterocomplexes [ $^{99\text{g}}\text{Tc}(\text{N})(\text{PXP})(\text{L})$ ] were prepared by reacting the ligand  $\text{H}_2\text{L}$  with the intermediate complexes [ $^{99\text{g}}\text{Tc}(\text{N})(\text{PXP})\text{Cl}_2$ ]. A representative procedure is given below for the ligands PNP3 and  $\text{H}_2\text{BZ1}$ .

[ $^{99\text{g}}\text{Tc}(\text{N})(\text{PNP3})\text{Cl}_2$ ] (51 mg, 0.077 mmol) was dissolved in 10 mL of a ethanol/dichloromethane mixture (1:1 v/v) under a nitrogen atmosphere. Triethylamine (0.2 mL) was added to the mixture followed by  $\text{H}_2\text{BZ1}$  (40 mg, 0.092 mmol). The reaction solution was refluxed for 60 min while keeping the nitrogen flux. After cooling, the solvent was removed by passing a weak nitrogen stream. A solid was collected and then washed with isopropyl alcohol, diethyl ether, and *n*-hexane. The resulting compound was dissolved in the minimum amount of acetonitrile, and the resulting solution was filtered and treated with diethyl ether. The slow precipitation of microcrystalline powder was observed, which was washed with diethyl ether and further dried by overnight high-vacuum suction.

Yields expressed as (number of moles of the final complex/number of moles of the starting complex)  $\times 100$  were in the range 70–80%.

HPLC chromatography of the yellow products isolated from reactions with the ligands  $\text{H}_2\text{BZ1}$  and PXP (PXP = PNP2, PNP3, PNP4) revealed that these species were actually composed by a mixture of two different compounds **A** and **B**, which were assigned to the syn and anti isomers of the complexes 1–3 (see Results and Discussion). However, the relative yields of the two isomers were found to be dependent on the type of diphosphine ligand utilized. Specifically, when PXP = PNP2 and PNP3, complex **A** was obtained almost quantitatively with a relative yield > 95%. On the contrary, with the ligand PNP4, the relative yields of compounds **A** and **B** were 79% and 21%, respectively.

Spectroscopic data and elemental analyses for Tc-99g complexes are reported in Table 3. Due to the low yields of isomer **B** for complexes 1–3, only isomer **A** was fully characterized.

**Preparation of the Complexes [ $^{99\text{m}}\text{Tc}(\text{N})(\text{PXP})(\text{BZ1})$ ] (PXP = PNP2, PNP3, PNP4).**  $\text{Na}^{99\text{m}}\text{TcO}_4$  (50 MBq) was added to a vial containing 5.0 mg of SDH, 0.1 mg of  $\text{SnCl}_2$  (suspended in 0.1 mL of saline) and 1.0 mL

of ethanol. The reaction mixture was kept at room temperature for 30 min. Then, 1.0 mg of the appropriate PXP ligand (dissolved in 0.25 mL of ethanol) and 2.5 mg of H<sub>2</sub>BZ1 (dissolved in 0.25 mL of ethanol) were added to the reaction vial, which was heated at 100 °C for 30 min. Chromatographic characterization of the resulting Tc-99m complexes (Table 1) showed the presence of two distinct products, **A** and **B**, with relative yields in the range 80–85% and 10–15%, respectively. Overall yields ranged between 90 and 96%.

**Preparation of the Complexes [<sup>99m</sup>Tc(N)(PNP4)-(L<sup>1</sup>)] (L<sup>1</sup> = C1, C2).** Na[<sup>99m</sup>TcO<sub>4</sub>] (50 MBq) was added to a vial containing 5.0 mg of SDH, 0.1 mg of SnCl<sub>2</sub> (suspended in 0.1 mL of saline), 0.5 mL of saline, and 0.5 mL of ethanol. The reaction mixture was kept at room temperature for 30 min. Then, 0.25 mL of a phosphate buffer (PBS, pH = 7.4), 0.1 mg of PNP4 (dissolved in 0.3 mL of ethanol), and 10.0 mg of H<sub>2</sub>L<sup>1</sup> (dissolved in 0.3 mL of ethanol) were added to the reaction vial, which was heated at 100 °C for 1 h. Yield > 90%. Chromatographic characterization is reported in Table 2.

**Determination of Partition Coefficients (Log *P*).** After HPLC purification, Log *P* values of Tc-99m complexes **1–3** were determined by measuring the activity partitioned between *n*-octanol (3.0 mL) and aqueous phosphate buffer (3.0 mL, 0.1 mol dm<sup>-3</sup>, pH = 7.4) under equilibrium conditions. Results are reported in Table 2. On the contrary, due to the impossibility to attain a true equilibrium condition with complexes **4** and **5**, their Log *P* values were not determined.

**Serum Stability.** After HPLC purification, 100 μL of the selected Tc-99m complex were added to a propylene test tube (5 mL) containing 900 μL of rat serum or, alternatively, 900 μL of saline. The resulting mixture was incubated at 37 °C for 2 h. RCP changes in time were checked at 15, 30, 60, and 120 min by TLC.

**In Vitro Reaction with Glutathione (GSH) and Cysteine.** A phosphate buffer (250 μL, 0.2 mol dm<sup>-3</sup>, pH = 7.4), water (100 μL), the appropriate HPLC-purified Tc-99m complex (100 μL), and an aliquot (50 μL) of a

stock aqueous solution of GSH (0.01 mol dm<sup>-3</sup>) were mixed in a propylene test tube (5 mL), and the mixture was incubated at 37 °C for 2 h. For the blank experiment, an equal volume of water was added in place of the GSH solution. Aliquots of the resulting solutions were withdrawn at 15, 30, 60, and 120 min after incubation and analyzed by TLC chromatography.

The same procedure applied above for GSH challenge was performed in two separate experiments using two different aqueous solutions of cysteine hydrochloride (0.01 and 0.001 M, respectively).

**Animal Studies.** All animal experiments were performed in compliance with relevant national laws and with the *Principles of Laboratory Animal Care* (NIH Publication #85-23, revised 1985). Purified fractions of the complexes were obtained by HPLC separation. Before injection, the collected activity was further diluted with PBS (0.1 M, pH, 7.4) to give a final solution that was 10% in ethanol content. Using Tc-99m complexes of **1–3**, both peaks corresponding to the two isomers **A** and **B** were recovered, and the resulting mixture was injected for biodistribution studies. Female Sprague–Dawley rats weighing 200–250 g were anesthetized with an intramuscle injection of a mixture of ketamine (80 mg kg<sup>-1</sup>) and xilazine (19 mg kg<sup>-1</sup>). A jugular vein was surgically exposed, and 100 μL (300–370 kBq) of the solution containing the radioactive complex was injected. The animals (*n* = 3) were sacrificed by cervical dislocation at different times postinjection. The blood was withdrawn from the heart through a syringe immediately after the sacrifice and counted. Harvested organs were rinsed in saline, weighed, and counted in a γ-counter. Results expressed as %ID/g tissue are reported in Tables 4–8. Brain uptake at 2 min was always corrected by subtracting blood activity measured at the same time point after injection of the radiocompound <sup>99m</sup>Tc-DTPA (diethylenetriaminepentaacetic acid = DTPA), which is unable to penetrate the intact BBB.

**In Vitro Binding Studies.** Binding affinities of [<sup>3</sup>H]-Ro151788 and [<sup>3</sup>H]-flunitrazepam were assayed as previously described with the following modifications (31, 32). Male Sprague–Dawley rats, weighing 200–250 g, were killed by decapitation and each cerebral cortex was extracted and stored at –80 °C until use. For assay, cerebral cortex was homogenized in 50 volumes (w/v) ice-cold assay buffer (0.050 M Tris-citrate buffer, pH = 7.1) with an Ultra-Turrax homogenizer (Jenkel & Kunkel) at a setting of 4 for 30 s. The resulting homogenate was centrifuged at 48000 × *g* for 10 min with a L8–50 M/E ultracentrifuge (Beckman). The isolated pellet was resuspended in 20-vol assay buffer and further homogenized at the same settings as detailed above. The resulting homogenate was, then, centrifuged once again. The described procedure was repeated four times and the final pellet was resuspended in 20-vol assay buffer.

The bindings of both [<sup>3</sup>H]-Ro151788 and [<sup>3</sup>H]-flunitrazepam were routinely assessed in triplicate (*n* = 3),

at 0 °C, and using 100  $\mu$ L of the above membrane preparation with a concentration in the range (0.20–4.0)  $\times 10^{-9}$  M. At the end of the incubation period, 3.0 mL of ice-cold assay buffer were added to each incubation tube, and its contents were immediately filtered under reduced pressure through a Whatman GF/B glass-fiber filter. Each filter was, then, washed three times with 3.0 mL of ice-cold buffer. Filter-bound radioactivity was measured by liquid scintillation spectrometry after addition of 3.0 mL of Aquasure (Packard), using a LS 5081  $\beta$ -counter (Beckman). Nonspecific binding was defined as the binding measured in the presence of  $1.0 \times 10^{-5}$  M nitrazepam (FIS). Specific binding was calculated by

subtracting the nonspecific binding from the total binding and expressed as fmol/mg of protein. The total protein content was determined by Bradford's method (Comassie Brilliant Blue, Biorad) using human serum albumin as a standard (Kabi-vitrum).

To study the effect of the free ligands and of the corresponding Tc-99g complexes **1–5** and on the specific binding of [<sup>3</sup>H]-Ro151788 and [<sup>3</sup>H]-flunitrazepam, binding inhibition experiments were conducted on isolated membranes obtained as described before. In particular, with complexes **1** and **2**, only the main isomeric form **A** was utilized. On the contrary, with complex **3** both isomers **A** and **B** were isolated and evaluated. In a typical experiment, 100  $\mu$ L of the membrane suspension and a final concentration of  $1.0 \times 10^{-9}$  M, the radioligand [<sup>3</sup>H]-Ro151788 (or, alternatively, of [<sup>3</sup>H]-flunitrazepam), dissolved in a Tris-citrate buffer, were used. The total volume was 0.250 mL, and the tubes were incubated for 1 h at 0 °C until incubation was stopped by rapid filtration through a glass-fiber filter as described above. Each filter was washed three times with 3.0 mL of ice-cold buffer and radioactivity measured. Interference of  $\beta$ -emission from <sup>99g</sup>Tc ( $E_{\beta\text{max}} = 0.212$  MeV,  $T_{1/2} = 2.02 \times 10^5$  y) on <sup>3</sup>H counting was significant only at the highest <sup>99g</sup>Tc concentrations as radioactivity was determined by

adjusting  $\beta$ -counter's window to exclude 85% of  $^{99g}\text{Tc}$  counts from the tritium channel. The 15%  $^{99g}\text{Tc}$  spill was subtracted from the  $^3\text{H}$  counts.

Results expressed as  $K_i$  values of the competing ligand (I) ( $K_i$  = dissociation constant at equilibrium), were determined according to the Cheng–Prusoff equation  $K_i = \text{IC}_{50}/(1 + [\text{R}]/K_R)$ , where  $\text{IC}_{50}$  is the concentration of I inhibiting 50% of radioligand's binding at the radioligand concentration  $[\text{R}]$ .

## RESULTS

**Synthesis of the Ligands.** The preparation of the ligand  $\text{H}_2\text{BZ1}$  (**V**) has been accomplished by a synthetic sequence according to the reactions showed in Scheme 1. Starting from the commercially available desmethyldiazepam (**I**), alkylation with ethyl bromoacetate in DMF in the presence of sodium hydride gave the intermediate **II** (**33**). This derivative was then transformed into the corresponding acid **III** (**34**) by basic hydrolysis with lithium hydroxide. 1-[3-(Dimethylamino)propyl]-3-ethylcarbodiimide (EDCI) promoted the coupling of **III** with S-trityl cysteine *tert*-butyl ester (**35**) to furnish compound **IV** that was finally transformed into **V** after removal of both trityl and Boc protecting groups by treatment with a mixture of triethylsilane ( $\text{Et}_3\text{SiH}$ ) and trifluoroacetic acid ( $\text{CF}_3\text{CO}_2\text{H}$ ) in DCM (**36**).

**Preparation and Characterization of Tc-99m and Tc-99g Complexes.** The Tc-99m analogues of complexes **1–5** were prepared through a simple two-step procedure involving the reaction of a nitrido Tc-99m precursor with the ligands PXP and  $\text{H}_2\text{L}$ . The preliminary step of this procedure was carried out at room temperature and led to the formation of a nitrido Tc-99m precursor through the reaction of  $[\text{}^{99m}\text{TcO}_4]^-$  with SDH in the presence of  $\text{SnCl}_2$  as reducing agent (**37**, **38**). This was then followed by the simultaneous addition of the two ligands PXP and  $\text{H}_2\text{L}$  that, after a short heating at  $100^\circ\text{C}$ , gave rise to the final asymmetrical complexes  $[\text{}^{99m}\text{Tc}(\text{N})(\text{PXP})(\text{L})]$  in high yield ( $>90\%$ ). In these reactions, no formation of the symmetrical complexes,  $[\text{}^{99m}\text{Tc}(\text{N})(\text{L})_2]$ , containing two identical bidentate ligands was detected.

Tc-99m complexes **1–5** were characterized by chromatographic methods. Results are reported in Table 2. When  $\text{L} = \text{BZ1}$ , both TLC and HPLC chromatography revealed that the resulting complexes formed as an isomeric pair, and that one isomer was predominant with a radiochemical yield in the range 60–85%. The formation of the two isomers was determined by the syn or anti orientation of the bioactive group of desmethyldiazepam relative to the terminal  $\text{Tc}\equiv\text{N}$  group. A representative HPLC chromatogram for the Tc-99m complex **2** is reported in Figure 4. The syn and anti isomers were separated by HPLC and their chemical properties measured independently. Partition coefficients of the syn and anti isomers of Tc-99m complexes **1–3** are given in Table 2.

Complexes **1–5** were prepared with the long-lived isotope Tc-99g through a simple ligand-substitution reaction of the weakly bound  $\text{Cl}^-$  groups by  $\text{L}$  onto the dichloride derivative of the metal synthon  $[\text{}^{99g}\text{Tc}(\text{N})(\text{PXP})]^{2+}$  in a dichloromethane/ethanol mixture. As observed in preparations with the  $\gamma$ -emitting nuclide Tc-99m, no formation of the symmetrical, disubstituted complexes ( $[\text{}^{99g}\text{Tc}(\text{N})(\text{L})_2]$ ) was detected also in reactions with Tc-99g. Characterization was accomplished by elemental analysis, infrared,  $^1\text{H}$  and  $^{31}\text{P}$  NMR spectra, and mass spectra (Table 3). Results supported the view that the complexes possess a five-coordinated geometry

**Figure 4.** HPLC chromatogram of the Tc-99g complex **2**.

with a  $\text{Tc}\equiv\text{N}$  group bound to the two phosphorus atoms of a neutral PXP ligand, and the negatively charged  $\text{O}^-$  and  $\text{S}^-$  atoms of one dianionic  $\text{L}$  ligand. The ligand BZ1 is coordinated through the terminal cysteine moiety (Figure 1), while the ligands C1 and C2 bind to the metal ion in the thiol form through the deprotonated SH and COOH functional groups (Figure 2). As a result, the complexes possess a vanishing charge.

The chemical identity of Tc-99m complexes was assessed by comparing their HPLC chromatograms with those of the corresponding Tc-99g analogues. A close matching of HPLC retention times of Tc-99m complexes with those of the analogous Tc-99g is usually taken as a strong indication that the two series of compounds have the same chemical structure. Indeed, HPLC chromatography of Tc-99g complexes displayed a pattern similar to that observed for the analogous Tc-99m complexes. In particular, HPLC of the complexes **1–3** showed the presence of two peaks at the same retention times of the corresponding Tc-99m complexes, thus giving further support for the existence of a syn, anti isomeric pair. The origin of syn and anti isomerism is presumably due to the chirality of the central carbon atom of the coordinated cysteine ring, allowing the pendant benzodiazepine group to assume a syn or anti position with respect to the apical  $\text{Tc}\equiv\text{N}$  group within the pseudo square pyramidal arrangement. However, a major difference between the two concentration scales was observed. Specifically, at the macroscopic level, one isomer was obtained almost quantitatively with complexes **1** and **2**, the other isomer being produced in a very small amount ( $<4\%$ ). In contrast, the two isomers of complex **3** were produced in the percentage ratio 75:20.

**Stability.** The complexes **1–3** were found to be stable both in physiological solution and in plasma. They were also inert toward transchelation by cysteine and glutathione. On the contrary, though the complexes **4** and **5** were almost stable in physiological solution, its RCP in serum decreased to 60% after 2 h. Moreover, transchelation by both cysteine and glutathione was complete in  $0.01\text{-mol dm}^{-3}$  solutions after 1 h. Despite this, the kinetics of transchelation and of decomposition in serum were considered sufficiently slow for conducting biodistribution studies in animals.

**Biological Evaluation.** The ability of the resulting Tc-99m complexes to penetrate the intact blood–brain barrier (BBB) was evaluated in rats. In particular, mixtures of syn and anti isomers were used for biodis-

tribution studies with the Tc-99m analogues of **1–3**. Biodistribution data are reported in Tables 4–8.

Affinity for benzodiazepine receptors was assessed through in vitro binding experiments on isolated membranes of rat's brain using the Tc-99g complexes **1–5**. Specifically, the mixture of syn and anti isomers of complexes **1** (isomeric ratio 96:2) and **2** (isomeric ratio 93:4) were used for in vitro measurements. In contrast, the binding affinities of both isomers of complex **3** were separately evaluated.

Results revealed that the complexes **1–4** did not show any relevant brain uptake. In contrast, a significant brain localization was observed for complex **5** at 2 min after injection, but followed by a fast washout. Competitive, in vitro binding experiments were carried out on isolated rat cerebral membranes and demonstrated that complexes **1–5** do not possess a strong affinity for benzodiazepine receptors. Specifically,  $K_i$  values for complexes **1–5** and for the free ligand H<sub>2</sub>BZ1, measured in competitive inhibition experiments with [<sup>3</sup>H]-RO151788, were >1  $\mu$ M. In contrast,  $K_i$  of the compound diazepam used as a reference was 7.5 nM.

## DISCUSSION

The chemical structure of the ligand HBZ1 was designed by considering a plain application of the 'bifunctional approach'. In fact, the bifunctional ligand HBZ1 can be viewed as composed of two different molecular pieces formed by a cysteine group and a diazepam derivative linked together. The cysteine group provides the chelating system for the metal, while the diazepam derivative plays the role of a biologically active moiety. A key advantage of this procedure is that the species H<sub>2</sub>BZ1 is capable to coordinate as a dianionic ligand, through the deprotonated thiol sulfur atom and the carboxylic oxygen atom of the cysteine group, thus ensuring that the resulting complexes possess a neutral charge. This is a necessary requirement to promote the passage of the blood–brain barrier by a Tc-99m radiopharmaceutical.

The coupling between the strong electrophilic metal fragment [Tc(N)(PXP)]<sup>2+</sup> and the nucleophilic  $\pi$ -donor bidentate ligand H<sub>2</sub>BZ1 led to the formation of the neutral asymmetrical heterocomplexes **1–3**. These preparations provide a definite example of the application of the 'metal fragment approach' based on the selective reaction of a precursor metal synthon with a ligand possessing a specific set of coordinating atoms. The strong affinity of the nucleophilic [S<sup>-</sup>,O<sup>-</sup>]-cysteine chelating system for the fragment [Tc(N)(PXP)]<sup>2+</sup> allowed us to obtain the final products in high-yield and without the concomitant formation of the corresponding symmetrical nitride complexes containing two identical BZ1 ligands.

Although complexes **1–3** were found to be stable in solution and resistant to transchelation by cysteine and GSH, complexes **4** and **5** showed a lower stability and kinetic inertness. This fact could be presumably attributed to the largest seven-membered chelating ring formed by the ligands H<sub>2</sub>C1 and H<sub>2</sub>C2 upon coordination to the metal center as compared to the shorter six-membered ring formed by the ligand H<sub>2</sub>BZ1.

Biodistribution studies in rats were carried out mostly to assess the ability of the resulting complexes to cross the BBB barrier. This requires that a suitable mechanism for trapping the activity into the cerebral tissue for a sufficient time should be operative. Biological results revealed that Tc-99m analogues of complexes **1–3** are not able to localize into the rat brain, and this behavior

was irrespective of syn and anti isomerism. Moreover, in vitro binding experiments showed that complexes **1–3** have lost almost entirely the affinity for benzodiazepine receptors. Binding affinities of both the syn and anti isomers of complex **3** were evaluated in separate experiments, but no significant difference was observed between the two isomeric forms. This fact indicates that receptor interaction does not provide a suitable brain trapping mechanism for these complexes, and therefore no clear insight into their ability to penetrate the intact BBB could be obtained. A possible explanation of this outcome could be found by considering that previous studies of NOESY NMR spectra of analogous asymmetrical heterocomplexes designed to target 5HT1A receptors revealed the existence of a weak interaction between the pendant bioactive moiety and the group attached to the nitrogen atom of the PNP ligand in both the syn and anti configurations. This interaction prevented the bioactive group to acquire the correct configuration for binding to the receptor and could be also effective in complexes discussed here (39).

The biological evaluation of complexes containing the BZ1 ligand gave support to the conclusion that the bifunctional approach might not provide an efficient route to the design of benzodiazepine receptor-specific nitrido Tc-99m radiopharmaceuticals starting from the metal fragment [<sup>99m</sup>Tc(N)(PXP)]<sup>2+</sup>. Therefore, the alternative 'integrated approach' was utilized in the attempt to lower the molecular size of the complexes while maintaining the biological activity of the starting drug. According to this method, the design of the 'integrated complex' was performed by seeking for a region of desmethyldiazepam that is considered nonessential for preserving its biological properties and could be, therefore, conveniently replaced by the metal-containing fragment. Previous studies (40) showed that binding affinity for this drug is associated with the region indicated by arrows in Figure 1. Thus, the phenyl ring fused with the seven-membered ring in the precursor biomolecule was completely removed to give an open system as illustrated in Figure 2. As a final step, thiol and carboxylic groups were placed at the two terminus of the resulting open system to provide the required  $\pi$ -donor atoms for binding to the metal fragment [<sup>99m</sup>Tc(N)(PXP)]<sup>2+</sup>. Figure 2 shows the chemical representation of the final ligands (H<sub>2</sub>C1 and H<sub>2</sub>C2) designed through the application of the integrated design. These compounds easily reacted in the thiol form with the fragment [<sup>99m</sup>Tc(N)(PNP4)]<sup>2+</sup> to afford the final Tc-99m complexes **4** and **5** pictured in Figure 2. Although the integrated concept was essential in providing the route to complexes **4** and **5**, these compounds cannot be strictly considered as true 'integrated complexes'. Indeed, the molecular size and dimension of the metal fragment [<sup>99m</sup>Tc(N)(PNP4)]<sup>2+</sup> evidently do not fit within the structure of that unessential part of the H<sub>2</sub>BZ1 ligand brought aside to give the ligands H<sub>2</sub>C1 and H<sub>2</sub>C2. A classification like that of a 'benzodiazepine mimetic' may, therefore, appear more appropriate.

Biological evaluation of complexes **4** and **5** still gave results not entirely satisfactory. Actually, though both complexes **4** and **5** possessed the correct matching of physical characteristics such as molecular weight and lipophilicity, only **5** showed a significant brain uptake at 2 min postinjection. Moreover, affinity of these complexes for benzodiazepine receptors was found to be almost negligible. These data suggest that the chemical modification brought about by the application of the integrated design has caused a strong perturbation of the starting bioactive drug. The difference in brain uptake

observed between complexes **4** and **5** is not easily interpretable considering that they differ only by a lateral isobutyl group, though the relative instability of these complexes in physiological conditions may also play a role in providing a biological trapping mechanism into the cerebral tissue. Investigation of these aspects is currently underway.

## CONCLUSIONS

The present study illustrates the application of the 'metal-fragment' approach based on the metal synthon  $[\text{Tc}(\text{N})(\text{PXP})]^{2+}$  to the design and synthesis of a new class of small-molecule Tc-99m radiopharmaceuticals for imaging benzodiazepine receptors in the central nervous system. Results indicate that the labeling method is highly efficient and sufficiently flexible to be potentially utilized in the preparation of diagnostic tracers for a wide range of biological targets. As demonstrated by the weak brain accumulation of complex **5**, there does not apparently exist any basic molecular feature of these complexes preventing their passage of the BBB barrier. However, since BBB crossing appears to be better favored for complexes having a reduced molecular size, it appears reasonable to expect that asymmetrical heterocomplexes containing the light PNP4 diphosphine ligand might find some potential application in the study of Tc-99m radiopharmaceuticals for the central nervous system. Moreover, though poor binding affinities for benzodiazepine receptors were found for the complexes described here, a careful selection of the most suitable length of the spacer connecting the metal fragment to the benzodiazepine moiety may prevent any perturbation of this latter group by the inorganic block, thus leaving the biomolecule free to interact with the receptor.

Box 124, 221 00 Lund, Sweden. Received July 21, 2003

Fluorescence labeling of naturally occurring saccharides provides a tool for studying lectins. A practical and efficient two-step protocol for fluorescence labeling of reducing sugars without disrupting their pyranose structure has been developed, consisting of generation of the amino sugar using  $\text{NH}_4\text{HCO}_3$ -(s)/ $\text{NH}_3$ (aq, concentrated) followed by BOP-mediated acylation with derivatives of 5- or 6-carboxy-fluorescein. The acylated conjugates were subsequently run against galectins-1, -3, and -8,  $\beta$ -galactoside recognizing lectins of current interest, in a fluorescence polarization binding assay. Upon analyzing a collection of isomerically pure 5- and 6-carboxyfluorescein derivatives with different tether lengths, we found that conjugates based on 5-carboxyfluorescein gave significantly better results than the ones based on 6-carboxyfluorescein and that galectins-1 and -8 favored conjugates with different tether lengths than did galectin-3. The results show that fluorescence labeling can be chemically tuned to find optimal probes for individual galectins but also probes interacting well with many galectins.

## INTRODUCTION

The galectins, a subfamily of animal lectins, are defined by shared conserved sequence elements and affinity for  $\beta$ -galactosides, with about 10 members in humans (1). Galectins are implicated in, most notably, cancer, inflammation, and immunity among many other cellular events; however, a comprehensive description of their overall biological function has so far been elusive (2, 3).

Our research groups have been particularly interested in expressing and studying galectin-1, -3, and -8. One method employed in probing their function has been to develop inhibitors with  $K_d$ <sup>1</sup> in the low micromolar range (4). With the prospect of learning more about the galectins' functions, we have also developed a simple method for the screening of naturally occurring  $\beta$ -galactosides and their fine specificity. A fluorescence polarization (FP) assay was chosen to measure the affinity between galec-

tins and naturally occurring saccharides because it is a highly sensitive and robust method (5).

For the FP assay, fluorescently labeled saccharides are needed. A library of such probes can be used to profile the specificity of a target lectin by measuring their direct binding to the lectin by FP. A selected probe can also be used to screen the potency of nonfluorescent saccharides as inhibitors of the probe–lectin interaction.

The aim of the present investigation was to develop an efficient and practical method to label natural saccharides with a fluorophore to be used as probes. The well-studied carboxyfluorescein was chosen as the fluorescent moiety due to suitable properties such as appropriate excitation lifetime, relatively high absorptivity, high quantum yield, and ready availability. It was considered desirable to keep the reducing saccharide residue in the ring (pyranose) form, as this appears to be required for efficient binding of galectins in many cases (6–8) (Figure 1). Therefore, reductive amination, commonly used to tag saccharides, could not be used (9). Instead glycosylamines were first generated using a published one-step introduction of a primary amine onto the reducing end (10) and then conjugated with a suitable carboxyfluorescein derivative selected out of a premade library with different tethers and other features. A simple, mild, one-step procedure to conserve and not to alter complex saccharides was devised for the final conjugation. This convergent strategy is similar to one reported during this research by Danishefsky et al. for glycopeptide synthesis in which the glycan was also the limiting factor (11).

**Figure 1.** Schematic of galectin interaction with lactose **1** and an analogue **2**. The lactose is depicted to resemble its natural conformation. Parts of the galectin are drawn around it with the conserved signature amino acids indicated interacting with the saccharide via hydrogen bonds (dotted lines) or hydrophobic interaction (the Trp residue). Based on Figure 4 in Barondes et al., 1994 (7).

a Waters 2487 Dual Wavelength Absorbance Detector, and a Waters 600 Pump equipped with No. 3 pump heads, a Rheodyne 7725i injector, and a 5 mL sample loop. A Waters Nova-Pak HR Silica column (25 × 100 mm, 6  $\mu$ m, 60 Å) with corresponding Guard-Pak (25 × 10 mm) was fitted in a radial compression module. The flow rate was 14 mL/min, and a gradient mobile phase was employed (CH<sub>3</sub>CN:H<sub>2</sub>O 10:90 up to 23:77 over 26 min and then up to 100:0 over an additional 20 min). Millenium<sup>32</sup> (v. 3.20) software was used for data acquisition and analysis.

**Beckman System Gold Instrument:** The HPLC system consisted of a Programmable Solvent Module 126 equipped with a Rheodyne 7725i injector and a 5 mL sample loop, a Programmable Detector Module 166, a Pharmacia LKB Frac-100 fraction collector, and Supelco Supelcosil column (SPLC-18-DB, 10 × 250 mm, 5  $\mu$ m). The Beckman System Gold Personal Chromatography Software (v. 7.0) was used for controlling the HPLC system and for data acquisition and analysis.

The flow rate was 5 mL/min, and a gradient mobile phase was used (CH<sub>3</sub>CN 0.1% TFA/H<sub>2</sub>O 0.1% TFA 5:95 was held for 3 min before being raised to 25:75 over 30 min and then up to 100:0 over additional 20 min).

**NMR.** <sup>1</sup>H NMR were performed on Bruker Avance 300 or Bruker Avance 500 machines. All samples were run at room temperature using a zg30 pulsprogram. Compounds **16** and **17** were run on a Bruker Avance DRX400.

**MS.** Two mass spectrometers were used. A Q-TOF Global, Micromass (UK) was used in high-resolution mode. Samples were dissolved in MeOH with clusters of CF<sub>3</sub>COONa used as internal standard and injected using direct infusion. Samples run in negative mode unless otherwise stated. An ABI-Sciex Qstar, Canada, with an ESI-TurboIon source and with the QTOF geometry. The instrument was used in positive mode.

**TLC.** Glass backed plates from Silicycle were used for TLC (60 Å, 250  $\mu$ m, F-254 indicator). Eluents were CH<sub>2</sub>-Cl<sub>2</sub>:CH<sub>3</sub>OH:H<sub>2</sub>O 100:10:1, 65:35:5, or 50:50:10.

**Chemicals and Solvents.** Chemicals were supplied by Sigma-Aldrich and used as is unless otherwise noted. Me<sub>2</sub>SO was either from SureSeal bottle or distilled under vacuum over CaH<sub>2</sub> prior to use, EtOH was of HPLC grade, and CH<sub>3</sub>NO<sub>2</sub> and DIPA were distilled from CaH<sub>2</sub> prior to use. LNT-2 and LNnT were generously donated by Dr. David Zopf at Neose Inc., Philadelphia, PA.

**Synthetic Procedures.** *General Procedure for the Coupling of Methyl Ester-Protected Amino Acids with 5- or 6-Carboxyfluorescein.* 5- or 6-Carboxyfluorescein (700 mg, 1.29 mmol), amino acid methyl ester hydrochloride (2.57 mmol), BOP (683 mg, 1.54 mmol), and HOBT (209 mg, 1.54 mmol), in dry glassware, were dissolved in Me<sub>2</sub>SO (12.9 mL) and DIPEA (1.34 mL) and stirred at room temperature for 13 h. NaOH (aq, 1 N, 12.9 mmol) was slowly added and the reaction mixture stirred for 30 min after final addition at room temperature. HCl (aq, 1 N, 22 mmol) was added causing precipitation. The reaction mixture was diluted with Me<sub>2</sub>SO, loaded onto a C18-silica column (5 g), and washed with HCOOH (aq, 1%, 300 mL). The C18-column was eluted with MeOH (100 mL), and the MeOH was removed in vacuo. The remaining solids were redissolved in CH<sub>2</sub>Cl<sub>2</sub> and minimal amount of MeOH and purified using flash chromatography (CH<sub>2</sub>-Cl<sub>2</sub>:MeOH:HCOOH 100:2:1 → 100:5:1 → 100:7.5:1 → 100:10:1) to give the product.

*General Procedure for the Coupling of Lactosylamine with 5- or 6-Carboxyfluorescein and their Carboxylic Acid Derivatives.* Carboxylic acid (0.179 mmol), crude lactosylamine **10/11** (30.5 mg, 0.089 mmol), BOP (87 mg, 0.197 mmol), and HOBT (26.6 mg, 0.197 mmol) in dry glassware, were dissolved in Me<sub>2</sub>SO (1.8 mL) and DIPEA (78  $\mu$ L, 0.45 mmol) and stirred at room temperature for 15 h. The reaction mixture was diluted with Me<sub>2</sub>SO, loaded onto a C18-silica column (5 g), and washed with a 1% HCOOH solution (aq, 150 mL). The C18-column was eluted with CH<sub>3</sub>CN:MeOH (70:30). The solvents were removed in vacuo, and the residue was redissolved in Me<sub>2</sub>SO (2 mL) followed by H<sub>2</sub>O (6 mL) and purified using HPLC divided over two runs (see procedure for Waters Instrument). The pure fractions from the two runs were pooled to give the product.

*General Procedure for the Coupling of Reducing Oligosaccharides in 1–2 mg Scale with 5- or 6-Carboxyfluorescein and Their Carboxylic Acid Derivatives.* Reducing oligosaccharide (3.66  $\mu$ mol), NH<sub>4</sub>HCO<sub>3</sub> (1.16 mg, 14.6  $\mu$ mol), and NH<sub>3</sub> (aq, 25%, 146  $\mu$ L) were stirred at 43 °C for 19 h in a sealed Eppendorf vial. A stream of air was used to remove some NH<sub>3</sub> from the stirred solution before the remainder was lyophilized over 18 h. Carboxylic acid (14.6  $\mu$ mol), BOP (7.1 mg, 16.1  $\mu$ mol), and HOBT (2.2 mg, 16.1  $\mu$ mol) were added to the crude in the vial followed by addition of Me<sub>2</sub>SO (146  $\mu$ L) and DIPEA (36.6  $\mu$ mol). The reaction was kept in the dark and stirred at room temperature for 6 h. The reaction mixture was purified without previous workup on the Beckman HPLC system to give the product.

*(2R)-2,3-Dihydroxypropyl  $\beta$ -D-Galactopyranoside.* Fully acetylated galactose (100 mg, 0.26 mmol) and (2S)-2,3-propylideneglycerol (67 mg, 0.51 mmol) were dissolved in CH<sub>2</sub>Cl<sub>2</sub> (2.56 mL). BF<sub>3</sub>·OEt<sub>2</sub> (35.4  $\mu$ L, 0.28 mmol) was added at room temperature under N<sub>2</sub> atmosphere and the reaction stirred for 3 h. The reaction mixture was diluted with CH<sub>2</sub>Cl<sub>2</sub> and washed with NaHCO<sub>3</sub> (aq, sat, 3 × 10 mL), and the organic phase was dried over MgSO<sub>4</sub> and concentrated in vacuo. The residue was purified by flash chromatography over silica gel (toluene:acetone 7:1) to give 37.5 mg of the glycosylated galactose intermediate. The intermediate was dissolved in AcOH (aq, 80%, 10 mL) and stirred at 60 °C for 3 h before solvents were removed in vacuo followed by coevaporation with toluene (3 × 10 mL) to give 26.5 mg of the depropylidenated second intermediate. The second intermediate was dissolved in NaOMe (MeOH, 0.01 M, 10 mL) and stirred at room temperature for 45 min. The reaction mixture was neutralized with AcOH (aq, 10%), and solvents were

removed in vacuo. The residue was purified by flash chromatography over silica gel ( $\text{CH}_2\text{Cl}_2$ :MeOH:H<sub>2</sub>O 65:35:5) to give **2**. <sup>1</sup>H NMR ( $\text{D}_2\text{O}$ , 300 MHz):  $\delta$  4.30 (d, 1 H, *J* 7.7 Hz,  $\beta$ -H-1), 3.93–3.38 (m, 11 H, *H*-2 to *H*-6 +  $\text{OCH}_2$  +  $\text{CH}$  +  $\text{CH}_2\text{OH}$ ).

**5(6)-Carboxyfluorescein.** Resorcinol (40 g, 0.36 mol), 1,2,4-tricarboxylic anhydride (35 g, 0.18 mol, mortared), and  $\text{ZnBr}_2$  (60 g, 0.27 mol) were melted at 180 °C. The mixture solidified after 30 min, and the reaction mixture was allowed to cool after a total of 1 h of heating. A 1 N HCl solution (700 mL) was added to the flask, and the temperature was maintained at 110–120 °C for 1 h. The hot acidic solution was filtered and the filtrate saved. Trapped solids were put back in the flask with the remaining solids, and 1 N HCl solution (700 mL) was added, heated at 110–120 °C for 1 h, and filtered. The procedure was repeated a third time. Orange-brown solids precipitated quickly in the three filtrates. The solids were filtered off separately once the filtrates had reached rt, and each was washed with 1 N HCl solution (100 mL) and H<sub>2</sub>O (2  $\times$  100 mL) to give 5(6)-carboxyfluorescein in a total off 27.5 g (40%). The three crops contained different ratios of the 5- and 6-regioisomer.

**5- and 6-Dipivaloylfluoresceincarboxylate Diisopropylammonium Salt (3 and 5).** 5(6)-Carboxyfluorescein (6.3 g, 16.7 mmol) and pivaloyl anhydride (12.6 mL, 61.7 mmol) were refluxed under an Ar atmosphere for 2 h before the reaction mixture was allowed to reach rt. THF (20 mL) and H<sub>2</sub>O (10 mL) were added, and the mixture was stirred for 18 h at room temperature. Et<sub>2</sub>O (50 mL) was added, and the aqueous layer was removed followed by extraction of the organic layers with H<sub>2</sub>O (3  $\times$  25 mL), 1 N HCl solution (50 mL), and brine (50 mL). The organics were dried over  $\text{MgSO}_4$  and the solvents removed in vacuo. The residue was dissolved in EtOH (63 mL) and DIPA (6.3 mL) and kept at –20 °C for 2 h. The solids formed were filtered off and washed with cold EtOH (2  $\times$  10 mL, –20 °C – 10 °C) to give 2.76 g of the 6-regioisomer **5**. The mother liquor was concentrated in vacuo, and the residue was dissolved in EtOH (50 mL) and DIPA (5 mL) and stored at –20 °C. The solids were filtered off and washed with EtOH (15 mL, –20 °C – 10 °C) to give 0.4 g of the 6-isomer. Another crop of the 6-isomer was crystallized from EtOH (20 mL) and DIPA (5 mL) leaving only 6% of the 6-isomer in the mother liquor. The mother liquor was concentrated in vacuo, and the residue was redissolved in Et<sub>2</sub>O (50 mL) and washed with HCl (1 N, 50 + 3  $\times$  25 mL) and brine (50 mL). The Et<sub>2</sub>O phase was dried over  $\text{MgSO}_4$ , and the solvent was removed providing 2.45 g of **3**. Isolated yields based on 5(6)-carboxyfluorescein were thus 27% of **3** and 29% of **5**. <sup>1</sup>H NMR according to ref 12.

**5-Carboxyfluorescein (6).** 5-Dipivaloylcarboxyfluorescein (**3**) (300 mg, 0.55 mmol) was dissolved in MeOH (8.3 mL) and NaOH (aq, 1 N, 5.5 mmol) and stirred at room temperature for 50 min. A 1 N HCl solution (6.5 mmol) was added, and volatiles were removed in vacuo. The solids were filtered off and washed with H<sub>2</sub>O (2  $\times$  5 mL) and Et<sub>2</sub>O (2  $\times$  5 mL) to give 190 mg (92%) of **6**. <sup>1</sup>H NMR ( $\text{CD}_3\text{OD}$ , 300 MHz):  $\delta$  8.92 (d, *J* 1.3 Hz, *Ar* *H*-4), 8.48 (dd, *J*<sub>1</sub> 1.5 Hz, *J*<sub>2</sub> 7.9 Hz, *Ar* *H*-6), 7.57 (d, *J* 8.6 Hz, *Ar* *H*-7), 7.39 (d, *J* 9.1 Hz, *Ar*), 7.29 (d, *J* 2.0 Hz, *Ar*), 7.12 (dd, *J*<sub>1</sub> 2.1 Hz, *J*<sub>2</sub> 9.1 Hz, *Ar*). HR-ESI-QTOF calcd for  $\text{C}_{21}\text{H}_{11}\text{O}_7$  ( $\text{M} - \text{H}^+$ ) 375.0510, obsd 375.0502.

**6-Carboxyfluorescein (7).** 6-Dipivaloylfluoresceincarboxylate diisopropylethylammonium salt (**5**) (3.25 g, 5.04 mmol) was dissolved in MeOH (60 mL) and NaOH (aq, 1 N, 30.2 mmol) and stirred at room temperature for 1 h. A solution of hydrochloric acid (1 N, 40 mL) was added, and volatiles were removed in vacuo causing precipita-

tion. The solids were filtered off and washed with H<sub>2</sub>O (50 mL) and Et<sub>2</sub>O (2  $\times$  50 mL) to give 1.8 g (95%) of **7**. <sup>1</sup>H NMR ( $\text{CD}_3\text{OD}$ , 300 MHz):  $\delta$  8.46 (m, 2 H, *Ar* *H*-4 + *Ar* *H*-5), 8.04 (app. s, 1 H, *Ar* *H*-7), 7.47 (d, 2 H, *J* 9.2 Hz, *Ar*), 7.34 (d, 2 H, *J* 2.1 Hz, *Ar*), 7.17 (dd, 2 H, *J*<sub>1</sub> 2.3 Hz, *J*<sub>2</sub> 9.2 Hz, *Ar*). HR-ESI-QTOF calcd for  $\text{C}_{21}\text{H}_{11}\text{O}_7$  ( $\text{M} - \text{H}^+$ ) 375.0505; obsd 375.0511.

**6-(Carboxymethylaminocarbonyl)fluorescein (8a).** The reaction was carried out as in the general procedure for coupling with amino acids using glycine methyl ester hydrochloride to give 246 mg (78%) of **8a**. Purification by flash chromatography on silica gel using the same system as for **8b** but using dry packing due to the poor solubility of **8a**. <sup>1</sup>H NMR ( $\text{CD}_3\text{OD}$ , 300 MHz):  $\delta$  8.49 (app s, 1 H, *Ar* *H*-4), 8.25 (app d, 1 H, *J* 8.0 Hz, *Ar* *H*-6), 7.31 (d, 1 H, *J* 8.0 Hz, *Ar* *H*-7), 6.69 (d, 2 H, *J* 2.3 Hz, *Ar*), 6.61 (d, 2 H, *J* 8.7 Hz, *Ar*), 6.54 (dd, 2 H, *J*<sub>1</sub> 2.3 Hz, *J*<sub>2</sub> 8.7 Hz, *Ar*), 4.10 (s, 2 H,  $\text{C}(\text{O})\text{CH}_2\text{N}$ ). HR-ESI-QTOF calcd for  $\text{C}_{23}\text{H}_{14}\text{NO}_8$  ( $\text{M} - \text{H}^+$ ) 432.0734, obsd 432.0732.

**6-(2-Carboxyethylaminocarbonyl)fluorescein (8b).** The reaction was carried out as in the general procedure for coupling with amino acids using  $\beta$ -alanine methyl ester hydrochloride to give 372 mg (64%) of **8b**. <sup>1</sup>H NMR ( $\text{CD}_3\text{OD}$ , 300 MHz):  $\delta$  8.41 (d, 1 H, *J* 0.9 Hz, *Ar* *H*-4), 8.18 (dd, 1 H, *J*<sub>1</sub> 1.6 Hz, *J*<sub>2</sub> 8.1 Hz, *Ar* *H*-6), 7.29 (d, 1 H, *J* 7.9 Hz, *Ar* *H*-7), 6.68 (s, 2 H, *J* 2.2 Hz, *Ar*), 6.59 (d, 2 H, *J* 7.9 Hz, *Ar*), 6.53 (dd, 2 H, *J*<sub>1</sub> 2.3 Hz, *J*<sub>2</sub> 8.8 Hz, *Ar*), 3.68 (t, 2 H, *J* 6.8 Hz,  $\text{NCH}_2$ ), 2.67 (t, 2 H, *J* 6.7 Hz,  $\text{C}(\text{O})\text{-CH}_2$ ). HR-ESI-QTOF calcd for  $\text{C}_{24}\text{H}_{16}\text{NO}_8$  ( $\text{M} - \text{H}^+$ ) 446.0881, obsd 446.0892.

**6-(3-Carboxypropylaminocarbonyl)fluorescein (8c).** The reaction was carried out as in the general procedure for coupling with amino acids using GABA methyl ester hydrochloride to give 255 mg (76%) of **8c**. <sup>1</sup>H NMR ( $\text{CD}_3\text{OD}$ , 300 MHz):  $\delta$  8.42 (app s, 1 H, *Ar* *H*-4), 8.19 (dd, 1 H, *J*<sub>1</sub> 1.4 Hz, *J*<sub>2</sub> 8.0 Hz, *Ar* *H*-6), 7.29 (d, 1 H, *J* 8.1 Hz, *Ar* *H*-7), 6.68 (s, 2 H, *J* 2.2 Hz, *Ar*), 6.59 (d, 2 H, *J* 8.7 Hz, *Ar*), 6.53 (dd, 2 H, *J*<sub>1</sub> 2.3 Hz, *J*<sub>2</sub> 8.7 Hz, *Ar*), 3.48 (t, 2 H, *J* 6.9 Hz,  $\text{NCH}_2$ ), 2.42 (t, 2 H, *J* 6.7 Hz,  $\text{C}(\text{O})\text{-CH}_2$ ), 1.95 (app q, *J*<sub>1</sub> 7.3 Hz, *J*<sub>2</sub> 6.7 Hz,  $\text{CH}_2$ ). HR-ESI-QTOF calcd for  $\text{C}_{25}\text{H}_{18}\text{NO}_8$  ( $\text{M} - \text{H}^+$ ) 460.1037, obsd 460.1031.

**6-(Carboxymethylaminocarbonyl)fluorescein (9a).** The reaction was carried out as in the general procedure for coupling with amino acids using glycine methyl ester hydrochloride to give 100% yield of **9a**. <sup>1</sup>H NMR ( $(\text{CD}_3)_2\text{CO}$ , 300 MHz):  $\delta$  8.32 (bt, 1 H, *NH*), 8.23 (dd, 1 H, *J*<sub>1</sub> 7.9 Hz, *Ar* *H*-5), 8.05 (d, 1 H, *J* 8.0 Hz, *Ar* *H*-4), 7.74 (app s, 1 H, *Ar* *H*-7), 6.73 (d, 2 H, *J* 1.8 Hz, *Ar*), 6.68 (d, 2 H, *J* 8.6 Hz, *Ar*), 6.60 (dd, 2 H, *J*<sub>1</sub> 2.0 Hz, *J*<sub>2</sub> 8.6 Hz, *Ar*), 4.06 (d, 2 H, *J* 5.8 Hz,  $\text{CH}_2$ ). HR-ESI-QTOF calcd for  $\text{C}_{23}\text{H}_{14}\text{NO}_8$  ( $\text{M} - \text{H}^+$ ) 432.0719, obsd 432.0733.

**6-(2-Carboxyethylaminocarbonyl)fluorescein (9b).** The reaction was carried out as in the general procedure for coupling with amino acids using  $\beta$ -alanine methyl ester hydrochloride to give 253 mg (91%) of **9b**. <sup>1</sup>H NMR ( $(\text{CD}_3)_2\text{CO}$ , 300 MHz):  $\delta$  8.18 (dd, 1 H, *J*<sub>1</sub> 1.3 Hz, *J*<sub>2</sub> 7.9 Hz, *Ar* *H*-5), 8.03 (d, 1 H, *J* 7.9 Hz, *Ar* *H*-4), 7.70 (app s, 1 H, *Ar* *H*-7), 6.74 (d, 2 H, *J* 2.3 Hz, *Ar*), 6.66 (d, 2 H, *J* 8.6 Hz, *Ar*), 6.59 (dd, 2 H, *J*<sub>1</sub> 2.3 Hz, *J*<sub>2</sub> 8.7 Hz, *Ar*), 3.55 (m, 2 H,  $\text{NCH}_2$ ), 2.56 (t, 2 H, *J* 6.8 Hz,  $\text{C}(\text{O})\text{-CH}_2$ ). HR-ESI-QTOF calcd for  $\text{C}_{24}\text{H}_{16}\text{NO}_8$  ( $\text{M} - \text{H}^+$ ) 446.0876, obsd 446.0865.

**6-(3-Carboxypropylaminocarbonyl)fluorescein (9c).** The reaction was carried out as in the general procedure for coupling with amino acids using GABA methyl ester hydrochloride to give 95% yield of **9c**. <sup>1</sup>H NMR ( $\text{CD}_3\text{OD}$ , 300 MHz):  $\delta$  8.11 (dd, 1 H, *J*<sub>1</sub> 0.9 Hz, *J*<sub>2</sub> 7.9 Hz, *Ar* *H*-5), 8.05 (d, 1 H, *J* 8.0 Hz, *Ar* *H*-4), 7.61 (app s, 1 H, *Ar* *H*-7), 6.68 (d, 2 H, *J* 2.2 Hz, *Ar*), 6.59 (d, 2 H, *J* 8.6 Hz, *Ar*), 6.53 (dd, 2 H, *J*<sub>1</sub> 2.2 Hz, *J*<sub>2</sub> 8.7 Hz, *Ar*), 3.33 (t, 2 H, *J* 6.9

Hz,  $\text{NCH}_2$ ), 2.30 (t, 2 H,  $J$  7.3 Hz,  $\text{C}(\text{O})\text{CH}_2$ ), 1.81 (app. q, 2 H,  $\text{CH}_2$ ). HR-ESI-QTOF calcd for  $\text{C}_{25}\text{H}_{18}\text{NO}_8$  ( $\text{M} - \text{H}^+$ ) 460.1032, obsd 460.1039.

**Lactosylamine (10).** Lactose **1** (500 mg, 1.46 mmol) and  $\text{NH}_4\text{HCO}_3$  (115 mg, 1.46 mmol) were dissolved in  $\text{NH}_3$  (aq, 28%) and stirred in a stoppered flask at room temperature for 15 h. The reaction mixture was concentrated to ca. half volume in vacuo and lyophilized once.  $^1\text{H}$  NMR showed the major products to be lactosylamine **10** (46%) and lactosylcarbamate **11** (35%).  $^1\text{H}$  NMR ( $\text{D}_2\text{O}$ , 300 MHz):  $\delta$  5.05 (d, 0.10 H,  $J$  3.8 Hz,  $\alpha$   $\text{H}-1$ ), 4.55 (d, 0.36 H,  $J$  9.2 Hz,  $\beta$   $\text{H}-1$ ), 4.27 (d, 1 H,  $J$  7.7 Hz,  $\beta$   $\text{H}-1'$ ), 3.94 (d, 0.46 H,  $J$  8.8 Hz,  $\beta$   $\text{H}-1$ ), 3.90–3.05 (m, 12 H,  $\text{H}-2$  to  $\text{H}-6 + \text{H}-2'$  to  $\text{H}-6'$ ). HR-ESI-QTOF calcd for  $\text{C}_{12}\text{H}_{24}\text{NO}_{10}$  ( $\text{M} + \text{H}^+$ ) 342.1400, obsd 342.1405.

**Compound 12.** The reaction was carried out as in the general procedure for coupling with crude lactosylamine **10/11**, using **6** to give **12** in 24% isolated yield. However, impurities coluted with product, and repeated HPLC runs and a flash chromatography on silica gel were required to give pure product.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 500 MHz):  $\delta$  8.55 (app s, 1 H,  $\text{Ar H}-4$ ), 8.18 (app d, 1 H,  $J$  7.9 Hz,  $\text{Ar H}-6$ ), 7.33 (d, 1 H,  $J$  8.0 Hz,  $\text{Ar H}-7$ ), 6.83 (d, 2 H,  $J$  9.6 Hz,  $\text{Ar}$ ), 6.68 (d, 2 H,  $J$  2.2 Hz,  $\text{Ar}$ ), 6.58 (dd, 2 H,  $J_1$  1.9 Hz,  $J_2$  8.9 Hz,  $\text{Ar}$ ), 5.80 (d, 0.15 H,  $J$ ,  $\alpha$   $\text{H}-1$ ), 5.20 (d, 1 H,  $J$  8.9 Hz,  $\beta$   $\text{H}-1$ ), 4.40 (d, 1 H,  $J$  9.6 Hz,  $\beta$   $\text{H}-1'$ ), 3.92–3.47 (m, 12 H,  $\text{H}-2$  to  $\text{H}-6 + \text{H}-2'$  to  $\text{H}-6'$ ). HR-ESI-QTOF calcd for  $\text{C}_{33}\text{H}_{34}\text{NO}_{16}$  ( $\text{M} + \text{H}^+$ ) 700.1872, obsd 700.1838.

**Compound 13.** The reaction was carried out as in the general procedure for coupling with crude lactosylamine **10/11**, using **7** to give **13** in 32% isolated yield.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 500 MHz):  $\delta$  8.19 (app d, 1 H,  $J$  8.1 Hz,  $\text{Ar H}-5$ ), 8.07 (d, 1 H,  $J$  8.0 Hz,  $\text{Ar H}-4$ ), 7.73 (app s, 1 H,  $\text{Ar H}-7$ ), 6.68 (app. s, 2 H,  $\text{Ar}$ ), 6.62 (d, 2 H,  $J$  8.7 Hz,  $\text{Ar}$ ), 6.54 (app d, 2 H,  $J$  8.7 Hz,  $\text{Ar}$ ), 5.69 (d, 0.11 H,  $J$  5.6 Hz,  $\alpha$   $\text{H}-1$ ), 5.08 (d, 1 H,  $J$  9.1 Hz,  $\beta$   $\text{H}-1$ ), 4.33 (d, 1 H,  $J$  7.7 Hz,  $\beta$   $\text{H}-1'$ ), 3.80–3.30 (m, 12 H,  $\text{H}-2$  to  $\text{H}-6 + \text{H}-2'$  to  $\text{H}-6'$ ). HR-ESI-QTOF calcd for  $\text{C}_{33}\text{H}_{32}\text{NO}_{16}$  ( $\text{M} - \text{H}^+$ ) 698.1721, obsd 698.1702.

**Compound 14a.** The reaction was carried out as in the general procedure for coupling with crude lactosylamine **10/11**, using **8a** to give **14a** in 34% isolated yield.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 500 MHz):  $\delta$  8.50 (app s, 1 H,  $\text{Ar H}-4$ ), 8.23 (d, 1 H,  $J$  8.00 Hz,  $\text{Ar H}-6$ ), 7.30 (d, 1 H,  $J$  8.0 Hz,  $\text{Ar H}-7$ ), 6.68 (d, 2 H,  $J$  2.3 Hz,  $\text{Ar}$ ), 6.63 (d, 2 H,  $J$  8.8 Hz,  $\text{Ar}$ ), 6.54 (dd, 2 H,  $J_1$  2.2 Hz,  $J_2$  8.7 Hz,  $\text{Ar}$ ), 5.58 (d, 0.07 H,  $J$  5.4 Hz,  $\alpha$   $\text{H}-1$ ), 4.99 (d, 1 H,  $J$  9.2 Hz,  $\beta$   $\text{H}-1$ ), 4.37 (d, 1 H,  $J$  7.7 Hz,  $\beta$   $\text{H}-1'$ ), 4.16 (d, 2 H,  $J$  3.8 Hz,  $\text{C}(\text{O})\text{CH}_2\text{N}$ ), 3.90–3.35 (m, 12 H,  $\text{H}-2$  to  $\text{H}-6 + \text{H}-2'$  to  $\text{H}-6'$ ). HR-ESI-QTOF calcd for  $\text{C}_{33}\text{H}_{37}\text{N}_2\text{O}_{17}$  ( $\text{M} + \text{H}^+$ ) 757.2086, obsd 757.2097.

**Compound 14b.** The reaction was carried out as in the general procedure for coupling with crude lactosylamine **10/11**, using **8b** to give **14b** in 51% of **14b**.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 500 MHz):  $\delta$  8.41 (app s, 1 H,  $\text{Ar H}-4$ ), 8.16 (app d, 1 H,  $J$  7.8 Hz,  $\text{Ar H}-5$ ), 7.28 (d, 1 H,  $J$  8.0,  $\text{Ar H}-7$ ), 6.68 (d, 2 H,  $J$  1.9 Hz,  $\text{Ar}$ ), 6.61 (d, 2 H,  $J$  8.7 Hz,  $\text{Ar}$ ), 6.54 (dd, 2 H,  $J_1$  1.9 Hz,  $J_2$  8.6 Hz,  $\text{Ar}$ ), 5.58 (d, 0.08 H,  $J$  6.5 Hz,  $\alpha$   $\text{H}-1$ ), 4.96 (d, 1 H,  $J$  9.2 Hz,  $\beta$   $\text{H}-1$ ), 4.35 (d, 1 H,  $J$  10.6 Hz,  $\beta$   $\text{H}-1'$ ), 3.88–3.43 (m, 14 H,  $\text{H}-2$  to  $\text{H}-6 + \text{H}-2'$  to  $\text{H}-6' + \text{NCH}_2$ ), 2.61 (t, 2 H,  $J$  4.7 Hz,  $\text{C}(\text{O})\text{CH}_2$ ). HR-ESI-QTOF calcd for  $\text{C}_{36}\text{H}_{39}\text{N}_2\text{O}_{17}$  ( $\text{M} + \text{H}^+$ ) 771.2243, obsd 771.2282.

**Compound 14c.** The reaction was carried out as in the general procedure for coupling with crude lactosylamine **10/11**, using **8c** to give **14c** in 44% isolated yield.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 500 MHz):  $\delta$  8.43 (app s, 1 H,  $\text{Ar H}-4$ ), 8.17 (dd, 1 H,  $J_1$  1.2 Hz,  $J_2$  7.9 Hz,  $\text{Ar H}-6$ ), 7.29 (d, 1 H,  $J$  8.0 Hz,

$\text{Ar H}-7$ ), 6.68 (d, 2 H,  $J$  2.3 Hz,  $\text{Ar}$ ), 6.63 (d, 2 H,  $J$  8.7 Hz,  $\text{Ar}$ ), 6.54 (dd, 2 H,  $J_1$  2.0 Hz,  $J_2$  8.7 Hz,  $\text{Ar}$ ), 5.56 (d, 0.10 H,  $J$  5.5 Hz,  $\alpha$   $\text{H}-1$ ), 4.95 (d, 1 H,  $J$  9.2 Hz,  $\beta$   $\text{H}-1$ ), 4.36 (d, 1 H,  $J$  7.7 Hz,  $\beta$   $\text{H}-1'$ ), 3.85–3.40 (m, 14 H,  $\text{H}-2$  to  $\text{H}-6 + \text{H}-2'$  to  $\text{H}-6' + \text{NCH}_2$ ), 2.38 (m, 2 H,  $\text{C}(\text{O})\text{CH}_2$ ), 1.97 (m, 2 H,  $\text{CH}_2$ ). **Compound 15a.** The reaction was carried out as in the general procedure for coupling with crude lactosylamine **10/11**, using **9a** to give **15a** in 38% isolated yield.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 500 MHz):  $\delta$  8.06 (dd, 1 H,  $J_1$  1.4 Hz,  $J_2$  8.1 Hz,  $\text{Ar H}-5$ ), 7.97 (d, 1 H,  $J$  8.0,  $\text{Ar H}-4$ ), 7.59 (app s, 1 H,  $\text{Ar H}-7$ ), 6.57 (d, 2 H,  $J$  2.4 Hz,  $\text{Ar}$ ), 6.52 (d, 2 H,  $J$  8.7 Hz,  $\text{Ar}$ ), 6.43 (dd, 2 H,  $J_1$  2.4 Hz,  $J_2$  7.1 Hz,  $\text{Ar}$ ), 5.38 (d, 0.09 H,  $J$  5.47,  $\alpha$   $\text{H}-1$ ), 4.79 ( $\beta$   $\text{H}-1$ ), 4.23 (d, 1 H,  $J$  7.63,  $\beta$   $\text{H}-1'$ ), 3.91 (s, 2 H,  $\text{C}(\text{O})\text{CH}_2\text{N}$ ), 3.80–3.30 (m, 12 H,  $\text{H}-2$  to  $\text{H}-6 + \text{H}-2'$  to  $\text{H}-6'$ ). HR-ESI-QTOF calcd for  $\text{C}_{35}\text{H}_{35}\text{N}_2\text{O}_{17}$  ( $\text{M} - \text{H}^+$ ) 755.1936, obsd 755.1909.

**Compound 15b.** The reaction was carried out as in the general procedure for coupling with crude lactosylamine **10/11**, using **9b** to give 20.3 mg (30%) of **15b**.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 500 MHz):  $\delta$  8.11 (app d, 1 H,  $J$  8.0 Hz,  $\text{Ar H}-5$ ), 8.06 (d, 1 H,  $J$  8.0 Hz,  $\text{Ar H}-4$ ), 7.60 (app s, 1 H,  $\text{Ar H}-7$ ), 6.68 (app s, 2 H,  $\text{Ar}$ ), 6.63 (s, 2 H,  $J$  8.7 Hz,  $\text{Ar}$ ), 6.54 (dd, 2 H,  $J_1$  2.2 Hz,  $J_2$  8.7 Hz,  $\text{Ar}$ ), (d, 0.09 H,  $J$  5.5 Hz,  $\alpha$   $\text{H}-1$ ), 4.87 ( $\beta$   $\text{H}-1$ ), 4.60 (s, 0.21 H,  $\text{NH}$ ), 4.34 (d, 1 H,  $J$  7.6 Hz,  $\beta$   $\text{H}-1'$ ), 3.80–3.30 (m, 14 H,  $\text{H}-2$  to  $\text{H}-6 + \text{H}-2'$  to  $\text{H}-6' + \text{NCH}_2$ ), 2.51 (m, 2 H,  $\text{C}(\text{O})\text{CH}_2$ ). HR-ESI-QTOF calcd for  $\text{C}_{36}\text{H}_{37}\text{N}_2\text{O}_{17}$  ( $\text{M} - \text{H}^+$ ) 769.2092, obsd 769.2104.

**Compound 15c.** The reaction was carried out as in the general procedure for coupling with crude lactosylamine **10/11**, using **9c** to give **15c** in 26% isolated yield.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 500 MHz):  $\delta$  8.09 (m, 2 H,  $\text{Ar H}-4 + \text{Ar H}-5$ ), 7.65 (app s, 1 H,  $\text{Ar H}-7$ ), 6.85 (d, 2 H,  $J$  8.8 Hz,  $\text{Ar}$ ), 6.69 (d, 2 H,  $J$  1.8 Hz,  $\text{Ar}$ ), 6.60 (dd, 2 H,  $J_1$  8.8 Hz,  $\text{Ar}$ ), 5.47 (d, 0.09 H,  $J$  5.5 Hz,  $\alpha$   $\text{H}-1$ ), 4.86 (d, 1 H,  $J$  9.5 Hz,  $\beta$   $\text{H}-1$ ), 4.62 (app s, 1 H,  $\text{NH}$ ), 4.34 (d, 1 H,  $J$  7.6 Hz,  $\beta$   $\text{H}-1'$ ), 3.90–3.30 (d, 14 H,  $\text{H}-2$  to  $\text{H}-6 + \text{H}-2'$  to  $\text{H}-6' + \text{NCH}_2$ ), 2.28 (m, 2 H,  $\text{C}(\text{O})\text{CH}_2$ ), 1.88 (m, 2 H,  $\text{CH}_2$ ). HR-ESI-QTOF calcd for  $\text{C}_{37}\text{H}_{39}\text{N}_2\text{O}_{17}$  ( $\text{M} - \text{H}^+$ ) 783.2249, obsd 783.2222.

**Compound 16.** The reaction was carried out as in the general procedure for coupling with crude glycosylamines of oligosaccharides, using lacto-*N*-triose to give **16** in 37% isolated yield.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 400 MHz):  $\delta$  8.60 (app s, 1 H,  $\text{Ar H}-4$ ), 8.28 (dd, 1 H,  $J_1$  1.6 Hz,  $J_2$  8.1 Hz,  $\text{Ar H}-6$ ), 7.39 (d, 1 H,  $J$  7.9 Hz,  $\text{Ar H}-7$ ), 6.93–6.66 (m, 6 H,  $\text{Ar}$ ), 4.98 (d, 1 H,  $J$  9.0 Hz,  $\beta$   $\text{H}-1$ ), 4.63 (d, 1 H,  $J$  8.4 Hz,  $\beta$   $\text{H}$ ), 4.37 (d, 1 H,  $J$  7.3 Hz,  $\beta$   $\text{H}$ ), 4.16 (s, 2 H,  $\text{C}(\text{O})\text{CH}_2$ ), 4.04 (d, 1 H,  $J$  2.2 Hz,  $\text{H}-4$ ), 3.89–3.34 (m, 17 H,  $\text{H}-2$  to  $\text{H}-6 + \text{H}-2'$  to  $\text{H}-6' + \text{H}'-2$  to  $\text{H}'-6$ ), 1.99 (s, 3 H,  $\text{NAc}$ ). HR-ESI-QTOF calcd for  $\text{C}_{43}\text{H}_{50}\text{N}_3\text{O}_{22}$  ( $\text{M} + \text{H}^+$ ) 960.2880, obsd 960.2908.

**Compound 17.** The reaction was carried out as in the general procedure for coupling with crude glycosylamines of oligosaccharides, using lacto-*N*-neo-tetrose to give **17** in 44% isolated yield.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 400 MHz):  $\delta$  8.60 (app s, 1 H,  $\text{Ar H}-4$ ), 8.28 (dd, 1 H,  $J_1$  1.6 Hz,  $J_2$  8.0 Hz,  $\text{Ar H}-6$ ), 7.39 (d, 1 H,  $J$  8.1 Hz,  $\text{Ar H}-7$ ), 6.93–6.66 (m, 6 H,  $\text{Ar}$ ), 4.94 (d, 1 H,  $J$  9.1 Hz,  $\beta$   $\text{H}-1$ ), 4.65 (d, 1 H,  $J$  8.3 Hz,  $\beta$   $\text{H}$ ), 4.37 (d, 2 H,  $J$  7.4 Hz,  $\beta$   $\text{H} + \beta$   $\text{H}$ ), 4.16 (s, 2 H,  $\text{C}(\text{O})\text{CH}_2$ ), 4.04 (d, 1 H,  $J$  2.5 Hz,  $\text{H}-4$ ), 3.90–3.33 (m, 23 H,  $\text{H}-2$  to  $\text{H}-6 + \text{H}-2'$  to  $\text{H}-6' + \text{H}'-2$  to  $\text{H}'-6 + \text{H}''-2$  to  $\text{H}''-6$ ), 1.99 (s, 3 H,  $\text{NAc}$ ). HR-ESI-QTOF calcd for  $\text{C}_{49}\text{H}_{60}\text{N}_3\text{O}_{27}$  ( $\text{M} + \text{H}^+$ ) 1122.3408, obsd 1122.3452.

**Recombinant Galectins.** Recombinant rat galectin-1 and human galectin-3 were produced in *E. coli* BL21 (pET1d and pET-3c vectors, respectively) and purified by chromatography on lactosyl-Sepharose as described (Cop-

per et al., 1991 for galectin-1; Massa et al., 1993, for galectin-3) (13, 14). The *N*-terminus of Gal-8 and thioredoxin was expressed as a fusion protein in *E. coli* BL21 (pET32 vector) and purified by chromatography on lactosyl-Sepharose as described (14). Before use, lactose was removed by dialysis against PBS (118 mM NaCl, 67 mM Na/K-phosphate, pH 7.2) and the galectin concentrated using CentriPrep concentrators (Millipore, Bedford, MA).

**Fluorescence Polarization Binding Assay.** To measure direct binding of fluorescent probe to galectin, FP was measured from above in 96-well microtiter plates (black polystyrene, Costar, Corning, NY) using a PolarStar instrument (BMG, Offenburg, Germany). The final sample volume in each well was 200  $\mu$ L. For direct binding a series of different concentrations of galectin-3 were prepared in a microtiter plate (100  $\mu$ L per well). Then 100  $\mu$ L fluorescent probe was added to a final concentration of 0.1 or 1.0  $\mu$ M, and the plate was incubated under slow rotary shaking in the dark for 5 min. Control wells containing only fluorescent probe or fluorescein were included. All dilutions and measurements were done in PBS.

The FP is measured by two photomultipliers (PMT1 and PMT2) receiving light through two perpendicularly polarized channels. The values are given as polarization units ( $P = \text{PMT1} - \text{PMT2} / (\text{PMT1} + \text{PMT2})$ ) (5, 17). The fluorescein containing well was used to balance the gain of the photomultipliers (setting the K factor, according to instrument manual) assuming that free fluorescein should give a value of 35 mP. The total fluorescence intensity was measured as the sum of the two PMT channels, to detect quenching of the bound probe (difference between probe only or probe with maximum amount of galectin).

The temperature was set to 24, 30, 35, 40, or 45 using the thermostat of the instrument. To measure at about 5  $^{\circ}$ C, the plate was cooled on ice for 5 min before FP-recording. The temperature in selected wells was measured before and after recording using a TEMP 4 Acorn Series thermistor temperature sensor (Oakton Instruments, Vernon Hills, IL).

Data plotting, regression analysis, and curve construction was done using Prism 3.0 (GraphPad Software, San Diego, CA).

## RESULTS AND DISCUSSION

### Structural Considerations for Design of Probes.

The probes described here were designed with consideration of the structural features of galectin-carbohydrate interaction (4, 7, 8, 15), even if they would be useful for many other carbohydrate binding proteins as well. As shown in Figure 1, a Gal residue is most tightly bound to the galectin carbohydrate recognition domain (CRD) via a number of hydrogen bonds (dotted lines above 1) and a hydrophobic stacking interaction with a Trp side chain (below 1). The Glc residue of lactose and the corresponding residue of other disaccharides (e.g. LacNAc) interact much less with the protein and only along one of its sides. This interaction, however, is important, as the binding affinity of Gal alone is about 100 fold lower compared to that of lactose. The fine specificity of galectins arises mainly from differential recognitions of additional saccharides or other modifications of the disaccharide at position Gal HO-3 (and lesser extent position HO-2) which project into an extended groove on the galectin. Another source of fine specificity is the differential recognition of saccharides where the 4Glc of lactose has been replaced by another residue (e.g.

4GlcNAc, 3GlcNAc, or 3GalNAc), which projects similar enough structural features toward the protein (6, 16). The fluorescent probe, therefore, should preserve the structure of the saccharide parts interacting with galectin, while the fluorophore should be sufficiently removed not to cause adverse interactions itself.

Previous studies indicate that if the Glc ring is opened, the binding affinity for galectin-1 becomes much lower, apparently because the steric restriction of the interacting groups are required (6). To test this further, 2 was synthesized as an analogue permitting exactly the same hydrogen bond interactions to the protein as lactose but lacking the restriction of the Glc pyranose ring. This compound bound galectins-1 and -3 by over 10-fold less well than lactose (data not shown). These results reaffirmed that it was highly desirable to derivatize the saccharides keeping the reducing residue ring closed. The commonly used reductive amination would open the ring and, hence, significantly alter the interaction with the protein.

Another consideration is the tether length between the saccharide and the fluorescein moiety. As seen from Figure 1, the reducing end of lactose is not buried but is well exposed from the protein and points out into the solution. This made it likely that the tethers would not have to be very long and only limited interaction between the protein and fluorescein and tether was expected. On the other hand, a too long tether could lead to less optimal results in the FP assay due to movement of the fluorophore independent of the bound saccharide (17). Hence, we linked carboxyfluorescein to lactosylamine directly or via tethers consisting of glycine (three more atoms),  $\beta$ -alanine (four more atoms), or GABA (five more atoms).

Although carboxyfluorescein is synthesized and commonly used as mixture of two regioisomers, namely 5- and 6-carboxyfluorescein (6, 7) (18), we found it important to examine each isomer separately as they might differ in their interactions, albeit limited as mentioned above, with the protein. A few reports suggest differences in behavior and subsequent binding assays for the two isomers (19, 20). The two isomers have almost identical spectroscopic properties, making a direct comparison of lectin-binding properties possible (21). Working with single isomers also significantly simplified chromatographic separations and subsequent characterizations by NMR.

**Synthesis of Saccharide-Fluorescein Probes.** Due to the cost of commercial (21), regioisomerically pure 5- and 6-carboxyfluorescein (6, 7) in gram amounts, we synthesized the dipivaloyl-protected derivatives (mixture of 3 and 5), permitting separation by crystallization essentially as described (12, 22) (Scheme 1). Then 6 and 7, for untethered coupling to the glycosylamine, were obtained by direct deprotection by ester saponification of 3 and 5, respectively. The tethered derivatives 8a-c and 9a-c were obtained by coupling of 3 and 5, respectively, with the methyl esters of glycine,  $\beta$ -alanine, and GABA followed by the deprotection in a one-pot, two-step procedure. The yields of 9a-c were good to excellent, whereas the yields of 8a-c were only fair. We believe this is due to losses in the purification caused by the poor solubility of 6 and 8a-c, as compared to 7 and 9a-c, resulting in chromatographic difficulties.

Lactosylamine 10, was synthesized according to standard literature procedure (Scheme 2) (10). The reaction in Scheme 2 gives predominately a mixture of lactosylamine 10 and lactosylcarbamate 11.

The crude lactosylamine/lactosylcarbamate **10/11** mixture was acylated with **6–9c** to give compounds (**12–15c**) in up to 65% yield after HPLC purification (Table 1, yields based on the combined amounts of **10** and **11**). It was expected that the lactosylcarbamate **11** would rapidly decarboxylate to **10** during the reaction. However, NMR of crude reaction mixture **10/11** showed lactosylcarbamate remaining after 3 days in  $\text{D}_2\text{O}$  solution at room temperature. Whether this affects the rates and yields in the coupling to **6–9c** remains to be studied.

A number of alternative coupling agents were investigated for the acylation reaction (EDC/NHS, EDC/HOBt, EDC/Pfp, DCC/HOBt, BTC, EEDQ,  $\text{COCl}_2$ , FDP, FDDP,

PyBOP, BOP, BOP/HOBt, HBTU). However, only the BOP-reagents, HBTU, and BTC gave observable product, with best yields for the BOP reagents. Accordingly, compounds **12–15c** were synthesized using the combination BOP/HOBt/DIPEA/ $\text{Me}_2\text{SO}$  (**23**) as shown in Table 1. We also note that a “standard” combination like EDC/NHS/DIPEA/ $\text{Me}_2\text{SO}$  gave good to excellent yields in coupling **6–9c** with noncarbohydrate amines such as the primary methyl esters of glycine,  $\beta$ -alanine, GABA, and also norephedrine (96% yield), the latter used as a structural mimic of the reducing end of a glycosylamines.

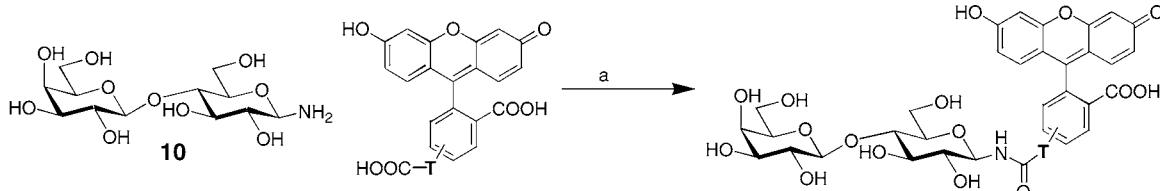

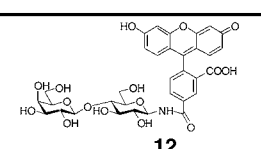

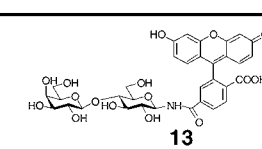

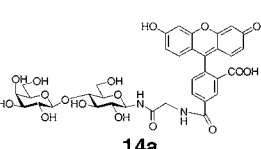

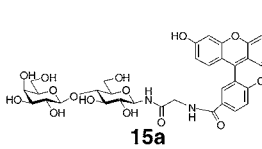

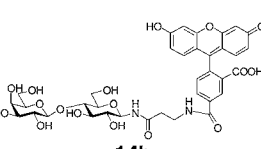

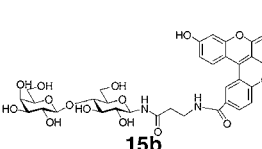

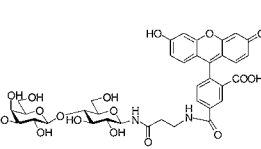

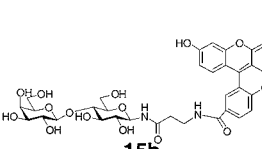

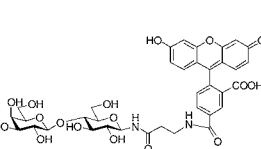

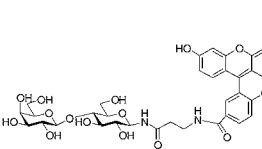

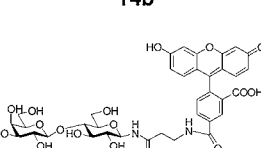

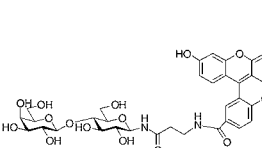

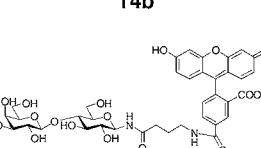

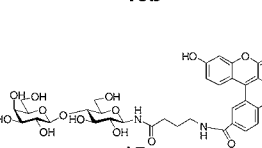

Having established the acylation conditions, the **10/11** mixture was reacted with the different relative amounts of carboxyfluorescein derivatives (Table 1). In most cases, the yields of purified saccharide derivative varied from about 30 to 65%. In all cases there was a competing formation of carboxyfluorescein amide, which was even observed as the major product in entry 10 (Table 1). This is due to significant amounts of ammonia remaining in the crude lactosylamine **10** after a single lyophilization. The residual ammonia can be removed with, for example, repeated lyophilizations, but at the expense of partial hydrolysis of **10**, which was highly undesirable in our synthetic approach, since for more complex saccharides, available in small amounts, the glycosylamine will be the limiting factor. Alternatively using an excess of the other reagents (e.g. **9b**/BOP/HOBt in entries 11–13) scavenged the ammonia and afforded good yield of the desired product vis-à-vis the glycosylamine.

**Binding of the Probes to Galectins in a Fluorescence Polarization Assay.** The saccharide–fluorescein conjugates (**12–15c**) were used as probes to test their binding to galectins-1, -3, and -8N by fluorescence polarization (Figure 2). A fixed amount of probe (0.1  $\mu\text{M}$ ) was mixed with different concentrations of galectin ( $X$ -axis) and FP was measured ( $Y$ -axis). A rise in the FP values with increasing galectin concentration indicates binding since the bound probe gives a higher FP value. All the data points agreed well, when fit by nonlinear regression, to curves corresponding to a simple one to one galectin–probe interaction. The position of the curves along the  $X$ -axis represents the affinity with lower  $K_d$  values the further left the curve is. The approached maximum value correlates with the size of the protein–probe complex but is abrogated by independent movements of the fluorophore (propeller effects). Large differences in the binding ability of the different probes for the different galectins are apparent.

The best probes were found among the 5-carboxyfluorescein derivatives (**14a–c**) whereas the corresponding 6-carboxyfluorescein (**15a–c**) bound more poorly to all the galectins. However, significant binding of **15b** and **15c** to galectin-8N showed that also the 6-carboxyfluorescein derivatives can bind to the appropriate protein, and hence, their apparent total lack of binding to galectins-1 and -3 is maybe due to steric hindrance and/or propeller effects. This surprising finding is of great practical importance thus implicating the importance of using pure fluorescein isomers. If such a difference was present also in earlier studies where the mixed isomers have been used it might have confounded the results.

The tether length also greatly affected binding. Both probes with direct amide linkage to carboxyfluorescein (**12**, **13**) bound poorly to galectins-3 and -8N, apparently due to severe steric repulsions with the galectin CRDs. Compound **14a** with a glycine tether is the best probe for galectin-3, **14c** with GABA tether is preferred by

<sup>a</sup> Lactosylamine **10** (1 eq), acid ( $x$  equiv), BOP ( $x$  equiv), HOBT ( $x$  equiv), and DIPEA ( $2.5x$  equiv). Reaction 0.1 M (**10**) in Me<sub>2</sub>SO and stirred at room temperature for 2–12 h. <sup>b</sup> Capital T in top scheme represents the various tethers in the case of compounds **14a–c** and **15a–c** and a covalent bond for compounds **12** and **13**. <sup>c</sup> The yields are purified product as mol % of the crude **10/11** mixture.

galectin-1, and **14c** and **14b** (GABA and  $\beta$ -alanine tethers) are about equally good for galectin-8N.

**Application to Complex Saccharides.** To test our protocol on more complex, biologically interesting oligosaccharides, lacto-*N*-triose (LNT-2) and lacto-*N*-neo-

tetraose (LNT-3), were conjugated to structure **8a** to optimize for testing against galectin-3. In both cases 2 mg of oligosaccharide was reacted with 4 equiv of **8a** to result in 37% and 44% isolated yield of **16** and **17** (Figure 3), calculated on the reducing sugars. Thus, the fluores-

**Figure 2.** Binding curves of **12–15c** in the fluorescence polarization assay against galectins-1, -3, and -8N.

cein-labeling methodology optimized for lactose is clearly applicable on small amounts of larger and more complex oligosaccharides. Results from these and other labeled oligosaccharides in the fluorescence polarization assay will be reported elsewhere.

## CONCLUSION

The present results demonstrate a convergent procedure with a simple final step to conjugate different premade carboxyfluorescein derivatives to the reducing end of complex saccharides, available in limiting amounts, with conservation of the reducing sugar ring. The simplicity of our fluorescein-labeling procedure renders it ideal for use with small amounts of complex natural oligosaccharides.

The probes were shown to be applicable to probe galectin binding abilities in a FP assay. A dependence of

**Figure 3.** Fluorescent derivatives of LNT-2 and LNNt with tether optimized for galectin-3.

carboxyfluorescein isomer and tether length demonstrated the importance of selecting the optimal derivative for use with complex saccharides. The use of the same selected derivative with a large range of complex saccharides will create a probe library for defining lectin specificity. Even if the yields are only 30–50%, based on the saccharide, they are sufficient for generating useful amounts of probe even from small amounts of saccharide. This is because the FP assay is very sensitive; 1 mg probe suffices for about 50 000 assays with the 200  $\mu$ L assay volume used in this paper, and this can most likely be improved by minaturization.

We thank Angelina So, University of Waterloo, ON, Canada, and Alex Young, University of Toronto, ON, Canada, for HRMS analyses and Barbro Kahl-Knutsson, Lund University, for help with FP-analysis. E.F. thanks the Natural Science and Engineering Research Council of Canada and the University of Waterloo for financial support, and H.L. thanks the Swedish Research Council (grant 12165) for financial support. U.J.N. thanks the program “Glycoconjugates in Biological Systems” sponsored by the Swedish Strategic Research Foundation for financial support.

**Supporting Information Available:**  $^1\text{H}$  NMR spectra of compounds **2**, **6–9c**, **10/11**, **12–15c**, **16**, and **17**. This material is available free of charge via the Internet at <http://pubs.acs.org>.

# Aryldiazomethanes for Universal Labeling of Nucleic Acids and Analysis on DNA Chips

Ali Laayoun,<sup>\*,†</sup> Mitsuharu Kotera,<sup>\*,‡</sup> Isabelle Sothier,<sup>†</sup> Emmanuelle Trévisiol,<sup>‡</sup> Eloy Bernal-Méndez,<sup>†</sup> Cécile Bourget,<sup>‡</sup> Lionel Menou,<sup>†</sup> Jean Lhomme,<sup>‡</sup> and Alain Troesch<sup>†</sup>

BioMérieux, Advanced Technology/Molecular Diagnostics, Chemin de l'Orme - 69280 Marcy l'Etoile, France, and LEDSS, UMR5616 CNRS - BP53, Université Joseph Fourier, 38041 Grenoble, France. Received July 31, 2003; Revised Manuscript Received October 3, 2003

DNA and RNA labeling and detection are key steps in nucleic acid-based technologies, used in medical research and molecular diagnostics. We report here the synthesis, reactivity, and potential of a new type of labeling molecule, *m*-(*N*-Biotinoylamino)phenylmethyldiazomethane (*m*-BioPMDAM), that reacts selectively and efficiently with phosphates in nucleotide monomers, oligonucleotides, DNA, and RNA. This molecule contains a biotin as detectable unit and a diazomethyl function as reactive moiety. We demonstrate that this label fulfills the requirements of stability, solubility, reactivity, and selectivity for hybridization-based analysis and especially for detection on high-density DNA chips.

## INTRODUCTION

In recent years, a vast amount of genetic information has been obtained from numerous genome sequencing projects. The availability of these data has boosted the development and use of nucleic acid-based technologies in biomedical research and in vitro diagnostics to identify and quantify organisms that are present in biological samples, study genome expression levels, and detect genetic mutations and polymorphisms.

A typical nucleic acid-based assay usually comprises different steps, i.e., target isolation, enzymatic amplification, and detection by hybridization onto specific complementary probe(s). The analysis of target/probe hybrids is a key step in this process and generally requires the use of reporter molecules to specifically label the nucleic acids. Depending on the test format, those reporter molecules are incorporated either in the target (during the enzymatic amplification or postsynthesis) or in the detection probes. It is essential that these labeling methods do not disrupt the base pairing capability which is critical for preserving specificity during enzymatic incorporation and the subsequent hybridization detection step. This requirement is particularly important for microarrays or DNA chips, which represent one of the most promising methods for assessing genetic diversity at a large scale and a high resolution. This technology is based on the hybridization of labeled nucleic acid targets onto large sets of oligonucleotide probes (1, 2). Enzymatic incorporation of the label, either during target amplification or postsynthetically, represents the most widely used labeling method in DNA chip analysis (3–5) but presents some drawbacks. The amplified product may become altered in the presence of modified, labeled nucleotides. Also, postsynthetic labeling methods make use of ad-

ditional enzymatic steps which require precise calibration of the enzyme activity to achieve a reproducible labeling yield. Moreover, because the enzymes used depend on the target type (DNA or RNA), no specific method is universally applicable to all nucleic acids. A more convenient alternative is to label the target chemically and a variety of chemical methods for direct modification and derivatization of nucleic acids with functional groups have been proposed (6–10). Chemical labeling generally occurs at the bases, thereby altering the hybridization properties.

We have previously described a strategy for labeling RNA molecules on their terminal phosphate (11, 12). This chemical labeling takes advantage of the fragmentation step, which is required for the hybridization to high-density DNA chips (3), to attach the reporter molecule 5-(bromomethyl)fluorescein (5-BMF) to the 3'-phosphate of cleaved RNA fragments. In our model experiments, we reported higher labeling densities than with enzymatic incorporation of labeled ribonucleotides (11). The hybridization efficiency was shown to be preserved, but labeling yields on single- and double-stranded DNA were poor (13). We now report a new type of labeling reagent, *m*-BioPMDAM (3) (*m*-(*N*-Biotinoylamino)phenylmethyldiazomethane), that selectively and more efficiently reacts on the phosphates of nucleic acid sequences. The molecule includes in its structure a biotin unit covalently linked to the reactive phenyldiazomethane moiety. Its synthesis is described. In a model study we show that *m*-BioPMDAM reacts selectively on the phosphate of a series of 3'-nucleotide monophosphates, and it can be used to label oligonucleotides and long DNA and RNA sequences, prior to their analysis on high-density DNA chips.

## EXPERIMENTAL PROCEDURES

All commercially available chemical reagents and solvents were used without purification. D-biotin was purchased from Lancaster Synthesis (Windham, NH) or Avocado Research Chemicals (Heysham, UK). MnO<sub>2</sub> and Celite-545 were purchased from Merck (Fontenay-sous-bois, France), molecular sieves (3 Å, powder) from Acros Organics (Noisy-le-Grand, France), boric acid from Eu-

robio (Les Ulis, France), and 3'-GMP from ICN Biomedicals (Costa Mesa, CA). All other nucleotides were from Sigma (Saint Quentin-Fallavier, France). TLC: Merck silica gel 60 F<sub>254</sub> plates. Preparative reverse phase column chromatography: Merck LiChroprep RP 18 silica gel (40–63  $\mu$ m). Mp: Electrothermal Serie IA9100 apparatus, uncorrected. UV: Perkin-Lambda 15UV/VIS. IR: Perkin-Elmer Impact 400 spectrophotometer. NMR: Bruker AC 200, Avance 300 spectrometers. For <sup>1</sup>H NMR, CDCl<sub>3</sub> as solvent,  $\delta_{\text{H}} = 7.24$ , DMSO-*d*<sub>6</sub> as solvent,  $\delta_{\text{H}} = 2.49$ ; for <sup>13</sup>C NMR, CDCl<sub>3</sub> as solvent,  $\delta_{\text{C}} = 77.5$ , DMSO-*d*<sub>6</sub> as solvent,  $\delta_{\text{C}} = 39.5$ . Mass spectra: Delsi-Nermag R10–10 or VG Platform (Micromass) spectrometers.

**Synthesis of *m*-BioPMDAM (3).** 3-(*N*-Biotinoylamino)acetophenone (**1**). To a solution of D-biotin (1.0 g, 4.1 mmol) in dry DMF (45 mL) cooled to 0 °C under argon were added successively *N*-methylmorpholine (590  $\mu$ L, 5.33 mmol) and isobutyl chloroformate (840  $\mu$ L, 6.60 mmol). The solution was stirred for 30 min, and then 3-aminoacetophenone (824 mg, 6.10 mmol) and *N*-methylmorpholine (480  $\mu$ L, 4.35 mmol) in 10 mL of DMF were added. The solution was stirred at 0 °C for 2 h, and then the solvent was removed under vacuum. The residue was dissolved in 3 mL of MeOH, and then 50 mL of water were added. The resulting precipitate was filtered, washed successively with water, CH<sub>2</sub>Cl<sub>2</sub>, and ether, and dried to give 1.2 g of crude **1**. Recrystallization from MeOH–water gave **1** (1.01 g, 70%) as a white powder. Mp 145 °C; IR (KBr):  $\nu = 3280, 2931, 2857, 1691, 1590, 1540, 1487, 1434, 1298, 1266 \text{ cm}^{-1}$ ; <sup>1</sup>H NMR (300 MHz, DMSO-*d*<sub>6</sub>):  $\delta = 1.3\text{--}1.7$  (m, 6H), 2.33 (t,  $J = 8 \text{ Hz}$ , 2H), 2.55 (s, 3H), 2.58 (d,  $J = 12 \text{ Hz}$ , 1H), 2.83 (dd,  $J = 12$  and  $5 \text{ Hz}$ , 1H), 3.13 (m, 1H), 4.15 (m, 1H), 4.31 (m, 1H), 6.34 (s, 1H), 6.41 (s, 1H), 7.44 (t,  $J = 8 \text{ Hz}$ , 1H), 7.64 (d,  $J = 8 \text{ Hz}$ , 1H), 7.85 (d,  $J = 8 \text{ Hz}$ , 1H), 8.17 (s, 1H), 10.05 (s, 1H). <sup>13</sup>C NMR (50 MHz, DMSO-*d*<sub>6</sub>):  $\delta = 197.5, 171.3, 162.6, 139.5, 137.1, 128.9, 123.3, 122.8, 118.0, 60.9, 59.0, 55.2, 39.6, 36.0, 28.0, 27.9, 26.5, 24.9$ ; MS (FAB/glycerol):  $m/z$  362 [M + H]<sup>+</sup>.

3-(*N*-Biotinoylamino)acetophenone Hydrazone (**2**). To a solution of **1** (500 mg, 1.38 mmol) in absol ethanol (8 mL) was added 200  $\mu$ L (4.15 mmol) of hydrazine monohydrate. The solution was refluxed for 2 h. After cooling, the white precipitate was filtered, washed with water and ether, and then dried to give **2** (385 mg, 74%) as a white powder. Mp 185 °C; IR (KBr):  $\nu = 3298, 2931, 2857, 1698, 1665, 1626, 1541, 1494, 1470, 1446, 1330, 1265 \text{ cm}^{-1}$ ; <sup>1</sup>H NMR (300 MHz, DMSO-*d*<sub>6</sub>):  $\delta = 1.3\text{--}1.7$  (m, 6H), 1.98 (s, 3H), 2.26 (t,  $J = 8 \text{ Hz}$ , 2H), 2.56 (d,  $J = 12 \text{ Hz}$ , 1H), 2.81 (dd,  $J = 12$  and  $5 \text{ Hz}$ , 1H), 3.11 (m, 1H), 4.13 (m, 1H), 4.29 (m, 1H), 6.39 (s, 3H), 6.42 (s, 1H), 7.22 (m, 2H), 7.50 (d,  $J = 8 \text{ Hz}$ , 1H), 7.84 (s, 1H), 9.82 (s, 1H). <sup>13</sup>C NMR (75 MHz, DMSO-*d*<sub>6</sub>):  $\delta = 171.6, 163.1, 142.2, 140.6, 139.5, 128.7, 120.0, 118.2, 115.9, 61.4, 59.6, 55.8, 40.2, 36.6, 28.6, 28.4, 25.5, 11.7$ ; MS (FAB/glycerol):  $m/z$  376 [M + H]<sup>+</sup>.

3-(*N*-Biotinoylamino)phenylmethyldiazomethane (**3**, *m*-BioPMDAM). To a solution of **2** (180 mg, 0.48 mmol) in DMF (2 mL) was added MnO<sub>2</sub> (340 mg, 3.9 mmol). After 30 min of stirring at room temperature, the reaction mixture was filtered through a Celite (0.5 cm thickness)–molecular sieves 3 Å (powder, 0.5 cm thickness) pad. The reaction mixture was concentrated in vacuo to 0.5 mL, and then 5 mL of ether was added. The resulting precipitate was filtered, washed with ether, and dried to give **3** (170 mg, 95%) as a pink powder. Mp 160 °C; IR (KBr):  $\nu = 3278, 2935, 2859, 2038, 1704, 1666, 1605, 1577, 1536, 1458, 1430, 1263 \text{ cm}^{-1}$ ; <sup>1</sup>H NMR (300 MHz,

DMSO-*d*<sub>6</sub>):  $\delta = 1.3\text{--}1.7$  (m, 6H), 2.11 (s, 3H), 2.28 (t,  $J = 8 \text{ Hz}$ , 2H), 2.57 (d,  $J = 12 \text{ Hz}$ , 1H), 2.81 (dd,  $J = 12$  and  $5 \text{ Hz}$ , 1H), 3.11 (m, 1H), 4.13 (m, 1H), 4.29 (m, 1H), 6.33 (s, 1H), 6.41 (s, 1H), 6.60 (m, 1H), 7.25 (m, 3H), 9.84 (s, 1H). <sup>13</sup>C NMR (75 MHz, DMSO-*d*<sub>6</sub>):  $\delta = 171.6, 163.1, 140.5, 132.8, 129.7, 116.4, 114.6, 111.7, 61.4, 59.6, 55.7, 51.7, 40.2, 36.6, 28.6, 28.4, 25.4, 9.8$ ; MS (FAB/thioglycerol):  $m/z$  346 [M + H – N<sub>2</sub>]<sup>+</sup>.

**Stability of *m*-BioPMDAM (3).** The purity of **3** was evaluated by <sup>1</sup>H NMR in DMSO-*d*<sub>6</sub> by the integration ratio between the multiplet signals at 6.60 ppm and at 4.13 ppm (relaxation delay: 10 s). The initial purity of *m*-BioPMDAM (**3**) prepared above was 80–90%. The stability was evaluated by the same manner using a DMSO-*d*<sub>6</sub> solution of **3** (30 mM).

**Alkylation of Nucleotide Monomers with *m*-BioPMDAM (3).** *Analytical.* Each nucleotide monomer (0.04 mM): 3'-UMP, 3'-AMP, 3'-CMP, or 3'-GMP was incubated with 2 mM of *m*-BioPMDAM in a mixture of DMSO:CH<sub>3</sub>CN:H<sub>2</sub>O (1:3:1, vol/vol/vol) containing 2 mM H<sub>3</sub>BO<sub>3</sub> (pH 7.3) at 60 °C. Reaction mixtures (250  $\mu$ L) were then washed with CH<sub>2</sub>Cl<sub>2</sub> and alkylation rates estimated using capillary electrophoresis.

*Capillary Electrophoresis (CE) Procedure.* CE experiments were performed with a Beckman P/ACE 5000 capillary electrophoresis instrument (Beckman Coulter, Fullerton, CA). An untreated fused silica capillary (75  $\mu$ m  $\times$  50 cm) was used. The applied voltage was 30 kV (normal polarity) and the capillary temperature maintained at 23 °C. The electrophoregrams were recorded at 254 nm. Borate buffer solution (0.1 M, pH 8.3) was prepared from boric acid by adjusting pH with NaOH solution and filtered through 0.2  $\mu$ m filter. Samples were injected by pressure (0.5 psi, 5 s). Before each run, the capillary was regenerated by using successively NaOH solution (0.1 N, 2 min), pure water (2 min), and borate buffer (2 min) by pressure (20 psi).

*Preparative Run (4).* A mixture of 9.3 mg (21  $\mu$ mol) of 3'-UMP (disodic salt tetrahydrated), 2 mL of H<sub>3</sub>BO<sub>3</sub> solution (0.1 M), 2 mL of CH<sub>3</sub>CN, 6 mL of methanol, and 75 mg (200  $\mu$ mol) of *m*-BioPMDAM (**3**) was stirred at room temperature for 2.5 h. To the resulting mixture were added CH<sub>2</sub>Cl<sub>2</sub> (30 mL) and H<sub>2</sub>O (3 mL). Aqueous phase was separated and further washed twice with CH<sub>2</sub>Cl<sub>2</sub> (30 mL) and then concentrated. The crude product was purified by reverse-phase silica gel chromatography (LiChroprep RP 18 silica gel, 40–63  $\mu$ m, eluant: 0–30% MeOH/H<sub>2</sub>O) to afford 10 mg (69%) of solid **4**. The designations "a" and "b" in the <sup>1</sup>H NMR data refer to the two sets of signals for two diastereoisomers. <sup>1</sup>H NMR (300 MHz, D<sub>2</sub>O):  $\delta = 1.35\text{--}1.75$  (m, 6H, CH<sub>2</sub>-biotin), 1.46 and 1.48 (2d,  $J = 7 \text{ Hz}$ , 3H, CH<sub>3</sub>), 2.36 and 2.37 (2t,  $J = 7 \text{ Hz}$ , CH<sub>2</sub>-biotin), 2.70 (d,  $J = 13 \text{ Hz}$ , 1H, CH<sub>2</sub>-biotin), 2.92 and 2.93 (2dd,  $J = 13$  and  $5 \text{ Hz}$ , 1H, CH<sub>2</sub>-biotin), 3.28 (m, 1H, CH-biotin), 3.33 (m, 1H, H<sub>a</sub>-2'), 3.47 and 3.57 (ABX,  $J = 13, 4$ , and  $2 \text{ Hz}$ , 2H, H<sub>b</sub>-5',5''), 3.69 and 3.80 (ABX,  $J = 13, 4$ , and  $3 \text{ Hz}$ , 2H, H<sub>a</sub>-5',5''), 3.84 (m, 1H, H<sub>b</sub>-4'), 3.99 (t,  $J = 5 \text{ Hz}$ , 1H, H<sub>b</sub>-2'), 4.06 (m, 1H, H<sub>a</sub>-4'), 4.10 (m, 1H, H<sub>a</sub>-3'), 4.19 (m, 1H, H<sub>b</sub>-3'), 4.36 (m, 1H, CH-biotin), 4.52 (m, 1H, CH-biotin), 5.23 (m, 1H, CHOP), 5.52 (d,  $J = 3 \text{ Hz}$ , 1H, H<sub>a</sub>-1'), 5.62 (d,  $J = 5 \text{ Hz}$ , 1H, H<sub>b</sub>-1'), 5.75 and 5.76 (2d,  $J = 8 \text{ Hz}$ , 1H, H-5), 7.13–7.22 (m, 1H), 7.24–7.34 (m, 2H), 7.44 (s broad, 1H), 7.65 and 7.68 (2d,  $J = 8 \text{ Hz}$ , 1H, H-6); <sup>31</sup>P NMR (81 MHz, D<sub>2</sub>O):  $\delta = -0.38, -0.52$ ; ESI-MS:  $m/z$  670 [M + H]<sup>+</sup>.

**Adducts 5–7.** These adducts were obtained by the same procedure as described above for **4**.

**Adduct 5:** yield 12 mg (60%). <sup>1</sup>H NMR (300 MHz, D<sub>2</sub>O):  $\delta = 1.3\text{--}1.7$  (m, 6H, CH<sub>2</sub>-biotin), 1.45 and 1.48 (2d,

$J = 7$  Hz, 3H, CH<sub>3</sub>), 2.37 (t,  $J = 7$  Hz, CH<sub>2</sub>-biotin), 2.70 (d,  $J = 13$  Hz, 1H, CH<sub>2</sub>-biotin), 2.92 and 2.93 (2dd,  $J = 13$  and 5 Hz, 1H, CH<sub>2</sub>-biotin), 3.20 (m, 1H, H<sub>a</sub>-2'), 3.27 (m, 1H, CH-biotin), 3.47 and 3.60 (ABX,  $J = 13$ , 4 and 2 Hz, 2H, H<sub>b</sub>-5',5''), 3.69 and 3.82 (ABX,  $J = 13$ , 4 and 2 Hz, 2H, H<sub>a</sub>-5',5''), 3.86 (m, 1H, H<sub>b</sub>-4'), 3.93 (t,  $J = 5$  Hz, 1H, H<sub>b</sub>-2'), 4.04 (m, 2H, H<sub>a</sub>-3' and H<sub>a</sub>-4'), 4.13 (m, 1H, H<sub>b</sub>-3'), 4.34 (m, 1H, CH-biotin), 4.52 (m, 1H, CH-biotin), 5.22 (m, 1H, CHOP), 5.52 (d,  $J = 3$  Hz, 1H, H<sub>a</sub>-1'), 5.65 (d,  $J = 5$  Hz, 1H, H<sub>b</sub>-1'), 5.90 and 5.91 (2d,  $J = 8$  Hz, 1H, H-5), 7.10–7.20 (m, 1H), 7.21–7.35 (m, 2H), 7.43 and 7.46 (2s broad, 1H), 7.58 and 7.61 (2d,  $J = 8$  Hz, 1H, H-6); <sup>31</sup>P NMR (121 MHz, D<sub>2</sub>O):  $\delta = -0.38, -0.49$ ; ESI-MS:  $m/z$  669 [M + H]<sup>+</sup>.

Adduct **6**: yield 14 mg (74%). <sup>1</sup>H NMR (300 MHz, D<sub>2</sub>O):  $\delta = 1.20$ – $1.63$  (m, 6H, CH<sub>2</sub>-biotin), 1.45 and 1.49 (2d,  $J = 7$  Hz, 3H, CH<sub>3</sub>), 2.27 and 2.29 (2t,  $J = 7$  Hz, CH<sub>2</sub>-biotin), 2.64 and 2.66 (2d,  $J = 13$  Hz, 1H, CH<sub>2</sub>-biotin), 2.83 and 2.85 (2dd,  $J = 13$  and 5 Hz, 1H, CH<sub>2</sub>-biotin), 3.34 (m, 1H, CH-biotin), 3.47 and 3.62 (ABX,  $J = 13$ , 3 and 2 Hz, 2H, H<sub>b</sub>-5',5''), 3.70 and 3.83 (ABX,  $J = 13$ , 4 and 2 Hz, 2H, H<sub>a</sub>-5',5''), 3.80 (t,  $J = 4$  Hz, 1H, H<sub>a</sub>-2') 3.96 (m, 1H, H<sub>b</sub>-4'), 4.18 (m, 1H, H<sub>a</sub>-4'), 4.24 (m, 1H, CH-biotin), 4.36 (m, 1H, H<sub>a</sub>-3'), 4.41–4.50 (m, 3H, H<sub>b</sub>-3', CH-biotin, H<sub>b</sub>-2'), 5.24 (m, 1H, CHOP), 5.62 (d,  $J = 5$  Hz, 1H, H<sub>b</sub>-1'), 5.65 (d,  $J = 4$  Hz, 1H, H<sub>a</sub>-1'), 7.06–7.20 (m, 2H), 7.28 (m, 1H), 7.34 and 7.42 (2s broad, 1H), 8.09 and 8.09 (2s, 1H, H-8), 8.12 (s, 1H, H-2); <sup>31</sup>P NMR (121 MHz, D<sub>2</sub>O):  $\delta = -0.27, -0.49$ ; ESI-MS:  $m/z$  693 [M + H]<sup>+</sup>.

Adduct **7**: yield 10 mg (65%). <sup>1</sup>H NMR (300 MHz, D<sub>2</sub>O):  $\delta = 1.24$ – $1.69$  (m, 6H, CH<sub>2</sub>-biotin), 1.46 and 1.49 (2d,  $J = 7$  Hz, 3H, CH<sub>3</sub>), 2.27 and 2.30 (2t,  $J = 7$  Hz, CH<sub>2</sub>-biotin), 2.64 and 2.67 (2d,  $J = 13$  Hz, 1H, CH<sub>2</sub>-biotin), 2.84 and 2.85 (2dd,  $J = 13$  and 4 Hz, 1H, CH<sub>2</sub>-biotin), 3.17 (m, 1H, CH-biotin), 3.50 and 3.62 (ABX,  $J = 13$ , 4 and 2 Hz, 2H, H<sub>b</sub>-5',5''), 3.70 and 3.82 (ABX,  $J = 13$ , 4 and 2 Hz, 2H, H<sub>a</sub>-5',5''), 3.71 (m, 1H, H<sub>a</sub>-2') 3.95 (m, 1H, H<sub>b</sub>-4'), 4.13 (m, 1H, H<sub>a</sub>-4'), 4.27 (m, 1H, CH-biotin), 4.37 (t,  $J = 5$  Hz, 1H, H<sub>b</sub>-2'), 4.45 (m, 1H, H<sub>a</sub>-3'), 4.48 (m, 1H, CH-biotin), 4.51 (m, 1H, H<sub>b</sub>-3'), 5.24 (m, 1H, CHOP), 5.50 (d,  $J = 3$  Hz, 1H, H<sub>a</sub>-1'), 5.51 (d,  $J = 5$  Hz, 1H, H<sub>b</sub>-1'), 7.12–7.23 (m, 2H), 7.26–7.29 (m, 1H), 7.38 and 7.49 (2s broad, 1H), 7.74 (s, 1H, H-8); <sup>31</sup>P NMR (121 MHz, D<sub>2</sub>O):  $\delta = -0.23, -0.34$ ; ESI-MS:  $m/z$  709 [M + H]<sup>+</sup>.

**Evaluation of Diazo Labeling of Oligonucleotides.** The three oligonucleotide sequences, fragments of the *Mycobacterium tuberculosis* (*Mtb*) 16S rRNA sequence, were 5'-ACACCTCTCAGGCCGCTACCCGTCGTCGCCTTGTTAGGCC-3'; 5'-CCGTCGTCGCCTTGTTAGGCCGTCACCCACCAACAAGCT-3', and 5'-GTCACCCACCAACAAGCTGATAGGCCGCGGGCTCATCCACACCG-3'. These DNA oligomers, bearing fluorescein at their 5'-end, were obtained from Eurogentec (Seraing, Belgium). Five picomoles of each oligonucleotide were treated with 2, 5, 10, and 20 mM *m*-BioPMDAM at 95 °C, in pure water, for 10 min. After the labeled targets were hybridized to the *Mycobacterium* DNA chip (15), the 5'-fluorescein label was detected and the emitted signal was denoted as S1. The chip was then stained for 10 min at room temperature, with 6  $\mu$ L (6  $\mu$ g) of an anti-biotin antibody (Rockland Immunochemical, Gilbertsville, PA) labeled with fluoresceins (two labels per antibody) and diluted in 0.05 M Tris pH 7, 0.5 M NaCl, 0.02% Tween-20, 500  $\mu$ g/mL BSA. After it was washed, the chip was scanned and the registered signal was noted as S2. In all cases, the background was deducted. The difference of signal intensities (taking into account the number of fluoresceins per anti-biotin anti-

body) was used to estimate the number of biotin labels per oligonucleotide.

**Nucleic Acid Targets Preparation.** Preparation and amplification of the *Mtb* 16S rRNA locus was carried out from freshly grown colonies, according to the procedure described by Troesch et al. (15) with the following modifications. PCR amplification was carried out in a 50  $\mu$ L reaction volume using the Fast Start Taq DNA polymerase (Roche Molecular Biochemicals, Mannheim, Germany), 200  $\mu$ M of each deoxyribonucleotide triphosphate (Promega, Madison, WI), and 0.3  $\mu$ M of primers. PCR was performed in a Perkin-Elmer 9700 thermal cycler with an initial denaturation step at 94 °C for 5 min and cycling conditions of 94 °C for 30 s, 68 °C for 30 s, 72 °C for 45 s for 35 cycles, and 72 °C for 7 min for the last cycle. The promoter-tagged PCR amplicons were used for generating single-stranded RNA targets by in vitro transcription. Each 20- $\mu$ L reaction mixture contained 8  $\mu$ L of PCR product (approximately 50 ng). Transcription was carried out using the in vitro transcription kit megascript (Ambion, Austin, TX). The reaction was performed at 37 °C for 2 h.

Genomic DNA from *Mtb* was extracted from a freshly grown liquid culture by universal lysis protocol (18) and using Genomic-tip 500/G (Qiagen, Venlo, The Netherlands), following the manufacturer's instructions.

**Labeling of RNA. Labeling During Cleavage (LDC).** Five microliters (0.04  $\mu$ g) of in vitro transcripts was incubated at 60 °C for 10 min in labeling buffer (I) containing 30 mM imidazole, 5 mM MnCl<sub>2</sub>, 2 mM *m*-BioPMDAM or at 60 °C for 30 min in labeling buffer (II) containing 6 mM imidazole, 60 mM MnCl<sub>2</sub>, 2 mM 5-(bromomethyl)fluorescein (5-BMF) (Molecular Probes, Eugene, OR).

**Labeling Plus Cleavage (LPC).** Conditions were the same as for LDC protocol, except that labeling and cleavage were done sequentially: 10 min at 60 °C for labeling with 2 mM *m*-BioPMDAM, followed by 10 min at 60 °C for cleavage with 30 mM imidazole, 5 mM MnCl<sub>2</sub> or 10 min at 60 °C for labeling with 2 mM 5-BMF, followed by 10 min at 60 °C for cleavage with 6 mM imidazole, 60 mM MnCl<sub>2</sub>.

**Labeling of DNA. Labeling During Cleavage (LDC).** Ten microliters of DNA amplicons (0.75  $\mu$ g) were incubated at 95 °C for 10 min in 3 mM HCl, 10 mM *m*-BioPMDAM or in 3 mM HCl, 10 mM 5-BMF.

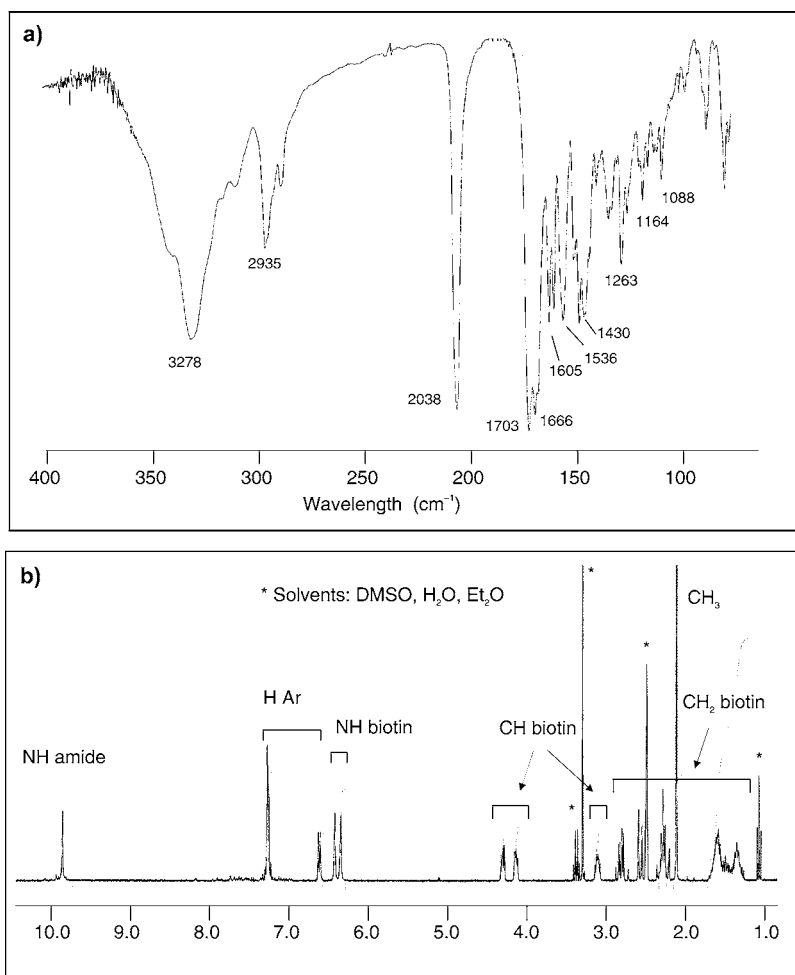

**Labeling Plus Cleavage (LPC).** For LPC of DNA, conditions were the same as for LDC, except that labeling and fragmentation were done sequentially: 10 min at 95 °C for labeling with 10 mM *m*-BioPMDAM or 10 mM 5-BMF, followed by 10 min at 95 °C for cleavage in 3 mM HCl. Labeling of 10  $\mu$ L DNA amplicons, in LPC procedure, with Biotin-Chem-Link distributed by Roche Molecular Biochemicals (Mannheim, Germany) and "Label IT Biotin" reagent from Mirus (Madison, WI) was carried out according to the supplier's instructions. The fragmentation was achieved in 3 mM HCl, 10 min at 95 °C.

**Labeling Plus Cleavage of Genomic DNA.** gDNA of *Mtb* (10  $\mu$ g) was labeled in 30 mM *m*-BioPMDAM at 95 °C for 25 min and then fragmented by 10 mM HCl at 95 °C for 5 min.

**Purification of Labeled Targets.** For all labeling protocols, unreacted label was removed prior to the hybridization step by means of silica membrane purification, 6S Qiavac columns (Qiagen, Venlo, The Netherlands), according to the manufacturer's instructions.

**Probe Array Hybridization and Analysis.** The *Mycobacterium* DNA chip (bioMerieux, Marcy-l'Etoile, France) is divided into 23000 specific 35 by 35  $\mu$ m

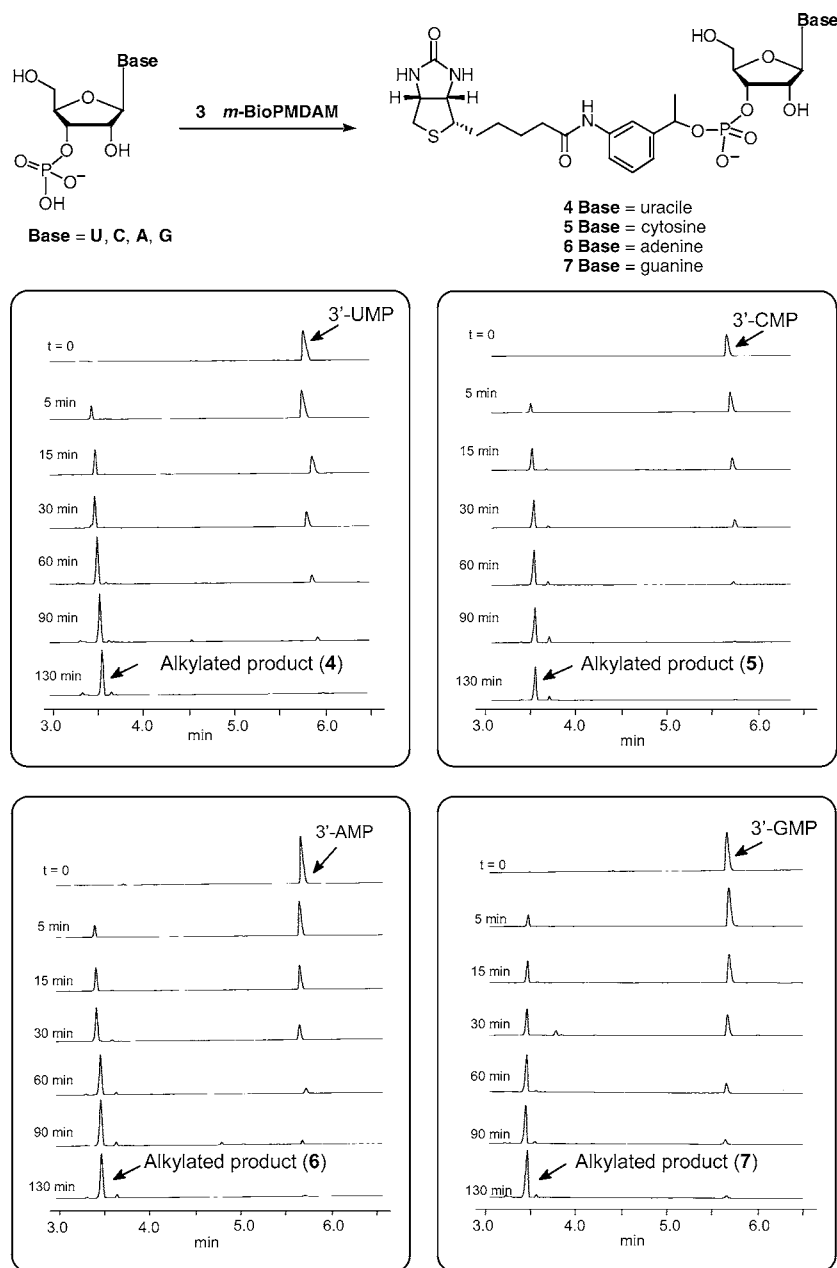

**Figure 1.** IR (a) and <sup>1</sup>H NMR (b) spectra of *m*-BioPMDAM (**3**).

**Scheme 1**

synthesis sites, over a 5.25- by 5.25-mm area. The four-probe interrogation strategy, similar to that described by Troesch et al. (15), was used to identify sequence variation in 16S rRNA and *rpoB* loci. Briefly, for every base interrogated within a given reference sequence, four probes of equal lengths are synthesized on the chip (usually 20mers). Those four probes are identical except at the interrogation position (centrally located within the probe), thus representing perfect hybridization match and the three possible mismatches. Base calls are determined by comparing the signal intensity of the labeled

target for the four probes. The DNA chips used in the study were manufactured by Affymetrix (Santa Clara, CA). One hundred microliters of the labeled and purified nucleic acid fragments were added to 400  $\mu$ L of hybridization buffer (15), containing 0.9 M NaCl, 60 mM NaH<sub>2</sub>PO<sub>4</sub> pH 7.4, 6 mM EDTA, 0.05% Triton X-100, 3 M betaine, 5 mM DTAB (dodecyl trimethylammonium bromide) and denatured at 95 °C for 10 min. DNA fragments labeled with "Label IT" Biotin reagent were denatured with denaturation buffers according to the supplier's protocol. Hybridization onto the *Mycobacterium*

**Figure 2.** Capillary electrophoresis (CE) study of the alkylation of the nucleotide monophosphates with *m*-BioPMDAM (**3**).

DNA chip was performed at 45 °C during 30 min and the chip was washed twice in 0.45 M NaCl, 30 mM NaH<sub>2</sub>PO<sub>4</sub>, 3 mM EDTA pH 7.4, 0.005% Triton X-100 at 30 °C (15). For biotinylated fragments, the DNA chip was stained for 10 min with a solution made of 600  $\mu$ L of 0.05 M Tris pH 7, 0.5 M NaCl, 0.02% Tween-20, 500  $\mu$ g/mL BSA and 6  $\mu$ L of Streptavidin-R-Phycoerythrin conjugate (300  $\mu$ g/mL; DakoCytomation, Glostrup, Denmark). After a washing step in 0.9 M NaCl, 0.06 M NaH<sub>2</sub>PO<sub>4</sub>, 6 mM EDTA pH 7.4, 0.05% Triton X-100, the fluorescent signal emitted by the target bound to the DNA chip was detected by a GeneArray scanner (Agilent, Palo Alto, CA), at a pixel resolution of 3  $\mu$ m. Probe array cell intensities, nucleotide base calls and reports were generated by functions available on the GeneChip software (Affymetrix, Santa Clara, CA).

## RESULTS AND DISCUSSION

Most electrophilic reagents, halides, sulfates, sulfonates, epoxid, etc, react with nucleotides and nucleic

acids essentially at the oxygen or nitrogen nucleophilic sites of the nucleobases (14). Design of the labeling reagent *m*-BioPMDAM was based on preliminary model studies which had shown that aryldiazomethanes did react at the phosphate group with nucleotide monophosphates (unpublished results). *m*-BioPMDAM (**3**) was thus prepared, that includes in its structure the reactive phenylmethyl diazomethane unit (PMDAM) covalently linked through an amide bond to the biotin (Bio) moiety.

**Synthesis of the *m*-BioPMDAM Reagent (**3**).** *m*-BioPMDAM **3** was prepared from commercial 3-aminoacetophenone and D-biotin with a 49% global yield (Scheme 1). Coupling of the two entities was accomplished in DMF using isobutyl chloroformate as coupling reagent in the presence of *N*-methylmorpholine (70% yield). The methyl ketone function of the resulting conjugate **1** was transformed into the hydrazone **2** by warming with hydrazine monohydrate in ethanol in 74% yield. MnO<sub>2</sub> oxidation of **2** yielded the diazo reagent *m*-BioPDAM **3** as a pink powder that was characterized notably by the <sup>1</sup>H and <sup>13</sup>C

**Figure 3.**  $^1\text{H}$  NMR spectra of the alkylation products with *m*-BioPMDAM (**3**) (a) of the 3'-UMP, (b) of the 3'-CMP, (c) of the 3'-AMP, and (d) of the 3'-GMP.

NMR spectrum (Figure 1a). It exhibited in the IR the characteristic vibration at 2038  $\text{cm}^{-1}$  (Figure 1b).

Simple alkyl diazoalkanes are unstable compounds. Substitution by aryl and electron-attracting groups generally increase the stability of the diazo function. It was thus essential to test the stability of the *m*-BioPMDAM reagent. Stability in solution was evaluated by  $^1\text{H}$  NMR spectroscopy. The half-life of *m*-BioPMDAM in DMSO- $d_6$  solution (30 mM) at room temperature is  $t_{1/2} = 3$  days.

**Reaction of *m*-BioPMDAM with 3'-Nucleotide Monophosphates.** To study the site selectivity of the reaction of *m*-BioPMDAM we examined its reaction with representative nucleotide phosphates that incorporate the four different nucleobases, i.e., 3'-AMP, 3'-GMP, 3'-CMP, 3'-UMP. Reactions were most conveniently monitored at the analytical stage using capillary electrophoresis. To dissolve both the charged hydrophilic nucleotides and the lipophilic *m*-BioPMDAM reagent, a homogeneous mixture of solvents (DMSO: $\text{CH}_3\text{CN}:\text{H}_2\text{O}$ ) was used. The reaction was run under buffered conditions at pH 7.3 using a large excess of *m*-BioPMDAM label. Figure 2 shows the evolution of the reactions run at 60 °C with the different nucleotides as monitored by capillary electrophoresis. The reaction profiles are quite similar for the four nucleotides examined. One very major (or unique) reaction product was formed and the kinetics of the reactions were quite comparable. In the experimental conditions used, the time required for 50% transformation of all nucleotides was about 15 min and transformation was complete after 130 min.

The reaction products were identified by running the reactions at the preparative scale (20  $\mu\text{mol}$ -scale). They were isolated and characterized by their analytical and spectroscopic data. The adducts were obtained in 70% average yield after purification, and they exhibited in  $^1\text{H}$  NMR spectra all peaks corresponding to the indicated structures (Figure 3). We note the presence of two diastereoisomers in a 1/1 ratio as reflected by the splitting of the sugar protons (H1', H2', H3', H4', H5'-5''). The CH proton vicinal to the phosphate appears at 5.2 ppm. The proton-decoupled phosphorus NMR spectra equally indicate the presence of two diastereoisomers giving rise to two peaks: at  $\delta = -0.23$  and  $-0.34$  ppm for the adduct with 3'-GMP, to be compared with the  $\delta = +4.0$  ppm value observed for 3'-GMP nucleotide. The same observation was done for all adducts.

**Reaction of *m*-BioPMDAM with Oligonucleotides.** Reaction of *m*-BioPMDAM with three synthetic oligodeoxyribonucleotides, fragments of a 16S rRNA *Mycobacterium tuberculosis* (*Mtb*) sequence containing a fluorescein label at their 5'-end, was studied. A mix of the three oligonucleotides was labeled with different concentrations of *m*-BioPMDAM, purified, and then hybridized onto a *Mycobacterium* DNA chip (15). Median intensity of fluorescence signals emitted by the hybridized oligonucleotides, before and after a "posthybridization" staining step (with anti-biotin antibody bearing fluoresceins), were measured (see Experimental Procedures). The comparison of the two intensity values showed that approximately 3 of every 10 phosphates were labeled in our model experiments, suggesting that selective alkylation by *m*-BioPMDAM occurred on internucleotidic phosphates as well. This is substantially more than the one label per nucleic acid fragment indicated as the best yield in prior work with 5-(bromomethyl)fluorescein and iodoacetamido-fluorescein as labeling reagents (11–13).

**Labeling of RNA and DNA with *m*-BioPMDAM.** We further evaluated the labeling efficiency on longer DNA and RNA targets generated by enzymatic amplifi-

cation (16S rDNA hypervariable region of *Mtb*, 202 nt) (15), prior to their hybridization to the *Mycobacterium* DNA chip. Cleavage of labeled DNA and RNA targets into smaller fragments is a prerequisite for improving the uniformity and specificity of hybridization onto the DNA chip (3). RNA targets were cleaved with  $\text{Mn}^{2+}$  and imidazole (16). The DNA targets were fragmented by acidic treatment that promoted random depurination and cleavage (17). Labeling was accomplished during or before the cleavage step, and the labeled fragments were then hybridized to the *Mycobacterium* DNA chip. Base-calling, that measures the percent of homology between the experimentally derived sequence and the ref 202 nt sequence tiled on the array, was accurate for all experiments conducted with *m*-BioPMDAM. The signal intensities were strong and the signal/background ratios high, all significantly better than with 5-(bromomethyl)fluorescein, determined for comparison (Table 1). This was especially true for DNA target labeling which was poor with the latter compound but gave good results with *m*-BioPMDAM.

DNA amplicons labeling was also evaluated using two commercially available chemistries, used to label nucleic acids for DNA array analysis (Table 2). "Biotin-Chem-Link" is based on the use of monofunctional-platinum derivatives (10), that bind to nitrogen atom in guanine and adenine, whereas "Label IT Biotin" reagent uses a nondisclosed chemistry to covalently attach the label to nucleic bases in DNA. With these two technologies, targeting the nucleobases, signal intensities, and base call percentages were significantly lower compared to those obtained with phosphate labeling via diazo chemistry (Table 2). This is especially true in GC-rich region, as depicted in Figure 4. The data clearly corroborates that

**Figure 4.** Analysis of a GC-rich region of 16S rRNA *Mycobacterium tuberculosis* (5'CCGCGGCC). Targets were labeled with *m*-BioPMDAM (A), Biotin-Chem-Link (B), or LabelIT Biotin (C) and hybridized to a *Mycobacterium* DNA chip. Signal intensities for the four different probes at each interrogation position are shown on the y axis, and base-calling results are shown on the x axis. Underlined: incorrect nucleotide calls, n: undetermined. The graphs highlight the hybridization specificity and the good discrimination obtained with *m*-BioPMDAM labeled targets.

the label attachment on nucleic bases, via a covalent or noncovalent binding, alters the base-pairing efficiency and hybridization specificity, in particular in DNA chip applications requiring sequence calling at high resolution. *m*-BioPMDAM was also tested in other DNA chip applications requiring such resolution, like detection of antibiotic-resistant mutations in *Mtb* and of anti-retroviral drug mutations in HIV-1 (data not shown) or typing of *Staphylococcus aureus* strains (19), and the results confirmed the base-pairing specificity. Moreover, labeling was equally efficient for cleaved or uncleaved targets. This suggests that diazo labeling can be used for other detection systems that do not require target fragmentation before hybridization, e.g., low-density probes detection formats.

The potential of diazomethyl chemistry for labeling natural (not enzymatically amplified) nucleic acid targets was evaluated by labeling genomic DNA (gDNA) extracted from *Mtb*. Hybridization of directly labeled genomic DNA to high-density DNA chips would represent a simple mean to perform genome-wide scale analysis. SDS-PAGE showed that gDNA molecules were labeled (Figure 5). Indeed, a slight gel-shift was observed, after *m*-BioPMDAM treatment (lane 2) due to the neutralization of negative charges on the phosphodiester groups. Addition of neutravidin to the labeled sample shifted *Mtb* gDNA strongly toward higher molecular weights (lane 3). Interestingly, this shift was also observed with cleaved gDNA, showing that all fragments were labeled by biotin

**Figure 5.** *Mtb* gDNA labeled with *m*-BioPMDAM (3). Products were analyzed by SDS-PAGE and ethidium Bromide staining. Lane 1: sheared gDNA, not treated with *m*-BioPMDAM. Lane 2: gDNA labeled with *m*-BioPMDAM. Lane 3: 10 µL of labeled gDNA in lane 2 incubated for 5 min with 5 µL of 2 mg/mL neutravidin (Pierce) prior to electrophoresis. Lane 4: gDNA labeled with *m*-BioPMDAM (lane 2) and fragmented by 10 mM HCl at 95 °C for 5 min. Lane 5: 10 µL of labeled and cleaved gDNA in lane 4 incubated with 5 µL of 2 mg/mL neutravidin during 10 min.

(lanes 4 and 5). The base-calling accuracy obtained after analysis of the fragments on the chip (>90%, data not shown) shows that diazo labeling can be used to attach a detectable tag to a natural nucleic acid (the entire *Mtb* genome, in our experiment) before DNA chip analysis.

## CONCLUSION

The *m*-BioPMDAM reagent described here has been shown to selectively react on phosphates in nucleotide monomers and polynucleotides and has been successfully used to label RNA and DNA targets, of different sequence composition and length. The labeling reagent is stable and can be provided as a ready-to-use component. The highly reactive diazo function is used to obtain the rapid (15–30 min, depending on target type) and selective alkylation of both internucleotidic and terminal phosphates, with labeling of approximately 3 of every 10 phosphates in our model experiments. This represents a very high labeling density with no negative impact on base-pairing efficiency (as shown by the high base-calling percentage obtained in DNA chip analysis). Moreover, diazo labeling chemistry is not sensitive to buffer components or contaminants in a nucleic acid sample; the targets are labeled as such without any prior purification step (whereas purification is necessary with the approach using monofunctional-platinum derivatives). The final conjugate is very stable, even under heat-denaturing conditions and long hybridization time (overnight).

The labeling method described here requires a posthybridization staining step to introduce the fluorescent dye (via a streptavidin-fluorescent label conjugate). This step could be avoided, thus simplifying the experimental protocol, by using a diazo-compatible dye, where the fluorescent moiety is directly attached to the diazo reactive group. Our work on development of such fluorescent diazo compounds is currently in progress.

Overall, these features make diazo labeling particularly well-suited for conducting extensive analysis on DNA chips, such as whole genome RNA and DNA analysis and parallel testing of numerous targets in routine diagnosis.

## ACKNOWLEDGMENT

We thank C. Tora for technical assistance in the synthesis of the diazo compounds and F. Telles for her contribution to the gDNA experiments. E.B.M. acknowledges a Marie Curie Industry Host Fellowship (Quality of Life Program).

## Site-Specific Cleavage of RNA and DNA by Complementary DNA–Bleomycin A5 Conjugates

Pavel E. Vorobjev,<sup>†</sup> Janet B. Smith,<sup>‡</sup> Inna A. Pyshnaya,<sup>†</sup> Asya S. Levina,<sup>†</sup> Valentina F. Zarytova,<sup>†</sup> and Eric Wickstrom<sup>§,\*</sup>

Laboratory of Nucleic Acid Chemistry, Institute of Bioorganic Chemistry, Russian Academy of Sciences, Novosibirsk 630090, Russia, and Department of Microbiology and Immunology, and Department of Biochemistry and Molecular Pharmacology, Kimmel Cancer Center, and Cardeza Foundation for Hematologic Research, Thomas Jefferson University, Philadelphia, Pennsylvania 19107 Received August 23, 2003

Bleomycin displays clinical chemotherapeutic activity, but is so nonspecifically toxic that it is rarely administered. It was therefore of interest to determine whether bleomycin could be directed to cleave RNA or DNA at a specific site by conjugation to a complementary oligonucleotide. A 15 nt *MYC* complementary oligodeoxynucleotide (HMYC55) bearing a 5' bleomycin A5 (Blm) residue was designed to base-pair with nt 7047–7061 of human *MYC* mRNA. Reactivity of the Blm–HMYC55 conjugate (and mismatch controls) with a *MYC* mRNA 30-mer, a *MYC* DNA 30-mer, and a *MYC* 2'-*O*-methyl RNA 30-mer, nt 7041–7070, was analyzed in 100  $\mu$ M FeNH<sub>4</sub>SO<sub>4</sub>, 50 mM  $\beta$ -mercaptoethanol, 200 mM LiCl, 10 mM Tris-HCl, pH 7.5, at 37 °C. Cleavage of the substrate RNA or DNA occurred primarily at the junction of the complementary DNA-target RNA duplex, 18–22 nt from the 5' end of the RNA. Reaction products with lower mobility than the target RNA or DNA also formed. Little or no reaction was observed with more than three mismatches in a Blm–oligodeoxynucleotide conjugate. Neither the short RNA or DNA cleavage fragments nor the low mobility products were observed in the absence of Fe(II), or the presence of excess EDTA. The target RNA was also cleaved efficiently by bleomycin within a hybrid duplex with a preformed single-nucleotide bulge in the RNA strand. New Blm–oligodeoxynucleotide conjugates containing long hexaethylene glycol phosphate based linkers between oligodeoxynucleotide and bleomycin were designed to target this bulge region. These conjugates achieved 8–18% cleavage of the target RNA, depending on the length of the linker. Blm–oligodeoxynucleotide conjugates thus demonstrated sequence specificity and site specificity against RNA and DNA targets.

### INTRODUCTION

The ability to turn off individual genes at will in growing cells provides a powerful tool for elucidating the role of a particular gene and for therapeutic intervention when that gene is overexpressed or mutated. Following the first suggestion that a complementary oligonucleotide could be prepared to target a naturally occurring nucleic acid sequence (1), an antisense oligonucleotide was first utilized successfully against Rous sarcoma virus (2). Since then, complementary oligonucleotides were first used to inhibit the expression of an activated oncogene, *MYC*, in human HL-60 promyelocytic leukemia cells (3). Antisense DNA inhibition has been applied to a wide variety of target genes in cells (4), animals (5), and humans (6).

Chemically reactive oligonucleotide derivatives on the complementarity principle underlie the design of a new generation of antiviral and antitumor therapeutic drugs (7). In particular, the chain scission antibiotic bleomycin A5 has been conjugated to complementary oligonucleotides to allow site-directed cleavage of DNA (8). Bleo-

mycin (Blm) is an antibiotic derived from the soil bacterium *Streptomyces verticillus* (9). The nonspecific cleavage of double stranded DNA or higher ordered tRNA by bleomycin results in antibacterial as well as antitumor activity (10). The bleomycins are glycopeptides with a molecular weight of approximately 1500 Da. Differences exist among bleomycin molecules due to differences in the composition of their terminal amines. There are four functional domains within the bleomycin structure (9) (Figure 1). Bleomycins are classified according to the different terminal amines attached to the bithiazole group at the C-terminus. It is the bithiazole residue and the C-terminal amine that are responsible for binding to DNA. Thus, the differences in the C-terminal amines in the various classes of bleomycin result in different binding affinities, with subsequent differences in cleavage efficiencies.

Bleomycins contain metal binding domains at the N-terminus, and binding of a divalent metal cation is thought to be necessary for this domain to become functional. Although Fe(II) is one of the most efficient ions that serve this function, other divalent cations may also form a complex with the N-terminal domain (10). Cleavage of yeast tRNA<sup>Phe</sup> by free bleomycin has been observed, dependent on the secondary and tertiary structure, as well as the primary sequence, of the tRNA, resulting in cleavage at numerous positions; the percentage of cleavage at each site was quite low (10). It is known that some RNAs serving different biological functions are

<sup>§</sup> Department of Biochemistry and Molecular Pharmacology, Thomas Jefferson University.

**Figure 1.** Bleomycin A5-oligonucleotide. The metal-binding domain (1) at the amino terminus of bleomycin is responsible for cleavage and also interacts with the nucleic acid target. The disaccharide domain (2) favors the binding of oxygen, which is necessary for oxidative cleavage of the nucleic acid. The structure of spacer region (3) plays a significant role in defining optimal conformation of the molecule, thus influencing the efficiency of DNA cleavage. The DNA-binding domain (4) at the C-terminal end of bleomycin forms a strong noncovalent complex with the nucleic acid.

efficiently cleaved by free bleomycin. In particular, the cleavage of 5S yeast ribosomal RNA occurs at U nucleotide residues in the 5'-GUA-3' sequences preceding single-nucleotide bulges (11). Apparently, these regions of the RNA structure serve as sites of the preferential binding of bleomycin in the conformation favorable for selective oxidation of the ribose residue.

We hypothesized that the cleavage activity of bleomycin could be targeted to a specific DNA or mRNA sequence by conjugation of bleomycin to the 5' end of a complementary oligodeoxynucleotide. We also hypothesized that the cleavage of the target RNA could be increased significantly by formation of one-nucleotide bulge motifs in the RNA:antisense duplex.

Previously we reported that a 15 nt antisense oligonucleotide, MMYC55, targeted to a C-terminal site in murine *c-myc* mRNA inhibited tumor growth in a mouse

model of B-cell lymphoma (12), in agreement with earlier observations of inhibition of human *MYC* expression in human HL60 cells by the corresponding HMYC55 antisense 3'-N-phosphoramidate (13).

## EXPERIMENTAL PROCEDURES

**Oligonucleotides.** The oligonucleotide portion of Blm-HMYC55 conjugate was designed to base-pair with the sense strand of the human *MYC* mRNA corresponding to those same nucleotides (Figure 2). The target sequence, nucleotides 7041–7070 (14), encodes 30 nucleotides encoding residues 382–391 of the C-terminal domain of Myc protein. Below the target RNA in Figure 2 are the three Blm-oligonucleotide reagents that were used in the experiments described. Three internal mismatches (underlined sequence) in HMYC56 disrupt continuous base-pairing to the target, allowing six base-pairs to form on either side of the mismatch zone. The random reagent includes 15 nucleotides that are unable to base-pair stably with the target RNA. We hypothesized that cleavage of the target RNA could occur at the junction of the 5' end of the Blm-HMYC55 antisense reagent and the RNA target, 21 nucleotides from the 5' end of the RNA target (blue arrow in Figure 2). Alternatively, we hypothesized that cleavage of the target RNA could occur at a single nucleotide bulge (blue arrow in Figure 3) created near the 5' end of the RNA upon formation of bulged hybrid duplexes with 3'-Blm-linker-oligonucleotide 16-mers (Figure 3).

Bleomycin A5 was obtained from the Institute of Organic Synthesis (Riga, Latvia). The *MYC* sense DNA and RNA 30-mer targets, DNA 15-mers HMYC55, HMYC56, HMYC57, MMYC57 (Figure 2), and DNA 16-mer B1, and its hexaethylene glycol-containing analogues (Figure 3) were synthesized by the phosphoramidite approach, then purified by ion exchange and reversed-phase HPLC. The hexaethylene glycol phosphoramidite synthon for Blm-B2–B4 oligonucleotides was synthesized as described previously (15). Bleomycin A5 was conjugated with oligonucleotides as described (16, 17). Oligonucleotides were activated with a mixture of triphenylphosphine and 2,2'-dipyridyl disulfide in the presence of (dimethylamino)pyridine *N*-oxide. Bleomycin A5 was attached to the activated 5'-phosphate of oligonucleotides through the terminal spermidine amino group.

Analytical denaturing gel electrophoresis of Blm-DNA conjugates revealed single bands. MALDI-TOF mass

**Figure 4.** *MYC* RNA reactions with 10  $\mu$ M Blm–HMYC55 vs 10  $\mu$ M Blm–HMYC56. Each 10  $\mu$ L reaction mixture also contained 1  $\mu$ M *MYC* target RNA 30-mer, 50 mM  $\beta$ -mercaptoethanol, 200 mM LiCl, 10 mM Tris-HCl, pH 7.5. Bleomycin reactions were initiated by the addition of 100  $\mu$ M  $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2$ , and were incubated at 37  $^\circ\text{C}$ . Lane C: *MYC* RNA in reaction conditions for 120 min; lane OH $^-$ : 0.2 M  $\text{NaHCO}_3$ , pH 8.9, 30 min. at 37  $^\circ\text{C}$ .

spectroscopy of the antisense Blm–linker-oligodeoxynucleotide 16-mer with 2, 3, or 4 hexaethylene glycol phosphate linkers (Figure 3c) was consistent with prediction: for  $n = 2$ , calculated 6985.8 Da, measured 6982.6 Da; for  $n = 3$ , calculated 7330.1 Da, measured 7330.7 Da; for  $n = 4$ , calculated 7674.4 Da, measured 7688.0 Da. Concentrations of oligonucleotides were measured spectrophotometrically. Calculated molar extinction coefficients at 260 nm were 149 300/M $\cdot$ cm for Blm–HMYC55, 156 000/M $\cdot$ cm for Blm–HMYC56, 163 700/M $\cdot$ cm for Blm–HMYC57, 159 600/M $\cdot$ cm for Blm–MMYC57, 157 400/M $\cdot$ cm for Blm–Bn, 305 500/M $\cdot$ cm for 30-mer target DNA, and 307 700/M $\cdot$ cm for 30-mer target RNA.

The 5'-biotinyl *MYC* sense RNA 30-mer and homologous 5'-biotinyl DNA were obtained from CyberSyn (Aston PA) following synthesis by the phosphoramidite approach and purified by gel electrophoresis. PAGE-purified RNA and DNA were desalted on a C<sub>18</sub> SepPak (Whatman). The *MYC* sense RNA and DNA 30-mer targets were also 5'-labeled with [ $\gamma$ -<sup>32</sup>P]ATP catalyzed by T4 polynucleotide kinase (20).

**Cleavage Reactions.** Unless otherwise noted, cleavage reactions contained 1  $\mu$ M target RNA or DNA, 10  $\mu$ M Blm–DNA, 100  $\mu$ M  $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2$ , 50 mM  $\beta$ -mercaptoethanol, 200 mM LiCl, 10 mM Tris-HCl, pH 7.5. The total volume of each reaction was adjusted to 10  $\mu$ L with argon-saturated diethylpyrocarbonate-treated double-deionized water. The reaction was incubated at 37  $^\circ\text{C}$  for 2 h, unless otherwise noted. In some cases, reaction mixtures were treated subsequently with base (0.25 M hydrazine-HCl, pH 8.0, for RNA target, or 0.1 M *n*-butylamine, for DNA target) to hydrolyze unstable intermediate products and resolve low mobility complexes. RNA was incubated 30 min. at 37  $^\circ\text{C}$  in 0.2 M  $\text{NaHCO}_3$ , pH 8.9, to generate alkaline hydrolysis ladders.

**Electrophoretic Analysis.** Each reaction was terminated by addition of four volumes of gel loading buffer II (Ambion, Austin TX) (95% formamide, 18 mM EDTA, 0.025% NaDodSO<sub>4</sub>, 0.025% xylene cyanol FF, and 0.025% bromophenol blue) and stored at –20  $^\circ\text{C}$  until electrophoresis on a 20% denaturing polyacrylamide gel at 50 V/cm until the bromophenol blue dye reached  $\frac{3}{4}$  of the way into the gel. 5'-Biotinyl-RNA and DNA gels were electroblotted onto Zeta-probe nylon membrane (Bio-Rad) at 12 V for 33 min. The RNA or DNA was immobilized by UV-cross-linking using UV-transilluminator. Detection of the RNA and DNA, which were labeled at the 5' end with biotin, was performed using the Ambion Bright-

Star BioDetect Kit. The resulting chemiluminescence was recorded onto Kodak XOMAT film with a typical exposure time of 15 min. Quantitative estimations were made using [<sup>32</sup>P]RNA and [<sup>32</sup>P]DNA targets. Products of cleavage were separated by electrophoresis on 20% denaturing polyacrylamide gel. Gels were dried on a Fisher Biotech FB GD 45 gel drier and autoradiographed with Kodak XOMAT film. Developed films were quantitated on a Kodak 440CF imaging system.

## RESULTS

**Sequence Dependence of RNA Reactions.** The time course of the reaction of *MYC* RNA 30-mer with Blm–HMYC55 vs Blm–HMYC56 was analyzed (Figure 4). The reactions were carried out as described in Materials and Methods above, initiated by the simultaneous addition of Fe(II) and  $\beta$ -mercaptoethanol. In the presence of conjugated Blm–HMYC55, cleavage of *MYC* RNA was observed, 18–22 nucleotides from the 5' end of the RNA. These sites correlated with the positioning of bleomycin by the antisense portion of the reagent (blue arrow in Figure 2). The same bands were observed in the presence of Blm–HMYC56 (3 nt mismatch) at much lower intensities. The reactions with Blm–HMYC55, but not Blm–HMYC56, also produced products that migrated more slowly than the original RNA target, suggesting an additional reaction mechanism more complex than cleavage.

No reaction products were observed in the presence of HMYC55 plus free Blm, or Blm conjugated to a non-complementary MMYC57 15-mer (not shown). Treatment of reacted RNA samples with 0.25 M hydrazine-HCl, pH 8.0, for 30 min. at 37  $^\circ\text{C}$  did not change the band intensities (not shown).

**Sequence Dependence of DNA Reactions.** When a *MYC* DNA 30-mer was also reacted with Blm–HMYC55, and the time course compared for both the RNA and DNA targets, the same analogous low mobility products were seen, along with 18–22 nt DNA fragments (Figure 5). The cleavage product bands reached a plateau early in the 50 min incubation, but the slowly moving products increased linearly throughout the course of the reaction. Lower levels of the reaction products were also observed, in the case of the DNA target (Figure 6), with Blm–HMYC56 (3 mismatches), Blm–HMYC57 (2  $\times$  2 mismatches), but not with random Blm–MMYC57 (12 mismatches). Blm–MMYC57 produced a 5 nt DNA fragment which can be observed also in reaction with free

bleomycin. Generally, the alkaline treatment reveals additional products of DNA cleavage by bleomycin. Samples of 2 h. DNA reactions were treated with 0.1 M *n*-butylamine for 8 min. at 95 °C before electrophoresis (Figure 6). Treatment with *n*-butylamine eliminated the slowly moving bands and increased the intensities of the cleavage bands.

**Concentration Dependence.** To examine the dependence of product formation on Blm-HMYC55 concentration, a ramp of concentrations from 0.1  $\mu$ M to 10  $\mu$ M, reacting with 1  $\mu$ M *MYC* RNA or DNA, was studied (Figure 7). This experiment revealed that as the Blm-HMYC55 concentrations increased, the extent of cleavage products and slowly migrating products after 50 min also

**Figure 8.** MYC [ $^{32}$ P]RNA and [ $^{32}$ P]DNA reactions with Blm–HMYC55. Each 10  $\mu$ L reaction mixture also contained 1  $\mu$ M MYC target RNA 30-mer or DNA 30-mer, 50 mM  $\beta$ -mercaptoethanol, 200 mM LiCl, 10 mM Tris-HCl, pH 7.5. The reactions were initiated by the addition of 100 mM  $\text{Fe}(\text{NH}_4)_2(\text{SO}_4)_2$ , and were incubated at 37  $^\circ\text{C}$  for 50 min. Lane 1: MYC DNA in reaction conditions; lane 2: 1  $\mu$ M of Blm–HMYC55 added; lane 3: 10  $\mu$ M of Blm–HMYC55 added; lane 4: MYC RNA in reaction conditions; lane 5: 10  $\mu$ M of Blm–HMYC55 added.

increased, reaching a plateau at 5  $\mu$ M for the RNA target, and 1  $\mu$ M for the DNA target. However, product yield remained low; in no case was all target RNA or DNA consumed. Quantitative estimations were made using [ $^{32}$ P]RNA and [ $^{32}$ P]DNA targets. For both targets the amount of slowly moving products did not exceed 3% (Figure 8). The maximum amount of rapidly moving products formed with the RNA target by 10  $\mu$ M Blm–HMYC55 was two times higher (6%). Under the same conditions, 25% of the DNA target was cleaved. Control reactions extended to 7 h revealed no slowly migrating products without bleomycin, with 1  $\mu$ M free bleomycin, with 1  $\mu$ M Blm–HMYC56, with 1  $\mu$ M Blm–HMYC55 but without mercaptoethanol, or with a mixture of 1  $\mu$ M free bleomycin and 1  $\mu$ M HMYC55 (not shown).

**Fe(II) Dependence.** The appearance of tRNA<sup>Phe</sup> cleavage products in the presence of free bleomycin,

without free Fe(II) (10), invited a similar experiment with Blm–HMYC55 (Figure 9). Preincubation of RNA or DNA with 10 mM EDTA prior to adding Blm–DNA, without any subsequent addition of Fe(II), did not result in any of the slowly moving products or specific cleavage products seen before.

**2'-OH Dependence.** Considering the cleavage of RNA by Blm–HMYC55, one possible mechanism characteristic of RNA is self-hydrolysis by a 2'-OH, mediated by some general base moiety of adjacent bleomycin. Substitution of the MYC RNA target with MYC 2'-O-methyl RNA, suggested by Dr. Serge Beaucage, provided a simple test of that model. Without free Fe(II), no products were observed upon incubation of 1  $\mu$ M MYC 2'-O-methyl RNA with Blm–HMYC55. Both rapidly migrating and slowly migrating products were observed in the presence of Fe(II) (Figure 10).

**Cleavage of the RNA by Free Bleomycin at a Bulged Site.** In the case of imperfect complementation between the 16-base oligodeoxynucleotide B1 (Figure 3) and the [ $^{32}$ P]RNA target, an imperfect duplex with a one-nucleotide bulge at U7 in the RNA chain was presumably formed. Efficient cleavage of the [ $^{32}$ P]RNA target by free bleomycin, 30% in 2 h, was observed at U6 adjacent to the presumed bulge at U7 (Figure 11).

**Cleavage of the RNA by Bleomycin–DNA Conjugate at a Bulged Site.** Analogous bulged duplexes of [ $^{32}$ P]RNA with Blm–(hexaethylene glycol phosphate)<sub>n</sub>–B1 DNA conjugates were studied. For the bleomycin residue that was attached to the 3'-terminus of B1 to reach the desired cleavage site, flexible linkers consisting of two, three, or four residues of hexaethylene glycol phosphate, respectively, were included in the Blm–DNA conjugates (Figure 3). Molecular modeling suggested that the lengths of all three linkers are larger than the distance between the 3'-terminal phosphate group of oligonucleotide B1 in conjugates Blm–B2, Blm–B3, and Blm–B4 and the cleaved U6 residue in the RNA target involved in the hybrid duplexes.

In the presence of conjugates Blm–B2, Blm–B3, and Blm–B4, cleavage of the RNA target occurred at U6 (Figure 11). The efficiency of cleavage in the complex depended on the length of the linker between the bleo-

mycin residue and the oligonucleotide: 8% with Blm-B2, 12% with Blm-B3, and 18% with Blm-B4.

## DISCUSSION

These results reveal that targeted cleavage of RNA or DNA by antisense-conjugated bleomycin is possible. Bleomycin conjugated to HMYC55 cleaved the complementary *MYC* RNA or DNA target at the junction between the DNA:RNA duplex and the RNA single strand, the site to which the oligodeoxynucleotide portion of the reagent directed the bleomycin molecule (Figure 2). It was essential for the antisense oligodeoxynucleotide to be conjugated to bleomycin and fully base-paired in order for cleavage of the RNA target to occur (Figures 4, 6).

In addition, reaction of *MYC* RNA or DNA with Blm-HMYC55 yielded slowly migrating products. Considering the extent of formation of the slowly migrating products, it would be valuable to identify their composition and structure. Mild treatment of reacted RNA samples with hydrazine-HCl did not convert much of the slowly migrating bands to high mobility RNA fragments. On the other hand, more vigorous treatment of reacted DNA

samples with *n*-butylamine fully converted slowly migrating bands to high mobility cleavage fragments.

The slowly migrating products included less than 1% of total band intensity in those reactions that included the Blm-HMYC56 3-mismatch control, and none were detected in the presence of the Blm-HMYC57 4-mismatch control, Blm-random, or free Blm. Reactions in the absence of  $\text{Fe}(\text{II})$  (Figure 9) did not result in any of the slowly moving products or cleavage products, implying the absence of an  $\text{Fe}(\text{II})$ -independent cleavage mechanism. One of the conceivable routes for the formation of such cross-links is the interaction of primary or secondary amines on bleomycin with base labile lesions, which are formed on DNA or RNA as a consequence of oxidation by activated bleomycin (18).

The low extent of target RNA or DNA cleavage by Blm-HMYC55 might reflect a requirement for a rarely occurring conformation. In light of these considerations, it is possible that greater reactivity might result from the use of short tandem oligonucleotides (19), or some other oligonucleotide design, instead of a single completely complementary 15-nt oligonucleotide.

The experiments with Blm-(hexaethylene glycol phosphate) $_n$ -B1 DNA conjugates provided an interesting test of the latter suggestion. Considerably greater cleavage of the target RNA was achieved using conjugates that induce a single nucleotide bulge in the RNA strand of the hybrid duplex. The increase in the extent of cleavage with the lengthening of the linker probably indicates that a particular conformation is favored for efficient cleavage.

Further investigations will be necessary to determine whether complementary bleomycin-oligodeoxynucleotide conjugates exhibit greater antisense efficacy in cells than do complementary oligodeoxynucleotides alone and whether bleomycin-oligodeoxynucleotide conjugates are less toxic than free bleomycin in normal cells.

## ACKNOWLEDGMENT

We thank Dr. Serge Beaucage for suggesting the 2'-*O*-methyl RNA experiment. This work was supported by RFBR grant 99-04-49731a and 02-04-49597a to V.F.Z., Fogarty International Research Collaboration Award TW01094 to V.F.Z. and E.W., and NIH grant CA42960 to E.W.

# Chemoenzymatic Synthesis and Antibody Detection of DNA Glycoconjugates

Yingli Wang and Terry L. Sheppard\*

Department of Chemistry and The Robert H. Lurie Comprehensive Cancer Center, Northwestern University, 2145 Sheridan Road, Evanston, Illinois 60208-3113. Received August 20, 2003; Revised Manuscript Received October 14, 2003

A chemoenzymatic approach for the efficient synthesis of DNA–carbohydrate conjugates was developed and applied to an antibody-based strategy for the detection of DNA glycoconjugates. A phosphoramidite derivative of *N*-acetylglucosamine (GlcNAc) was synthesized and utilized to attach GlcNAc sugars to the 5'-terminus of DNA oligonucleotides by solid-phase DNA synthesis. The resulting GlcNAc–DNA conjugates were used as substrates for glycosyl transferase enzymes to synthesize DNA glycoconjugates. Treatment of GlcNAc–DNA with  $\beta$ -1,4-galactosyl transferase (GalT) and UDP–Gal produced *N*-acetylglucosamine-modified DNA (GlcNAc–DNA), which could be converted quantitatively to the trisaccharide Lewis X (LeX)–DNA conjugate by  $\alpha$ -1,3-fucosyltransferase VI (FucT) and GDP–Fuc. The facile enzymatic synthesis of LeX–DNA from GlcNAc–DNA also was accomplished in a one-pot reaction by the combined action of GalT and FucT. The resulting glycoconjugates were characterized by gel electrophoresis, matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS), and glycosidase digestion experiments. Covalent modification of the 5'-terminus of DNA with carbohydrates did not interfere with the ability of DNA glycoconjugates to hybridize with complementary DNA, as indicated by UV thermal denaturation analysis. The trisaccharide DNA glycoconjugate, LeX–DNA, was detected by a dual DNA hybridization/monoclonal antibody (mAb) detection protocol ("Southwestern"): membrane-immobilized LeX–DNA was visualized by Southern detection with a radiolabeled complementary DNA probe and by Western chemiluminescence detection with a mAb specific for the LeX antigen. The efficient chemoenzymatic synthesis of DNA glycoconjugates and the Southwestern detection protocol may facilitate the application of glycosylated DNA to cellular targeting and DNA glycoconjugate detection strategies.

## INTRODUCTION

Cell surface glycoconjugates, composed of carbohydrates covalently linked to biomolecules such as lipids or proteins, are key elements in biological molecular recognition processes (1). Glycoconjugates have been implicated in cancer metastasis (2), immune response to pathogenic infection (3), and inflammation (4). For example, the Lewis X (LeX) blood group antigen (BGA) represents an important and well-characterized oligosaccharide in human biology (5). The LeX trisaccharide, Gal $\beta$ 1–4(Fuc $\alpha$ 1–3)GlcNAc, and its BGA analogues are involved in the infection of human cells by parasites (6) and bacteria (7). LeX antigens also serve as tumor markers, since their presence appears to correlate with the metastatic potential of tumor cells (8). The readout and response to cell surface glycoconjugates are performed largely by specific carbohydrate binding proteins, called lectins (9). In addition to naturally occurring lectins, monoclonal antibodies (mAb's) that bind specifically to oligosaccharide structures in glycoconjugates have been isolated. The availability of mAb's specific to carbohydrate antigens has enhanced the understanding of the biological roles of glycoconjugates (10) and formed the basis for antibody-based detection methods for cellular glycosylation states (11, 12). Because of the specificity inherent in protein–carbohydrate interactions, syn-

thetic carbohydrate mimics (13), carbohydrate-anchored liposomes (14), and carbohydrate-modified dendrimers (15, 16) have been prepared to investigate carbohydrate–lectin interactions and drug development applications.

In contrast to the abundance of glycosylated proteins and lipids in biological systems, few examples of glycosylated nucleic acids have been reported (17–19). An interesting counterexample was provided by Borst and co-workers, who discovered the existence of 5-( $\beta$ -D-glucosylhydroxymethyl)-2'-deoxyuridine, the "J" nucleoside, in the DNA of *Trypanosoma brucei* (20) and other kinetoplastids (21). Although the biological role of the J-base remains under investigation, it has been implicated in gene expression regulation (22, 23).

The discovery of glycosylated DNA and the importance of carbohydrates in cellular molecular recognition processes have spurred the design, synthesis, and evaluation of artificial DNA glycoconjugates that combine the desirable recognition properties of DNA and carbohydrates. Two main approaches for the conjugation of carbohydrate moieties to DNA recently have been developed: (1) incorporation of glycosylated phosphoramidite building blocks into DNA through solid-phase DNA synthesis (24–28) and (2) postsynthetic glycosylation of a reactive site on synthetic or plasmid DNA (29–31). Despite the reported successes for decoration of DNA with carbohydrates, all current methods require laborious chemical synthesis of a carbohydrate derivative suitable for conjugation to DNA. Although synthesis of monosaccharide derivatives is relatively straightforward, the attachment

### Scheme 1. Chemoenzymatic Synthesis of DNA Glycoconjugates

of complex carbohydrates to DNA is hampered by the synthetic effort required to prepare the oligosaccharide portion with appropriate stereo- and regiochemical control.

Chemoenzymatic synthesis was developed recently to streamline the synthesis of complex carbohydrates (32), glycopeptides (33), and glycopolymers (34). The approach involves the synthesis of a core carbohydrate that serves as a glycosyl acceptor for a glycosyl transferase enzyme. The glycosyl transferase, which utilizes a sugar–nucleotide donor, catalyzes the stereo- and regiospecific glycosylation of the acceptor sugar with the donor carbohydrate. The chemoenzymatic method was successfully employed for the synthesis of sialyl Lewis X (sLeX) BGA (35) and for conjugating sLeX antigens to glycoproteins (36, 37) and synthetic peptides (38). The chemoenzymatic method offers the advantages of enzymatic selectivity, rate acceleration, and compatibility with aqueous reaction media, while avoiding complex protection and deprotection strategies that are required for chemical synthesis of carbohydrates (32). Furthermore, the approach is quite general, provided that the glycosyltransferase enzymes with the desired carbohydrate specificity are available.

Herein we describe a chemoenzymatic approach for the synthesis of DNA glycoconjugates that combines the advantages of chemical synthesis of glycosylated DNA with the efficiency and selectivity conferred by glycosyl transferase enzymes. Our approach is outlined in Scheme 1. We selected **LeX–DNA** as our initial chemoenzymatic target because of the important role of LeX antigens in several biological recognition events. In addition, its sialylated derivative (sLeX) was synthesized previously by both conventional synthetic organic approaches (39, 40) and chemoenzymatic methods (35). Finally, the LeX antigen offers the potential for lectin or antibody-based detection of the LeX–trisaccharide conjugated to DNA. As illustrated in Scheme 1, the target LeX–trisaccharide antigen is tethered to the 5′-end of the DNA oligonucleotide through organic spacers designed to ensure independent functioning of the carbohydrate and DNA portions of the hybrid molecule. We envisaged that **LeX–DNA** would be derived from the sequential enzymatic glycosylation of a monosaccharide-derivatized, **GlcNAc–DNA**. The **GlcNAc–DNA** would be obtained by coupling of the GlcNAc phosphoramidite (**1**) to the 5′-end of a DNA oligonucleotide during solid-phase DNA synthesis. We now report the successful chemoenzymatic synthesis of DNA glycoconjugates, according to Scheme 1, and describe the properties of these hybrid bioconjugates. Our studies show that glycosylation of the 5′-end of DNA oligonucleotides does not interfere with the ability of

DNA glycoconjugates to base pair with complementary DNA. In addition, the **LeX–DNA** offers a new orthogonal detection method for glycosylated DNA, the “Southwestern” detection, in which the oligonucleotide domain is detected by hybridization with a complementary labeled DNA probe, and the LeX–trisaccharide is specifically recognized by an anti-LeX mAb and coupled to a chemiluminescence detection scheme.

### EXPERIMENTAL PROCEDURES

**General Procedures.** All glassware was oven-dried (140 °C). Anhydrous reagents were supplied by Aldrich in Sure-Seal bottles. N<sub>2</sub> was used as an inert atmosphere. All reagents were supplied by Aldrich and were used without further purification unless otherwise noted. Silica gel (40–63 μm, EM Science) was used for flash column chromatography. EM Science Kieselgel 60 F254 plates (0.25 mm) were used for analytical thin-layer chromatography (TLC). Compounds on TLC were visualized by staining with Verghn’s reagent (0.26 M ammonium molybdate, 6.0 mM ceric sulfate in 10% aqueous H<sub>2</sub>SO<sub>4</sub>) (41) followed by warming of the silica gel plate. <sup>1</sup>H and <sup>13</sup>C NMR spectra were recorded at 500 and 125 MHz, respectively, on a Varian 500 instrument, unless noted otherwise. Chemical shift values are reported in parts per million (ppm) in the following format: chemical shift (multiplicity, integration, coupling constant in Hertz, proton assignment). Proton assignments for <sup>1</sup>H spectra were determined using <sup>1</sup>H–<sup>1</sup>H NMR COSY data. <sup>31</sup>P NMR data were recorded at 162 MHz on a Varian 400 spectrometer and were referenced to an external standard of 85% phosphoric acid. Mass spectral data for small molecules were obtained by FAB on a Micromass 70SE–4F spectrometer with 3-nitrobenzyl alcohol or glycerol as the matrix. T4 polynucleotide kinase was obtained from US Biochemical (USB). Terminal deoxynucleotidyl transferase was purchased from Promega. [α-<sup>32</sup>P]-dATP (3000 Ci/mmol) and [γ-<sup>32</sup>P]-ATP (7000 Ci/mmol) were purchased from ICN. Radioactive bands in polyacrylamide gels were visualized using a Molecular Dynamics Storm Phosphorimager and quantitated using Molecular Dynamics ImageQuant software. LeX-conjugated bovine serum albumin (LeX–BSA), bovine recombinant β-1,4-galactosyltransferase expressed from *Spodoptera frugiperda*, human recombinant α-1,3-fucosyltransferase (VI) expressed from *Spodoptera frugiperda*, UDP-α-D-galactose disodium salt, GDP-β-L-fucose disodium salt, anti-LeX (mouse, 32.7 μg/mL), and anti-mouse IgM (goat, peroxidase conjugate, 1 mg/mL) were purchased from Calbiochem. Zeta-probe GT membrane was purchased from Biorad. ECL PLUS western blotting detection kit was purchased from Amersham. Molecular biology grade 4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid (HEPES) was purchased from Sigma.

**6-Benzoyloxyhexyl 2-Acetamido-3,4,6-tri-O-acetyl-2-deoxy-β-D-glucopyranoside (3)** (42). 1-Chloro-2-acetamido-3,4,6-tri-O-acetyl-2-deoxy-α-D-glucopyranoside (**43**) (**2**) (1 g, 2.73 mmol) and 6-benzoyloxyhexanol (**44**) (700 mg, 3.31 mmol) were dissolved in anhydrous CH<sub>2</sub>Cl<sub>2</sub> (27 mL) under N<sub>2</sub>. AgOTf (912.3 mg, 3.55 mmol) was added, and the solution was stirred for 30 min at 25 °C in the dark. The reaction was filtered through a 1 cm Celite pad, and the pad was washed with EtOAc (200 mL). The filtrate was concentrated to 100 mL and washed consecutively with saturated aqueous NaHCO<sub>3</sub> (30 mL), H<sub>2</sub>O (30 mL) and saturated aqueous NaCl (30 mL). The organic layer was dried over MgSO<sub>4</sub>, filtered, concentrated, and purified by flash chromatography (30% hexane/EtOAc) to yield **3** (392.6 mg, 27%). <sup>1</sup>H NMR (CDCl<sub>3</sub>): δ 7.34 (m,

5H, Ar-*H*), 5.52 (d, 1H,  $J_{\text{NH},2} = 8.2$  Hz, NHAc), 5.31 (dd, 1H,  $J_{3,4} = 9.6$  Hz,  $J_{3,2} = 9.6$  Hz, H3), 5.07 (dd, 1H,  $J_{4,3} = 9.6$  Hz,  $J_{4,5} = 9.6$  Hz, H4), 4.68 (d, 1H,  $J_{1,2} = 8.8$  Hz, H1), 4.50 (s, 2H, ArCH<sub>2</sub>), 4.27 (dd, 1H,  $J_{6,5} = 4.5$  Hz,  $J_{6,6'} = 12.5$  Hz, H6), 4.13 (dd, 1H,  $J_{6',5} = 1.5$  Hz,  $J_{6',6} = 12.5$  Hz, H6'), 3.87 (m, 1H, H5), 3.78 (m, 1H, H2), 3.69 (m, 1H, OCH<sub>2</sub>(CH<sub>2</sub>)<sub>5</sub>OBn), 3.46 (t, 2H,  $J = 6.8$  Hz, CH<sub>2</sub>OBn), 3.43 (m, 1H, OCH<sub>2</sub>(CH<sub>2</sub>)<sub>5</sub>OBn), 2.09 (s, 3H, AcO), 2.05 (s, 3H, AcO), 2.03 (s, 3H, AcO), 1.93 (s, 3H, AcN), 1.60 (m, 4H, OCH<sub>2</sub>CH<sub>2</sub>(CH<sub>2</sub>)<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OBn), 1.36 (m, 4H, O(CH<sub>2</sub>)<sub>2</sub>-(CH<sub>2</sub>)<sub>2</sub>(CH<sub>2</sub>)<sub>2</sub>OBn). <sup>13</sup>C NMR (CDCl<sub>3</sub>):  $\delta$  170.7, 170.6, 170.1, 169.3, 138.5, 128.3, 127.6, 127.5, 100.7, 73.0, 72.5, 71.8, 70.4, 69.9, 68.9, 62.3, 55.0, 29.9, 29.5, 26.1, 25.9, 23.5, 21.0, 21.0, 20.9. HRMS-FAB ( $m/z$ ): [M + Na]<sup>+</sup> calcd, 560.2472; found, 560.2473.

**6-Hydroxyhexyl 2-Acetamido-3,4,6-tri-*O*-acetyl-2-deoxy- $\beta$ -D-glucopyranoside (**4**)** (45). A solution of **3** (200 mg, 0.37 mmol) in 2 mL of 95% EtOH was stirred at RT under 250 psi H<sub>2</sub> in the presence of 10% Pd/C (35 mg) for 72 h. The solution was filtered, concentrated, and purified by flash chromatography to yield **4** (163.1 mg, 98%). <sup>1</sup>H NMR (CDCl<sub>3</sub>):  $\delta$  5.54 (d, 1H,  $J = 8.5$  Hz, NHAc), 5.30 (dd, 1H,  $J_{3,2} = 10$  Hz,  $J_{3,4} = 10$  Hz, H3), 5.08 (dd, 1H,  $J_{4,3} = 10$  Hz,  $J_{4,5} = 10$  Hz, H4), 4.68 (d, 1H,  $J_{1,2} = 8.0$  Hz, H1), 4.27 (dd, 1H,  $J_{6,5} = 4.5$  Hz,  $J_{6,6'} = 12.5$  Hz, H6), 4.13 (dd, 1H,  $J_{6',5} = 1.5$  Hz,  $J_{6',6} = 12.5$  Hz, H6'), 3.89 (m, 1H, H5), 3.83 (m, 1H, H2), 3.72 (m, 1H, OCH<sub>2</sub>(CH<sub>2</sub>)<sub>5</sub>OH), 3.65 (t, 2H,  $J = 6.4$  Hz, OCH<sub>2</sub>(CH<sub>2</sub>)<sub>4</sub>CH<sub>2</sub>-OH), 3.49 (m, 1H, OCH<sub>2</sub>(CH<sub>2</sub>)<sub>5</sub>OH), 2.10 (s, 3H, AcO), 2.04 (s, 3H, AcO), 2.03 (s, 3H, AcO), 1.96 (s, 3H, AcN), 1.58 (m, 4H, OCH<sub>2</sub>CH<sub>2</sub>(CH<sub>2</sub>)<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OH), 1.38 (m, 4H, O(CH<sub>2</sub>)<sub>2</sub>(CH<sub>2</sub>)<sub>2</sub>(CH<sub>2</sub>)<sub>2</sub>OH). <sup>13</sup>C NMR (CDCl<sub>3</sub>):  $\delta$  170.8, 170.7, 170.4, 169.4, 100.8, 72.5, 71.8, 69.8, 68.9, 62.7, 62.4, 54.8, 32.8, 29.4, 25.9, 25.6, 23.5, 21.1, 21.0, 20.9. HRMS-FAB ( $m/z$ ): [M + Na]<sup>+</sup> calcd, 470.2002; found, 470.2003.

**6-*O*-(2-Cyanoethyl-*N,N*-diisopropylphosphoroamidyl)hexyl 2-Acetamido-3,4,6-tri-*O*-acetyl-2-deoxy- $\beta$ -D-glucopyranoside (**1**)**. 2-Cyanoethyl-*N,N*-tetraiso-propylphosphorodiamidite (92.4  $\mu$ L, 0.29 mmol) was added to a solution of **4** (100 mg, 0.22 mmol) and diisopropylammonium tetrazolidine (23 mg, 0.13 mmol) in anhydrous CH<sub>2</sub>Cl<sub>2</sub> (5.5 mL) under N<sub>2</sub>. The reaction was stirred at 25 °C for 30 min and quenched by addition of CH<sub>2</sub>Cl<sub>2</sub> (5.5 mL) and H<sub>2</sub>O (5.5 mL). The phases were separated, and the aqueous phase was back-extracted twice with CH<sub>2</sub>Cl<sub>2</sub> (5.5 mL). The combined organic layers were washed consecutively with saturated aqueous NaHCO<sub>3</sub> (2  $\times$  11 mL), H<sub>2</sub>O (2  $\times$  5.5 mL), and saturated aqueous NaCl (5.5 mL). The solution was dried over MgSO<sub>4</sub>, filtered, concentrated, and purified by flash chromatography (1% Et<sub>3</sub>N, 20% acetone/EtOAc) to yield **1** (111.1 mg, 77%). The final product was coevaporated with anhydrous acetonitrile and dried in vacuo for 12 h. Compound **1** was stored at -20 °C. <sup>1</sup>H NMR (CD<sub>3</sub>CN):  $\delta$  6.39 (d, 1H,  $J = 9.2$  Hz, NHAc), 5.12 (t, 1H,  $J_{3,4} = 10$  Hz, H3), 4.92 (t, 1H,  $J_{4,3} = 10$  Hz, H4), 4.84 (d, 1H,  $J = 8.0$  Hz, H1), 4.21 (dd, 1H,  $J_{5,6} = 4.0$  Hz,  $J_{6,6'} = 10.8$  Hz, H6), 4.13 (dd, 1H,  $J_{6',6} = 10.8$  Hz, H6'), 3.75 (m, 4H, H5, N[CH(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub>, OCH<sub>2</sub>CH<sub>2</sub>CN), 3.60 (m, 4H, H2, OCH<sub>2</sub>-(CH<sub>2</sub>)<sub>5</sub>OP, OCH<sub>2</sub>(CH<sub>2</sub>)<sub>4</sub>CH<sub>2</sub>OP), 3.48 (m, 1H, OCH<sub>2</sub>(CH<sub>2</sub>)<sub>5</sub>-OP), 2.16 (s, 3H, AcO), 2.13 (s, 3H, AcO), 2.01 (s, 3H, AcO), 1.80 (s, 3H, AcN), 1.58 (m, 4H, OCH<sub>2</sub>CH<sub>2</sub>(CH<sub>2</sub>)<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>OH), 1.35 (m, 4H, O(CH<sub>2</sub>)<sub>2</sub>(CH<sub>2</sub>)<sub>2</sub>(CH<sub>2</sub>)<sub>2</sub>OH), 1.17 (t, 12H,  $J = 6.5$  Hz, N[CH(CH<sub>3</sub>)<sub>2</sub>]<sub>2</sub>). <sup>13</sup>C NMR (CDCl<sub>3</sub>):  $\delta$  170.8, 170.5, 170.1, 170.0, 101.3, 73.3, 72.0, 70.2, 69.5, 64.1, 63.9, 62.7, 59.0, 58.8, 54.5, 43.6, 43.4, 31.8, 31.7, 29.9, 26.2, 26.1, 24.8, 24.7, 23.0, 20.9, 20.8, 20.8, 20.8,

20.7. <sup>31</sup>P NMR (CD<sub>3</sub>CN):  $\delta$  147.549 (s, P-1). HRMS-FAB ( $m/z$ ): [M + H]<sup>+</sup> calcd, 648.3261; found, 648.3263.

**DNA Synthesis, Deprotection, and Purification.** Unmodified DNA oligonucleotides were synthesized by Integrated DNA Technologies (Coralville, IA), purified by 20% denaturing polyacrylamide gel electrophoresis (dPAGE), and characterized by MALDI-TOF MS. Carbohydrate-modified DNA oligonucleotides were synthesized by automated methods on a Pharmacia Gene Assembler at the 1.3  $\mu$ mol scale. The triethyleneglycol phosphoramidite and natural nucleoside phosphoramidites, utilizing labile base protecting groups (Pac-dA-CE, Ac-dc-CE, *i*Pr-Pac-dG-CE and dT-CE), were obtained from Glen Research (Sterling, VA). Phosphoramidite **1** was used at a concentration of 0.1 M in anhydrous CH<sub>3</sub>-CN for DNA synthesis. After synthesis, the DNA-carbohydrate conjugates were deprotected in 28% ammonium hydroxide for 24 h at 37 °C. The ammonia solution was removed using a Speedvac concentrator, and the residue was redissolved in 200  $\mu$ L of TE Buffer (10 mM Tris, 1 mM EDTA, pH 7.5) and combined with 200  $\mu$ L of 2x gel loading buffer (2x GLB: 20% (v/v) sucrose, 0.1 M EDTA, 0.1% (w/v) SDS, 0.05% (w/v) bromophenol blue, 0.05% (w/v) xylene cyanol, 16 M Urea). The DNA glycoconjugates were purified using 20% dPAGE (29:1 acrylamide:bisacrylamide, 8 M urea, 89 mM Tris, 89 mM borate, 1 mM Na<sub>2</sub>EDTA) with 1x TBE (89 mM Tris, 89 mM borate, 1 mM Na<sub>2</sub>EDTA) as a running buffer. DNA in gels was imaged by short-wave UV shadowing, excised with a flame-sterilized razor blade, and eluted from the gel pieces with crush and soak buffer (10 mM Tris-HCl, 200 mM NaCl, 1 mM EDTA, pH 7.5) at 25 °C for 12 h. The eluent and the gel pieces were combined and filtered through a 0.2  $\mu$ m filter. NaOAc (3 M, pH 5.2, 0.1x v:v) and ethanol (3.0x v:v) were added into the filtrate, and the precipitation solution was incubated at -20 °C for 2 h. The supernatant was removed, and the pellets were dried on a Speedvac concentrator, redissolved in 500  $\mu$ L ddH<sub>2</sub>O, and desalted on a G-25 Sephadex column (NAP, Amersham). Purified DNA glycoconjugates were quantitated by UV absorption at 260 nm using extinction coefficients based on nearest-neighbors method (46).

**3'-Radiolabeling of DNA Glycoconjugates.** DNA glycoconjugate (~100 pmol) was incubated at 37 °C for 45 min with 50 units of terminal deoxytransferase (TDT) in a 20  $\mu$ L reaction containing 100 mM cacodylate pH 6.8, 0.1 mM DTT, 1 mM CoCl<sub>2</sub>, and 40 pmol [ $\alpha$ -<sup>32</sup>P]-dATP. 2x GLB (20  $\mu$ L) was added to the reaction, and the sample was purified by nondenaturing 20% PAGE (29:1 acrylamide:bisacrylamide, 89 mM Tris, 89 mM borate) with 1x TB (89 mM Tris, 89 mM borate) as running buffer. The gel was imaged onto film, and the band corresponding to radiolabeled DNA conjugate was excised with a flame-sterilized razor blade. The DNA was removed from the gel slices by elution into 300  $\mu$ L of ddH<sub>2</sub>O for 12 h at 4 °C.

**5'-Radiolabeling of DNA Oligonucleotides.** DNA oligonucleotide (100 pmol) was incubated at 37 °C for 40 min with 24.5 units of polynucleotide kinase (USB) in a 20  $\mu$ L reaction containing 10 mM Tris-acetate, 10 mM magnesium acetate, 50 mM potassium acetate, and 24 pmol (8.4 Ci/ $\mu$ L) of [ $\gamma$ -<sup>32</sup>P]-ATP (7000 Ci/mmol). 2x GLB (25  $\mu$ L) then was added to the reaction, and the sample was purified by nondenaturing 20% PAGE and isolated as described for 3'-radiolabeling.

**Synthesis of LacNAc-DNA by  $\beta$ -1,4-Galactosyltransferase-Catalyzed Glycosylation of GlcNAc-DNA.** GlcNAc-DNA (40 nmol) was incubated at 37 °C for 8 h with 0.1 unit of  $\beta$ -1,4-galactosyltransferase in a

60  $\mu$ L solution containing 50 mM HEPES pH 7.5, 20 mM Mn(OAc)<sub>2</sub>, 0.5 mg/mL  $\alpha$ -lactalbumin, and 0.13 mM Gal-UDP. 2x GLB (60  $\mu$ L) was added to the reaction, and the sample was purified by nondenaturing 20% PAGE with 1x TB as the running buffer. The DNA glycoconjugates were imaged by short-wave UV shadowing, excised with a flame-sterilized razor blade, and retrieved from the gel pieces by soaking in 300  $\mu$ L of ddH<sub>2</sub>O at 4  $^{\circ}$ C for 12 h. The purified DNA glycoconjugate was desalted by reverse phase HPLC (RP-HPLC).

**DNA Desalting by RP-HPLC.** Gel purified DNA glycoconjugates were desalted by RP-HPLC on a Waters series 600 HPLC system using an XTerra reverse-phase C-18 column (3.5  $\mu$ m, 4.6 mm  $\times$  50 mm). After injection of the oligonucleotide, a 30 min 100% water wash at 1 mL/min was used to elute buffer salts. The desalted DNA glycoconjugates then were eluted with 95% CH<sub>3</sub>CN/H<sub>2</sub>O. DNA-containing peaks (254 nm absorption) were collected and dried by lyophilization.

**Synthesis of LeX-DNA by  $\alpha$ -1,3-Fucosyltransferase (VI)-Catalyzed Glycosylation of LacNAc-DNA.** LacNAc-DNA (40 nmol) was incubated at 37  $^{\circ}$ C for 8 h with 1.4 mU of  $\alpha$ -1,3-fucosyltransferase (VI) in a 60  $\mu$ L solution containing 50 mM HEPES, pH 7.5, 20 mM Mn(OAc)<sub>2</sub>, 0.5 mg/mL  $\alpha$ -lactalbumin, and 0.13 mM Fuc-GDP. 2x GLB (60  $\mu$ L) was added to the reaction, and the sample was purified by a nondenaturing 20% PAGE with 1x TB as the running buffer. The glycoconjugates were recovered and desalted as described previously.

**Synthesis of LeX-DNA by  $\alpha$ -1,3-Fucosyltransferase (VI)- and  $\beta$ -1,4-Galactosyltransferase-Catalyzed Glycosylation of GlcNAc-DNA.** GlcNAc-DNA (40 nmol) was incubated at 37  $^{\circ}$ C for 8 h with 0.1 unit of  $\beta$ -1,4-galactosyltransferase and 1.4 mU of  $\alpha$ -1,3-fucosyltransferase (VI) in a 60  $\mu$ L solution containing 50 mM HEPES pH 7.5, 20 mM Mn(OAc)<sub>2</sub>, 0.5 mg/mL  $\alpha$ -lactalbumin, 0.13 mM Fuc-GDP, and 0.13 mM Gal-UDP. 2x GLB (60  $\mu$ L) was added to the reaction, and the sample was purified and isolated as described previously.

**MALDI-TOF MS.** Mass spectral data for oligonucleotides were obtained on a PerSeptive Biosystems, Inc. (Foster City, CA), Voyager-DE PRO Biospectrometry Workstation MALDI-TOF mass spectrometer. An N<sub>2</sub> laser was used (337 nm wavelength, 3 ns pulse). All spectra were acquired in the negative ion mode averaging 300 shots. Matrix for **GlcNAc-DNA-1**, **LacNAc-DNA-1**, and **LeX-DNA-1** was prepared by mixing 80  $\mu$ L of a 0.2 M solution of 2,4,6-trihydroxyacetophenone in 1:1 CH<sub>3</sub>CN:H<sub>2</sub>O and 10  $\mu$ L of 0.3 M aqueous ammonium citrate. Matrix for **GlcNAc-DNA-2**, **LacNAc-DNA-2**, and **LeX-DNA-2** was prepared by mixing 20  $\mu$ L of a 0.2 M solution of 2,4,6-trihydroxyacetophenone in 1:1 CH<sub>3</sub>CN:H<sub>2</sub>O, 10  $\mu$ L of a 0.2 M solution of 2,3,4-trihydroxyacetophenone in 1:1 CH<sub>3</sub>CN:H<sub>2</sub>O, and 10  $\mu$ L of 0.2 M aqueous ammonium citrate. Poly(dT)<sub>10</sub>, poly(dT)<sub>24</sub> and poly(dT)<sub>37</sub> were obtained from Integrated DNA Technologies and used for internal calibration. All observed masses were in agreement with calculated values (*m/z*): **GlcNAc-DNA-1**: calcd, 5084.39; found, 5084.15. **LacNAc-DNA-1**: calcd, 5246.53; found, 5247.15. **LeX-DNA-1**: calcd, 5392.67; found, 5389.94. **GlcNAc-DNA-2**: calcd, 9498.19; found, 9499.58. **LacNAc-DNA-2**: calcd, 9660.33; found, 9657.92. **LeX-DNA-2**: calcd, 9806.47; found, 9806.62.

**UV Thermal Denaturation Analysis.** Thermal denaturation data were acquired on a Cary 500 spectrophotometer equipped with a multicuvette thermoelectric controller in 10 mm quartz cuvettes. Duplex oligonucleo-

tides were prepared from 2  $\mu$ M of each strand in buffer consisting of 10 mM sodium phosphate, 0.1 mM EDTA, 150 mM NaCl, pH 7.0. Strands were annealed by heating to 95  $^{\circ}$ C for 15 min and cooling to 25  $^{\circ}$ C over 2 h. The samples were degassed under vacuum for 3 min prior to melting analysis. The absorbance was measured at 260 nm as the samples were heated from 25  $^{\circ}$ C to 98  $^{\circ}$ C at 0.5  $^{\circ}$ C/min. Melting temperatures (*T<sub>m</sub>*) were determined from plots of  $dA_{260}/dT$  vs *T* and are derived from replicate melting experiments using two independent samples.

**Membrane Blotting of DNA Glycoconjugates, DNA Oligonucleotides, and LeX-BSA.** A wet Zeta-probe GT membrane was placed on top of a moist 3MM Whatman filter paper, and all air bubbles were removed. DNA glycoconjugates (50 pmol), standard DNA oligonucleotides (50 pmol), and LeX-BSA (50 pmol) were spotted on the membrane by pipetting. The membrane then was heated at 80  $^{\circ}$ C for 45 min and cooled to RT.

**Detection of DNA Glycoconjugates with Anti-LeX Antibody.** Blotted membranes were incubated in 5% nonfat dry milk (NFDM) in TTBS (0.02 M Tris, 0.5 M NaCl, 0.05% Tween 20, pH 7.5) and shaken at 25  $^{\circ}$ C for 1 h to block nonspecific binding. The membrane was transferred to a solution of 5% NFDM/TTBS with anti-LeX antibody (mouse, 65.4 ng/mL) and incubated at 25  $^{\circ}$ C for 1 h. The membrane was washed with 0.2% NFDM/TTBS for 3  $\times$  5 min and incubated in a solution of anti-mouse IgM (goat, HRP conjugate, 200 ng/mL) in 5% NFDM/TTBS at 25  $^{\circ}$ C for 1 h. The membrane was washed 3 times for 5 min each in 0.2% NFDM/TTBS, then for 15 min with TBS (0.02 M Tris base, 0.5 M NaCl, pH 7.5). The membrane was developed for 5 min using an ECL PLUS western blotting detection kit. The wet membrane was wrapped with plastic wrap and exposed to film (KODAK O-XMAT-LS).

**Detection of DNA Glycoconjugates with Radiolabeled Complementary DNA Probes.** Blotted membranes were incubated in hybridization buffer (0.5 M phosphate buffer, 1 mM EDTA, 7% SDS, pH 7.2) at 65  $^{\circ}$ C for 30 min. The membrane was transferred to hybridization buffer containing radiolabeled (400 kcpm) complementary DNA oligonucleotide and incubated at 55  $^{\circ}$ C for 30 min. The membrane was washed consecutively with wash buffer I (40 mM phosphate, 1 mM EDTA, 5% SDS, pH 7.2) for 3 min at 55  $^{\circ}$ C, and wash buffer II (40 mM phosphate, 1 mM EDTA, 1% SDS, pH 7.2) for 3 min at 55  $^{\circ}$ C. The membrane was air-dried, wrapped with plastic, and imaged with a phosphor screen.

## RESULTS AND DISCUSSION

**Synthesis of GlcNAc Phosphoramidite (1).** The chemical component of the chemoenzymatic approach, outlined in Scheme 1, involved the synthesis of GlcNAc phosphoramidite (**1**) and preparation of **GlcNAc-DNA**. Our carbohydrate target (**1**) featured a GlcNAc sugar with a linker that originated at the glycosidic position of the sugar and terminated in a phosphoramidite group for use in standard solid-phase DNA synthesis. The glycosidic linker site was chosen for two major reasons. First, literature precedent (24, 47–49) suggested that stereocontrolled incorporation of linker groups at glycosidic sites would be accessible by standard glycosylation methods. Second, since our enzymatic approach relied on the availability of unmodified sugar hydroxyls for optimal activity of the glycosyl transferases, attachment of DNA to the nonreducing end of the glycoconjugate offered considerable advantages.

The GlcNAc phosphoramidite (**1**) was prepared using the route detailed in Scheme 2. The anomeric chloride

**Scheme 2. Synthesis of GlcNAc Phosphoramidite Derivative 1****Scheme 3. Chemoenzymatic Synthesis of LeX-DNA**

starting material (**2**) was synthesized from D-glucosamine in 76% yield as described (43). The known monobenzyl ether of 1,6-hexanediol (**44**) was glycosylated with GlcNAc donor **2** in the presence of silver triflate to form 6-benzyloxyhexyl 2-acetamido-3,4,6-tri-O-acetyl-2-deoxy-β-D-glucopyranoside (**3**) (24). The anomeric configuration for **3** was confirmed as β, based on the inferred trans diaxial orientation of H1 and H2 by  $^1\text{H}$  NMR experiments ( $J_{1,2} = 8.8$  Hz). Isomeric structures (such as ortho ester) were ruled out by  $^{13}\text{C}$  NMR chemical shift analysis. The benzyl group was removed from **3** by hydrogenolysis (50) using Pd/C catalyst to provide alcohol **4** in 98% yield. Finally, the protected GlcNAc derivative **4** was converted to the phosphoramidite target (**1**) by standard methods (51). All synthetic intermediates were characterized by  $^1\text{H}$  and  $^{13}\text{C}$  NMR and HRMS-FAB MS. Phosphoramidite **1** also was characterized by  $^{31}\text{P}$  NMR.

**Synthesis of GlcNAc-DNA Glycoconjugates.** The GlcNAc phosphoramidite (**1**) was used for the synthesis of GlcNAc-modified oligonucleotides by solid-phase DNA synthesis. Two sequences were synthesized, **GlcNAc-DNA-1** and **GlcNAc-DNA-2**, as shown in Scheme 3. A water-soluble and biologically compatible triethylene glycol linker was inserted between GlcNAc and the DNA sequence to prevent steric interference between the carbohydrate and the DNA oligonucleotide. After synthesis, oligonucleotides were deprotected in 28% aqueous ammonia for 24 h at 37 °C, which also removed the O-acetyl protecting groups from the GlcNAc precursor. The coupling yield of **1** during DNA synthesis could not be determined directly by standard assays, due to the

**Figure 1.** Stepwise enzymatic synthesis of LeX-DNA-1. (A) Galactosyl transfer to **GlcNAc-DNA-1**; lanes 2–5: GalT-catalyzed glycosylation of **GlcNAc-DNA-1** for 30 s, 1, 2, and 3 min; (B) Fucosyl transfer to **LacNAc-DNA-1**; lane 1: **LacNAc-DNA-1**; lanes 2–5: FucT-catalyzed glycosylation of **LacNAc-DNA-1** for 30 s, 1, 2, and 3 min.

lack of a dimethoxytrityl protecting group. However, in all cases, only one DNA product was observed during the gel electrophoresis purification of **GlcNAc-DNA**, indicating that the coupling efficiency of **1** was comparable to that of the natural nucleotides (>90%). **GlcNAc-DNA** was further characterized by matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF MS). The DNA glycoconjugates gave the expected masses: **GlcNAc-DNA-1**,  $[M]^-$  calcd, 5084.39; found, 5084.15; **GlcNAc-DNA-2**,  $[M]^-$  calcd, 9498.19; found, 9499.58.

**Enzymatic Synthesis and Characterization of DNA Glycoconjugates.** The enzymatic conversion of **GlcNAc-DNA** into **LeX-DNA**, described in Scheme 3, proceeds by two sequential glycosyl transfer reactions:  $\beta$ -1,4-galactosyltransferase (GalT) catalyzed conversion of **GlcNAc-DNA** to **LacNAc-DNA** and  $\alpha$ -1,3-fucosyltransferase VI (FucT) mediated transformation of **LacNAc-DNA** to **LeX-DNA**. We envisaged two possible reaction sequences for the enzymatic synthesis of **LeX-DNA** from **GlcNAc-DNA**. The first was a stepwise route, in which **LacNAc-DNA** would be synthesized using GalT, and the disaccharide-DNA hybrid would be isolated and utilized in a FucT-catalyzed step to synthesize **LeX-DNA**. The sequence of these two reaction steps could not be exchanged because the substrate of FucT is **LacNAc-DNA** (52). A second approach, commonly used for the chemoenzymatic synthesis of glycosylated peptides and proteins (32), was a one-pot, two-step reaction sequence in which the two enzymes were incubated simultaneously with UDP-Gal, GDP-Fuc, and the **GlcNAc-DNA** substrate. In this approach, **LacNAc-DNA**, produced by the GalT reaction, would be glycosylated in situ by FucT to provide **LeX-DNA**. Both approaches proved successful for the enzymatic synthesis of **LeX-DNA** from **GlcNAc-DNA**.

The synthesis of **LacNAc-DNA** and **LeX-DNA** by stepwise action of GalT and FucT is detailed in Figure 1 for DNA glycoconjugates based on sequence **DNA-1** (Scheme 3). Enzymatic glycosylation reactions were performed on **GlcNAc-DNA-1** that had been labeled at its 3'-end with a  $^{32}\text{P}$  tracer, and were assayed by denaturing polyacrylamide gel electrophoresis (dPAGE). Figure 1A illustrates the time course for the conversion of **GlcNAc-DNA-1** (0.1  $\mu\text{M}$ ) to **LacNAc-DNA-1** at 37 °C (50 mM HEPES pH 7.5, 20 mM  $\text{Mn}(\text{OAc})_2$ , 0.5 mg/mL  $\alpha$ -lactalbumin, 2.5  $\mu\text{M}$  Gal-UDP, and 25 units/ $\mu\text{L}$

**Figure 2.** One-pot enzymatic synthesis of **LeX-DNA-1**. Lane 1: **GlcNAc-DNA-1**; lanes 2–5: GalT-catalyzed glycosylation of **GlcNAc-DNA-1** for 15 s, 45 s, 1 min, 10 min; lane 6: **GlcNAc-DNA-1**; lanes 7–10: GalT- and FucT-catalyzed one-pot glycosylation of **GlcNAc-DNA-1** for 15 s, 45 s, 1 min, 10 min.

GalT). Under these conditions, **GlcNAc-DNA-1** (lane 1) was transformed to a product with lower gel mobility (lanes 2–5). More than 50% of **GlcNAc-DNA-1** was converted to product in the first 30 s (lane 2), and the GalT-dependent reaction was >90% complete within 3 min (lanes 3–5). The product (top band, lanes 2–5) showed a mobility shift corresponding to an increase in molecular weight, which was consistent with the synthesis of **LacNAc-DNA-1**. To verify the identity of the lower mobility product, a preparative scale (40 nmole) GalT reaction was performed on unlabeled **GlcNAc-DNA-1** to provide adequate material for further characterization. The product was purified by nondenaturing PAGE, desalted by RP-HPLC, and analyzed by MALDI-TOF MS. The isolated product gave the expected mass for **LacNAc-DNA-1**:  $[M]^-$  calcd, 5246.53; found, 5247.15.

Purified **LacNAc-DNA-1**, which had been synthesized by enzymatic galactosyl transfer, was utilized as a substrate for the FucT-mediated conversion to **LeX-DNA-1**. The reaction mixture (0.1  $\mu$ M 3'-labeled **LacNAc-DNA-1**, 50 mM HEPES, 20 mM Mn(OAc)<sub>2</sub>, 0.5 mg/mL  $\alpha$ -lactalbumin, 2.5  $\mu$ M Fuc-GDP, and 0.35 units/ $\mu$ L FucT) was incubated at 37 °C. Reaction aliquots were removed at specific intervals across 30 s–3 min and analyzed by dPAGE. The results are shown in Figure 1B. The FucT reaction led to a fucosylated DNA product shown by a lower gel mobility band (top band, lanes 2–5), compared with **LacNAc-DNA-1** (lane 1). The reaction proceeded efficiently and was >90% complete in less than 3 min (lane 5). To demonstrate that the product of the FucT reaction was indeed **LeX-DNA-1**, a preparative scale (40 nmole) enzymatic fucosylation reaction was performed. The product was purified by nondenaturing PAGE/RP-HPLC and characterized by MALDI-TOF MS. As was the case for the GalT chemistry, the FucT reaction led to the expected product: **LeX-DNA-1** ( $[M]^-$  calcd, 5392.67; found, 5389.94).

Having demonstrated the efficient stepwise synthesis of **LeX-DNA-1** from **GlcNAc-DNA-1**, we examined the potential for one-pot assembly of **LeX-DNA** by tandem action of GalT and FucT. The time course of the one-pot reaction was analyzed by dPAGE.

The left panel of Figure 2 (lanes 1–5) demonstrates the stepwise conversion of **GlcNAc-DNA-1** to **LacNAc-DNA-1**, which serves as a control for the one-pot reaction. The results of the one-pot tandem reaction are shown in the right panel of Figure 2 (lanes 6–10). Based on gel mobility shifts, the **GlcNAc-DNA-1** starting material (lane 6) was first transformed to **LacNAc-DNA-1** (lane 7). The resulting **LacNAc-DNA-1** underwent further conversion to **LeX-DNA-1** (lanes 8–10). The one-pot reaction led to complete conversion of **GlcNAc-DNA-1** to **LeX-DNA-1** within minutes. Consistent with the substrate specificity of FucT (52), incubation of **GlcNAc-DNA** with FucT produced no new products.

To assess the generality of enzymatic glycosylation of chemically synthesized DNA glycoconjugates, the GalT and FucT experiments were repeated for **GlcNAc-DNA-2**. **LacNAc-DNA-2**, obtained from a GalT reaction, and **LeX-DNA-2**, derived from a one-pot tandem reaction of **GlcNAc-DNA-2** with GalT and FucT, showed gel shift profiles (Supporting Information) similar to those observed for the **DNA-1** glycoconjugates (Figure 2). Preparative enzymatic glycosylations of **GlcNAc-DNA-2** produced DNA glycoconjugates that gave the expected masses by MALDI-TOF MS: **LacNAc-DNA-2** ( $[M]^-$  calcd, 9660.33; found, 9657.92); **LeX-DNA-2** ( $[M]^-$  calcd, 9806.47; found, 9806.62).

**Characterization of DNA Glycoconjugates by Glycosidase Digestion.** To further characterize the identity and specificity of glycosyl transfer reactions of DNA glycoconjugates, "on target" enzymatic digestion experiments (53) were performed. In this approach, DNA glycoconjugates were subjected to digestion by specific glycosidase enzymes on MALDI-TOF MS sample preparation plates. MALDI-TOF mass spectra were obtained for the DNA glycoconjugates before and after digestion with an exoglycosidase specific for a terminal sugar. Successful digestion of the terminal glycosidic bond would reveal the precursor DNA glycoconjugate by MALDI-TOF MS and validate the regiochemistry and stereochemistry of the glycosyl transfer reaction. For compatibility with the MALDI-TOF MS conditions, ammonium acetate (25 mM) was used as the digestion buffer. The on-target digestion of **GlcNAc-DNA-1** was carried out with  $\beta$ -N-acetylglucosaminidase, which specifically cleaves  $\beta$ -linked GlcNAc residues. Incubation of **GlcNAc-DNA-1** at 37 °C for 26 h and subsequent MALDI-TOF MS analysis showed conversion of **GlcNAc-DNA-1** to the **DNA-1** glycol linker conjugate (Supporting Information). The conversion of **GlcNAc-DNA-1** to the parent **DNA-1** structure validates the  $\beta$ -stereochemistry of GlcNAc attachment to the linker. The on-target digestion of **LacNAc-DNA-1** with  $\beta$ -1,4-galactosidase was performed at 37 °C for 14 h. The post-digestion MALDI-TOF MS revealed a peak with the same  $m/z$  as **GlcNAc-DNA-1**, which indicated that the galactose residue was attached to the 4-position of the GlcNAc sugar with  $\beta$ -stereochemistry. Taken together, "on target digestion" of DNA glycoconjugates supports our previous assignments of the identities of **GlcNAc-DNA** and **LacNAc-DNA**.

**Duplex Stability of DNA Glycoconjugates.** Applications of DNA glycoconjugates that take advantage of DNA's coding potential require that DNA glycosylation does not interfere with the base pairing properties of DNA. To assess the effect of carbohydrate modifications on DNA duplex stability, UV thermal denaturation analysis was undertaken with DNA duplexes containing **GlcNAc-DNA**, **LacNAc-DNA**, and **LeX-DNA** strands. The glycosylated DNA sequences were annealed with a complementary DNA strand (**DNA-1'**, Figure 3) at 95 °C for 15 min and cooled to RT over 2 h in a solution containing 2  $\mu$ M of each single strand, 10 mM phosphate buffer, 0.1 mM EDTA and 150 mM NaCl at pH 7.0. For comparison, unmodified **DNA-1** was annealed with **DNA-1'** under identical conditions. As demonstrated in Figure 3, UV thermal denaturation analysis of the unmodified **DNA-1/DNA-1'** (solid squares) duplex showed a cooperative denaturation profile, with a melting temperature ( $T_m$ ) of 63 °C. The duplexes comprised of **DNA-1** glycoconjugates with **DNA-1'** (open symbols, Figure 3) showed no significant destabilization of the duplex due to the carbohydrate modifications ( $T_m$  63–65 °C). Similarly,

**Figure 3.** Thermal denaturation analysis of DNA-1 glycoconjugates. Conditions: 2  $\mu$ M each single strand, 10 mM sodium phosphate, 0.1 mM EDTA, 150 mM NaCl, pH 7.0. Heating rate: 0.5  $^{\circ}$ C/min. **DNA-1'**: 5' CCGTCGGCGAAGATG 3'. Legend: Solid squares: **DNA-1/DNA-1'**; Open circles: **GlcNAc-DNA-1/DNA-1'**; Open triangles: **LacNAc-DNA-1/DNA-1'**; Inverted triangles: **LeX-DNA-1/DNA-1'**.

thermal denaturation analysis of duplexes composed of **DNA-2** glycoconjugates and **DNA-2'** under the same conditions showed that carbohydrate modification leads to a small decrease in the cooperativity of the DNA melting transition, but the duplex thermal stability was relatively unperturbed (Supporting Information).

**Southwestern Detection of LeX-DNA.** DNA glycoconjugates represent bioconjugates that possess the properties of both DNA and carbohydrates. Because of the central importance of these two classes of biomolecules, numerous approaches for the detection of DNA or glycoconjugates have been developed. Hybridization assays such as the Southern blot (54), in which a radiolabeled complementary nucleic acid probe binds specifically to a target DNA sequence, have been invaluable for DNA detection. In glycobiology, mAb's have been used to detect the presence of specific carbohydrate antigens (55, 56). Much in the same way that mAb's are used to detect proteins in "Western blots," carbohydrate detection by antibodies involves readout of a primary mAb-carbohydrate binding event by a secondary labeled antibody. DNA glycoconjugates, by virtue of their carbohydrate and nucleic acid characteristics, offer a platform for orthogonal detection of either biomolecular component. To assess the feasibility of a combined "Southwestern" detection approach for DNA glycoconjugates, the **LeX-DNA** hybrid was used as a model system for antibody detection. DNA glycoconjugates were bound to nylon membranes and probed either with an antibody specific for the LeX trisaccharide or with a radiolabeled DNA probe complementary to the sequence of the DNA glycoconjugate.

An assay for the antibody-based detection of LeX antigens was developed using two types of antibodies: (1) a primary anti-LeX antibody (derived from mouse), which interacts specifically with the LeX antigen, and (2) a secondary anti-mouse antibody (derived from goat), which was conjugated to horseradish peroxidase (HRP). Binding of the secondary antibody to the primary antibody-LeX complex would localize HRP to membrane spots bearing LeX antigens. Membranes then would be visualized using a HRP-catalyzed chemiluminescence assay. To demonstrate the antibody-based detection strategy, DNA glycoconjugates were spotted on a membrane (see Figure

**Figure 4.** Southwestern detection of DNA glycoconjugates. (A) Anti-LeX detection by chemiluminescence using anti-LeX antibody and (B) DNA detection using radiolabeled complementary DNA strands. Spot 1: LeX-BSA; spot 2: unmodified **DNA-1**; spot 3: **GlcNAc-DNA-1**; spot 4: **LacNAc-DNA-1**; spot 5: **LeX-DNA-1**; spot 6: LeX-BSA; spot 7: unmodified **DNA-2**; spot 8: **GlcNAc-DNA-2**; spot 9: **LacNAc-DNA-2**; spot 10: **LeX-DNA-2**. **DNA-1'**: 5' CCGTCGGCGAAGATG 3'; **DNA-2'**: 5' CAAATCTTTGTCCCCGGTCGGCGAAGATG 3'.

4). A membrane was prepared for each DNA sequence (Figure 4, **DNA-1**, left panels; **DNA-2**, right panels). For each DNA series, unmodified DNA (spots 2 and 7), **GlcNAc-DNA** (spots 3 and 8), **LacNAc-DNA** (spots 4 and 9) and **LeX-DNA** (spots 5 and 10) were spotted on a Zeta-probe GT membrane. Figure 4A demonstrates the results of antibody detection of LeX antigens. As a positive control, LeX-conjugated bovine serum albumin protein (LeX-BSA) was spotted on each membrane (spots 1 and 6). As expected, spots containing materials with LeX trisaccharides, LeX-BSA (spots 1 and 6, Figure 4A) and **LeX-DNA** (spots 5 and 10, Figure 4A) were detected by chemiluminescence with the anti-LeX antibody. In contrast, unmodified DNA (spots 2 and 7) and glycosylated DNA that lacked the LeX antigen, **GlcNAc-DNA** (spots 3 and 8) and **LacNAc-DNA** (spots 4 and 9), were not detected by the antibody specific for LeX recognition (Figure 4A).

To assess whether the same membrane spots could be visualized by nucleic acid hybridization, a Southern detection experiment was performed. The membranes from Figure 4A were stripped to remove antibody and subsequently probed with radiolabeled complementary DNA strands. Due to the pairing properties of DNA glycoconjugates, it was expected that all spots containing nucleic acid would be visualized by phosphorimager analysis of bound probe. As demonstrated in Figure 4B, spots 2–5, which contained **DNA-1**, and spots 7–9, which contained **DNA-2**, gave strong signals in the presence of complementary DNA probe. In contrast, spots containing only protein and carbohydrate (LeX-BSA, spots 1 and 6, Figure 4B) produced no signals, because the protein cannot hybridize with radiolabeled DNA strands. The combined Southwestern detection of DNA glycoconjugates further validated the identity of the DNA glycoconjugate synthesized by the chemoenzymatic approach: sequence-specific DNA binding and LeX-specific antibody recognition were observed in the presence of the target, in both cases. Furthermore, the orthogonal blotting approach of DNA glycoconjugates by radiolabeled complementary strands or anti-LeX antibodies suggests that the DNA and the carbohydrate components of DNA glycoconjugates function independently. These studies demonstrate the potential for detection of specific DNA glycoconjugates by standard glycobiology and molecular biology methods.

Our future plans for DNA glycoconjugates synthesized by chemoenzymatic methods include nucleic acid delivery, targeting and DNA imaging. One direction includes

the application of chemoenzymatic synthesis of DNA glycoconjugates to antisense oligonucleotide delivery strategies. Specifically, antisense DNA oligonucleotides conjugated to cell-type specific antigens will be used for the selective targeting of DNA to cancer cells. Second, in combination with targeting, it may be possible to adapt our chemoenzymatic method to facilitate cellular uptake of DNA. Finally, the utility of the antibody-based DNA detection approach will be explored as an alternative to standard DNA detection strategies and applied toward the visualization of DNA compartmentalization in cells.

In conclusion, a new chemoenzymatic approach to the synthesis of DNA glycoconjugates was developed. **GlcNAc-DNA** was synthesized by solid-phase DNA synthesis using GlcNAc phosphoramidite derivative **1**. Oligosaccharide structures, such as LacNAc or LeX, were elaborated on the **GlcNAc-DNA** core by stepwise or one-pot glycosyl transferase enzyme reactions. The combination of chemical synthesis with the efficiency and specificity of enzymatic synthesis may allow for the rapid preparation of complex DNA glycoconjugates of biochemical or therapeutic interest. For example, it may be possible to extend the methodology to the synthesis of **sLeX-DNA**, in which the biologically important sLeX antigen (*4, 35*) would be synthesized from a simple DNA glycoconjugate. Alternatively, the approach may be applied to the synthesis of cell-specific carbohydrate antigens that may be used to target cellular delivery or uptake of DNA or antisense nucleic acid molecules (*57*). Finally, the combination of these chemoenzymatic methods with the demonstrated orthogonal DNA glycoconjugate detection approach may offer potential for in situ detection of these hybrid biomaterials for biochemical experiments or under cellular conditions.

#### ACKNOWLEDGMENT

This research was supported by a National Cancer Institute SPORE in Prostate Cancer Career Development Award to T.L.S., administered through The Robert H. Lurie Comprehensive Cancer Center of Northwestern University. The MALDI-TOF MS instrument was purchased with funds provided by a NIH Scientific Instrumentation grant (1-S10-RR13810). We acknowledge the use of instruments in the Keck Biophysics Facility at Northwestern University.

**Supporting Information Available:** Characterization data for **1**, mass spectrometric data for modified oligonucleotides, glycosylation assays, "on target" enzymatic digestion assays, and melting curve data.
