# ***Bioconjugate Chemistry***

## **EDITORIAL**

We welcome Professor Teruo Okano as Associate Editor of *Bioconjugate Chemistry*. Dr. Okano is Professor and Director of the Institute of Advanced Biomedical Engineering and Science at Tokyo Women's Medical University. He has an outstanding record in biomaterials and drug delivery, and we look forward to his service to the journal.

At the same time, Professor Mitsuru Hashida has finished his term as Associate Editor and will be stepping down. We thank Professor Hashida for his help, advice, and contributions to *Bioconjugate Chemistry*, and we wish him all the best in his future endeavors.

## **Thanks to Our Reviewers**

It is a pleasure to acknowledge the contributions of the reviewers of manuscripts submitted in 2002 for publication in *Bioconjugate Chemistry*. Their unselfish service has been essential in the shaping of the 13th volume of the journal. The scientific community is fortunate that its members are willing to share their time and specialized knowledge in this way. The reviewers are listed on the following page.

*Claude F. Meares*  
*Editor-in-Chief*

## Synthesis of Target-Specific Radiolabeled Peptides for Diagnostic Imaging

Jakub Fichna and Anna Janecka\*

Department of Medicinal Chemistry, Medical University of Lodz, Lindleya 6, 90-131 Lodz, Poland.  
Received April 23, 2002

### INTRODUCTION

Radiopharmaceuticals are drugs containing atoms of some radioactive elements. They are designed for diagnostic or therapeutic purposes, to deliver small doses of ionizing radiation to the disease sites in the body. Radiopharmaceuticals, unlike classical chemotherapeutics, act against malignant cells with high specificity. Radiopharmaceuticals are mostly small organic molecules, such as peptides or peptidomimetics, but they can also be macromolecules, for example antibodies.

Biodistribution of radiopharmaceuticals can be determined either by their chemical and physical properties or by their biological interactions. Radiopharmaceuticals, which act through receptor binding, are called target-specific. Ideally, these radiopharmaceuticals are designed to locate with high specificity at cancerous tumors, even if their location in the body is unknown, while producing minimal radiation damage to normal tissues (1–6). In the past decade significant progress has been made in the development of peptide-based target-specific radiopharmaceuticals, which have become an important class of imaging agents for the detection of various diseases, such as tumors, thrombosis, and inflammation.

Many excellent reviews have been published discussing different aspects of radionuclide chemistry and therapy (7–9) and the use of radiopharmaceuticals for diagnosis and treatment of different pathological conditions (10–19). Most popular technetium radiopharmaceuticals (20–28), as well as those incorporating other radionuclides (29, 30), have been reviewed. Antibodies (24, 25), peptides (23, 30–35), and steroids (36) as targeting molecules have been described.

In this review, which is limited to the use of small peptides as targeting molecules, we attempt to summarize, from the chemical point of view, the development of labeling methods, in particular the application of different bifunctional chelating agents. We also give a short description of radionuclides used with these agents. Radiopharmaceuticals based on small peptides, which are in clinical use or under investigation in preclinical and clinical trials, are also mentioned.

### LABELING METHODS

**Direct Labeling.** Direct labeling methods (Table 1) are mostly based on the binding of a radionuclide to thiol groups in the targeting molecule, that seems relatively

easy to perform (37, 38). However, such a labeling process is difficult to control, for its detailed chemistry is unknown and may lead to unplanned changes in the structure, stability, and pharmacokinetic properties of the labeled molecule. Furthermore, very little is known about the number of donor atoms in the labeled molecule and the geometry of radionuclide coordination. The stability in vivo of a synthesized complex also remains uncertain.

The direct labeling approach is rather unsuitable for small peptides, which either do not possess disulfide linkage or are unable to maintain their activity after reduction. For example Thakur (39) has reported the alteration of the receptor binding properties of the radiolabeled somatostatin analogues, when the disulfide bridge was reduced to free thiol groups and subsequently radiolabeled with  $^{99m}\text{Tc}$ . However, direct labeling has been successfully applied for labeling of the platelet receptor-binding peptide with  $^{99m}\text{Tc}$  (40, 41) and for high molecular weight proteins such as antibodies and their fragments (42, 43).

**Chelate Methods.** In chelate methods (Table 1) a radionuclide is bound to the targeting molecule indirectly, through a bifunctional chelating agent (BFCA) (Figure 1).

In general, a radiopharmaceutical containing a BFCA consists of the following parts: a targeting molecule, BFCA, radionuclide, and a linker (22). The targeting molecule is a carrier of a radionuclide to the receptor site in vivo. A radionuclide serves as a radiation source. A BFCA, covalently attached to the targeting molecule, functions as the coordinator of the radionuclide. A linker, not always necessary, is a spacer residue, which separates a targeting molecule from a chelating agent.

Functional groups, naturally present in the peptide or introduced synthetically, are responsible for covalent attachment of BFCA. Naturally occurring functional groups include terminal, as well as side-chain amino and carboxy groups, thiol groups from cysteine, and *p*-hydroxyphenyl from tyrosine. BFCA must contain a conjugation group, which is used for attachment of the peptide.

Several types of conjugation groups, active esters, isothiocyanates, maleimides, hydrazides, and  $\alpha$ -haloamides are used to form BFCA–peptide linkages (Figure 2).

Active esters can be used to form an amide bond between a carboxy group of a BFCA and an amino group in a peptide ligand. Since they are at a low level of activation, side-reactions during coupling are generally less of a problem than with most amide bond forming procedures. Commonly used are *p*-nitrophenyl, pen-

**Table 1. General Overview of Applied Labeling Methods**

labeling method	main principle	targeting molecule	advantages	disadvantages	ref
direct labeling	radionuclide binds directly to active groups present in the targeting molecule	high molecular weight molecules	easy to perform	unknown chemistry	(32, 35, 37, 38)
chelate methods				unknown geometry of a radionuclide-targeting molecule complex possible damage to targeting molecule during labeling process	
prelabeling	labeling of BFCA followed by conjugation with the targeting molecule	small peptides	relatively easy to control, well-defined chemistry	time-consuming	(26, 32)
postlabeling	conjugation of BFCA to targeting molecule, followed by labeling of conjugate	small peptides	most popular method	complicated purification of obtained radiopharmaceutical possible damage to targeting molecule during labeling process	(35, 44)
			targeting molecule functional groups remain unlabeled		
			well-defined chemistry possible use of classical solid-phase or solution methods of the peptide synthesis		

**Figure 1.** Schematic structure of a radiopharmaceutical. BFCA can complex a metal and also contains a functional group which forms a covalent linkage to a biological molecule, such as peptide.

tafluorophenyl, *N*-hydroxysuccinimide, and sulfo-*N*-hydroxysuccinimide active esters. The *N*-hydroxysuccinimide esters are very reactive with high selectivity toward aliphatic amines (22, 45). The choice of an active ester to be used for BFCA-peptide bond formation is partly dictated by sheer reactivity, but the ease of coproduct removal is also an important consideration. Thus, for water-insoluble BFCA-peptide conjugates, a succinimide ester coupling is especially convenient because both *N*-hydroxysuccinimide and sulfo-*N*-hydroxysuccinimide are very water-soluble (46, 47) and easy to remove. But for water-soluble BFCA-peptide conjugates *p*-nitrophenyl or pentafluorophenyl esters, which are ether-soluble, may be a better choice (48).

Isothiocyanates, like active esters, react with amino groups of a peptide forming thiourea bonds. Since they react best in the higher pH, they cannot be used with peptides susceptible to alkaline conditions.

The third class are maleimides, which react with thiols and form thioether bonds. The optimum pH for the reaction is near 7. At higher pH maleimides may hydrolyze to form nonreactive maleic acids (49, 50).

Hydrazides are conjugation groups which react with the aldehyde group of a peptide to form a hydrazone-

**Figure 2.** Reaction schemes for BFCA-peptide conjugation.

peptide conjugate. They are suitable for peptides containing 2-amino alcohol structure like in serine, threonine, and hydroxylysine, which can be very rapidly oxidized

by periodate at pH = 7 to generate an aldehyde. The use of a low molar ratio of periodate to peptide minimizes the potential for side-reactions during the oxidation. The formed hydrazones are stable at pH 6–8 for at least 12 h at 22 °C (51).

$\alpha$ -Haloamides are suitable for conjugation with peptides containing a free SH group. Chloroacetyl- or bromoacetyl amides are used (52, 53).

The bifunctional approach is often associated with the term 'pharmacokinetic modifier' (PKM). Liu and Edwards (22) define PKM as a linker between a targeting molecule and a BFCA. PKM is a spacer residue, separating the radionuclide from the binding site of the molecule to minimize the risk of its undesired modification. The use of a linker helps to choose a BFCA and a radionuclide more independently. The most popular linkers are long poly(ethylene glycol) (PEG) or hydrocarbon chains to increase the lipophilicity and polyamino acid sequences, such as polyglycine, to increase the hydrophilicity, as well as esters and disulfides capable of rapid metabolism.

The distinction between chelate methods can be made depending on the sequence of the steps used for the synthesis of a radiolabeled peptide.

**Prelabeling Method.** The pre-labeling method (pre-formed chelate approach) is based on the labeling of a BFCA with its subsequent activation and conjugation, through covalent bonds, to a peptide. In this approach the chemistry of a process is well defined and easily controlled. As the labeling and conjugation steps are separated, it can be ensured that the radionuclide is attached directly to a chelate moiety and the peptide amino groups remain unlabeled (22). However, the pre-labeling of a BFCA may impair the conjugation process and complicate purification of a radiopharmaceutical. The method is time-consuming, so not appropriate for use with short-lived isotopes, generally associated with imaging. As such the prelabeling method is rarely used for synthesis of radiolabeled peptides.

**Postlabeling Method.** The postlabeling method (indirect labeling approach), the most popular approach in the synthesis of radiopharmaceuticals, requires the synthesis of a BFCA–peptide conjugate and is followed by its labeling. In this method BFCA may be attached to N- or C-terminus, as well as to a side chain of a peptide or it can be even incorporated into a peptide backbone. The postlabeling method is characterized by a well-defined chemistry and relative simplicity. For convenient, high yield synthesis of radiopharmaceuticals, applied BFCA should be compatible with the solid-phase or solution methods of peptide synthesis. However, harsh conditions required for effective labeling of conjugates may sometimes cause changes in the amino acid sequence or peptide backbone conformation and even begin the decomposition of the whole radiopharmaceutical (35).

## BIFUNCTIONAL CHELATING AGENTS

BFCAs are used to connect a radionuclide and a targeting molecule to form a radiopharmaceutical. An ideal BFCA should coordinate the radionuclide with a high yield, to form a relatively stable complex. The agent must comply with the nature and oxidation state of a radionuclide and should prevent any accidental changes in its redox potential.

It is important to carefully choose a proper BFCA, as the conjugation with targeting molecule requires specific conditions: pH, temperature, reaction time. The stereochemistry of a BFCA is important when synthesizing radiopharmaceuticals targeting specific receptors.

**Figure 3.** Structure of DTPA and its analogues: (a) DTPA; (b) cDTPA; (c) mDTPA.

**DTPA.** DTPA (*N*<sup>5</sup>-diethylenetriaminopentaacetic acid) belongs to the group of polyaminocarboxy chelates (Figure 3a). It is a strong chelating group, mostly linked with <sup>111</sup>In, a trivalent radionuclide. It can be attached to larger proteins, e.g., albumins and antibodies (49, 50, 54), as well as to small peptides, like somatostatin analogues (55, 56). The conjugation of DTPA with macromolecules has been successfully performed by the use of isobutyl chloroformate as a coupling reagent (57). For small peptides, however, DTPA derivatives such as DTPA bicyclic anhydride (cDTPA) and monoreactive DTPA derivative, 3,6-bis(carboxymethyl)-9-(((2-maleimidoethyl)-carbamoyl)methyl)-3,6,9-triazaundecanedioic acid (mDTPA), have been applied (Figure 3b and 3c).

Hnatowich et al. (54) have developed a simple method of covalent coupling of cDTPA to peptides at their amino groups. The efficiency of this method is relatively high and it has several advantages. The coupling reaction runs in an aqueous solution and is a simple, one-step process. The side product of the reaction, a double substituted DTPA derivative, and unreacted material can be both easily separated from the main product by gel chromatography. The conjugated peptide maintains its affinity toward specific receptors. The sample, purified before the addition of a radionuclide, can be stored and labeled only when required. For peptides containing lysine the conjugation occurs especially at its  $\epsilon$ -amino group, as more basic than N-terminal amino group. The method is therefore inappropriate for somatostatin analogues, as the lysine residue is situated within the active site of the molecule and the conjugation may result in the loss of receptor binding activity. For that reason a modified method, proposed by Bakker et al. (55) for DTPA-octreotide, is used to conjugate the somatostatin analogue with cDTPA. In this approach lysine residue within the active site of the peptide is protected with *tert*-butoxy-carbonyl group (Boc), before the reaction with cDTPA and deprotected after the conjugation (Figure 4). This method enables a selective reaction of the N-terminal amino group with BFCA, whereas the lysine residue within the bioactive site remains unsubstituted.

A monoreactive DTPA derivative, mDTPA, with four carboxy groups protected as *tert*-butyl esters, was introduced by Arano et al. (57) (Figure 5). Since mDTPA possesses only one free carboxy group, the formation of undesired intermolecular linkages with peptides is prevented. High solubility of mDTPA in various solvents makes this BFCA appropriate for both liquid- and solid-phase peptide synthesis.

A great obstacle in the efficient radiolabeling of DTPA conjugates is the presence of trace metals in the prepara-

**Figure 4.** Synthesis of DTPA–octreotide, starting with cDTPA.

tion, as they compete with radionuclides in the process of labeling. For that reason a significant, 40- to 70-fold molar excess of peptide conjugate and ultrapure radionuclide derivative of the highest possible specific activity are required (55).

DTPA conjugates have been shown to form  $^{111}\text{In}$ -chelate structures (Figure 6), which are eight coordinate, using all three amino and four carboxy groups, while the eighth position around the radionuclide is occupied by the amide carbonyl oxygen (58).  $^{111}\text{In}$ –DTPA conjugates possess excellent *in vivo* stability (59–61).

Many research groups put much effort in the synthesis of kinetically stable DTPA–peptide conjugates that form complexes with  $^{90}\text{Y}$  (62). Substitutions, particularly in the carbon atoms of the DTPA backbone, sterically hinder the opening of the chelate ring that must occur during radionuclide complex dissociation and increase the *in vivo* stability of the radiopharmaceutical. The first class of modified DTPA conjugates was constructed by attaching *p*-isothiocyanatobenzyl moiety to one DTPA backbone ethylene group and appending methyl to another ethylene group in the same backbone (Figure 7a,b). The second class of modified DTPA conjugates was developed by replacing one of the ethylene groups by a cyclohexyl moiety (Figure 7c). Such modifications increase the rigidity in the DTPA backbone and the *in vivo* stability of obtained radiopharmaceuticals (62–64). Synthesis of new derivatives constructed on DTPA core has been recently reported (65, 66).

$^{99\text{m}}\text{Tc}$  is less suitable for the labeling of DTPA–peptide conjugates, as this radionuclide, even at high concentrations, has low affinity and poor selectivity to the binding sites of this BFCA (67).

**DOTA.** DOTA (1,4,7,10-tetraazacyclododecane-*N,N,N',N''*-tetraacetic acid) (Figure 8a) and its derivatives proved to be a good alternative for DTPA. They play an important role in clinical applications, as they form

very stable complexes with a variety of trivalent radionuclides, such as  $^{66,67,68}\text{Ga}$ ,  $^{86,90}\text{Y}$ ,  $^{111}\text{In}$ ,  $^{149}\text{Pm}$ ,  $^{177}\text{Lu}$  (68–73) and divalent radionuclides,  $^{27}\text{Mg}$ ,  $^{47}\text{Ca}$ ,  $^{64}\text{Cu}$  (74).

Two different approaches for DOTA conjugation with peptides have been developed. In the first approach one of the four carboxy groups in DOTA is activated to facilitate the reaction with primary amines in the peptide and form a stable amide bond linkage. In the second approach DOTA derivatives with additional side chains are used. A peptide ligand is attached to the side chain of DOTA derivative. Several DOTA derivatives have been synthesized so far, like PA–DOTA ( $\alpha$ -[2-(4-aminophenyl)-ethyl]-1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid) and *p*-NCS-Bz–DOTA ((2-(4-isothiocyanatobenzyl)-1,4,7,10-tetraazacyclododecane-*N,N',N'',N'''*-tetraacetic acid) (Figure 8b and 8c) (69). Recently Eisenwiener et al. (44) have introduced two new DOTA derivatives, DOTASA(*t*-Bu)<sub>4</sub>, (1-(1-carboxy-2-carbo-*tert*-butoxyethyl)-4,7,10-(carbo-*tert*-butoxymethyl)-1,4,7,10-tetraazacyclododecane) and DOTAGA(*t*-Bu)<sub>4</sub>, (1-(1-carboxy-3-carbo-*tert*-butoxypropyl)-4,7,10-(carbo-*tert*-butoxymethyl)-1,4,7,10-tetraazacyclododecane) (Figure 8d), which convenient synthesis is outlined in Figure 9. The conjugation of all DOTA derivatives to a peptide is performed through an amino group of a peptide.

Fully eight coordinate structure has been reported for all DOTA complexes (60) using four amino and four carboxy groups. In the case when one carboxy group is used for conjugation, the amide carbonyl oxygen occupies the eighth position around the radionuclide.

DOTA and derivatives were successfully conjugated to a number of somatostatin analogues, and obtained radiopharmaceuticals had good pharmacological parameters (72–78). DOTA conjugates are especially suitable for radionuclide therapy, as they can be radiolabeled with  $^{67}\text{Ga}$  (75),  $^{90}\text{Y}$  (71, 76), and  $^{111}\text{In}$  (73). De Jong et al. (68) have demonstrated that  $^{90}\text{Y}$ –DOTA conjugates have very good pharmacokinetic properties *in vivo*. However, in these conjugates the chelate is situated closer to the peptide, the labeled conjugate is more rigid and less flexible, which makes binding with the receptor more difficult. Reubi et al. (79) reported the best pharmacological properties for  $^{67}\text{Ga}$ –DOTA complexes. The radionuclide coordination geometry, including the number of uncomplexed carboxy and amino groups, increases the flexibility of a ligand and allows its better adjustment to the receptor binding site.

**TETA.** TETA (1,4,8,11-tetraazacyclotetradecane-1,4,8,11-tetraacetic acid) (Figure 10) is one of the most studied chelating agents for copper in peptide targeted radio-

**Figure 5.** Reaction scheme for synthesis of mDTPA.

**Figure 6.** Possible structure of  $\text{In}^{3+}$ -DTPA-peptide.

**Figure 7.** Structures of DTPA derivatives: (a) 2-(*p*-isothiocyanatobenzyl) diethylenetriaminopentaacetic acid; (b) 2-(*p*-isothiocyanatobenzyl)-6-methyldiethylene-triaminopentaacetic acid (1B4H-DTPA); (c) 2-(*p*-isothiocyanatobenzyl) cyclohexyldiethylene-triaminopentaacetic acid (CHX-DTPA).

therapy. TETA has been successfully used as a BFCA with somatostatin analogues (30).

**NOTA.** NOTA (1,4,7-triazacyclononane-1,4,7-triacetic acid) (Figure 11a), its phosphonate analogue NOTP (1,4,7-triazacyclononane-*N,N,N'*-tris(methylenephosphonic) acid) (Figure 11b) and the monoethyl ester of NOTP, NOTPME (1,4,7-triazacyclononane-*N,N,N'*-tris(methylenephosphonate-monoethyl ester)) (Figure 11c) were studied for possible use in radiopharmaceuticals. Complexes with  $^{67}\text{Ga}$  (80) and  $^{111}\text{In}$  (81) were reported.

A monoreactive NOTA derivative, NODAGA(*t*Bu)<sub>3</sub> (1-(1-carboxy-3-carbo-*tert*-butoxypropyl)-4,7-(carbo-*tert*-butoxymethyl)-1,4,7-triazacyclononane) (Figure 11d) was synthesized by Eisenwiener et al. (82). The synthesis is outlined in Figure 12. This BFCA is useful for the coupling to the N-terminus of peptides on solid-phase and in solution. The NODAGA-peptide conjugates were labeled with  $^{67}\text{Ga}$  and  $^{111}\text{In}$  in high yields and good specific activities. NODAGA-based derivatives carry a spacer function between the BFCA and the peptide which improves the receptor binding affinity.

**HYNIC.** HYNIC (2-hydrazinonicotinic acid) (Figure 13), first described by Abrams et al. (83) has been used as a BFCA for radiolabeling of different groups of molecules, such as  $\gamma$ -globulins (83, 84), chemotactic peptides (85, 86), and somatostatin analogues (87–90). Structural organization of HYNIC determines its application, as it can only occupy one or two coordination sites of the radionuclide. That is why a coligand such as tricine or EDDA (ethylenediaminediacetic acid) should be also coordinated to complete the coordination sphere

**Figure 8.** Structures of DOTA and its derivatives: (a) DOTA; (b) PA-DOTA; (c) *p*-NCS-Bz-DOTA; (d) DOTASA(*t*-Bu)<sub>4</sub>, *n* = 1 and DOTAGA(*t*-Bu)<sub>4</sub>, *n* = 2.

of a radionuclide (91, 92) (Figure 14). The conjugation of coligands helps in modifying the properties of obtained radiopharmaceutical, such as hydrophilicity or pharmacokinetics. However, the requirement for the use of coligands makes the chemistry of the synthesis more complicated, and multiple possible products and side-products can be obtained.

HYNIC-coligand conjugates were reported to have low stability (22). The search for stable HYNIC-coligand complexes is now carried on and phosphines seem to be the most promising coligands so far (92, 93). HYNIC derivatives, together with phosphines and tricine, form ternary complexes [ $^{99\text{m}}\text{Tc}(\text{HYNIC-TM})(\text{tricine})(\text{phosphine})$ ] (TM-targeting molecule). Such complexes are stable in solution, and their hydrophilicity can be modified by changing functional groups attached to phosphine backbone or by substitution of tricine by other glycine derivatives.

HYNIC is often used as a BFCA for somatostatin analogues. The desired amide bond formation should occur between the carboxy group of HYNIC and the N-terminal amino group of a peptide. However, in somatostatin analogues the presence of lysine makes it difficult to obtain a monosubstituted product. Krois et al. (87) have compared available methods of HYNIC-octreotide conjugation, and none of them seemed efficient enough. The method of protecting the lysine amino group with (Boc)<sub>2</sub>O reported by Bakker et al. (55) proved to be unsatisfactory, as the final product was contaminated with Boc-disubstituted derivative, difficult to separate. The activation of HYNIC to *N*-hydroxysuccinimide ester to facilitate the conjugation step, a method suggested by Abrams et al. (83), also produced poor results. An improved method of HYNIC-octreotide conjugation, reported by Krois et al. (87), is based on the incorporation of the chelator at an early stage of *ab ovo* peptide synthesis performed by solution method. That approach produced high yield of conjugate, practically free of any contamination.

**Figure 9.** Synthesis of DOTASA(*t*-Bu)<sub>4</sub> and DOTAGA(*t*-Bu)<sub>4</sub>.

**Figure 10.** Structure of TETA.

**Figure 11.** Structures of NOTA and its derivatives: (a) NOTA, (b) NOTP, (c) NOTPME, (d) NODAGA(*t*-Bu)<sub>3</sub>.

**Multidentate Chelators.** The class of tetradentate chelators includes N<sub>3</sub>S triamidothiol, N<sub>2</sub>S<sub>2</sub> diamidodithiols (94), and N<sub>2</sub>S<sub>4</sub> diaminotetrathiols (26) (Figure 15) and a number of their derivatives, containing sulfur and nitrogen atoms, incorporated into chelating backbones.

N<sub>2</sub>S<sub>4</sub> chelators contain two amino and four thiol donors and they have been used for <sup>99m</sup>Tc- and <sup>186</sup>Re-labeling of antibodies (95, 96). N<sub>2</sub>S<sub>2</sub> containing two amido and two thiol donors have been used for <sup>99m</sup>Tc- and <sup>186</sup>Re-labeling of proteins, peptides, and oligonucleotides. Since most of the N<sub>2</sub>S<sub>2</sub> derivatives form highly lipophilic rhenium and technetium complexes, they are used whenever hydrophobic targeting systems are applied (97). Both N<sub>3</sub>S- and

N<sub>2</sub>S<sub>2</sub>-derived BFCAs form high specific activity complexes, and for that reason they can be used in the preformed chelate labeling method. In case of small molecules (steroids, low molecular weight peptides) these BFCAs complex <sup>186/188</sup>Re in the postconjugation labeling process (28). BFCAs based on N<sub>3</sub>S backbone are used for the synthesis of <sup>168/188</sup>Re radiopharmaceuticals (98).

The most frequently applied BFCAs from that group are MAG<sub>3</sub> (mercaptoacetyl-glycylglycylglycine) and MAG<sub>2</sub>-GABA (mercaptoacetyl-glycylglycyl-γ-butyric acid), containing the spacer groups glycine and GABA, respectively (Figure 16). GABA spacer group is two carbon units longer than glycine; therefore, it may exhibit more useful properties, such as higher yield in radionuclide labeling or better receptor binding due to the changes in intramolecular organization (99–101).

BFCAs listed above have been widely used as metal chelating agents in both diagnostic and therapeutic procedures. Attempts to design new derivatives with improved properties are still under way (66, 102).

## RADIONUCLIDES

Each radionuclide is characterized by a specific coordination chemistry and therefore must be conjugated with a specific BFCA with specific donor atoms and ligand frameworks to retain its own radioactivity.

The selection of an appropriate radionuclide is an inherent determinant in developing any therapeutic radiopharmaceutical. Important factors to consider include half-life of the radioactive nuclide, its mode of decay, and its cost and availability (Table 2). The half-life is a critical factor. For diagnostic imaging the half-life of a radionuclide must be long enough to enable the synthesis of the labeled compound and to facilitate the accumulation in the target tissue, while allowing clear-

ance through the nontarget organs. Ideally, the half-life should be as short as possible to reach these two goals. Radionuclides most commonly used in radiopharmaceuticals range in half-lives from minutes (<sup>62</sup>Cu) to days (<sup>177</sup>Lu).

**Copper (<sup>64</sup>Cu).** There are two radionuclides of copper used in the radiopharmaceutical labeling. <sup>64</sup>Cu ( $t_{0.5}$  = 12.7 h) is a  $\beta^+$ -, 0.653 MeV (17.4% abundance), and  $\beta^-$ -emitter, 0.579 MeV (39% abundance), and it decays by electron capture. A good review on the biological chemistry of copper is a book by Linder (104).

**Gallium (<sup>66</sup>Ga, <sup>67</sup>Ga, <sup>68</sup>Ga).** Gallium radionuclides can be either used for  $\gamma$ -scintigraphy or positron emission tomography (PET) imaging. <sup>66</sup>Ga ( $t_{0.5}$  = 9.5 h) is a medium half-life  $\beta^+$ -emitting radionuclide obtained from <sup>66</sup>Zn(p,n)<sup>66</sup>Ga cyclotron, applied in the limited number of cases. <sup>67</sup>Ga ( $t_{0.5}$  = 78.3 h) is produced in <sup>68</sup>Zn(p,2n)<sup>67</sup>Ga cyclotron. <sup>68</sup>Ga ( $t_{0.5}$  = 1.1 h) is obtained from the <sup>68</sup>Ge/<sup>68</sup>Ga generator and it has been used in a limited number of clinical studies (105, 106).

**Yttrium (<sup>86</sup>Y, <sup>90</sup>Y).** There are two radionuclides of yttrium used in the radiopharmaceutical labeling. <sup>86</sup>Y ( $t_{0.5}$  = 14.7 h) is a  $\beta^+$ -emitting radionuclide, often used as an equivalent for <sup>90</sup>Y in the PET imaging. <sup>90</sup>Y ( $t_{0.5}$  = 64 h) is a  $\beta^-$ -emitter, which is probably the most frequently used radionuclide for targeted radiotherapy in human studies. It has a relatively high energy transfer and therefore can be used for imaging of bulky disease sites of solid tumors. <sup>90</sup>Y can be relatively easily obtained in a high-specific activity from <sup>90</sup>Sr (107–109). <sup>90</sup>Y is also available as a GMP commercial product.

**Technetium (<sup>99m</sup>Tc).** <sup>99m</sup>Tc is used in about 85% of all diagnostic applications. It has ideal properties for diagnostic imaging. The half-life of 6 h is long enough to synthesize the <sup>99m</sup>Tc-labeled radiopharmaceuticals and perform imaging studies, yet short enough to minimize the radiation dose to a patient. <sup>99m</sup>Tc emits a 140 keV  $\gamma$ -ray with 89% abundance which is close to optimum for imaging with the present  $\gamma$  cameras. This energy is sufficient for emerging from inside the body and for imaging internal organs. <sup>99m</sup>Tc is readily available at low costs from its parent nuclide <sup>99</sup>Mo ( $t_{0.5}$  = 66 h) from a <sup>99</sup>Mo/<sup>99m</sup>Tc generator. At the concentration levels used for imaging ( $<10^{-6}$  M) neither its  $\gamma$ -radiation nor the soft  $\beta$ -decay is hazardous (110).

**Indium (<sup>111</sup>In).** <sup>111</sup>In has the half-life of 67 h which makes this isotope ideal for labeling immunoglobulins, where imaging is performed over intervals of several days. This nuclide decays by electron capture with emission of  $\gamma$ -photons of 173 and 247 keV (89% and 95% abundance, respectively), which allows its use in  $\gamma$ -scintigraphy.

The first peptide radiopharmaceutical approved for clinical use was the <sup>111</sup>In labeled somatostatin analogue OctreoScan. Nevertheless, because of its less favorable half-life, <sup>111</sup>In is inferior to <sup>99m</sup>Tc for diagnosis. <sup>111</sup>In is often used as an equivalent for <sup>90</sup>Y in scintigraphic

imaging in humans by using dosimetry cameras, since <sup>90</sup>Y radionuclide does not emit  $\gamma$ -rays (32).

**Promethium (<sup>149</sup>Pm).** <sup>149</sup>Pm is a moderate energy  $\beta^-$ -emitter (1.07 MeV, 95.9% abundance) with a half-life of 53 h. <sup>149</sup>Pm also emits a low abundance of an imageable  $\gamma$ -ray (286 keV, 3%) that may allow in vivo tracking of the therapeutic dose (111).

**Lutetium (<sup>177</sup>Lu).** The most frequently used radionuclide of lutetium is <sup>177</sup>Lu ( $t_{0.5}$  = 160.8 h) which is a  $\beta^-$ - and also a  $\gamma$ -emitter (103).

#### RADIOPHARMACEUTICALS BASED ON SMALL PEPTIDES

Small peptides play a very important role in vivo, where they regulate many physiological processes (Table 3). Low molecular weight peptides have attracted much attention recently as radiopharmaceuticals due to their relatively low immunogenicity, good pharmacokinetic properties, and binding affinities. They are relatively easier to synthesize and modify than larger molecules (112). Many radiopharmaceuticals based on small peptides have been used as diagnostics for clinical purposes (Table 4). They have been radiolabeled with various radionuclides (Table 5).

Because of the lack of tertiary structure, small peptides are less susceptible to a loss of integrity through labeling conditions. However, when minor modifications occur in their structure, they can result in important changes in the lipophilicity and charge with consequences for biodistribution and kinetics.

The physicochemical properties of the radiopharmaceuticals based on small peptides, including binding affinity in vivo, are determined not only by the nature of

the targeting molecule. They are also influenced by the radionuclide–BFCA complex properties, as a BFCA contributes greatly to the overall size and molecular weight of a conjugate. Furthermore, the incorporation of a spacer-linker between the radionuclide–BFCA complex and a peptide can also modify the binding interactions (22, 142, 143).

**Somatostatin Analogues.** The peptide that has attracted the greatest interest as an imaging agent is somatostatin (SST). Somatostatin is a tetradecapeptide that regulates the secretion of numerous hormones. In addition, receptors for somatostatin are expressed on a variety of human tumors and that fact has become a basic

principle for the use of somatostatin analogues in radiochemistry and tumor imaging (147–150).

Although the first report of *in vivo* imaging with a somatostatin analogue appeared in 1976 (151), further development was delayed because the native peptide is rapidly degraded by plasma and tissue proteases. In years that followed somatostatin analogues that are more resistant to biological degradation have been developed.

The cyclic octapeptide, octreotide (152), is a good replacement for somatostatin in the clinical application, since it shows similar bioactivity, it has a relatively high metabolic stability and its pharmacokinetic properties are better. Octreotide is less susceptible to enzymatic degradation *in vivo* due to the incorporation of the N-terminal D-Phe and the C-terminal amino alcohol, Thr(ol), into its molecule (153, 154).

The pharmacophoric group in octreotide is a sequence of four amino acids: -Phe<sup>3</sup>-D-Trp<sup>4</sup>-Lys<sup>5</sup>-Thr<sup>6</sup>-, organized into a  $\beta$ -turn conformation by a disulfide bond, formed between cysteine residues at the N- and C-terminus of the peptide backbone (112).

Many octreotide analogues have been synthesized and some of them proved to be useful as targeting molecules (113). Their structures are shown in Figure 17.

Somatostatin radiopharmaceuticals which have received the most attention were octreotide conjugates with DTPA, DOTA (132–136), and HYNIC (115–118, 137) (Table 6). Since the *in vivo* stability of DOTA octreotide conjugates is higher than DTPA derivatives, the former draw more attention of research groups.

<sup>64</sup>Cu-TETA-octreotide and <sup>64</sup>Cu-TETA-Tyr<sup>3</sup>-octreotide can be used to detect somatostatin receptor-positive tumors in humans. Their favorable dosimetry and pharmacokinetics indicate that they are promising radiopharmaceuticals for PET imaging of patients with endocrine tumors. The radiotherapy results, along with absorbed dose estimates to target and clearance organs, confirm that <sup>64</sup>Cu-labeled somatostatin analogues warrant continued consideration as agents for targeted radiotherapy (152, 153).

**Bombesin Analogues.** Bombesin (BN), a 14-amino acid peptide originally isolated from frog skin and its mammalian equivalent, a 27-amino acid gastrin-releas-

ing peptide (GRP) (157, 158) belong to the bombesin family of peptides. Receptors for bombesin/GRP are expressed in the central nervous system and peripheral tissues such as intestines or pancreas. They are also present on tumors, which include lung, prostate, breast, gastric, colon, and pancreatic cancer. Since bombesin/GRP peptides function in most cases as autocrine growth factors, the disruption of bombesin/GRP triggered biochemical pathways would result in the inhibition of cancer growth. This is the main principle of bombesin/GRP analogues application in tumor diagnosis (159–161).

Several attempts have been made to synthesize and evaluate the properties of bombesin/GRP analogues as future radiopharmaceuticals. Baidoo et al. (119) have synthesized N<sub>2</sub>S<sub>2</sub>-bombesin derivative, subsequently labeled with <sup>99m</sup>Tc, which proved to be a promising diagnostic agent. Bombesin-DTPA conjugates labeled with <sup>99m</sup>Tc have also been reported (162, 163).

**Vasoactive Intestinal Peptide Analogues.** Vasoactive intestinal peptide (VIP) is a 28-amino acid neuroendocrine mediator, one of the inhibitory neurotransmitters in the gut (62). VIP receptors are expressed on central nervous system and pancreatic tissues, as well as on adenocarcinomas.

The synthesis of VIP analogue conjugates seems complicated, since both N- and C-terminus play an important role and their substitution effects intrinsic activity and receptor binding, respectively. However, the <sup>99m</sup>Tc-radio-labeled derivatives of VIP have been reported (124, 164).

**RGD-Containing Peptides and RGD Peptidomimetics.** Peptides containing RGD (Arg-Gly-Asp) sequence interact *in vivo* with integrins, adhesion molecules present on cell membranes of most tissues, responsible for platelet adhesion and activation and leukocyte mobility, as well as cancer cell dissemination. As a result, RGD-containing peptides and RGD peptidomimetics bind to cancer cells and may be used as tumor diagnostic agents (123). Peptides with RGD sequence bind also to glycoprotein IIb/IIIa receptors expressed on activated platelets and are used as thrombus imaging agents or antithrombotics (165–169).

A group of potent RGD-containing analogues, candidates for thrombus imaging agents, was reported (170–172). To minimize the effect of <sup>99m</sup>Tc-labeling on RGD sequence integrity, Jackson et al. (170) have incorporated spacers between a BFCA and a targeting molecule. New thrombus imaging agents contain modified RGD sequences (52, 165, 173), so that the amino acid residue in the peptidomimetic triplet forms a N<sub>2</sub>S<sub>2</sub> group and functions also as a BFCA.

**$\alpha$ -Melanocyte Stimulating Hormone.** Labeled analogues of a tridecapeptide  $\alpha$ -melanocyte stimulating hormone ( $\alpha$ -MSH) are used for melanoma tumor imaging, as its receptors are overexpressed on the membranes of malignant cells (174–176). The most promising derivatives so far are <sup>111</sup>In-labeled conjugates with DTPA, as well as analogues containing N<sub>3</sub>S chelating moiety, labeled with <sup>99m</sup>Tc at the N-terminus (139, 140, 177).

**Neurotensin Analogues.** Neurotensin (NT) is a 13-amino acid neurotransmitter in the central nervous system and a local hormone stimulating growth functions. Neurotensin analogues are used for detection of tumors, such as meningiomas or pancreas, prostate, lung, and colon carcinomas. So far, DTPA conjugates with NT and analogues were synthesized (141, 142).

**Substance P Analogues.** The receptors for substance P (SP), an 11-amino acid neuromodulator and neurotransmitter, are overexpressed on breast, thyroid, and

glial tumors (143). DTPA conjugates of SP analogues, complexed with  $^{111}\text{In}$ , were reported (127, 128).

**Chemotactic Peptides.** *N*-Formylmethionyleucylphenylalanine (fMLF) is a microbial product, which binds to receptors present on inflammatory cells, granulocytes, and leukocytes.  $^{99\text{m}}\text{Tc}$ -HYNIC and  $^{111}\text{In}$ -DTPA conjugates were synthesized by means of SPPS method and evaluated as potential infection and inflammation imaging agents (144).

## CONCLUSIONS

Nature has designed peptides to regulate many body functions. The concept of designing radiopharmaceuticals based on small peptides is very promising. In the past decade radiolabeled peptide-based radiopharmaceuticals have become an important class of imaging agents for the detection of a wide variety of tumors, as well as thrombosis, infection, and inflammation. The major advantage of developing peptide-based radiopharmaceuticals is that, once the receptor-binding sequence of the peptide molecule is identified, it may be readily synthesized and modified according to pharmacokinetic requirements.

The application of radiolabeled peptides for diagnostic imaging and therapy is rapidly gaining importance in nuclear medicine. Biologically active molecules that selectively interact with specific cell types are attractive vehicles for the delivery of radioactivity to target tissues. The typical approach for imaging a cellular receptor is to synthesize appropriate radiolabeled peptide analogues that possess high binding affinity for the receptor of interest. Various receptors are overexpressed on particular tumor types, and peptides binding to these receptors can be used to visualize tumor lesions scintigraphically.

Small radiolabeled synthetic peptides are preferred over macromolecules such as proteins and antibodies for imaging applications, since they present several advantages. Small peptides can be easily synthesized. They can withstand harsher chemical conditions for radiolabeling. They penetrate tumors more easily than bigger molecules, and they are less likely to induce an immunogenic response.

However, the negative aspects of use of radiolabeled peptides should also be pointed out. Among them one should take into consideration a low tumor uptake relative to a total dose and a normal tissue uptake, very rapid targeting and clearance which creates the necessity to use shorter-lived isotopes. Other pharmacokinetic and toxicity issues still need to be addressed.

The synthesis of radiolabeled peptides is not an easy process. Binding of a radionuclide to a peptide can be achieved either directly or through a bifunctional chelating agent (BFCA). In the latter approach two methods can be distinguished: prelabeling method, based on the labeling of BFCA with its subsequent conjugation to a peptide and postlabeling method which requires the synthesis of BFCA-peptide conjugate, followed by its labeling. The postlabeling chelate method is the most popular approach in the synthesis of radiopharmaceuticals. Several BFCAs have been designed so far. The most popular are DTPA, DOTA, NOTA, and HYNIC. Conjugation of a BFCA to a peptide is not easy to perform considering multiple functional groups in a BFCA, as well as in a peptide molecule. Not many radiopharmaceuticals based on bioactive peptides have been in clinical use so far. The majority of them are somatostatin analogues. Further studies must be undertaken to explain the chemistry of radiolabeling and to develop better methods

of BFCA-peptide conjugate synthesis. The development of new radiopharmaceuticals is a multidisciplinary effort and requires the collaboration from scientists in organic, inorganic, and analytical chemistry, as well as biochemistry and nuclear medicine.

## Synthesis of Antisense Oligonucleotides Conjugated to a Multivalent Carbohydrate Cluster for Cellular Targeting

Martin A. Maier,<sup>†</sup> Constantin G. Yannopoulos,<sup>‡</sup> Nazim Mohamed,<sup>‡</sup> Arlene Roland,<sup>‡</sup> Hans Fritz,<sup>§</sup> V. Mohan,<sup>†</sup> George Just,<sup>‡</sup> and Muthiah Manoharan<sup>\*,†</sup>

Department of Medicinal Chemistry, Isis Pharmaceuticals, Inc., 2292 Faraday Avenue, Carlsbad, California 92008, Department of Chemistry, McGill University, 801 Sherbrooke Street West, Montreal, PQ H3A2K6, Canada, and Beckman Coulter GmbH, Europark Fichtenhain B13, D-47807 Krefeld, Germany. Received April 10, 2002; Revised Manuscript Received July 18, 2002

Carrier-mediated delivery holds great promise for significantly improving the cellular uptake and therefore the therapeutic efficacy of antisense oligonucleotides in vivo. A multivalent carbohydrate recognition motif for the asialoglycoprotein receptor has been designed for tissue- and cell-specific delivery of antisense drugs to parenchymal liver cells. To combine low molecular weight with high receptor affinity, the synthetic ligand contains three galactosyl residues attached to a cholane scaffold via  $\epsilon$ -aminocapramide linkers. Three-dimensional structural calculations indicate that this unique design provides proper spacing and orientation of the three galactosyl residues to accomplish high affinity binding to the receptor. Covalent conjugation of the bulky carbohydrate cluster to oligonucleotides has been achieved by solid-phase synthesis using low-loaded macroporous resins and optimized synthesis protocols.

### INTRODUCTION

Specific inhibition of a gene through hybridization of a short single-stranded oligonucleotide (ON)<sup>1</sup> to complementary mRNA to prevent translation is known as the antisense strategy (1–3). This therapeutic technology originates from the specific molecular recognition event between the mRNA of the gene to be inhibited and the synthetic oligonucleotide drug. In addition to this key pharmacodynamic process, many pharmacokinetic processes must occur for gene inhibition to result. Between delivery into the patient's body and degradation or inhibition of translation of the target mRNA, the success of this drug development technology relies on many receptor–ligand recognition processes.

Unmodified ONs<sup>1</sup> lack stability against enzymatic degradation and, due to their size and polyanionic character, suffer from poor cellular uptake. Under in vivo conditions they are cleared rapidly from the body through renal excretion. To address these problems, numerous modifications have been introduced (4–7). Most, however, simply alter the chemical and physicochemical properties of the nucleic acids and enhance the biological efficacy of the derivatives by increasing their nuclease stability, binding affinity, and overall uptake. On the other hand, tissue- and cell-specific drug targeting can only be achieved by employing carrier-drug complexes or conju-

gates that contain a ligand recognized by a receptor on the target cell. Carbohydrate-based conjugates allow targeting of a certain class of cell membrane receptors that are referred to as lectins (8, 9). These receptors recognize a specific carbohydrate motif and internalize their ligands by endocytosis.

The ASGP-R<sup>1</sup> first identified by Pricer and Ashwell (10) is specifically located on parenchymal liver cells, i.e., hepatocytes, and recognizes terminal galactose or lactose residues (9). In the case of lactose, the glucose moiety functions as a tether and the galactose serves as the ligand. The ligands are internalized via receptor-mediated endocytosis (11) and transferred to lysosomes (12). On the basis of previous binding studies with isolated glycoproteins and glycopeptides, various synthetic cluster galactosides have been prepared and used to elucidate the structural requirements for high affinity binding to the receptor. The studies have demonstrated that the binding affinity of a carbohydrate ligand to the ASGP-R is highly influenced by the number and orientation of the

<sup>1</sup> Abbreviations: ONs, oligonucleotides; ASGP-R, asialoglycoprotein receptor; YEE(ahGalNAc)<sub>3</sub>, Tyr-Glu-Glu-(aminohexyl-*N*-acetylgalactosamine)<sub>3</sub>; CI, chemical ionization; ES-MS, electrospray mass spectrometry; TEA, triethylamine; DMT-Cl, 4,4'-dimethoxytrityl chloride; BOP, benzotriazol-1-yloxytris(dimethylamino)phosphonium hexafluorophosphate; HOBT, 1-hydroxybenzotriazole; HOSu, *N*-hydroxysuccinimide; tBDPSiCl, *tert*-butyldiphenylchlorosilane; DIEA, *N,N*-diisopropylethylamine; HATU, *O*-(7-azabenzotriazol-1-yl)-1,1,3,3-tetramethyluronium hexafluorophosphate; DMT/Fmoc, 9-fluorenylmethoxycarbonyl; CPG, controlled pore glass; ETT, 5-ethylthio-1*H*-tetrazole; PS-PEG, polystyrene poly(ethylene glycol); PTOs, phosphorothioate oligonucleotides; CGE, capillary gel electrophoresis; 2'-*O*-MOE, 2'-*O*-(2-methoxyethyl).

sugar residues, while the aglycon part plays a minor role in ligand recognition (13, 14). A dramatic increase in binding affinity was observed when mono- and triantennary galactosides were compared; this led to the term 'cluster effect' (15, 16). Furthermore, the distance between the vicinal sugar residues seems to have great influence on the binding. Elongation of the spacer from 4 to 20 Å led to a 2000-fold increase in the binding affinity of a synthetic galactoside cluster (17).

Several different approaches have been used to enable the glyco-targeted delivery of nucleic acids to hepatocytes. Wu and Wu developed a DNA carrier system based on a soluble noncovalent complex between nucleic acids and an ASGP-poly-L-lysine conjugate (18, 19). Polylysine covalently linked to asialoorosomucoid complexed with ON facilitated uptake of the ON into human hepatocellular carcinoma (HepG2) cells. In another noncovalent approach, DNA electrostatically bound to galactosylated polyethylenimine was used for *in vitro* gene delivery (20). Transfection with these complexes was found to be highly efficient and selective for hepatocytes. Similarly, additional coating of neutral lipopolyamine-condensed nucleic acids with lipids bearing a triantennary galactosyl residue drives the nucleolipidic particles to the asialoglycoprotein receptor of human hepatoma HepG2 cells (21, for a review of ligand-mediated gene delivery see ref 22). Transfection increases approximately 1000-fold with 25% galactolipid. Covalent conjugates of antisense ONs and ASGP were prepared via disulfide linkages and were found to exhibit an increased biological activity compared to the noncovalent complexes (23).

Chemically and structurally homogeneous conjugates have been prepared by covalent attachment of ONs to multivalent synthetic galactoside clusters (24, 25). Hangel et al. reported a 20- to 40-fold enhancement in cellular uptake in HepG2 cells when methylphosphonate ONs were conjugated to the triantennary *N*-acetylgalactosamine neoglycopeptide YEE(ahGalNAc)<sub>3</sub> (Figure 1a). This glycotriptide was reported to bind to Gal/GalNAc receptor sites on hepatocytes with a *K<sub>d</sub>* of 7 nM. Duff et al. showed that oligonucleotide phosphorothioates conjugated to this glycotriptide sequence specifically suppressed (greater than 90% inhibition) the integrated HBV viral expression in hepatoma cells at 1 μM concentration (26). Compared to the unconjugated compound, this was an increase in efficacy of at least 20-fold. Moreover, no toxicity was observed in the entire concentration range studied (1 to 20 μM). The studies indicated that the cellular delivery was not affected by the backbone charge of the ONs, as conjugates of both anionic oligodeoxyphosphorothioates and neutral oligodeoxymethylphosphonates showed a 20- to 40-fold increase in cellular uptake. *In vivo* experiments in mice showed rapid and high uptake of the conjugate in the liver after tail-vein injection (26).

More recently, improved targeted delivery of oligonucleotides to parenchymal liver cells has been demonstrated by Biessen et al. (25, 27). The ONs were conjugated to the ligand L<sub>3</sub>G<sub>4</sub> (Figure 1b) for the ASGP receptor. *In vitro* uptake studies and confocal laser scan microscopy studies demonstrated that L<sub>3</sub>G<sub>4</sub>-conjugated ONs were far more efficiently bound to and taken up by parenchymal liver cells than nonderivatized ONs. *In vivo* studies in rats showed that hepatic uptake was greatly enhanced from 19% for the unconjugated oligonucleotide to 77% of the injected dose after glycoconjugation. Importantly, accumulation into parenchymal liver cells was improved almost 60-fold after derivatization with

**Figure 1.** Carbohydrate clusters reported for liver cell specific targeting.

L<sub>3</sub>G<sub>4</sub>, and uptake has been attributed to the asialoglycoprotein receptor.

In the present work, the synthesis of a low molecular weight galactoside cluster (Gal<sub>3</sub>Chol) and its covalent conjugation to antisense ONs is described (28, 29). The chemically and structurally defined conjugates were made for targeted delivery to hepatocytes. The unique design of the carrier is based on structural features of known high affinity ligands for the ASGP-R and involves three β-aminogalactosyl residues attached to a rigid cholane scaffold via ε-aminocapramide linkers. In contrast to the reported glycopeptide approaches (Figure 1a/b), the rigid steroid scaffold was chosen to achieve a proper preorganization of the galactose residues and to minimize the loss in receptor binding due to entropic effects (30, 31). To circumvent solution phase conjugation, which generally requires high excess of valuable glycosylated carrier and laborious postsynthetic purification steps, we developed a solid-phase strategy for the conjugation of the carbohydrate cluster to the antisense ONs. The conjugation is compatible to the chemistry of oligonucleotide synthesis.

## EXPERIMENTAL PROCEDURES

**Materials.** Low resolution CI,<sup>1</sup> EI, and FAB mass spectra were obtained on a KRATOS MS 25RFA spectrometer in the direct-inlet mode. High-resolution FAB mass spectra were obtained on a ZAB 2F HS spectrometer from the McGill Biomedical Spectrometry Unit in the direct inlet mode. Positive mode ES-MS<sup>1</sup> of the carbohydrate cluster was performed on a Fisons VG Quattro II spectrometer from the McGill Biomedical Spectrometry Unit. Negative mode ES-MS of the carbohydrate cluster-oligonucleotide conjugates was performed on a Hewlett-Packard 1100 MSD Electrospray Mass

Spectrometer. Melting points were determined on a Gallenkamp block and are uncorrected. Thin-layer chromatography was performed using Kieselgel 60 F<sub>254</sub> aluminum-backed plates (0.2 mm thickness). Spots were visualized by UV and then by dipping in solution A followed by heating. (Solution A: Ammonium molybdate (2.5 g), ceric sulfate (1.0 g), and 10 mL of concentrated sulfuric acid in 100 mL of distilled water). <sup>1</sup>H NMR spectra were recorded on JEOL CPF 270 and Varian UNITY 500 spectrometers at 270 and 500 MHz, respectively. Peak assignments were made with homonuclear spin (H–H) decoupling experiments and COSY. <sup>13</sup>C NMR spectra were recorded on JEOL CFP 270 and Varian UNITY 500 spectrometers at 67.9 and 125.7 MHz, respectively. Peak assignments were made with 2D-heteronuclear correlation and 2D-heteronuclear Multiple Quantum Coherence spectroscopy. <sup>31</sup>P NMR spectra were recorded at 200 MHz on a Varian Gemini 200 Spectrometer. Spin multiplicities are given with the following abbreviations: s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet. All air sensitive reactions were carried out under argon flow with freshly distilled solvents (BDH grade). Pyridine was refluxed for 4 h with fine BaO and distilled over granular BaO under N<sub>2</sub>. TEA<sup>1</sup> and acetonitrile were distilled from CaH<sub>2</sub>. Methanol was distilled from magnesium. Anhydrous DMF was purchased from Aldrich. THF was distilled from sodium benzophenone ketyl. Dimethoxyethane was distilled from sodium benzophenone ketyl. Dry acetone was distilled from anhydrous calcium sulfate. The following chemicals were purchased from Aldrich: D-galactose, sodium azide, tetrabutylammonium hydrogen sulfate, hydrogen bromide (30%) in acetic acid, acetic anhydride, DMT-Cl,<sup>1</sup> DMAP, BOP,<sup>1</sup> citric acid, succinic anhydride, triphosgene, borane–THF complex (1 M in anhydrous THF), HOBT,<sup>1</sup> HOSu,<sup>1</sup> palladium on carbon (10%). tBDPSiCl,<sup>1</sup> DIEA<sup>1</sup> and cholic acid were purchased from Fluka (Milwaukee, WI) and HATU<sup>1</sup> was obtained from Applied Biosystems (Foster City, CA). The DMT/Fmoc<sup>1</sup> precursor 1-O-DMT-6-N–Fmoc-2-hydroxymethylhexane was provided by Clontech Labs (Palo Alto, CA). CPG<sup>1</sup> supports with pore sizes of 2000 Å and 3000 Å and ETT<sup>1</sup> were purchased from Glen Research (Sterling, VA). Macroporous aminofunctionalized polystyrene was obtained from Amersham-Pharmacia (Piscataway, NJ) and the PS-PEG<sup>1</sup> copolymer (TentaGel) from Rapp Polymere (Tübingen, Germany). The other reagents used for solid-phase synthesis were purchased from Applied Biosystems.

**Pentaacetyl-D-galactose 1.** To a solution of D-galactose (3 g, 16.65 mmol) in dry pyridine (33 mL) at 0 °C under Ar was slowly added acetic anhydride (31.5 mL, 333 mmol). The reaction mixture was stirred at 0 °C for 1 h before a catalytic amount of DMAP (200 mg, 1.67 mmol) was added. As the reaction mixture was allowed to reach rt, the reaction became slightly exothermic. After 6 h, the clear yellow mixture was slowly poured into 500 mL of fast stirring ice–water, giving a sticky solid. After ethyl acetate extraction (75 mL), evaporation of the solvent, and coevaporations with dry toluene, acetylated galactose **1** was obtained as an oil (5.77 g, 89%). <sup>1</sup>H NMR (270 MHz, CDCl<sub>3</sub>) δ 6.34 (br s, <sup>3</sup>J<sub>1'–2'</sub> = 1.2 Hz, 1H) H1'; 5.46–5.47 (m, 1H) H2'; 5.29–5.31 (m, 2H) H3' and H4'; 4.29–4.33 (m, 1H) H5'; 4.02–4.10 (m, 2H) H6a' and H6b'; 1.96–2.12 (4 × br s, 15H) acetyl H's. <sup>13</sup>C NMR (67.9 MHz, CD<sub>3</sub>OD) δ [170.3, 170.1, 170.1, 169.8] (4 s) all C=O C's, 89.7 C-1', 68.7, 67.4, 67.3, 66.4, 61.2, [20.9, 20.6, 20.6, 20.6, 20.5] all acetyl C's. LRMS (CI/NH<sub>3</sub>) *m/e*: 408 ([M + NH<sub>3</sub>]<sup>+</sup>, 12.2), 331 (100). *R<sub>f</sub>* = 0.71 in 10% methanol/ethyl acetate.

**1-α-Bromo-2,3,4,6-tetraacetyl-D-galactose 2.** Acetylated galactose **1** (5.77 g, 14.7 mmol) was dissolved in 20 mL of a solution of HBr in acetic acid (30% w/w, 14.7 mmol). After 1 h, all the acetic acid was evaporated and coevaporated with dry toluene. Bromogalactoside **2** was obtained as a brown oil (5.69 g, 94%). Due to instability of bromogalactoside, no further purification was done. <sup>1</sup>H NMR (270 MHz, CDCl<sub>3</sub>) δ 6.66 (d, <sup>3</sup>J<sub>1'–2'</sub> = 3.9 Hz, 1H) H1'; 5.45–5.48 (m, 1H) H4'; 5.36 (dd, <sup>3</sup>J<sub>3'–2'</sub> = 10.6 Hz, <sup>3</sup>J<sub>3'–4'</sub> = 3.2 Hz, 1H) H3'; 5.00 (dd, <sup>3</sup>J<sub>2'–1'</sub> = 3.9 Hz, <sup>3</sup>J<sub>2'–3'</sub> = 10.6 Hz, 1H) H2'; 4.41–4.46 (m, 1H) H5'; 4.05–4.10 (dddd, <sup>2</sup>J<sub>6b'–6a'</sub> = 11.3 Hz, <sup>3</sup>J<sub>6b'–5'</sub> = 6.2 Hz, <sup>3</sup>J<sub>6a'–5'</sub> = 6.8 Hz, 2H) H6a' and H6b'; [2.09 (s); 2.05 (s); 1.99 (s); 1.95 (s)] 12 H, all acetyl H's. <sup>13</sup>C NMR (67.9 MHz, CDCl<sub>3</sub>) δ [170.2, 169.9, 169.8, 169.7] all C=O C's, 88.3 C-1', 71.1, 68.0, 67.8, 67.0, 60.9, [20.7, 20.6, 20.6, 20.6, 20.5] all acetyl C's. LRMS (CI/NH<sub>3</sub>) *m/e*: 412 ([M + H]<sup>+</sup>, 1.4), 169 (100).

**1-β-Azido-2,3,4,6-tetraacetyl-D-galactose 3.** To a solution of bromogalactoside **2** (5.69 g, 13.8 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (57 mL) at room temperature was added NaN<sub>3</sub> (4.5 g, 69.1 mmol), tetrabutylammonium hydrogen sulfate (4.7 g, 13.8 mmol) and 57 mL of a saturated solution of NaHCO<sub>3</sub>. The reaction mixture was stirred vigorously at room temperature for 3 h and diluted with ethyl acetate (500 mL). The organic layer was washed with 200 mL of a saturated solution of NaHCO<sub>3</sub> and evaporated under reduced pressure. Azidogalactoside **3** was obtained as a pale yellow solid (5.02 g, 97%). Recrystallization from methanol yielded **3** as white crystals. mp 94–96 °C (reported: 103–104°). <sup>1</sup>H NMR (270 MHz, CDCl<sub>3</sub>) δ 5.37 (dd, <sup>3</sup>J<sub>4'–3'</sub> = 3.3 Hz, <sup>3</sup>J<sub>4'–5'</sub> = 1.1 Hz, 1H) H4'; 5.12 (dd, <sup>3</sup>J<sub>2'–1'</sub> = 8.6 Hz, <sup>3</sup>J<sub>2'–3'</sub> = 10.4 Hz, 1H) H2'; 5.00 (dd, <sup>3</sup>J<sub>3'–2'</sub> = 10.4 Hz, <sup>3</sup>J<sub>3'–4'</sub> = 3.3 Hz, 1H) H3'; 4.56 (d, <sup>3</sup>J<sub>1'–2'</sub> = 8.6 Hz, 1H) H1'; 4.11–4.13 (m, 2H) H5' and H-6b'; 3.95–4.00 (m, 1H) H-6a'; [2.12 (s); 2.04 (s); 2.01 (s); 1.94 (s)] 12 H, all acetyl H's. <sup>13</sup>C NMR (67.9 MHz, CDCl<sub>3</sub>) δ [170.3, 170.1, 169.9, 169.3] all C=O C's, 88.2, 72.8, 70.6, 68.1, 66.9, 61.2, [20.6, 20.6, 20.6, 20.6] all acetyl C's. LRMS (CI/NH<sub>3</sub>) *m/e*: 391 ([M + NH<sub>3</sub>]<sup>+</sup>, 34.5), 331 (100). *R<sub>f</sub>* = 0.48 in ethyl acetate/hexanes (1:1).

**1-β-Amino-2,3,4,6-tetraacetyl-D-galactose 4.** Azidogalactoside **3** (2.61 g, 6.98 mmol) was dissolved with 25 mL of methanol in a 100 mL hydrogenation flask. After 10–15 min of Ar purging, Pd on charcoal (10% w, 500 mg) was added. Under 40 p.s.i of H<sub>2</sub>, the reaction was allowed to proceed for 1 h. After filtration and evaporation, aminogalactoside **4** was obtained as a pale yellow oil (2.40 g, quantitative). <sup>1</sup>H NMR (270 MHz, CDCl<sub>3</sub>) δ 5.37–5.39 (m, 1H) H1'; 4.98–5.03 (m, 2H) H2' and H3'; 4.06–4.16 (m, 3H) H4', H5', and H6b'; 3.82–3.90 (m, 1H) H6a'; [2.13; 2.06; 2.03; 1.97] 4 (s), 12 H, all acetyl H's. <sup>13</sup>C NMR (67.9 MHz, CDCl<sub>3</sub>) δ [170.5, 170.4, 170.3, 170.1] all C=O C's, 85.3, 85.3, 71.5, 71.3, 69.8, 67.6, 61.8, [20.9, 20.79, 20.74, 20.67] all acetyl C's. LRMS (EI) *m/e*: 347 ([M]<sup>+</sup>, 51.4), 331 (100). *R<sub>f</sub>* = 0.08 in ethyl acetate/hexanes (1:1).

**1-(N-Carboxybenzyl-ε-aminocaproamidyl)-2,3,4,6-tetraacetyl-D-galactose 5.** To a solution of dry N-Cbz-ε-aminocaproic acid (1.93 g, 7.28 mmol) in dry DMF (3 mL) at room temperature under Ar were added BOP reagent (3.22 g, 7.28 mmol), 1-HOBT (0.98 g, 7.28 mmol), and TEA (1.47 mL, 10.59 mmol). The reaction mixture was stirred vigorously at room temperature for 30 min before addition of aminogalactoside **4** (2.3 g, 7.28 mmol). After 36 h, the reaction mixture was diluted with ethyl acetate (150 mL). The organic layer was washed with a saturated solution of NaHCO<sub>3</sub> (50 mL) and a 10% aq citric acid solution (50 mL) and dried under reduced

pressure. After flash column chromatography using (1)  $\text{CH}_2\text{Cl}_2$  and (2) 1.5% methanol/ $\text{CH}_2\text{Cl}_2$  as eluent mixture, galacto-amide **5** was obtained as a pale yellow oil (2.32 g, 60%).  $^1\text{H}$  NMR (500 MHz,  $\text{CDCl}_3$ )  $\delta$  7.25–7.29 (m, 5H) benzyl H's; 6.43 (d,  $^3J_{\text{NH-H}'} = 9.3$  Hz, 1H) amide NH; 5.37 (m, 1H) H4'; 5.20 (dd,  $^3J_{\text{H}1'-\text{H}2'} = 9.3$  Hz,  $^3J_{\text{H}1'-\text{H}2'} = 8.7$  Hz, 1H) H1'; 5.03–5.10 (m, 5H) H2', H3',  $\text{C}_6\text{H}_6\text{CH}_2\text{O}$ - and carbamate NH; 3.96–4.09 (m, 3H) H-5', H6a' and H6b'; 3.11 (br s, 2H)  $\text{CH}_2\text{NHC(O)}$ ; 2.09–2.14 (m, 2H) sugar-NHC(O) $\text{CH}_2$ -; [2.07; 1.98; 1.97; 1.93] 4 s 12H, all acetyl  $\text{CH}_3$  H's; 1.51–1.57 (m, 2H) C(O) $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}$ ; 1.41–1.47 (m, 2H) C(O) $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}$ ; 1.21–1.30 (m, 2H) C(O) $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}$ .  $^{13}\text{C}$  NMR (125.7 MHz,  $\text{CDCl}_3$ )  $\delta$  [173.1, 171.1, 170.4, 170.0, 169.7] all acetyl and amide C=O, 156.5 C=O carbamate, [128.5 and 128.1] benzyl C's, 78.4 C1', 72.3 C2', 70.9 C5', 68.4, 67.2, 66.5, 61.1 C6', 40.8 C(O) $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}$ , 36.6 C(O) $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}$ , 29.6 C(O) $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}$ , 26.1 C(O) $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}$ , 24.7 C(O) $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}$ , [20.76, 20.70, 20.60, 20.57] all acetyl  $\text{CH}_3$ . **24-[*O*-(*N,N*-Diisopropylamino)(2-cyanoethyl)phosphite]-5 $\beta$ -cholane-3 $\alpha$ ,7 $\alpha$ ,12 $\alpha$ -tris[[5-[2,3,4,6-tetra-*O*-acetyl- $\beta$ -D-galactopyranosyl]carbamoyl]pentyl]carbamate] 12.** A 0.274 mL amount of 0.5 M tetrazole in CH<sub>3</sub>CN was added dropwise to a stirred solution of **11** (0.32 g, 0.17 mmol) and *O*-cyanoethyl-bis(diisopropylamino)phosphine (0.065 mL, 0.206 mmol) in 10 mL of

anhydrous CH<sub>3</sub>CN under argon atmosphere and the mixture was stirred at room temperature for 30 min. The reaction was monitored by TLC (5% TEA in ethyl acetate/hexanes/methanol 6:3:1). After completion, tetrazole was neutralized with a few drops of TEA, and the mixture was diluted with ethyl acetate to a volume of 50 mL. The organic solution was washed twice with NaHCO<sub>3</sub> solution (10% in H<sub>2</sub>O) followed by brine, dried over Na<sub>2</sub>SO<sub>4</sub>, and concentrated to an oil. The product was precipitated twice in hexanes at 0 °C and dried in vacuo to give 0.3 g (85%) of pure phosphoramidite **12**: TLC (5% TEA in ethyl acetate/hexanes/methanol 6:3:1):  $R_f$  0.63; <sup>31</sup>P NMR (CDCl<sub>3</sub>)  $\delta$  147.1.

**Preparation of Solid Supports for the Synthesis of 5'-Conjugates.** Prior to coupling of the nucleoside succinates, the aminofunctionalized resins were washed twice with 5% DIEA in CH<sub>2</sub>Cl<sub>2</sub> followed by three washing steps with DMF. For 1 g of resin, a solution of 0.019 mmol of nucleoside succinate, 0.06 mmol of DIEA, and 0.019 mmol of HATU in DMF was prepared, allowed to pre-activate for 1–2 min, and added to the resin. After shaking the suspension overnight, the resin was washed three times with DMF and three times with CH<sub>3</sub>CN and dried in vacuo. The resin substitution was determined by a spectrometric DMT-assay and the remaining NH<sub>2</sub> groups were capped using a 1:1 mixture of the capping reagents from oligonucleotide synthesis (CapA/CapB). Finally, the resin was washed with CH<sub>3</sub>CN and dried in vacuo.

**3 $\alpha$ ,7 $\alpha$ ,12 $\alpha$ -Trihydroxyallyl Cholate 13.** To a solution of cholic acid (2 g, 4.895 mmol) in anhydrous DMF (12 mL) was added cesium carbonate (1.73 g, 4.895 mmol) at room temperature and under inert atmosphere. The mixture was stirred for 1 h before adding 7 equiv of allyl bromide (2.96 mL, 34.26 mmol). The reaction was monitored by TLC and, after being stirred for 2 h 40 min, 80 mL of water was added, and the solution was acidified with 2 N KHSO<sub>4</sub>. Extraction of crude **13** was carried out with CH<sub>2</sub>Cl<sub>2</sub> and ethyl acetate. The organic layers were washed with brine, dried with MgSO<sub>4</sub>, filtered, and evaporated to dryness under reduced pressure. After flash chromatography on silica gel with 70–100% ethyl acetate in hexanes as the eluent, the allyl ester **13** was isolated as a white solid (2.05 g, 93%).  $R_f = 0.43$  in ethyl acetate/hexane 7/3. °F = 152–154 °C. <sup>1</sup>H NMR (200 MHz, CD<sub>3</sub>OD, ppm)  $\delta$  6.05–5.63 (ddt,  $J_{\text{ab}} = 22.5$  Hz,  $J_{\text{ac}} = 10.4$  Hz,  $J_{\text{ad}} = 5.6$  Hz, 1H) –CH= (allyl); 5.37–5.15 (2dq,  $J_{\text{ba}} = 17.3$  Hz,  $J_{\text{bc}} = J_{\text{cb}} = 1.6$  Hz,  $J_{\text{ca}} = 10.4$  Hz, 2H) CH<sub>2</sub>= (allyl); 4.90 (s, 3 OH); 4.56 (dt,  $J_{\text{ddr}} = 1.4$  Hz,  $J_{\text{da}} = 5.6$  Hz, 2H) CH<sub>2</sub>O (allyl); 4.00–3.90 (broad, 1 H) 17-H; 3.80 (broad, 1H) 7-H; 3.45–3.27 (m, 1 H) 3-H; 2.50–1.10 (m, 23 H) CH and CH<sub>2</sub> (steran rings); 1.05 (d,  $J = 6$  Hz, 3H) 18-CH-CH<sub>3</sub>; 0.90 (s, 3H) 13-C-CH<sub>3</sub>; 0.70 (s, 3H) 10-C-CH<sub>3</sub>. <sup>13</sup>C NMR (25 MHz, CD<sub>3</sub>OD)  $\delta$  175.0, 133.8, 118.5, 74.7, 73.6, 69.8, 66.8, 49.0, 48.5, 44.3, 44.1, 42.1, 41.6, 37.9, 37.7 (2 peaks), 37.1, 33.5, 33.3, 32.4, 30.8, 30.0, 29.1, 25.6, 24.6, 19.1, 14.5. **3 $\alpha$ ,7 $\alpha$ ,12 $\alpha$ -tris[[5-[2,3,4,6-tetra-*O*-acetyl- $\beta$ -D-galactopyranosyl]carbamoyl]pentyl]carbamate]cholic Acid **16**.** To a solution of **15** (644 mg, 0.337 mmol) in anhydrous THF (7.7 mL) were added successively at room temperature and under inert atmosphere tetrakis(triphenylphosphine)palladium (160 mg, 0.135 mmol) and morpholine (305  $\mu\text{L}$ , 3.370 mmol). The reaction mixture was stirred for 20 min. Subsequently, the solvent was evaporated, and the crude compound was purified by chromatography on silica gel (0–20% methanol in ethyl acetate). The fractions containing **16** were collected, the solvent was evaporated, and the residual oil was poured in cold ether and stirred for 30 min to yield the cholic acid derivative **16** as a white precipitate. ( $R_f = 0.6$  in ethyl acetate/methanol 9:1); MALDI-TOF: 1874 [ $M - \text{H} + \text{Li}$ ].

**Functionalization of a Solid Support with Gal<sub>3</sub>Chol for the Synthesis of 3'-Conjugates (**17**).** The DMT/Fmoc linker succinate was prepared from 1.5 g (2.23 mmol) of 1-*O*-DMT-6-*N*-Fmoc-2-hydroxymethylhexane, 0.335 g (3.35 mmol) of succinic anhydride, and 0.14 g of DMAP, which were dissolved in 12 mL of  $\text{CH}_2\text{Cl}_2$ /pyridine (5:1) and stirred for 24 h. The reaction was monitored by TLC (1% TEA in  $\text{CH}_2\text{Cl}_2$ /methanol 9:1). After completion, the mixture was diluted with 50 mL of  $\text{CH}_2\text{Cl}_2$  and washed twice with 10% aq citric acid and once with brine.

The organic phase was dried over  $\text{Na}_2\text{SO}_4$  and evaporated in vacuo to give 1.46 g (85%) of the succinate. Loading of the succinate onto macroporous aminofunctionalized PS was performed as described above for the preparation of the solid supports for 5'-conjugation, whereas 0.03 mmol (23.2 mg) of succinate, 0.03 mmol (11.4 mg) of HATU, and 0.09 mmol (15  $\mu\text{L}$ ) of DIEA were used for 1 g of support. The loading of the support, as determined by DMT-assay, was 24  $\mu\text{mol/g}$ . Subsequently, the Fmoc group was removed from the amino terminus of the branched linker by treating the resin twice with a solution of 20% piperidine in DMF for 20 min. Finally, the carboxylic acid derivative of Gal<sub>3</sub>Chol **16** was attached to the amino group on the resin utilizing the HATU/DIEA activation described above. Briefly, 2 equiv (0.048 mmol/g resin) of **16** (87.7 mg), 2 equiv. (0.048 mmol) of HATU (18.3 mg), and 6 equiv (0.144 mmol) of DIEA (25  $\mu\text{L}$ ) were dissolved in DMF. After 3 min of preactivation, the mixture was added to the resin, and the suspension was shaken overnight. Subsequently, the Gal<sub>3</sub>Chol-substituted solid support **17** was washed thoroughly with DMF and  $\text{CH}_2\text{Cl}_2$ . The applied Kaisertest indicated a quantitative coupling reaction. However, a mixture of CapA/CapB (1:1) was applied to acetylate any residual unreacted amino groups.

**BET Surface Analysis of the Solid Supports.** The specific surface areas of the resins preloaded with the starting nucleoside were determined by BET analysis of the nitrogen adsorption isotherms using a SA 3100 Surface Area and Pore Size Analyzer from Beckman-Coulter (Krefeld, Germany). Therefore, samples of approximately 1 g of each material were degassed under reduced pressure for 10 h at 45  $^\circ\text{C}$  and 16 h at 40  $^\circ\text{C}$  for the CPG and PS supports, respectively. Nitrogen was added incrementally, and the data points derived from the adsorption isotherm were used to determine the monolayer volume and the specific surface area of the materials by BET calculation (32).

**Synthesis and Purification of Oligonucleotide–Gal<sub>3</sub>Chol Conjugates.** Solid-phase synthesis of PTOs<sup>1</sup> was carried out on an Applied Biosystems DNA/RNA synthesizer 380B using standard phosphoramidite chemistry and Beaucage reagent (0.05 M in  $\text{CH}_3\text{CN}$ ) as the sulfurizing agent. For synthesis of 5'-conjugates, the carbohydrate cluster was introduced as a phosphoramidite **12**. Prior to conjugation, the support-bound oligonucleotide (DMT-off) was placed in a Merrifield flask and washed thoroughly with anhydrous  $\text{CH}_3\text{CN}$ . The coupling was performed under argon atmosphere as a manual batch step using 3–30 equiv of phosphoramidite (0.05 M in  $\text{CH}_3\text{CN}$ ) and 15–150 equiv of the activation reagent tetrazole (0.5 M in  $\text{CH}_3\text{CN}$ ) or ETT (0.25 M in  $\text{CH}_3\text{CN}$ ). The suspension was shaken for 1 h. Subsequently, the solid support was washed three times with acetonitrile and the terminal P(III)-linkage was oxidized with Beaucage reagent (0.05 M in  $\text{CH}_3\text{CN}$ ) for 20 min. Finally, the resin was washed with  $\text{CH}_3\text{CN}$  before the conjugate was cleaved from the support and deprotected with concentrated aqueous ammonia (55  $^\circ\text{C}$ , 6 h). Using the Gal<sub>3</sub>Chol-modified PS **17** as the solid support, automated syntheses of 3'-conjugates were performed using standard protocols. The conjugates were purified by RP-HPLC using a 306 Piston Pump System, a 811C Dynamic Mixer, a 170 Diode Array Detector and a 215 Liquid Handler together with the Unipoint Software from Gilson (Middleton, WI). The HPLC conditions were as follows. Column: Waters Deltapak C<sub>18</sub> reversed phase (300  $\times$  3.9 mm, 15  $\mu$ , 300  $\text{\AA}$ ); Solvent A: 0.1 M  $\text{NH}_4\text{OAc}$  in  $\text{H}_2\text{O}$ ; Solvent B: 0.1 M  $\text{NH}_4\text{OAc}$  in  $\text{CH}_3\text{CN}/\text{H}_2\text{O}$  (80:20);

**Figure 2.** Geometry and conformation of the carbohydrate cluster conjugated to the 5'-position of a nucleoside via a thiophosphate linkage.

Gradient: 0–32 min 0–50% B. After chromatographic purification the oligonucleotides were desalted by RP-HPLC, analyzed by CGE<sup>1</sup> and ES-MS, lyophilized, and stored at  $-20^{\circ}\text{C}$ .

## RESULTS AND DISCUSSION

**Design and Synthesis of the Galactoside Cluster (Gal<sub>3</sub>Chol).** The application of glycosylated ligands for targeted delivery of antisense oligonucleotides has been shown to enhance their cell-specific uptake and efficacy in vitro and in vivo and may have significant implications for the antisense therapy (19, 23–25, 33–36). We report here on the development of a synthetic vector for targeting antisense ONs to parenchymal liver cells and the synthesis of various carrier–oligonucleotide conjugates.

According to the known structural features required for high affinity binding to the ASGP-R, a triantennary conjugate was chosen as the synthetic carbohydrate carrier. Synthesis of the carrier was achieved by connecting three  $\beta$ -aminogalactosyl residues to a rigid cholane scaffold via  $\epsilon$ -aminocapramide linkers. With this design, we created a ligand with favorable spacing and orientation of the galactose moieties for high affinity recognition by the membrane lectins. Three-dimensional molecular modeling involving structural calculations with energy minimization indicate that Gal<sub>3</sub>Chol has an umbrella-like conformation with the three galactosyl residues protruding from one side of the steroid backbone. The cluster forms a triangle with distances of about 11, 12, and 14 Å measured from tetrahydropyran ring oxygen to tetrahydropyran ring oxygen (Figure 2). Given the flexibility of the  $\epsilon$ -aminocapramide spacers, however, the cluster system will be able to adopt a wide range of conformations with varying intergalactosyl distances. Molecular dynamics simulations of a known high affinity oligosaccharide ligand indicate a relatively constant distance of 15 Å between two of the Gal residues (37). The spacing is crucial for the recognition by the receptor, while the distances to the other residue show a considerable degree of flexibility. Thus, the required flexibility

and proper spacing between the galactose residues can be achieved with the present design. The actual binding affinity of the conjugates for the ASGP-R, however, has not yet been determined.

Our goal was to combine high affinity binding with low molecular weight in order to enable the synthesis of structurally and chemically homogeneous conjugates through a straightforward solid-phase approach. Therefore, the carrier was designed to be chemically stable under the conditions of oligonucleotide synthesis and deprotection. Acyl groups, removable under the conditions of oligonucleotide deprotection, were chosen to protect the hydroxy functions of the sugar residues.

The acyl-protected  $\beta$ -aminogalactoside **4** was prepared in a four-step procedure (overall yield: 80%) from D-galactose (Scheme 1). After peracetylation of the sugar with acetic anhydride in pyridine, the anomeric position of **1** was converted to the bromide **2** with HBr/AcOH and subsequently treated with  $\text{NaN}_3$  under phase-transfer catalysis. The resulting azide **3** was reduced to the 1- $\beta$ -amino-2,3,4,6-tetraacetyl-D-galactose **4**. Subsequently, the acylated  $\beta$ -aminogalactoside was coupled to N-Cbz-protected  $\epsilon$ -aminocaproic acid (Scheme 2). With a coupling yield of about 60%, the combination of BOP/HOBT/TEA in DMF proved to be most suitable among the activation reagents tested. CBz provided stable protection of the  $\epsilon$ -amino group without any loss of acyl groups during the subsequent deprotection step. After removal of the CBz protection group from **5** ( $\text{H}_2$ , 10% Pd/C), the spacer 1-( $\epsilon$ -aminocaproamide)-2,3,4,6-tetraacetyl-D-galactose **6** was obtained in an isolated yield of 90%.

The scaffold was derived from cholic acid, with three hydroxyl groups as the anchors for triantennary linkers. Cholic acid was converted to the activated tricarboxylate **9** in three consecutive steps with an overall yield of 43%, to which the galactosylated spacers **6** were attached (Scheme 3). To achieve this, cholic acid was first converted to tetrahydroxycholane **7** using a  $\text{BH}_3\cdot\text{THF}$  com-

plex in THF for reduction of the carboxyl group. In the second step, the primary hydroxy function was protected with DMT. The DMT group was chosen since it is orthogonal to the acyl protection on the Gal residues and can be easily removed under mild acidic conditions. Finally, the remaining hydroxy functions of **8** were converted to HOSu-activated carbonates using triphosgene followed by *N*-hydroxysuccinimide.

The final assembly of the carbohydrate cluster was achieved by coupling the galactosylated spacers **6** to the activated cholane backbone **9** (Scheme 3, step d). This turned out to be the most difficult step of the entire synthesis, since attachment of all three bulky spacer molecules to the cholane backbone was apparently hampered by steric effects. The choice of the solvent turned out to be crucial for this process, and best results were obtained when the reaction was carried out in dry DMF at room temperature for about 15 h (79%). Subsequently, the crude product **10** was treated with acetic anhydride in pyridine to reinstall any acyl groups lost during the coupling reaction. Finally, the DMT group was removed with 3% TCA in  $\text{CH}_2\text{Cl}_2$ /methanol (90% isolated yield). The triantennary galactoside **11** was reacted with *O*-cyanoethyl-bis(diisopropylamino)phosphine and tetrazole in  $\text{CH}_2\text{Cl}_2$  to give the phosphoramidite **12** in 85% isolated yield.

As a second building block, a functionalized solid support was prepared for solid-phase synthesis of oligonucleotides 3'-conjugated to the Gal<sub>3</sub>Chol cluster. The cholic acid analogue **16** of the carbohydrate cluster was synthesized and attached to macroporous polystyrene, which was functionalized with a branched amino-C7-linker by using HATU/DIEA activation (Scheme 4). The solid support with a loading of 24  $\mu\text{mol NH}_2/\text{g}$  could be completely substituted with the Gal<sub>3</sub>Chol cluster using 2 equiv of the carboxylic acid. The triantennary galac-

toside **16** was synthesized analogously to the procedure described above for the cluster galactoside **11**, except that the activated cholane precursor **14** was prepared from allyl-protected cholic acid **13**.

**Solid-Phase Synthesis of Oligonucleotide-Gal<sub>3</sub>Chol Conjugates.** In previous reports of synthesis of covalent conjugates between ONs and synthetic glycosylated ligands, solution-phase strategies have been applied for conjugate formation. Hangeland and co-workers (24) reported a 14% yield for the covalent coupling of a synthetic triantennary glycopeptide to ON in solution by using 10 equiv of the glycopeptide. A 100-fold molar excess of a synthetic galactoside cluster was used for its solution-phase conjugation to antisense ON and a coupling yield of 31% was obtained (25). In contrast, we favored a solid-phase strategy for conjugate formation. We rationalized that this technique would minimize consumption of the precious galactoside cluster and would enable a facile isolation and purification of the products. Two different approaches were investigated, both being compatible with the conditions of oligonucleotide synthesis and deprotection. For a straightforward and chemically stable conjugation to the 5'-terminus, Gal<sub>3</sub>Chol was introduced as a phosphoramidite generating a phosphodiester or thiophosphate linkage to the resin-bound oligonucleotide. The lipophilic cholane backbone was expected to facilitate the purification of the

**Figure 3.** HPLC analysis of crude 5'-Gal<sub>3</sub>Chol conjugates of PTO 20mers (ON-1) synthesized on CPG (2000 Å) using (a) a 30-fold and (b) a 3-fold excess of Gal<sub>3</sub>Chol amidite. The signal of the conjugate is marked with an arrow.

conjugates by reversed phase HPLC. On the other hand, a solid support, prefunctionalized with Gal<sub>3</sub>Chol, was prepared for the synthesis of the 3'-conjugates.

**5'-Conjugation.** The coupling of Gal<sub>3</sub>Chol amidite to the 5'-end of resin-bound ON was performed in a manual batch step in order to allow extended reaction times and maximum coupling efficiency without the need for a large excess of amidite. Initial attempts were made on CPG support, a rigid, nonswellable silica matrix functionalized with long chain alkylamine spacers. CPG is the most commonly used solid support for ON synthesis. Rather low overall yields of about 10% were obtained despite the fact that the support had a large pore size of 2000 Å and the Gal<sub>3</sub>Chol amidite was applied in a 30-fold molar excess. Interestingly, however, reducing the molar excess of amidite to 3 equiv did not affect the overall synthesis yields (Figure 3). The HPLC profiles of crude 20mer PTOs 5'-conjugated to Gal<sub>3</sub>Chol (ON-1) are almost identical for 3 equiv and 30 equiv of amidite with overall yields of 10.0% and 9.8%, respectively. Differences in the intensity scale of the chromatograms are due to variations in the concentration of the samples injected and do not reflect any differences in the total yield of crude product. These results indicated that the moderate synthesis yields were not a consequence of an inherent low reactivity of the Gal<sub>3</sub>Chol amidite. Presumably, the 5'-termini of the resin-bound oligonucleotides (molecular weight: 6–7 kDa)

exhibited limited accessibility for the bulky Gal<sub>3</sub>Chol cluster (molecular weight: > 2 kDa).

We rationalized that the low coupling yields observed could either be a consequence of hindered diffusion of the cluster amidite through the macroporous interior of the resin beads or steric hindrance of the coupling reaction caused by a too dense loading of the ONs on the particle surface. Both effects are closely related to the microscopic structure of the solid support. To determine the main factor influencing the coupling reaction and to improve the yields of the conjugation reaction, several different amino-functionalized solid supports were prepared and evaluated. Supports were loaded with starting nucleoside to obtain a low substitution in the range of 10–20 μmol/g. Then, the materials were physicochemically characterized to determine their specific surface area by using the BET method to analyze the isotherm data derived from N<sub>2</sub> adsorption. Finally, their performance was compared in the synthesis of 20-mer PTOs 5'-conjugated to Gal<sub>3</sub>Chol. The results of this study are summarized in Table 1.

Apparently, the nature of the solid support has a major influence on the conjugation reaction. The lowest synthesis yields of about 2% were observed for the PS-PEG copolymer resin. Moderate synthesis yields could be obtained with all the CPG supports investigated. Surprisingly, an increase in the average pore size from 2000 to 3000 Å did not improve but rather led to a reduction of the synthesis yields from 10% to 6%. Best results were achieved by using a highly cross-linked PS as the solid support. An overall yield of about 25% was obtained with an initial resin substitution of 10–15 μmol nucleoside/g and by using tetrazole as the activation reagent. Assuming an average stepwise coupling yield of 98.5% for ON synthesis, this translates to a coupling yield for the Gal<sub>3</sub>Chol amidite of more than 34%. Most importantly, under these conditions the consumption of the valuable Gal<sub>3</sub>Chol amidite could be kept at a minimum of a 3-fold molar excess. Increasing the amount of amidite did not lead to further improvement in yield (data not shown).

The significant differences in the performance of the resins can be explained by looking at the physicochemical characteristics of the polymers, namely their microscopic structure and morphology. The applied PS-PEG copolymer, consists of a minimally cross-linked PS matrix, to which PEG chains with an average length of 3000 Da are grafted. The reaction sites are on the free end of the PEG tentacles and are almost quantitatively located in the lumen of the large swellable beads. The nature of this beaded gel resin makes a determination of porosity or specific surface area impossible. However, the poor synthesis yields indicate that the structure of the beads did not allow the unhindered diffusion of the bulky carrier molecules through the matrix and that only the easily accessible sites on the outer surface of the particles reacted with the Gal<sub>3</sub>Chol amidite.

CPG consists of a rigid, nonswelling silica matrix, functionalized with alkylamine spacers and available in a range of pore sizes. The particles exhibit an irregular shape with average sizes between 75 and 125 μm. CPG supports with average pore diameters of 2000 and 3000 Å, which were investigated in the present study, are commonly used for the synthesis of long oligonucleotides (>50 nucleotides). The inferior performance of the latter, even though it has the larger pore sizes, could be a consequence of the amount of water adsorbed on the silica surface in combination with the small excess of

amidite used. The surface area of the CPG (3000 Å) used in the synthesis was about 1.5-fold higher than of CPG (2000 Å).

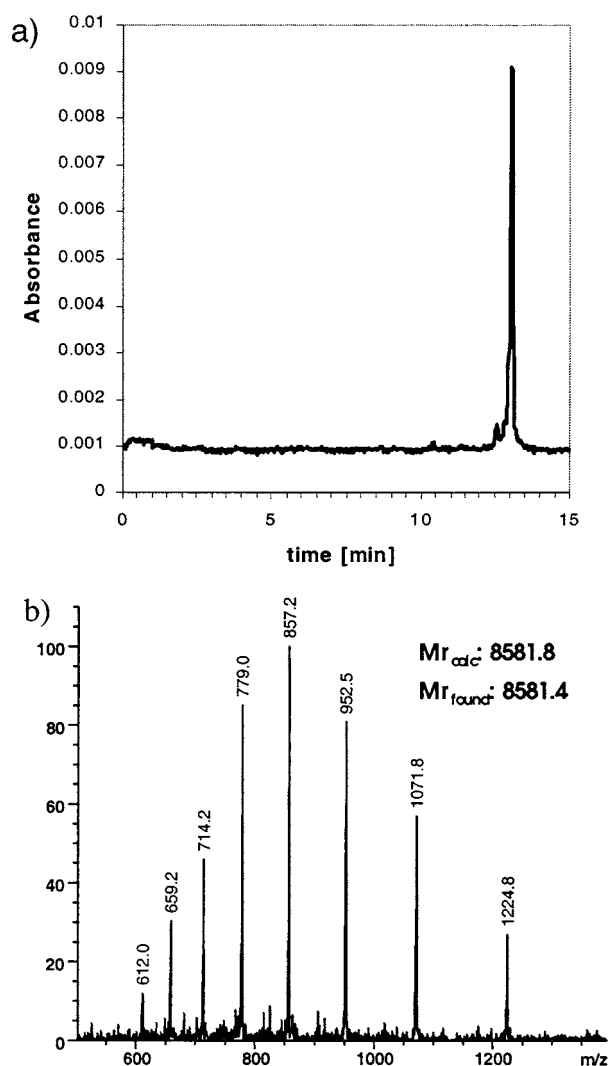

The PS support has an average pore size of 1000 Å, lower than of the CPG supports, indicating that another structural feature must be responsible for the differences in the synthesis yields observed for these macroporous CPG and polystyrene resins. In other words, hindered diffusion of the amidite due to narrow pores can be excluded as the main factor determining the yield of the coupling reaction. The physicochemical characterization of the materials by BET analysis revealed significant differences in the specific surface areas, from which the average surface area/molecule was calculated (Table 1). PS shows the highest value of surface area per g and also per molecule, 4- to 5-fold higher than the corresponding values for the two CPG supports. Therefore, it can be concluded that the density of the oligonucleotides on the particle surface had the most influence on the yield of conjugation reaction. Furthermore, the reduced average particle size of the PS support not only increases the available surface area/g but also provides an advantageous ratio of outer to inner surface functional groups. The application of the more reactive activator ETT instead of tetrazole did not lead to an improvement but rather a reduction of the synthesis yields. This result underscores the conclusion that steric factors rather than the reactivity of the amidite were crucial for the coupling efficiency.

**3'-Conjugation.** Given the results described above, macroporous PS was also considered to be the most suitable support for the synthesis of 3'-conjugates. Prior to the oligonucleotide synthesis, the galactoside cluster was attached to a branched amino-C7 linker on the support via an amide linkage. Interestingly, the amino groups present in an initial substitution of 24 μmol/g could be quantitatively functionalized with the activated ester of Gal<sub>3</sub>Chol, and the modified resin was suitable

for the automated synthesis of homogeneous oligonucleotide-3'-Gal<sub>3</sub>Chol conjugates (ON-2) using standard synthesis protocols. The 3'-conjugation, due to the absence of oligonucleotides on the support, proved to be a more facile and efficient method for introduction of the bulky galactoside cluster. These findings also confirm the conclusion that the density of the ONs on the surface of the resin particles plays the key role in determining the synthesis yields for 5'-conjugation.

In Table 2, the various ON-carbohydrate cluster conjugates that have been synthesized for biological studies are summarized. As an example, the analysis of purified ON-3 is shown in Figure 4. The 5'-Gal<sub>3</sub>Chol conjugate of a gapmer oligonucleotide containing 2'-O-MOE<sup>1</sup> sugars (38) in the wings and a 2'-deoxy center appears as a homogeneous product in the CGE profile and the ES-MS analysis confirms the correct molecular weight.

Since glycoconjugates are internalized via receptor-mediated endocytosis, the escape of the antisense ONs from the endosomal pathway is a prerequisite for hybridization to target mRNA in the cytosol or nucleus and to inhibit protein expression. For a specific release of ON from the carrier inside the target cell, the drug-carrier linkage has to be degradable under the conditions present in late endosomal or lysosomal compartments. This is not the case for the conjugates presented in this work. These conjugates were designed to be biologically stable in order to facilitate studies of the cellular uptake of these derivatives. However, the applied methods of solid-phase conjugation provide a variety of possibilities to further modify the ON-Gal<sub>3</sub>Chol linkage for a specific cleavage under biological conditions. For instance, commercially available disulfide-containing building blocks, introduced as the linkage between the ON and the carrier, can be cleaved under mild reducing conditions. Natural phosphodiester linkages at the 5' or 3' end of the ON are subject of hydrolysis by the nucleases present in the

**Figure 4.** (a) CGE and (b) ESI-MS analysis of a 2'-MOE gapmer oligonucleotide 5'-conjugated to the carbohydrate cluster Gal<sub>3</sub>Chol (ON-2); MW<sub>calc</sub>: 8581.8, MW<sub>found</sub>: 8581.4.

lysosomes and could also be utilized for a gradual release from the carrier.

#### CONCLUDING REMARKS

A synthetic ligand for the asialoglycoprotein receptor has been developed for tissue- and cell-specific targeting of antisense oligonucleotides to parenchymal liver cells. To combine low molecular weight with high receptor affinity, three galactosyl residues were attached to a rigid cholane scaffold via  $\epsilon$ -aminocapramide linkers. Computational calculations reveal an umbrella-like geometry with the galactosylated spacers protruding from one side of the steroid backbone and forming an almost equilateral triangle. Compared to the published results of known high affinity ligands, it can be assumed that the present tri-antennary setup provides proper spacing and orientation of the galactosyl residues required for high affinity binding. The galactoside cluster has been prepared in a convergent multistep synthesis starting from inexpensive natural products. It has been designed to be chemically stable under the conditions of oligonucleotide synthesis and deprotection, allowing its covalent conjugation to antisense oligonucleotides through solid-phase methods. On macroporous PS supports, efficient 5'-conjugation has been achieved while reducing the consumption of Gal<sub>3</sub>-Chol amidite to a level of 3 equiv, drastically lower than

the molar excess generally used for solution-phase conjugation. The results of the 3'-conjugation demonstrate that utilizing prefunctionalized supports provides an even more efficient way to introduce bulky synthetic ligands. A number of antisense ON-Gal<sub>3</sub>Chol conjugates have been prepared and characterized for initial biological studies. Future work will include the solid-phase synthesis of conjugates specifically cleavable under the conditions present in endosomes or lysosomes and studies of the in vivo fate, subcellular distribution, and pharmacological effects of these conjugates. To this end, medium-scale syntheses of these conjugates for three different target genes have been achieved.

#### ACKNOWLEDGMENT

The authors would like to thank Hans Norbert Grzeski for his technical assistance in BET surface analysis of the solid supports.

Revised Manuscript Received October 17, 2002

Fluorescent analogues (DB1 and TA1) of the secondary metabolites didemnin B (DB) and tamandarin A (TA) were synthesized to investigate the potential chemical defense mechanisms of tunicates in the family *Didemnidae*. These compounds were found to alter predator–prey relations. Five species of freshwater fish and one marine fish, the damselfish *Amphiprion ocellaris*, were acclimated to a diet of mosquito larvae. Fish showed an immediate, negative reaction to mosquito larvae treated with  $\geq 5$  ng of DB1 or TA1, with consumption of larvae resulting in regurgitation. Both freshwater and marine fish learned to avoid tainted prey by associating species of larvae with “distaste”. Distaste for a given organism also arose when depsipeptides DB1 or TA1 were transferred to the fish from the surrounding medium. Fluorescence microscopy in fish indicated that a similar processing and localization followed ingestion and absorption of DB1 or TA1. Fluorescent labeling of DB or TA provided an ideal tool to conduct short-term studies of predator–prey relationships between fish and marine invertebrate larvae.

### INTRODUCTION

Tunicates of the family *Didemnidae* produce a class of depsipeptides called the didemnins (Rinehart et al., 1981; Sakai et al., 1996; Li and Joullié, 1992; Rinehart, 2000; Vera and Joullié, 2002). Didemnin B (DB,<sup>1</sup> Figure 1) was one of the first members of this class to show biological activity. Recently, Vervoort et al. (2000) reported the isolation and characterization of tamandarin A (TA, Figure 1) from an unclassified didemnid from a shallow-water reef in Brazil. While the chemical structure and cellular activity of TA is comparable to that of DB, the two metabolites have not yet been shown to exhibit a common biochemical and ecological function. Here we provide further insight into the mechanisms underlying these activities.

Modification of a marine natural product (i.e., addition of a fluorescent tag) requires knowledge of its biological and ecological function (Faulkner, 2000a; Faulkner, 2000b; Moore, 1999). Both naturally occurring and synthetic didemnins are known to inhibit protein synthesis, initiate apoptosis, and reduce cell proliferation (Fimiani, 1987; LeGrue et al., 1988; Maldonado et al.,

1982; Montgomery et al., 1987; Rinehart et al., 1982). While the biochemical action of DB has not been fully determined (Beidler et al., 1999; Crews et al., 1994; Crews et al., 1996), a compilation of cellular, affinity and structure–activity relationship studies suggest that protein synthesis inhibition and cell proliferative activities arise through different pathways (Meng et al., 1998). Therefore, it was critical to demonstrate that incorporation of a fluorescent marker preserved the biological activity of the depsipeptides.

Using known structure–activity relationships (Rinehart, 2000; Sakai et al., 1996; Vera and Joullié, 2002), we appended a fluorescently labeled side-chain onto the didemnin and tamandarin macrocycles (Figure 1). A 7-*N,N*-dimethylaminocoumarin-4-acetic acid (DACA) label was used for this study (Portonovo et al., 2000), as its fluorescence (photophysical properties of probes DB1 and TA1 provided in Table 1) allowed visualization in vivo at concentrations comparable to those naturally expressed by the tunicates (Rinehart et al., 1981; Vervoort et al., 2000). As shown through established assays (Table 1), the didemnin analogue DB1 was better at reducing cell proliferation (GI<sub>50</sub> and TGI) than DB, offering activity at less than 1 nM. The activity of TA1 was comparable to that of TA. With these labels in hand, we examined their role in altering predator–prey relations.

Lindquist and Hay (1995) found that extracts of *Trididemnum solidum* (containing DA, DB, as well as other derivatives) deterred predators. In these and preceding studies (Lindquist et al., 1992), DB was shown to be critical in protecting the tunicate larvae (Young and Bingham, 1987; Van Duyl et al., 1981; Ford, 1996). Upon consuming bait containing  $\sim 23$   $\mu\text{g}$  of extract  $\text{mg}^{-1}$ , the pinfish *Lagodon rhomboides* regurgitated. These fish quickly learned to avoid this bait. Other organisms such as the anemone *Aiptasia pallida* consumed the depsipeptide-containing food and rapidly lost fitness, as expressed by a profound decrease in growth as well as sexual and asexual reproduction.

<sup>a</sup> GI<sub>50</sub>, TGI, and LC<sub>50</sub> were determined by screening through NCI's Developmental Therapeutics Program. Determination of protein synthesis inhibition (IC<sub>50</sub>) and photophysical properties are described in the methods. <sup>b</sup> The range provided illustrates the minimum and maximum activity found when screening DB against a series of tumor cell lines. <sup>c</sup> NCI-60 mean data from NCI-60 tumor cell screen. <sup>d</sup> Activity is measured in pancreatic carcinoma BX-PC3.

These studies showed that the didemnin-containing extracts protect both adult and larval tunicates from fish and invertebrate predators. What remained to be explained was how the tunicates could produce powerful inhibitors of cell proliferation and growth (Table 1) and yet not inhibit their own development. We hypothesized that fish might learn to avoid prey containing didemnins so that, over time, very low tissue concentrations would suffice to deter predation. We synthesized fluorescent analogues of the didemnins and tamandarins so that their uptake by predators of didemnin-containing organisms could be examined using analytically pure samples. To this end, five species of common freshwater fish and

one marine species, the damsselfish *Amphiprion ocellaris*, were chosen for the study of response to the uptake of DB1 and TA1. The reason for using multiple species was to ensure that the findings were generally applicable to fish from a variety of taxa and habitats. We used two species of mosquito larvae as prey and, in a series of experiments, examined the response of predators to both species, when containing the depsipeptides as well as when unprotected by these chemical defense agents.

#### MATERIALS AND METHODS

**Fish.** Studies were conducted in a laboratory setting from August 1999 to March 2000. A marine system was developed using the damsselfish *Amphiprion ocellaris*. This species was complemented with five freshwater species, all of which lack natural exposure to marine tunicates. Both fresh and marine systems were housed in 100 × 40 × 50 cm tanks (200 L), unless otherwise noted. The systems were recirculated and aerated. Five freshwater species were used: firehead tetra *Hemigrammus bleheri* (Gery and Mahnert, 1986); peppered corydoras *Corydoras paleatus* (Jenyns, 1840); common zebrafish *Danio rerio* (Hamilton, 1822); celebes medaka *Oryzias celebensis* (Weber, 1894); and glass catfish *Kryptopterus bicirrhus* (Cuvier and Valenciennes, 1840). *H. bleheri* and *K. bicirrhus* were kept at 13 dGH (hardness), pH 6.5 ± 0.3 and 23 ± 3 °C, *C. paleatus* and *D. rerio* at 13 dGH, pH 7.0 ± 0.8 and 20 ± 2 °C, *O. celebensis* at pH 8.5 ± 0.2 and 25 ± 2 °C, and *A. ocellaris* at 26 ± 2 °C with a salinity of 1.018, pH 8.1 ± 0.1. The media were changed weekly. Freshwater media were maintained at less than 0.05 ppm ammonia, 0.5 ppm of nitrite, and 50.0 ppm of nitrate. The adjustment of the pH was necessary to provide the ideal medium for the given fish. Using the

intensity of DACA fluorescence (Table 1), the rate of absorption of DB1 and TA1 either through larvae or the medium randomly deviated within 1.2% over the pH range of 5.5–7.5. Under the conditions used in the preceding experimentation, the variance of pH was irrelevant to the transfer of the analogues DB1 and TA1.

Studies were conducted on a given population of fish ( $N$ ) distributed into small schools ( $M$ ). Each school was held in an individual tank. The school size ( $S$ ), as given by  $S = NM^{-1}$ , was set to  $S = 2$  for *A. ocellaris*,  $S = 5$  for *C. paleatus*,  $S = 10$  for *H. bleheri*,  $S = 10$  for *K. bicirrhys*,  $S = 13$  for *O. celebensis*, and  $S = 30$  for *D. rerio*, unless otherwise noted. The number of feedings ( $F$ ) served to calibrate contact between fish (predator) and mosquito larvae (prey). Each fish species was acclimated over 3 weeks ( $F = 20$ ) to a diet of mosquito larvae by a daily feeding with *Anopheles stephensi* and *Culex pipiens* (referred to herein as acclimation). Each feeding consisted of a 20% excess of larvae in 1:1 ratio of *A. stephensi* to *C. pipiens* (i.e., the number of larvae added was 20% more than the number of fish). Feedings lasted for 30 min, at which point the remaining larvae were removed by net.

During acclimation, none of the six species of fish favored a given species of mosquito larvae, as determined by calculating the percentage of *A. stephensi* selected. Over the acclimation period, the percentage of *A. stephensi* selected was  $49.4 \pm 6.8$  for *H. bleheri* ( $N = 100$ ,  $M = 10$ ),  $52.7 \pm 4.3$  for *C. paleatus* ( $N = 50$ ,  $M = 10$ ),  $50.1 \pm 1.2$  for *D. rerio* ( $N = 300$ ,  $M = 10$ ),  $53.2 \pm 2.9$  for *O. celebensis* ( $N = 26$ ,  $M = 2$ ),  $49.0 \pm 5.6$  for *K. bicirrhys* ( $N = 100$ ,  $M = 10$ ), and  $49.4 \pm 6.8$  for *A. ocellaris* ( $N = 20$ ,  $M = 10$ ). The percentage of the fish that did not consume at each feeding was determined by counting the number of mosquito larvae that remained after feeding. Over repetitive feedings ( $F = 50$ ), 96.5% of *H. bleheri* ( $N = 100$ ,  $M = 10$ ), 97.5% of *C. paleatus* ( $N = 50$ ,  $M = 10$ ), 98.6% of *D. rerio* ( $N = 300$ ,  $M = 10$ ), 96.1% of *O. celebensis* ( $N = 26$ ,  $M = 2$ ), and 97.8% of *K. bicirrhys* ( $N = 100$ ,  $M = 10$ ), and 95.9% of *A. ocellaris* ( $N = 20$ ,  $M = 10$ ) consumed at least a single larva per feeding.

**Mosquito Larvae.** *A. stephensi* and *C. pipiens* larvae were selected with a length of 10–12 mm and weight of 8–12 mg. This size is  $\sim 6$ –12 times that of the larval tunicate *Trididemnum solidum* (Lindquist and Hay, 1995; Lindquist et al., 1992). While DB is not uniformly distributed throughout the adult tunicate (Rinehart, 2000), one can estimate the average tissue concentration based on the amount of metabolite isolated per mass of tunicate. For DB and TA, this concentration lies between 50 and 100 ppm. Since the larval mimics employed in this study were larger than tunicate larva, we charged each mosquito larva with  $50 \pm 4$  ng of DB1 or TA1, providing an average tissue concentration of  $\sim 4$ –6 ppm. This was accomplished by gently shaking each larva for 5 min in sterile Eppendorf tubes containing 50  $\mu$ L of 42 nM DB1 (or 45 nM TA1) diluted in 1 mL of sterilized mineral water. This transfer was verified by measuring the amount of analogue absorbed from the medium (using fluorescence spectroscopy) and/or by tissue analysis (method described below). By linearly adjusting the solution concentration of DB1 or TA1, this procedure could be used to load larvae with  $10 \pm 2$  to  $250 \pm 12$  ng larva $^{-1}$ .

**Molecular Tracking System.** The transmission between prey and predator was monitored using fluorescence from DB1 and TA1. Physiological processing of these ligands was examined on an Axiovert 100 with a conventional Zeiss DAPI filter set with excitation, G365; beam splitter, FT 395; emission, LP 420. Images were

**Figure 2.** *K. bicirrhys*. Physiological processing after ingestion of a *C. pipiens* larva containing  $50 \pm 4$  ng of DB1. Images provided in two views: white light (left) and fluorescence (right). Abbreviations: liver (L), kidney (K), pancreas (P), stomach (S), intestine (I), epurals (EP), hypurals ( $H_{1-5}$ ), hermal spines of the preural centra ( $HPU_2$ ), epural joint (JE), neural spines of the preural centra ( $NPU_3$ ), preural centra ( $PU_1$ ), parhypural (PH), ural centrum ( $U_1$ ), and uroneural (UN), neural spine (NS), hemal spine (HS), spinal chord (SC), vertebral centrum (VC), notochord (N). (a) Dorsal view of the digestive system. (b) Lateral view of stomach and intestine. In addition to the digestive system, DB1 also localizes within the skeleton. (c) Lateral view of the caudal fin. (d) Close-up of an epural joint. (e) Lateral view of posterior vertebrate. Comparable images were also produced by ingestion of a larva containing  $50 \pm 4$  ng of TA1 or exposure for 5 min to 100 mL of media containing  $10 \pm 2$  ng of either DB1 or TA1.

collected on a Zappa digital camera. Physiological examinations were performed after dissection of a random subsample of 3–5 fish per school. Advantageously, the lack of pigment in *Kryptopterus bicirrhys* allowed direct investigation in vivo. Images from this fish are provided in Figure 2. The localization studies were controlled by

comparing transfer with that of *N*-methyl-7-*N,N*-dimethylaminocoumarin-4-acetamide (i.e., a nondepsipeptide containing derivative of DACA). This derivative, unlike DB1 and TA1, provided weak nonspecific localization in fish tissue, therein further verifying that localization of fluorescence shown in Figure 2 arose from the depsipeptide-function of DB1 and TA1. Furthermore, a "no treatment" negative control revealed that any intrinsic fluorescence was below the limit of detection.

**Tissue Concentration Analysis.** Tissue concentrations of DB1 or TA1 were determined by ultramicrosonicating ~10 mg of tissue (either mosquito larvae or fish) in 30  $\mu$ L of phosphate buffer solution (PBS). The concentration of depsipeptide in the resulting sample was determined fluorometrically using the DACA label (excitation at  $\lambda_{\text{max}} = 370$  nm and emission at  $\lambda_{\text{max}} = 460$  nm, see Table 1).

**Rejection Studies.** After acclimation, colonies of fish were given mosquito larvae containing DB1 or TA1 (exposed larvae). The fish were allowed to feed on the larvae for 30 min, at which point excess larvae were collected using a net, and counted. After removal, the fish were again fed with an excess of a 1:1 mixture of nontreated *C. pipiens* and *A. stephensi* larvae. This method was used to collect data presented in Figures 3–8.

**Larval Success Study.** Modified 10 L tanks were constructed with a 2 mm mesh barrier that divided the vessel in two equal volumes. This barrier restricted fish to one side of the tank, while allowing larvae to freely access the entire tank. Larvae were added in a single transfer to the side of the tank containing the fish. Twenty larvae (either *C. pipiens* or *A. stephensi* larvae) were challenged to avoid consumption by fish ( $S = 20$ ). Larvae that crossed to the right side of the tank were removed and tallied (referred to as escaped). Without prior exposure to DB1 or TA1, naive *D. rerio* ( $N = 400$ ,  $M = 20$ ,  $S = 20$ ) hunted  $98 \pm 0.5\%$  of the larvae before they crossed the barrier (control). These fish were then removed and individually exposed for 30 min to 100 mL of media containing  $50 \pm 4$  ng of DB1 followed by a 5 min wash in 100 mL of depsipeptide-free media. The ability of these fish to learn was determined by counting the number of larvae that escaped and comparing with control. The data from this study is depicted in Figure 9.

**Fish Diversity Study.** Thirty tanks (200 L) were loaded with *Danio rerio* ( $N = 600$ ,  $M = 30$ ) and *Kryptopterus bicirrhys* ( $N = 600$ ,  $M = 30$ ). Each tank contained 20 *D. rerio* and 20 *K. bicirrhys*. The *D. rerio* were acclimated and pretrained over 10 feedings to avoid *C. pipiens* larvae, while the *K. bicirrhys* were only acclimated. Each of the tanks was fed over a period of 30 d ( $F = 30$ ) with a diet consisting of 30 *C. pipiens* containing  $50 \pm 4$  ng of DB1 and 20 depsipeptide-free *A. stephensi*. Five minutes after feeding, excess mosquito larvae were removed and the stomachs of the fish examined. Fish that failed to hunt a depsipeptide-free *A. stephensi* (i.e., consume no larvae or a fluorescent *C. pipiens*) were marked with a drop of paint. Fish that failed three times were removed from the tank. The results of this study are presented in Figure 11.

## RESULTS

**Biochemical Analyses.** Cell proliferation and protein synthesis assays were conducted on DB1 and TA1 to ensure proper biological activity. The effects of DB1 and TA1 on cell growth and proliferation were determined

via the NCI-60 tumor cell screen (Boyd and Paul, 1995). Protein synthesis inhibition was measured in MCF-7 cells using a protocol described by Toogood (Ahuja et al., 2000; Beidler, 1999). The results of these assays are summarized in Table 1.

**Transfer by Consumption.** Given its favorable lack of pigmentation, physiological studies began with *Kryptopterus bicirrhys*. Individual *K. bicirrhys* were fed with a larva containing  $50 \pm 4$  ng of DB1 or TA1 (exposed larva) and monitored over the course of 10 d. Immediately after swallowing the exposed larva, fluorescence from DB1 or TA1 crossed the stomach wall of the fish. Soon thereafter, fluorescence spread throughout the stomach and entered the intestine. This path was followed by regurgitation. Within 15 min of this regurgitation, fluorescence from DB1 was no longer apparent in the stomach, but remained within the intestine (Figure 2a,b). At a dose of  $50 \pm 4$  ng larva<sup>-1</sup>, fluorescence from DB1 remained in the intestine for up to 3 d. The rate of transfer, physiological processing, and intensity of localization could not be differentiated between DB1 and TA1 on *Kryptopterus bicirrhys*.

The amount of DB1 or TA1 required to cause regurgitation was then determined by measuring the residual concentration of depsipeptide in regurgitated mosquito larvae (using tissue concentration analysis, see methods). After 65 regurgitations in *D. rerio*,  $42 \pm 3$  ng of DB1 remained within the mosquito larva, indicating that each *D. rerio* regurgitated after absorbing a dose less than  $8 \pm 2$  ng of DB1. Under identical conditions,  $12 \pm 4$  ng of TA1 was transferred. The increased dose of TA1 may be explained by its reduced biological activity (Table 1). Comparable analysis in the other fish indicated that *H. bleheri* absorbed  $8 \pm 2$  ng DB1 and  $11 \pm 3$  ng TA1; *C. paleatus*,  $8 \pm 2$  ng DB1 and  $12 \pm 2$  ng TA1; *O. celebensis*,  $7 \pm 3$  ng DB1 and  $9 \pm 3$  ng TA1; *K. bicirrhys*,  $5 \pm 3$  ng DB1 and  $8 \pm 2$  ng TA1; and *A. ocellaris*,  $10 \pm 2$  ng DB1 and  $19 \pm 4$  ng TA1.

In addition to localization in the digestive system, fluorescence from DB1 and TA1 was also observed in the skeleton of all six fish species. This staining became visible 2 min after consumption and lasted for over a week. As illustrated Figure 2c–e, DB1 showed particular affinity for the endoskeleton at the joints of the eplurals and hypurals. In the spine (Figure 2e), there was a clear affinity for the notochord. The depsipeptides did not bind neural tissue, as even faint DACA fluorescence was not seen in the spinal chord, nerves, or motor neurons. Staining was seen not only in the caudal fin and spine but also in the jaw, chest, pelvic girdle, and dorsal fin.

We then compared this delivery with transfer of the depsipeptide from the medium. The rate and physiological accumulation of depsipeptides DB1 or TA1 in *K. bicirrhys* upon exposure for 5 min to 100 mL of media containing  $10 \pm 2$  ng of DB1 or TA1 was indistinguishable from that observed after ingestion of an exposed larva containing  $50 \pm 4$  ng of DB1 or TA1 (Figure 2). When transmitted from the medium, fluorescence from DB1 was initially observed in the skin, gills, and mouth of *K. bicirrhys*. Within minutes, this fluorescence disappeared and again localized in the intestine and joints. This observation suggests that the physiological target of DB1 and TA1 is independent of the digestive system. It also further indicates that the staining in Figure 2 arises from intact DB1 or TA1, and not from products of digestion or metabolism.

**Calibrating Rejection.** A series of experiments were conducted to examine the response of fish to the analogues. As shown in Figure 3, rejection was readily

**Figure 3.** Rejection of DB1. Fish given a *C. pipiens* larvae containing  $50 \pm 4$  ng of DB1 quickly learn to avoid the bait. The data are presented as the percentage of the school that did not consume a larva at each feeding. Six species are shown: *H. bleheri* (■,  $N = 100$ ,  $M = 10$ ), *C. paleatus* (◆,  $N = 50$ ,  $M = 5$ ), *D. rerio* (●,  $N = 300$ ,  $M = 10$ ), *O. celebensis* (□,  $N = 26$ ,  $M = 2$ ), *K. bicirrhys* (◇,  $N = 100$ ,  $M = 10$ ), and *A. ocellaris* (○,  $N = 20$ ,  $M = 10$ ).

**Figure 4.** Rejection of TA1. Fish given *C. pipiens* larvae containing  $50 \pm 4$  ng of TA1 learn to avoid the bait. The data are presented as the percentage of the school that did not consume a larva at each feeding. Six species are shown: *H. bleheri* (■,  $N = 100$ ,  $M = 10$ ), *C. paleatus* (◆,  $N = 50$ ,  $M = 5$ ), *D. rerio* (●,  $N = 300$ ,  $M = 10$ ), *O. celebensis* (□,  $N = 26$ ,  $M = 2$ ), *K. bicirrhys* (◇,  $N = 100$ ,  $M = 10$ ), and *A. ocellaris* (○,  $N = 20$ ,  $M = 10$ ).

reproduced when mosquito larvae were dosed with  $50 \pm 4$  ng of DB1 or TA1. Over 50% of all six species of fish avoided *C. pipiens* larvae containing  $50 \pm 4$  ng of DB1 after 5 feedings (Figure 3). After 10 feedings, only ~5% of these fish continued to consume the exposed larvae. A comparable outcome was observed with TA1 (Figure 4).

The intensity of this rejection increased with dose of depsipeptide (Figure 5). When loaded at  $10 \pm 2$  ng larva<sup>-1</sup>,  $20 \pm 1\%$  of the *Danio rerio* ( $N = 300$ ,  $M = 10$ ) avoided the exposed larvae after two feedings. When enhanced to  $50 \pm 4$  ng larva<sup>-1</sup>, the rejection after two feedings improved only slightly to  $25 \pm 2\%$ . A comparable response was seen in the other species of fish. Over the same regime ( $10 \pm 2$  ng larva<sup>-1</sup> vs  $50 \pm 4$  ng larva<sup>-1</sup>), the number of *H. bleheri* ( $N = 100$ ,  $M = 10$ ) deterred after 2 feedings improved from  $17 \pm 2\%$  to  $23 \pm 3\%$ , in *C. paleatus* ( $N = 40$ ,  $M = 4$ ) from  $18 \pm 3\%$  to  $26 \pm 2\%$ , in *O. celebensis* ( $N = 26$ ,  $M = 2$ ) from  $19 \pm 5\%$  to  $21 \pm 4\%$ , in *K. bicirrhys* ( $N = 100$ ,  $M = 10$ ,  $N = 10$ ) from  $16 \pm 3\%$  to  $28 \pm 3\%$ , and in *A. ocellaris* ( $N = 20$ ,  $M = 13$ ) from  $17 \pm 6\%$  to  $24 \pm 4\%$ .

While dosages above  $10 \pm 2$  ng larva<sup>-1</sup> modestly improved the induction of rejection, fluorescent examinations (Figure 2) indicated that the bulk of this effect arose from increasing the rate of analogue transfer. Fluorescent studies indicated that increasing the dose of DB1 above  $50 \pm 4$  ng larva<sup>-1</sup> did not alter the intensity of fluores-

**Figure 5.** *Danio rerio*. Concentration profile. Increasing concentration of DB1 in the larvae increases the rejection of *C. pipiens*. These data were collected by repeating Figure 3 with 0 ng (■),  $10 \pm 2$  ng (▲),  $50 \pm 4$  ng (●), and  $250 \pm 12$  ng (XXXXXX) of DB1 per larva.

cence observed in the joints of fish, rather, it enhanced the rate at which DB1 was absorbed in (or transferred to) the stomach of the fish. Given a larva that is 10 mg,  $50 \pm 4$  ng larva<sup>-1</sup> corresponds to 50 ppm, a concentration that lies at the lower end of that known to be expressed in tunicate tissue (i.e. 50–100 ppm). While this transfer could operate for the protection of adults, a single didemnid larvae is 0.8–1 mg (Lindquist and Hay, 1995). At this size a single 3 g fish would have to swallow at least 10 larvae to feel the effects of these agents.

A curious facet of these tunicate metabolites lies in their expression in the larval stage (Lindquist et al., 1992; Lindquist and Hay, 1995). In the preceding study, we found that the optimal tissue expression of DB1 and TA1 was around  $10 \pm 2$  ng larvae<sup>-1</sup>. At this expression, critical cell proliferation in the tunicate's larvae would also be at risk (i.e., anti-proliferative activity occurs at the pM range, Table 1), raising the question of how the tunicate and its larvae express the required amounts of depsipeptide without inhibiting their own growth. Consequently, we examined how predators (fish) assimilated the biochemical information provided by the chemical defense agents.

**Learned Avoidance.** Lindquist and Hay (1995) verified that fish learned to avoid the "distaste" of DB (Hay, 1996). While learning is well documented in fish, we were interested in understanding how this response was processed. We found that the toxicity of DB1 and TA1 was associated with the identity of the prey and not by a chemosensing (Rittschof, 1993). *Danio rerio* trained to avoid *C. pipiens* larvae avoided the larvae even when they did not contain DB1 (Figure 6). Not surprisingly, *D. rerio* trained to avoid *C. pipiens* readily consumed larvae from a second species, *A. stephensi* (Figure 7). *Danio rerio* trained to avoid *C. pipiens* however had to relearn to avoid *A. stephensi* containing either DB1 or TA1 (Figure 8). These observations indicate that *D. rerio* learned to avoid the depsipeptide by processing the structural or behavioral trait(s) of the larvae. This advantageously allowed fish to minimize their contact with the analogues.

**Indirect Transmission.** While not yet examined in the field, logistic analysis suggests that release mechanisms are also feasible. When a 3.8 g *Amphiprion ocellaris* was exposed to 200 ng of DB1 in 10 L of media for 5 min, the level of fluorescence from DB1 in its joints was indistinguishable from that shown in Figure 2. At this level of transfer, tunicates would have to deliver 20 ng L<sup>-1</sup> to their local medium. In a sea with a depth of 10 m and a density of 50 adult tunicates m<sup>-2</sup>, a single tunicate would need to release 4 μg of depsipeptide

**Figure 6.** *Danio rerio*. Rejection and learning. Schools of zebrafish ( $N = 300$ ,  $M = 10$ ) learned to reject *C. pipiens* containing  $50 \pm 4$  ng of DB1 over 5 daily feedings and continued to reject *C. pipiens* not containing DB1 thereafter. Data presented by plotting the percentage of zebrafish that did not consume a larva over a total of 10 feedings.

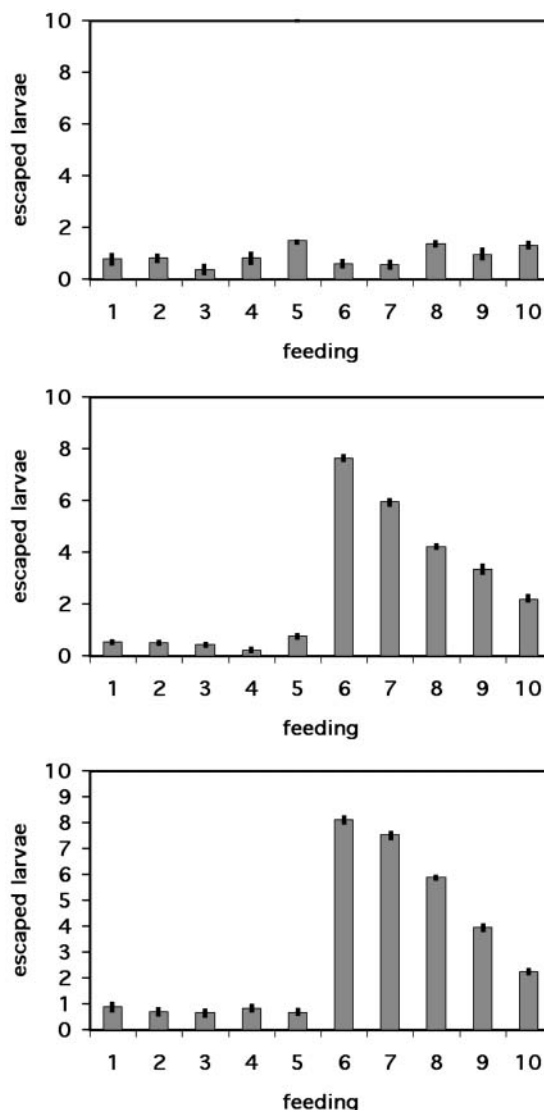

**Figure 7.** *Danio rerio*. Rejection and acceptance. Schools of zebrafish ( $N = 300$ ,  $M = 10$ ) that learned to reject *C. pipiens* containing  $50 \pm 4$  ng of DB1 over 5 daily feedings accepted DB1-free *A. stephensi* (feedings 6–10). Data presented depicts the percentage of zebrafish that did not consume a larva over a total of 10 feedings.

**Figure 8.** *Danio rerio*. Rejection and relearning. Schools of zebrafish ( $N = 300$ ,  $M = 10$ ) that learned to reject *C. pipiens* containing  $50 \pm 4$  ng of DB1 over 5 daily feedings had to relearn to avoid *A. stephensi* containing  $50 \pm 4$  ng of DB1 (feedings 6–10). Data presented depicts the percentage of zebrafish that did not consume a larva over a total of 10 feedings.

(typically  $50\text{--}250$   $\mu\text{g}$  of depsipeptide are isolated per tunicate). Here the colonial nature of these tunicates could be used to further concentrate the release and targeting of the metabolites.

We also examined the possibility of media transfer by examining the appetite of the fish after exposures to media-born DB1. As shown in Figure 9, fish quickly lost their appetite after exposure to  $0.5$  ng mL<sup>-1</sup> of DB1. Dose relation studies indicated that this effect required an exposure of 5 min in media containing  $80$  pM, or  $0.1$  ng mL<sup>-1</sup> of DB1. While temporary, this loss of appetite allowed the mosquito larvae to escape consumption (i.e., crossing the barrier). Interestingly, fish exposed to media

**Figure 9.** *Danio rerio*. Larval success study. (top) Zebrafish ( $N = 300$ ,  $M = 10$ ) in media without DB1 feed normally. (middle) Zebrafish ( $N = 300$ ,  $M = 10$ ) that were individually exposed to  $100$  mL media containing  $50 \pm 4$  ng of DB1 after the fifth feeding lost their ability to hunt depsipeptide-free *C. pipiens*. This loss was not permanent, as shown by the reduction in escaped larvae. (bottom) A comparable outcome was also observed by exposure to  $50 \pm 4$  ng of TA1 after the fifth feeding.

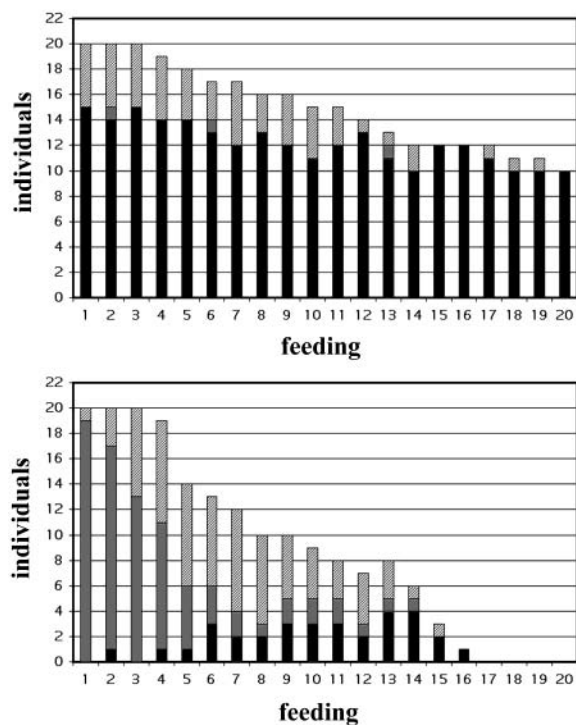

containing DB1 apparently improved their recognition of DB1-exposed *C. pipiens* (Figure 10). *Danio rerio* that only had brief contact to media containing DB1 learned to avoid the exposed *C. pipiens* much faster than fish that had no prior contact to DB1.

We then examined how media transfer could alter the competition between two species of fish. A total of five tanks were prepared with an equivalent number of *D. rerio* ( $N = 100$ ,  $M = 5$ ) and *K. bicirrhys* ( $N = 100$ ,  $M = 5$ ). Each tank was fed daily with  $30$  *C. pipiens* containing  $50 \pm 4$  ng of DB1 and  $20$  unexposed *A. stephensi* larvae. When examined without training, *D. rerio* and *K. bicirrhys* competed for bait at the same rate and success (not shown). The schools of *D. rerio* were then removed and trained over 10 feedings to avoid *C. pipiens*. As indicated in Figure 11, *D. rerio* excelled at catching the depsipeptide-free *A. stephensi*, while *K. bicirrhys* continued to consume the exposed *C. pipiens*.

We then modeled the effects that this competition would have on short-term decline, by tagging each fish

**Figure 10.** *Danio rerio*. Fish learn from media exposure. Exposure to media containing DB1 improved *D. rerio*'s ability to avoid exposed *C. pipiens*. Schools of *D. rerio* trained by exposure to media containing  $50 \pm 4$  ng of DB1 (◆,  $N = 300$ ,  $M = 10$ ) were more apt to avoid treated *C. pipiens* than naïve *D. rerio* (■,  $N = 300$ ,  $M = 10$ ). This experiment was conducted using the conditions described in the larval success study (see methods). The percent of *C. pipiens* larvae that escaped is shown.

**Figure 11.** *D. rerio* and *K. bicirrhys*. Fish diversity study. The influence of DB1 on an artificial ecosystem containing schools of *D. rerio* ( $N = 200$ ,  $M = 10$ ) and *K. bicirrhys* ( $N = 200$ ,  $M = 10$ ) was calibrated by examining the ability to hunt. Feedings were conducted with *C. pipiens* containing  $50 \pm 4$  ng of DB1 and depsipeptide-free *A. stephensi*. Fish that failed to hunt *A. stephensi* were marked with paint. Once they failed three times (three dots of paint), they were removed from the tank. (top) *D. rerio*, trained to avoid DB1, outlasted (bottom) naïve *K. bicirrhys*. The members of each species remaining are displayed as those who did not consume a larva (black), caught a *C. pipiens* (gray), and caught an *A. stephensi* (stripes).

after it failed to hunt properly. Tanks were prepared with 20 *D. rerio* trained to avoid *C. pipiens* and 20 untrained *K. bicirrhys*. Each of the tanks was provided over a period of 30 d ( $F = 30$ ) with a diet consisting of 30 *C. pipiens* containing  $50 \pm 4$  ng of DB1 and 20 depsipeptide-free *A. stephensi*. After 20 feedings, an average of  $11 \pm 3$  trained *D. rerio* ( $N = 100$ ,  $M = 20$ ) remained in each school. The naïve *K. bicirrhys* ( $N = 100$ ,  $M = 20$ ) were not as successful (Figure 11). Even after five feedings, the

number of successful or remaining *K. bicirrhys* was four less than that of the trained *D. rerio*. After 16 feedings (average presented graphically), no *K. bicirrhys* remained.

## DISCUSSION

There was a rapid, definitive response by six species of fish to larval mosquitoes containing analogues DB1 or TA1. Transfer of the chemical-defense agent from prey (mosquito larvae) to predator (fish) was rapid. Once localized in the intestine and skeleton, DB1 and TA1 were not cleared for several days. In all six species of fish, the processing of DB1 and TA1 was indistinguishable with respect to the kinetics of transfer and thermodynamic localization, as all species of fish displayed a comparable rate of absorption as well as physiological processing. The intensity of this response was sufficient to cause 50% of the fish that consumed larvae containing  $50 \pm 4$  ng of depsipeptide to avoid the treated larvae after only five daily feedings. Subsequent analyses indicated that this response arose after transfer of only 5–10 ng of depsipeptide. The effect was dose dependent and led to association of the larval species with distaste. Thus, once conditioned, the fish did not consume untreated larvae of the same species but fed upon another species of mosquito larvae.

The analog-mediated effect did not require ingestion. Transfer of the analogue from the medium to the fish also resulted in a decreased efficiency of hunting. Furthermore, the physiological localization of the analogues in fish was not altered by this mode of delivery.

Predator fitness potentially increases with their ability to recognize treated larvae. Fish that had been preconditioned to avoid the depsipeptide-treated larvae were able to hunt other species of larvae selectively and benefit; whereas, unconditioned fish had to learn to avoid the tainted larvae before they could effectively compete for food.

This study is among the first to show that TA has similar activity to DB (Liang et al., 2001). Analogues DB1 and TA1 shared a common potency and localization in the predators. The two species of family *Didemnidae* that produce DB and TA, while from remote geographic locations, use a common method to defend themselves and their otherwise vulnerable larvae by producing two structurally similar but not identical depsipeptides. The results of this study might be used to investigate predator–prey interactions in marine species other than tunicates.

## ACKNOWLEDGMENT

We thank W. Müller, W. Rettig, and B. Mallioux for their assistance. This work has been supported in part by grants from the National Institutes of Health (CA-40081) and the National Science Foundation (CHE 99-01449). This work was conducted under protocols that met standards of the National Institutes of Health, and the countries where experimentation was conducted.

Nonenveloped viruses provide the chemist with large, preassembled polyvalent protein scaffolds for modification. These structures are typically porous to small molecules but not to large ones. The solution-phase structures and reactivities of such assemblies may be substantially different than indicated by X-ray crystal structures. Here, the attachment of organic compounds to either the inside or outside surface of the cowpea mosaic virus (CPMV) coat protein was verified with an indicating antibody–antigen interaction. Antibody binding was subsequently blocked by the installation of poly(ethylene glycol) chains. These results typify the type of site-specific control that is available with CPMV and related virus building blocks.

### INTRODUCTION

Cowpea mosaic virus (CPMV) is a prototypical icosahedral plant virus having qualities that render it useful as a supramolecular chemical compound as well as a biological entity. It can be made and purified in large quantities (1, 2), is structurally characterized to near-atomic resolution (3), is stable to a variety of conditions compatible with both hydrophobic and hydrophilic molecules (4), and can be manipulated at the genetic level to introduce mutations at desired positions (5–9). Sixty identical asymmetric protein units, each composed of “large” and “small” polypeptide chains, comprise the CPMV coat protein (capsid). The virion is approximately 300 Å in diameter, with an average capsid thickness of 30 Å and RNA packaged in the interior. The structure therefore possesses inside and outside protein surfaces, which are chemically different. The most obvious distinction is the disposition of multiple positively charged residues on the interior surface, which presumably serve as points of association with the encapsidated polynucleotide. Thus, X-ray crystallography shows more than 10 lysines per asymmetric unit to be arrayed on the capsid interior, whereas only five lysine residues per asymmetric unit are found on the exterior surface. We have taken advantage of some of these properties to demonstrate the attachment of lysine- and cysteine-reactive small molecules to specific positions on the CPMV capsid (4, 10, 11).

While the positions of attachment to the coat protein sequence may be engineered and/or elucidated, such experiments do not provide independent information about the location of the reactive site relative to other structural elements of the virion in solution. In other words, the crystal structure of a virus provides a useful initial guide to its chemistry, but such a structure offers little information about capsid dynamics, which may bring apparently blocked residues to the surface. In fact,

dynamic structural transitions occur in many virions (12). For example, cleavage of an *N*-terminal sequence of flock house virus by added trypsin occurs readily, although the crystal structure shows this sequence to be attached to the interior surface of the capsid (13). Another example of dynamic behavior is afforded by cowpea chlorotic mottle virus, which undergoes reversible pH-dependent swelling, changing the virus diameter by approximately 10% (14). To evaluate the solution-phase chemical behavior of the lysine and cysteine residues, we require solution-phase methods to determine if the chemical linkages have been made on the inside vs the outside capsid surface. Here we describe the use of a Lerner-Janda blue fluorescent antibody to report on the position of its stilbene hapten (15, 16) and the modulation of this antibody–antigen interaction by covalent modification of the virus surface. The result of an initial version of this experiment was included in a previous report (4).

### EXPERIMENTAL PROCEDURES

*trans*-4-Aminostilbene, 5-aminofluorescein, and bromoacetyl bromide were purchased from Aldrich. Poly(ethylene oxide) reagents “mPEG-succinimidyl propionate-5000” (MW 5000) and “mPEG-succinimidyl propionate-2000” (MW 2000) were purchased from Shearwater Polymer Inc. Wild-type and mutant (VEFCysα) viruses were prepared as previously described (10, 11). Unless otherwise noted, “buffer” refers to 0.1 M potassium phosphate, pH 7.0. The virus was stored in buffer at a concentration of about 10 mg/mL. Size exclusion columns for purification of virus from reaction mixtures were prepared by preswelling Bio-Gel P-100 Gel (BioRad, 23 g) in buffer (400 mL, degassed overnight for use with mutants displaying exterior cysteine residues) and loading the gel into Bio-Spin disposable chromatography columns (BioRad). For 80 µL of virus solution (1 mg/mL), approximately 1 mL of the prepared gel is required. Sucrose gradient ultracentrifugation separation of virus samples was performed on 30 mL gradients [made of 20% (w/w) sucrose solution in buffer, frozen at –20 °C, and defrosted just before use] with centrifugation at 38000 rpm for 3 h (Beckman SW41 Ti rotor), giving rise to well-separated bands.

**Figure 1.** Plots showing the amount of the covalently attached fluorescein to (a) wild-type CPMV, and (b) the mutant virus VEFcys $\alpha$ , as a function of the ratio of reagent **6** to virus. Note that there are 60 asymmetric units per virus particle. Each data point shown is the average of three independent experiments with maximum error of  $\pm 9\%$  of the reported attachment value.

TEM analyses were performed by depositing 20  $\mu$ L aliquots of each sample onto 100-mesh carbon-coated copper grids for 2 min. The grids were then stained with 20  $\mu$ L of 2% uranyl acetate and viewed with Philips CM100 electron microscope. FPLC analyses were performed with AKTA Explorer (Amersham Pharmacia Biotech) equipment, using Superose-6 size-exclusion or Hitrap-Q ion-exchange columns. In the former case, 0.05 M potassium phosphate buffer (pH 7.0) was used as eluent; intact virions show retention times of approximately 25 min at an elution rate of 0.4 mL/min, whereas broken particles and individual subunit proteins elute only after 50–60 min. Ion-exchange FPLC was performed with 0.05 M potassium phosphate as the low-salt buffer and 1.0 M NaCl in 0.05 M potassium phosphate as high-salt eluent.

**4-(4-*E*-Styryl-phenylcarbamoyl)butyric Acid (1).** *trans*-4-Aminostilbene (426 mg, 2.18 mmol) and glutaric anhydride (250 mg, 2.19 mmol) were stirred in  $\text{CH}_2\text{Cl}_2$  (10 mL) at room temperature, the solution depositing a white precipitate within a few minutes. After 5 h, the solvent was removed to give carboxylic acid **1** as a pale yellow solid (671 mg, 99% yield).  $^1\text{H}$  NMR ( $\text{DMSO}-d_6$ )  $\delta$  12.02 (br s, 1H), 9.97 (s, 1H), 7.6 (m, 6H), 7.35 (t,  $J = 7.9$  Hz, 2H), 7.23 (d,  $J = 7.9$  Hz, 1H), 7.15 (s, 2H), 2.32 (m, 4H), 1.80 (m, 2H).  $^{13}\text{C}$  NMR ( $\text{DMSO}-d_6$ )  $\delta$  174.8, 171.3, 139.5, 137.9, 132.5, 129.3, 128.7, 127.9, 127.6, 126.9, 119.8, 36.2, 33.7, 21.2.

**4-(4-*E*-Styryl-phenylcarbamoyl)butyric Acid 2,5-Dioxo-pyrrolidin-1-yl Ester (2).** A solution of **1** (200 mg, 0.65 mmol) in 1:1:0.1  $\text{CH}_2\text{Cl}_2$ :MeCN:pyridine was treated with disuccinimidyl carbonate (182 mg, 0.71 mmol), and the reaction was stirred at room temperature under a drying tube. The small amount of solid that was undissolved at the beginning of the reaction was solubilized after several hours. After 12 h, the solvent was removed to give a wet, off-white solid;  $\text{CH}_2\text{Cl}_2$  was added and then removed to give a dry white solid. This material was purified by column chromatography on silica gel, using 2:1  $\text{CH}_2\text{Cl}_2$ :MeCN as eluent. The desired product, **2**, eluted near the solvent front and was isolated as a white solid (186 mg, 70% yield).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ )  $\delta$  7.96 (br s, 1H), 7.5 (m, 6H), 7.35 (m, 2H), 7.28 (m, 1H), 7.05 (s, 2H), 2.89 (s, 4H), 2.74 (t,  $J = 7.0$  Hz, 2H), 2.49 (t,  $J = 6.8$  Hz, 2H), 2.22 (m, 2H).

**(*E*)-4-Bromoacetamidostilbene (3).** A suspension of *trans*-4-aminostilbene (0.98 g, 5 mmol) and  $\text{NaHCO}_3$  (1.3 g, 15 mmol) in dry tetrahydrofuran (15 mL) was stirred at 0  $^\circ\text{C}$  for 15 min, followed by dropwise addition of a solution of bromoacetyl bromide (2.0 g, 10 mmol) in dry tetrahydrofuran (5 mL). After the mixture was stirred for 30 min, diethyl ether (50 mL) and saturated aqueous  $\text{NaHCO}_3$  (50 mL) were added. The organic layer was separated and concentrated to afford 1.4 g (91%) of the desired product as a brown powder. Further purification was performed by recrystallization from acetone.  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ):  $\delta$  8.16 (br, 1 H), 7.53–7.26 (m, 9 H), 7.08 (s, 2 H), 4.04 (s, 2 H).

**6- $\alpha$ -Bromoacetamidofluorescein (6)** (17). This compound was prepared analogously to **3**, using 6-aminofluorescein (1.74 g, 5 mmol). The crude product was purified by column chromatography over silica gel, eluting with ethyl acetate, giving **6** as a yellow powder (1.85 g, 79%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 500 Hz):  $\delta$  9.95 (s, 1 H), 7.98–7.70 (m, 4 H), 6.75–6.61 (m, 6 H), 4.00 (s, 2 H).

**General Procedure for Modification of CPMV with Chemical Reagents.** Organic reagents in DMSO solution were introduced into a solution of virus, such that the final solvent mixture was composed 80% buffer and 20% DMSO. Following incubation at 4  $^\circ\text{C}$  for 24–48 h, the mixture was purified by passage through a P-100 size exclusion column (centrifugation at 800  $g$  for 3–5 min). This filtration was repeated (typically two or three times) with fresh columns until all the excess reagents were removed. Purification of larger quantities of derivatized virus ( $>1$  mg) was performed by ultracentrifugation at 42000 rpm (Beckman 50.2 Ti rotor) through a 2 cm sucrose cushion, followed by solvation of the resulting material in buffer. Mass recoveries of derivatized viruses were typically 60–90%; all such samples were composed of  $>95\%$  intact particles as determined by analytical size-exclusion FPLC. Virus concentrations were measured by absorbance at 260 nm; virus at 0.1 mg/mL gives a standard absorbance of 0.8. The average molecular weight of the CPMV virion is  $5.6 \times 10^6$ .

**Stoichiometry of Virus Derivatization (Figure 1).** The reactions were performed at constant virus concentration (1 mg/mL) under the above conditions. After purification, the concentration of viruses and dyes were determined by absorbance spectroscopy. Fluorescein

**Scheme 1. Preparation of Virus–Stilbene Conjugates**

concentrations were obtained by measurement of absorbance at 495 nm, using a calibrated value of molar absorptivity ( $77\,000\text{ cm}^{-1}\text{ M}^{-1}$ ) determined by mixing known quantities of dye with CPMV (1 mg/mL). Each data point is the average of values obtained from three independent parallel reactions. The average deviation was 5%, and the maximum deviation was 9%. Most samples were also analyzed by anion-exchange FPLC to verify the integrity of the particles and the quantitation of their dye attachments.

**Wild-Type CPMV Lysine–Stilbene Conjugate (4) and Cysteine–Stilbene Conjugates (5a, 5b).** Wild-type CPMV (10 mg) and **2** (20  $\mu\text{mol}$ , ca. 200-fold excess relative to viral protein) in a solution of DMSO (1 mL) and buffer (4 mL) were shaken gently at 4  $^\circ\text{C}$  for 24 h. Initial separation of virus from reagent was accomplished by adding another 4 mL of buffer to induce precipitation of the organic reagent and spinning at 16000*g* for 2 min. The supernatant was further purified by ultracentrifugation at 42000 rpm over a 2 cm 40% (w/w) sucrose cushion, and the resulting transparent pellets were dissolved in 1 mL buffer. Measurement of  $\text{OD}_{260}$  provided a concentration of virus **4** of 9.1 mg/mL (91% yield). The syntheses of **5a** and **5b** were performed analogously, using wild-type or mutant CPMV (5 mg) and **3** (100  $\mu\text{mol}$ , ca. 2000-fold excess relative to viral protein), with the only difference being the reaction time (48 h for **5a** and 12 h for **5b**), reflecting the difference in reactivity between the two viruses.

**PEGylation of 5b.** Conjugate **5b** (2 mg) and **7a** or **8a** (20-fold excess with respect to viral protein) were incubated in 0.1 M  $\text{NaHCO}_3$  buffer (pH 8.4) at 4  $^\circ\text{C}$  for 48 h. The resulting viruses were purified by sucrose gradient sedimentation. The bands corresponding to virus were collected, concentrated by ultracentrifugation through a 2 cm sucrose cushion, and dissolved in PBS buffer.

**Formation of Antibody 19G2 Complexes.** All samples were dialyzed into PBS buffer at 4  $^\circ\text{C}$  before mixing with antibody 19G2. The concentration of 19G2 was 1.5 mg/mL and virus concentrations were made constant at 1.0 mg/mL. For denaturation, the viruses were heated for 1 h at 60  $^\circ\text{C}$  in 50 mM ammonium carbonate buffer containing 20% acetonitrile.

**RESULTS AND DISCUSSION**

**Preparation of CPMV–Stilbene Conjugates.** Stilbene derivatives **2** and **3**, prepared from *trans*-4-amino-

stilbene, were used to modify wild-type and mutant CPMV, as shown in Scheme 1. Reactions with **2** were performed under the conditions previously shown with dye-NHS esters to provide attachment of the small molecule predominantly at a single lysine residue of the coat protein (K38 in the small subunit), giving 60 stilbenes per virus particle (virus **4**) (10).

Stilbene bromoacetamide **3**, a readily available reagent for specific modification of sulfhydryl groups, was chosen for the derivatization of the cysteine mutant viruses and the modification of the cysteines of wild-type CPMV (Scheme 1). The use of **3** required a preliminary assessment of the reactivity of a model bromoacetamide with the virus. Thus, fluorescein derivative **6** was employed to establish the proper conditions for stilbene attachment to thiol residues of CPMV. Wild-type CPMV proved to be poorly reactive toward **6**, showing no dye attachment in a 6-h reaction and modest levels of covalent modification of the virus after 2 days. The dose–response for attachment under the latter conditions is shown in Figure 1; under the most forcing conditions (2000:1 molar ratio of **6** to viral protein), a maximum of 10 dye molecules per capsid were attached.

The CPMV mutant designated VEFcys $\alpha$  was chosen for comparison to the wild-type particle for reasons of stability and spacing of the inserted cysteine moieties. Figure 2 shows the site of the five-residue (GGCGG) insert made in the  $\beta\text{E}$ – $\beta\text{F}$  loop of the large subunit, between residues G98 and K99, and the roughly equidistant disposition of these sites about the external surface of the particle. The preparation and chemistry of this virus has been described elsewhere (11). As observed previously with maleimides, this mutant virus displayed much greater reactivity, in this case loading fluorescein bromoacetamide to the maximum value of 60 per particle within 12 h (Figure 1). On the basis of these results, stilbene bromoacetamide **3** was used to derivatize both wild-type and mutant CPMV at a reagent:protein ratio of 2000:1, to give viruses **5a** and **5b** (Scheme 1) in excellent chemical yield.

**Recognition of *trans*-Stilbene on CPMV with Blue-Fluorescent Antibody.** The addition of the monoclonal antibody 19G2 to a solution of virus **5b**, which bears stilbene groups at the designed cysteine residues on the exterior  $\beta\text{E}$ – $\beta\text{F}$  loop, gave an intense blue fluorescence under ultraviolet irradiation (Figure 3). No fluo-

**Figure 2.** (Left) Ribbon diagram of the asymmetric unit of the CPMV coat protein, showing the two component proteins (small subunit = domain A; large subunit = domains B + C), and the  $\beta$ E- $\beta$ F loop in red. (Right) View down the 2-fold axis of the wild-type CPMV structure ( $\alpha$  carbons only), depicting the pattern created on the surface of the particle by mutational insertion between R97-G98 and K99-Y100 of the  $\beta$ E- $\beta$ F loop, shown in red.

**Figure 3.** (Top) Black-and-white photographs taken under ultraviolet illumination of the following 50  $\mu$ L samples in PBS buffer, pH 7.4: (A) virus **5b** + 19G2; (B) **5b** alone; (C) 19G2 alone; (D) VEF-Cys $\alpha$  + 19G2 (concentrations: 19G2, 1.5 mg/mL; viruses, 1.0 mg/mL). (Bottom) representative TEM pictures (negative staining with uranyl acetate) showing the binding of **5b** with 19G2. (A) **5b**. (B) **5b** + 19G2; approximately 90% of all virus particles visualized in an exhaustive examination of these samples were found in the type of small clusters shown here. (C) **5b** + 19G2, subsequently treated with **1** (10 mg/mL, approximately 3500 molar equivalents relative to viral protein, at 4  $^{\circ}$ C for 12 h). All samples were diluted to a virus concentration of 0.2 mg/mL before TEM analysis.

rescence was observed for the underivatized virus in the presence of 19G2. The relatively low binding affinity of 19G2 for the stilbene hapten (in the  $\mu$ M range) (15) precludes the chromatographic purification of such adducts. However, the interaction could be independently visualized by transmission electron microscopy (TEM) as shown in Figure 3. The polyvalent display of hapten on the virus and the presence of two binding sites per

**Figure 4.** Black-and-white photographs taken under ultraviolet illumination of antibody 19G2 complexed with stilbene-decorated wild-type CPMV (A1) **4** + 19G2; (B1) **5a** + 19G2; (A2) denatured **4** + 19G2; (B2) denatured **5a** + 19G2. Sample volumes and conditions were as described in Figure 3.

immunoglobulin gave rise to clusters of virus particles formed only in the presence of both components; the addition of soluble, monomeric stilbene **1** breaks up these clusters. The blue fluorescent response was similarly observed for four other cysteine-containing mutants (11) of CPMV derivatized with reagent **2** (data not shown).

The basic function of the outer protein shell is to protect the fragile nucleic acid genome from physical, chemical, or enzymatic damage (18). While small molecules can pass through the capsid of CPMV easily, it should be difficult for proteins or other big molecules to reach the virus interior. The ability of blue-fluorescent antibodies to recognize *trans*-stilbene on the exterior CPMV surface thereby offers a convenient way to distinguish between attachments made to the inside vs the outside surface of CPMV, when the site of attachment is less certain than it is for **5b**.

Incubation of virus **4** with antibody 19G2 resulted in strong blue fluorescence under UV irradiation (Figure 4), confirming that NHS ester **1** reacts to a significant extent at exterior residues, consistent with the expected site of attachment (K38). Furthermore, the antibody should not give a strong positive response when presented with a hapten structure that is accessible only in a transient sense by virtue of an energetically unfavorable dynamic

**Scheme 2. Preparation of Virus–Stilbene-PEG Conjugates**

conformational change, unless the antibody-hapten binding energy (relatively weak in these systems) (15) is sufficient to overcome the conformational cost. In other words, residues recognized by this method as being on the virus exterior are likely to reside there in the most stable solution-phase structures of the capsid. In contrast, assays that involve a rapid and irreversible chemical reaction can more easily intercept an energetically disfavored subpopulation of conformers (12).

As shown in Figure 4, the S-alkylated product from wild-type CPMV, **5a**, was not recognized by the antibody, and thus the reactive residues are assigned to a position *inside* the particle. This is consistent with the X-ray crystal structure of CPMV, in which no cysteines are visibly exposed on the exterior surface. In the case of both **4** and **5a**, denaturing the derivatized virus allows for antibody binding and strong fluorescence with 19G2 (Figure 4). The capsid is thereby found to be sufficiently permeable to allow small molecules such as **2** and **3** to diffuse through, but the antibody is too large to do likewise.

**Position-Dependent Blocking of Antibody–Antigen Interaction.** Many therapeutic proteins have been coupled to poly(ethylene oxide) [commonly referred to as poly(ethylene glycol), or PEG] in order to prolong their circulating lifetimes and increase their potencies *in vivo* (19, 20). PEG attachment is also commonly used to passivate the immune response toward proteins (21, 22) and viruses (23). Here we show that PEGylation can be used to block the binding of a blue fluorescent antibody to its antigen. The decoration of CPMV with PEG produces substantial changes in the physical and chemical properties of the virus, which will be discussed elsewhere (24).

The cysteine-added mutants we have described thus far all retain the natural chemical reactivity of exposed lysines, and especially K38 (11). Derivatization of **5b** at lysine with commercially available *N*-hydroxysuccinimide PEG reagents **7a** and **7b** afforded virus conjugates **8a** and **8b**, as shown in Scheme 2. In this case, the virus products were purified by filtration through size-exclusion resin to remove the excess PEG reagent, followed by sucrose gradient sedimentation, ultracentrifugation pelleting, and resuspension in 0.1 M potassium phosphate buffer (pH 7.0). From previous studies under identical conditions with wild-type CPMV, we have established that approximately 60 copies of PEG-2000 are attached per virion with **7a**, and approximately 29 copies of PEG-5000 are attached per virion in the presence of **7b** (24). The products here were shown to be composed of intact virus particles by their sedimentation properties in sucrose gradients as well as by electron microscopy (data not shown). Upon incubation with 19G2, neither PEG-decorated virus showed fluorescence under

**Figure 5.** Steady-state fluorescence emission spectra with excitation at 327 nm: (a) **5b** + 19G2; (b) **8a** + 19G2; (c) **8b** + 19G2. For all samples, concentrations were 1.5 mg/mL in antibody and 1.0 mg/mL in virus.

**Figure 6.** Stereoimage of the 19G2  $F_{ab}$  fragment (green and orange) containing hapten **1** (red) docked with the CPMV coat protein asymmetric unit (small subunit in dark blue; large subunit in light blue), as described in the text. The orientation is chosen to minimize the distance between the carboxylate group of **1** and the site of VEFCys $\alpha$  mutation (residue 99 of the large subunit, shown in white). Lysine 38 of the small subunit is shown in purple.

UV irradiation (Figure 5), presumably because the PEG chains block the binding of antibody with the attached *trans*-stilbene on the virus.

An appreciation for the qualitative aspects of the interactions between antibody and a virus–hapten conjugate can be obtained by considering the crystal structure of the 19G2–**1** complex (involving only the antibody  $F_{ab}$  fragment (Protein Data Bank structure 1FL3, [www.rcsb.org/pdb/](http://www.rcsb.org/pdb/)). The hapten is bound in the expected planar, *trans*-configuration with the long axis directed toward the center of the mAb and the carboxy-terminated

linker at its periphery. Most of the side chains adjacent to the stilbene moiety are nonpolar, forming an uncharged, hydrophobic pocket (15). While not intended to be a detailed model, docking of this structure with that of the wild-type CPMV asymmetric unit, as seen in Figure 6, shows that the stilbene unit of **5b** should be easily accessible to the binding pocket of 19G2. The structures are positioned such that the carboxylic acid group of the hapten **1** (in red) is as close as possible to the location of the GGCGG insert (residue 99 of the large subunit, shown in white). Note the close approach of these two fragments, suggesting that the stilbene-decorated virus should suffer few steric barriers to forming a complex with the antibody. Furthermore, the attachment of a PEG chain to lysine 38 (purple) is likely to result in an unfavorable interaction with a loop of the antibody structure (marked with an arrow) that overhangs this position, preventing antigen–antibody binding, as observed.

## CONCLUSIONS

We have shown here that decoration of CPMV by bromoacetamide reagents is specific and selective for displayed cysteine residues, with the degree of loading controlled by reaction conditions in a predictable manner. It is noteworthy that these electrophilic reagents are quite hydrophobic, demonstrating that the virus survives the attachment of such species and the use of aqueous–organic cosolvent mixtures. Cysteine residues on the wild-type capsid are at least 6-fold less reactive than those displayed on the inserted loop of the VEF<sub>Cys</sub> mutant. Most importantly, the blue fluorescent antibody can be employed as a convenient probe of the location of its stilbene hapten on a nanoparticle scaffold, and that this interaction can be inhibited by the site-directed attachment of a PEG chain. These tools and insights will be employed in the design of virus-displayed antigens and other species.

## ACKNOWLEDGMENT

We thank The Skaggs Institute of Chemical Biology and the David and Lucille Packard Foundation (Interdisciplinary Science Program) for support of this work. Q.W. and K.S.R. are Skaggs Postdoctoral Fellows. We are grateful to Dr. L. Tang for assistance with representations of the CPMV–antibody interactions shown in Figure 6.

Revised Manuscript Received October 3, 2002

We have synthesized N-(2-hydroxypropyl)methacrylamide (HPMA) copolymer–cell penetrating peptide Tat conjugates and evaluated their subcellular distribution in A2780 human ovarian carcinoma cells by confocal fluorescence microscopy and subcellular fractionation. Our data indicate the transport of these conjugates by a single Tat molecule to both the cytoplasm and nucleus via a nonendocytotic and concentration independent process. The uptake was observed to occur within 3 min, as confirmed by live cell microscopy. In contrast, HPMA copolymers lacking the Tat peptide were internalized solely by endocytosis. For the first time, Tat-mediated cytoplasmic delivery of a polymer bound anticancer drug, doxorubicin, was also demonstrated. These findings establish the feasibility of overcoming major cellular and subcellular obstacles to intracellular macromolecular delivery and hold great promise for the development of polymer-based systems for the cytoplasmic delivery of therapeutic molecules.

## INTRODUCTION

Water-soluble polymers such as N-(2-hydroxypropyl)methacrylamide (HPMA)<sup>1</sup> copolymers are frequently employed as drug carriers because of their ability to improve the solubility of hydrophobic compounds, reduce nonspecific toxicity, and increase the therapeutic index of low molecular weight anticancer drugs (1, 2). Anticancer drugs bound to water-soluble polymeric carriers such as HPMA copolymers have exhibited decreased systemic toxicity, a result of the altered biodistribution of polymer-bound drugs as compared to free drugs. Further, cationic polymers poly(L-lysine) and polyethyleneimine are being increasingly investigated as nonviral vectors for nucleic acids and oligonucleotides due to the immunogenicity and toxicity problems associated with conventional viral vectors.

Binding a drug or nucleic acid to a polymer directs the conjugate to the lysosomes by endocytosis. Due to the impermeable nature of the lysosomal membrane, such vesicular entrapment poses a hindrance to molecules expressing biological activity in the cytoplasm or nucleus, thus necessitating the endosomal escape of the polymer conjugate. Drug release from the lysosomes can be facilitated by introducing drug–polymer linkages such as the tetrapeptide spacer glycylphenylalanylleucylglycine (GFLG), which are stable in the bloodstream but susceptible to enzymatic cleavage in the lysosomes (3). However, this approach cannot be implemented for the delivery of therapeutic molecules such as oligonucleotides

or proteins, as these molecules not only lack inherent membrane penetrating capabilities but are susceptible to both the acidic environment of the lysosomes and enzymatic degradation (4).

Recently, the ability of several peptides, called cell penetrating peptides or protein transduction domains (PTDs), to translocate across the cell membrane into the cytoplasm in an energy-independent (5), receptor-less manner has been discovered (6). These peptides which have been successfully employed as vectors for cytoplasmic and nuclear macromolecular transport include synthetic/chimeric peptides and protein derived peptides such as the *Drosophila* homeotic transcription factor ANTP, the herpes simplex virus type-1 transcription factor VP22 and the Tat peptide from the HIV-1 transactivating factor Tat. While the Tat protein itself has been proven to be taken up rapidly by cells in culture (7, 8), shorter sequences such as the Tat peptide (Y<sub>47</sub>GRKKRRQRRR<sub>57</sub>) have also been shown to transport full-length proteins such as a  $\beta$ -galactosidase–Tat fusion protein across not only the plasma membrane in different tissues but also the blood brain barrier, in mice (9). Additionally, the Tat PTD has successfully ferried derivatized nanoparticles (45 nm) into progenitor cells, thus allowing their facile detection by magnetic resonance imaging (10). Tat peptide containing peptide-based chelates of technetium-99m and rhenium have also been efficiently delivered to the cytoplasm and nucleus of living human cells (11). Both the Tat and ANTP peptides have shown prowess in delivering 2'-O-methyl phosphorothioate antisense oligonucleotides to the cytoplasm and nucleus, resulting in an increase in pharmacological activity without an accompanying loss in specificity of the antisense oligonucleotides (12).  $\lambda$  bacteriophages expressing the Tat peptide on their surface have also been shown to deliver DNA intracellularly (13). Recently, 200 nm liposomes bearing a Tat peptide-modified surface (500 Tat peptide molecules per liposome) were transported intracellularly in an energy independent fashion (14). Additionally, the Tat peptide has facilitated the

<sup>1</sup> Abbreviations: AIBN, 2,2'-azobis-isobutyronitrile; DMF, dimethylformamide; DMSO, dimethyl sulfoxide; Dox, Doxorubicin; HPMA, N-(2-hydroxypropyl)methacrylamide; MWCO, molecular weight cut off; SAMSA, 5-((2-S-acetylmercapto)succinoyl)-amino fluorescein; SMCC, succinimidyl 4-(N-maleimidomethyl)cyclohexane-1-carboxylate; TR, Texas Red.

uptake of cysteine-tagged antibody fragments in a compartmentalized manner; however, this suggests that the transport capabilities of the Tat peptide may be limited by size or the biological activity of the cargo (15).

We hypothesized that attachment of the Tat peptide to a water-soluble synthetic macromolecule will result in cytoplasmic delivery of the conjugate. To test this hypothesis, we synthesized several HPMA copolymer-Tat peptide conjugates and evaluated their internalization and subcellular trafficking in A2780 human ovarian carcinoma cells by confocal fluorescence microscopy and subcellular fractionation. We showed that these conjugates were localized to the cytoplasm and nucleus by a Tat-facilitated pathway as opposed to conjugates without the Tat peptide, which accumulated only in endocytotic vesicles.

#### EXPERIMENTAL PROCEDURE

**Synthesis of Polymer Precursors.** The HPMA copolymer containing amino groups in the side chains (**P-NH<sub>2</sub>**, where P represents the polymeric backbone), was prepared by copolymerization of HPMA and 3-(aminopropyl)methacrylamide hydrochloride (MA-AP), using 2,2'-azo-bis-isobutyronitrile (AIBN, Fluka) as the initiator and 3-mercaptopropionic acid (MPA) as the chain transfer agent (molar ratio 93:7.5:0.5, respectively) in methanol (10 wt % monomers in the mixture) at 50 °C for 24 h. The polymer was precipitated into ether, extensively dialyzed (MWCO 6–8 kDa), and freeze-dried.

The maleimide containing HPMA copolymer (**P-MAL**) was obtained by reaction of 160 mg P-NH<sub>2</sub> (0.070 mmol NH<sub>2</sub> groups) with 46.8 mg (0.140 mmol) of succinimidyl 4-(N-maleimidomethyl) cyclohexane-1-carboxylate (SMCC, Molecular Probes) and 22 mg (0.18 mmol) of diisopropylethylamine in DMF at room temperature for 12 h with stirring. The solvent was removed in vacuo, and the polymer was precipitated into acetone.

**Synthesis of Polymer Conjugates.** *P-Tat-FITC.* Tat-containing HPMA copolymer (P-Tat-FITC) was obtained by reaction of 40 mg (0.015 mmol maleimide groups) of P-MAL in 0.8 mL PBS buffer (pH 7.2), with 11.4 mg (0.0052 mmol) of Tat-FITC (Emory University Microchemical Facility, Atlanta) dissolved in 0.2 mL PBS (under nitrogen). The reaction mixture was stirred overnight in dark at room temperature. Five microliters of mercaptoethanol was added to inactivate the residual maleimide groups, and the polymer was then separated on a PD-10 column in PBS. P-Tat-FITC was isolated by dialysis (MWCO 6–8 kDa) against DI water and freeze-dried.

*P(TR)-Tat(FITC).* Double-label HPMA copolymer-Tat conjugate P(TR)-Tat(FITC) containing TR-labeled polymer backbone and Tat-FITC was prepared in several steps. HPMA copolymer containing TR and NH<sub>2</sub> (**P-TR-NH<sub>2</sub>**) was obtained by reaction of 100 mg P-NH<sub>2</sub> (0.044 mmol NH<sub>2</sub>) with 5 mg Texas Red succinimidyl ester (Molecular Probes) (0.0061 mmol) and 6 mg diisopropylethylamine (8  $\mu$ L) in 0.8 mL DMSO with stirring for 3 h. The mixture was then diluted with ethanol/H<sub>2</sub>O (1:1, 5 mL) and dialyzed against water acidified with dilute HCl (pH 3) followed by extensive dialysis against water. The content of TR in the freeze-dried polymer determined spectrophotometrically ( $\epsilon = 1.16 \times 10^5 \text{ M}^{-1} \text{ cm}^{-1}$ ,  $\lambda_{\text{max}}$  586 nm) in MeOH was 0.055 mmol/g. The residual amino groups present in P-TR-NH<sub>2</sub> were reacted with SMCC to yield a polymer containing both maleimide groups as well as TR. This polymer was treated with Tat-FITC to form a thioether linkage between the Tat and the polymer using similar procedures as described above.

*P-GFLG-Dox-Tat.* Dox containing HPMA copolymer-Tat conjugate (P-GFLG-Dox-Tat) was synthesized in several steps. First, the Dox containing monomer N-methacryloylglycylphenylalanylleucylglycylidoxorubicin (**MA-GFLG-DOX**) was synthesized (16) and copolymerized with HPMA and MA-AP (molar ratio 90.5:2.5:7) using AIBN as the initiator in methanol (12.5 wt % monomers in the mixture) at 50 °C for 24 h. The volume of the polymerization mixture was reduced by half, and the product precipitated in acetone/ether (3:1). The polymer was first dialyzed against 50% ethanol/H<sub>2</sub>O (containing 0.1% HCl) and then against DI water. The polymer isolated by freeze-drying contained 0.38 mmol/g (6.1 mol %) of the amino group containing side chains as determined by the Ninhydrin assay. The content of Dox determined spectrophotometrically ( $\epsilon = 11\,000 \text{ M}^{-1} \text{ cm}^{-1}$ ) in water was 0.11 mmol Dox/g (1.8 mol %; 6.4 wt %). The HPMA copolymer containing both Dox and maleimide groups (**P-Mal-Dox**) was then obtained by modification of amine groups with SMCC as described above. To purify the conjugate from free Dox, the polymer was purified twice on a Sephadex LH-20 column using MeOH/DMSO/CH<sub>3</sub>COOH (89:10:1) solvent mixture. The polymer was isolated after MeOH evaporation and precipitation in acetone/ether mixture. In the last step, the Tat peptide was conjugated to P-Mal-Dox via a thioether linkage as described above. The product was purified by dialysis and isolated by freeze-drying.

*Control Polymers.* The control polymers P-FITC and P-GFLG-Dox lacking the Tat peptide were synthesized as described (16, 17).

**Characterization of Polymer Precursors and Polymer Conjugates.** The polymer precursor P-NH<sub>2</sub> contained 6.6 mol % (0.44 mmol/g) of the amino group containing side chains as determined by the Ninhydrin assay. The molecular weight determined by size exclusion chromatography (SEC) on a Superose 6 (HR 10/30) column, AKTA system, PBS buffer was 26 000 Da;  $M_w$ :  $M_n$  = 1.5 and  $dn/dc = 0.156$ , using MiniDawn laser light scattering detector (Wyatt Technology, Santa Barbara).

The maleimide content of the polymer precursor **P-MAL** as determined by the SAMSA assay (Molecular Probes) was 0.37 mmol/g. The polymer did not contain any residual amine groups as determined by the Ninhydrin assay.

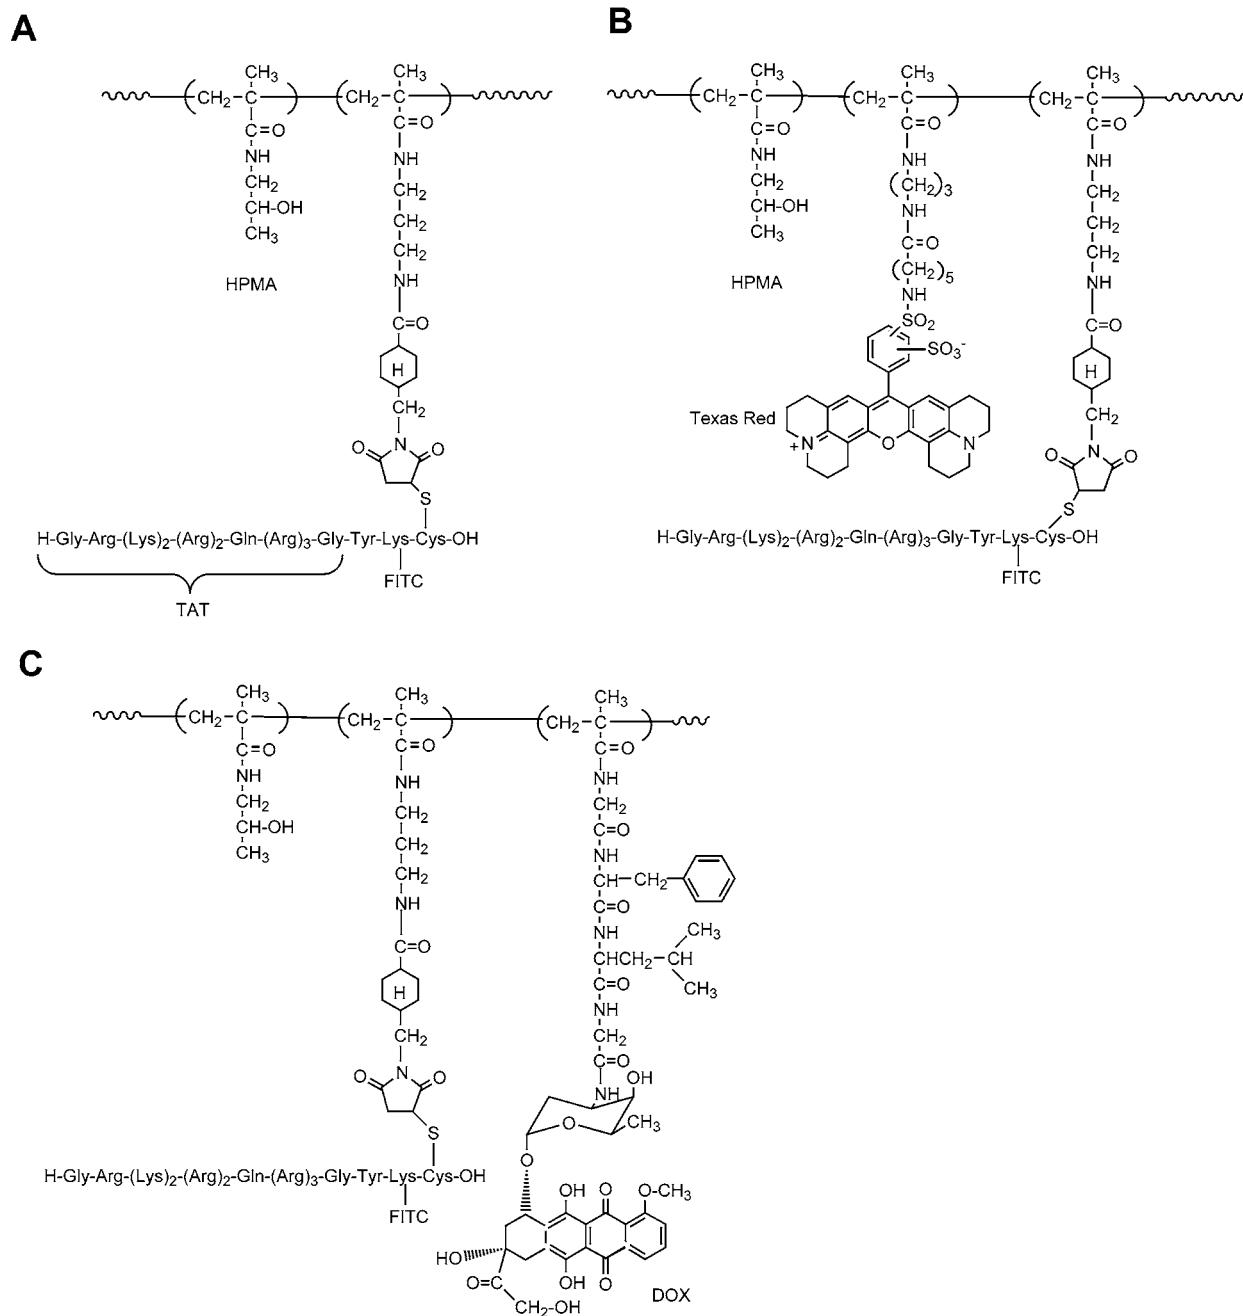

*P-Tat-FITC.* The Tat-FITC content in the polymer was determined by spectrophotometric determination of FITC ( $\epsilon = 80\,000 \text{ M}^{-1} \text{ cm}^{-1}$ ,  $\lambda_{\text{max}}$  500 nm) in 0.1 M borate buffer (pH 9.2).

*P(TR)-Tat(FITC).* The TR and Tat-FITC contents in the final polymer were determined spectrophotometrically at  $\lambda_{\text{max}} = 588 \text{ nm}$ ,  $\epsilon = 1.16 \times 10^5 \text{ M}^{-1} \text{ cm}^{-1}$  and  $\lambda_{\text{max}} = 504 \text{ nm}$ ,  $\epsilon = 80\,000 \text{ M}^{-1} \text{ cm}^{-1}$ , respectively.

*P-GFLG-Dox-Tat.* The content of Dox and Tat-FITC in this polymer was measured by two methods: (a) UV spectra in alkaline conditions (0.01 M NaOH), where the  $\lambda_{\text{max}}$  of Dox shifts to 590 nm and can be separated from FITC ( $\lambda_{\text{max}} = 500 \text{ nm}$ ); (b) amino acid analysis after acidic hydrolysis (Glu, Tyr).

**Cell Lines.** The A2780 human ovarian carcinoma cell line obtained from Dr. T. C. Hamilton (Fox Chase Cancer Center) was cultured in RPMI 1640 media (Sigma) supplemented with 10% fetal bovine serum (FBS, Hyclone) and 10  $\mu$ g/mL insulin and kept at 37 °C in a humidified atmosphere of 5% CO<sub>2</sub>.

**Confocal Fluorescence Microscopy.** For all studies, 500 000 A2780 cells were seeded on previously sterilized glass coverslips in 35 mm dishes (Becton Dickinson) 24 h before incubation to reach 90% confluence.

**Figure 1.** Structures of HPMA copolymer Tat conjugates (A) P-Tat-FITC, (B) P(TR)-Tat(FITC), and (C) P-GFLG-Dox-Tat.

For live microscopy (17), the cells were cultured in MEM Eagle media (Sigma) without phenol red, buffered with 0.25 mM HEPES (Sigma), containing 10% FBS and 0.292 mg/mL L-glutamine (Hyclone) in open air. A BioRad MRC 1024 confocal system with a krypton-argon laser, and a Nikon Diaphot microscope (100 X plan-apo objective, NA = 1.3, oil; for FITC, excitation = 488 nm, emission = 515 nm long pass filter) was used. For all fixed cell microscopy studies, cells were washed with DPBS after incubation with the polymer conjugates, fixed with 3% paraformaldehyde for 20 min at room temperature, mounted with SlowFade Light antifade medium, and sealed. In case of the nuclear localization study, cells were first incubated with 7.3  $\mu$ M P-Tat-FITC and then permeated with 0.1% Triton-X (Sigma). They were then treated with RNase in 2X SSC buffer (Sigma) at 37 °C for 20 min, followed by incubation with 1  $\mu$ M nuclear marker propidium iodide (Molecular Probes). Time de-

pendence studies were conducted by incubating cells with 7.3  $\mu$ M P-Tat-FITC for different time periods from 5 min to 1 h. For the concentration dependence studies, cells were incubated with concentrations ranging from 1.8 to 18  $\mu$ M P-Tat-FITC for 1 h at 37°C.

For all studies, the cells were imaged on a Zeiss (Thornwood, NY) LSM 510 confocal imaging system with an Axioplan 2 microscope (100 $\times$  plan-apo objective, NA = 1.4, oil) and an argon laser. (FITC, excitation = 488 nm, emission = 505 nm long-pass filter; propidium iodide, excitation = 543 nm, emission = 650 nm long-pass filter; Texas Red and Rhodamine, excitation = 543 nm, emission = 560 nm long-pass filter). The settings for all the confocal systems were adjusted so that control cells always yielded dark images.

**Subcellular Fractionation.** Percoll was used as the separation medium for subcellular fractionation. Ten million A2780 cells were cultured in 75 cm<sup>2</sup> flasks for 24

h prior to exposure to polymer–Tat conjugates. Cells were exposed to the conjugate P(TR)-Tat(FITC) for 4 h at 37 °C and then treated to the procedure as previously described(21) to obtain the lysosomal, plasma membrane, cytoplasmic and nuclear fractions. Fluorescence of FITC in each of these subcellular fractions was analyzed with an LS 55 luminescence spectrometer (Perkin-Elmer) (excitation-495 nm, emission-518 nm) and normalized to the protein content of each fraction (Coomassie Plus Protein Assay, Pierce). The fluorescence per microgram of protein associated with each fraction was expressed as a percentage of the total fluorescence per microgram of all fractions.

## RESULTS AND DISCUSSION

Several fluorescently labeled HPMa copolymer–Tat conjugates were synthesized by reacting the Tat peptide [H-Gly-Arg-(Lys)<sub>2</sub>-(Arg)<sub>2</sub>-Gln-(Arg)<sub>3</sub>-Gly-Tyr-Lys(FITC)-Cys-OH] with maleimide containing HPMa copolymer to form a thioether linkage (Figure 1). The Tat-FITC content in the P-Tat-FITC polymer as determined by UV spectroscopy was 0.038 mmol/g (one Tat peptide molecule per chain), indicating 40% binding efficiency of the Tat peptide to the polymer backbone. The double-label conjugate P(TR)-Tat(FITC) contained 0.034 mmol/g of TR and 0.056 mmol/g Tat-FITC. The content of Dox and Tat-FITC in the Dox containing HPMa copolymer–Tat conjugate P-GFLG-Dox-Tat determined by UV spectroscopy and amino acid analysis was 0.099 mmol/g (1.7 mol %) Dox and 0.064 mmol/g (1.2 mol %) Tat-FITC, respectively. The control polymer P-FITC and P-GFLG-Dox contained 0.038 mmol/g of FITC and 0.121 mmol/g of Dox, respectively, as determined by UV spectroscopy.

Confocal fluorescence microscopy of polymer–Tat conjugate P-Tat-FITC after 1 h incubation with the cells at 37 °C, exhibited powerful fluorescence associated with the plasma membrane. Diffuse fluorescence observed throughout the cell implied that the conjugate localized to the cytoplasm. Faint fluorescence in the nuclear region accompanied by areas of intense staining indicative of putative nucleolar accumulation were also seen (Figure 2A). Earlier reports demonstrate Tat-mediated transport of liposomes only into the cytoplasm (14); however, our data indicate both cytoplasmic as well as nuclear delivery of the polymer. The presence of punctate staining suggested that the conjugate was also internalized via endocytosis, which is typical of macromolecular uptake (18). In contrast, a control FITC-labeled polymer lacking the Tat peptide, P-FITC, was internalized solely by endocytosis even when high concentrations of the polymer were tested (Figure 2B).

To determine whether the Tat peptide mediated transport was by endocytosis, cells were incubated with either P-Tat-FITC or P-FITC at 4 °C for 1 h. Endocytosis, an energy dependent process is blocked at 4 °C (19). The internalization of P-Tat-FITC by the Tat mediated pathway was not inhibited, suggesting an energy independent, nonendocytotic uptake process (Figure 2C). However, cells incubated with P-FITC did not exhibit any fluorescence, as the endocytotic uptake of P-FITC was suppressed (Figure 2D).

Nuclear localization was corroborated by co-incubating the cells with P-Tat-FITC and the nuclear marker propidium iodide for 1 h at 37 °C. Confocal microscopy performed by separately tracking the FITC label on the conjugate (green) and propidium iodide (red) demonstrated areas of orange-yellow staining representing co-

**Figure 2.** Subcellular trafficking of various polymer conjugates incubated with A2780 cells by confocal fluorescence microscopy. (A) HPMa copolymer–Tat conjugate (P-Tat-FITC) for 1 h at 37 °C showed intense plasma membrane, cytoplasmic, and nuclear uptake. (B) FITC-labeled polymer lacking Tat peptide (P-FITC) for 1 h at 37 °C exhibited only endocytotic vesicles. (C) P-Tat-FITC for 1 h at 4 °C demonstrated Tat-mediated nonendocytotic transport of the conjugate. (D) P-FITC for 1 h at 4 °C showed no uptake. (E) P-Tat-FITC (green), (F) DIC image, and (G) nuclear marker propidium iodide (red) for 1 h at 37 °C. (H) Colocalization of the two dyes (orange-yellow staining) implied nuclear localization. Scale bar represents 10 μm.

localization of the two dyes in the nucleus (Figure 2E–H). One possible explanation for nuclear entry of the conjugate could be the presence of a nuclear localization signal RKKRR embedded in the Tat peptide sequence (6). Similarly, cytoplasmic import was verified by treating the cells with the membrane permeant cytoplasmic marker chloromethylbenzoylamino tetramethyl rhodamine (CMTMR) and P-Tat-FITC. The FITC label on the polymer–Tat conjugate (green) and CMTMR (red) were separately tracked and were found to co-localize,

**Figure 3.** Fluorescence images of cells incubated with P-Tat-FITC after 20 min, 2 h, and 4 h. thus confirming the cytoplasmic delivery of P-Tat-FITC (data not shown).

Recent studies have exhibited that fixing agents such as methanol, commonly employed for fixing cells in microscopy studies, lead to artificial cytoplasmic and nuclear accumulation as a consequence of membrane permeabilization (20). Microscopy of live cells, which precludes the use of fixing agents, was utilized to examine the subcellular distribution of the polymer–Tat conjugate. In agreement with data from fixed cell microscopy, cytoplasmic as well as nuclear uptake of the conjugate was observed, thus excluding the likelihood of artificial subcellular localization. Live microscopy studies also revealed internalization within 3 min, thus verifying the rapidity of the process (see movie in Supporting Information).

The time and concentration dependence of the internalization process was also investigated. Increasing incubation periods of P-Tat-FITC with the cells resulted in persistent membrane staining as well as a proportional increase in the fluorescence intensity within the cytoplasm and the nucleus, signifying augmented distribution of the conjugates with time. Images of the cells were taken at both low as well as high microscope settings in order to better visualize the changes in the plasma membrane and cytoplasm at different time points. Accumulation of the conjugate in the cytoplasm and nucleus was observed as quickly as 5 min. Endocytotic vesicles were more prominent at time points greater than 1 h as expected (Figure 3A–F). In the concentration dependent study, cells incubated with higher concentrations of P-Tat-FITC showed stronger fluorescence as compared to cells incubated with lower concentrations. Cytoplasmic and nuclear localization was observed for the entire concentration range (1.8–18  $\mu\text{M}$ ) tested, indicating concentration-independent subcellular fate (Figure 4A,B).

In the above experiments, the FITC label on the Tat peptide was traced, as the polymeric backbone was unlabeled. One concern was that subcellular proteolytic enzymes could potentially cleave the labeled Tat peptide from the polymeric backbone, resulting in the release of free, labeled Tat peptide within the cells. Thus, fluorescence in the cytoplasm and nucleus could represent the subcellular distribution of the cleaved fluorescent Tat peptide and not the polymer–Tat conjugate itself. To

**Figure 4.** Fluorescence images of cells incubated with (A) 1.8 and (B) 18  $\mu\text{M}$  P-Tat-FITC show both cytoplasmic as well as nuclear uptake. Scale bar represents 10  $\mu\text{m}$ .

address this problem, a double-label polymer–Tat conjugate [P(TR)-Tat(FITC)] was synthesized (Figure 1B). This conjugate bore a Texas Red (TR) label attached to the polymeric backbone in addition to the FITC label on the Tat peptide. Its subcellular distribution was evaluated by fluorescence microscopy. Similar uptake patterns in the cytoplasm and nucleus were observed with both dyes, establishing the Tat mediated cytoplasmic and nuclear delivery of the polymer–Tat conjugate (Figure 5A,B).

The ability of the Tat peptide to efficiently transport a drug across the plasma membrane into the cytoplasm was also assessed. To this end, Dox containing HPMA copolymer–Tat conjugate [P-GFLG-Dox-Tat] was synthesized (Figure 1C). This system was chosen as a model for demonstrating the significant nuclear and cytoplasmic transport achieved by the Tat peptide in comparison with that of the GFLG spacer. The subcellular distribution pattern in A2780 cells was studied by tracking the inherent fluorescence of Dox by confocal microscopy. At 37  $^{\circ}\text{C}$ , cytoplasmic as well as nuclear uptake of P-GFLG-Dox-Tat was observed (Figure 5C). The intensity of the Dox fluorescence signal was significantly stronger than that of the control P-GFLG-Dox copolymer lacking the Tat peptide (Figure 5D). This enhancement in the Dox uptake has two independent components—the enzymatic hydrolysis of the lysosomally degradable spacer GFLG (3) and Tat-mediated cytoplasmic delivery of Dox; a large contribution was attributed to the Tat mediated transport, as evidenced by studies at 4  $^{\circ}\text{C}$ . The intense fluorescent signal of P-GFLG-Dox-Tat observed at 4  $^{\circ}\text{C}$

**Figure 5.** Confocal fluorescence images of A2780 cells incubated with double label HPMA copolymer–Tat conjugate (P(TR)-Tat(FITC)) for 1 h at 37 °C. The two dyes (A) FITC and (B) TR show similar distribution, confirming the intracellular delivery of the polymer–Tat conjugate. Fluorescence images of cells incubated with different polymer conjugates containing anticancer drug doxorubicin with or without Tat. (C) P-GFLG-Dox-Tat for 4 h at 37 °C showed both cytoplasmic as well as nuclear localization. (D) P-GFLG-Dox for 4 h at 37 °C showed weaker signal. (E) P-GFLG-Dox-Tat at 4 °C continued to show cytoplasmic uptake in contrast with (F) P-GFLG-Dox at 4 °C, where uptake was completely abolished. Scale bar represents 10  $\mu$ m.

proved that the Tat peptide could successfully transport polymer bound doxorubicin into the cytoplasm independent of the GFLG spacer (Figure 5E). In contrast, no signal was visible with P-GFLG-Dox, as endocytosis was inhibited, as expected (Figure 5F). The use of the P-GFLG-Dox-Tat model system clearly demonstrates the superior transducing capabilities of the Tat peptide.

The cytoplasmic and nuclear uptake of the polymer–Tat conjugate was independently verified by subcellular fractionation. The polymer–Tat conjugate mainly amassed in the lysosomal and plasma membrane fraction after 4 h incubation. Further, the conjugate localized in smaller fractions in the cytoplasm and nucleus. This subcellular distribution pattern was a significant improvement over that of the P-FITC conjugate, which localized to the lysosomes (Figure 6). Our approach utilizing subcellular fractionation in conjunction with live and fixed cell confocal microscopy shows advantages over conventional methods such as flow cytometry (which represents surface binding and not internalization) and functional assays, which may be typical only of a sub-population of cells (20).

In conclusion, these results validate our hypothesis that the Tat peptide can transport a synthetic macromolecule across the plasma membrane and deliver it into the cytosol as shown by confocal fluorescence microscopy and subcellular fractionation. Our data indicated that

**Figure 6.** Subcellular fractionation showing the subcellular distribution of the polymer–Tat conjugate and control polymer P-FITC in the different organelle fractions.

incubation of HPMA copolymer–Tat conjugate with human ovarian carcinoma cells resulted in internalization of the conjugate by two processes, namely, endocytosis and a Tat-mediated nonendocytotic process. The Tat-mediated process, characterized by intense membrane staining and cytoplasmic and nuclear uptake, was not inhibited at 4 °C, indicating an energy independent pathway. Studies performed so far have demonstrated the delivery of proteins, nanoparticles, and liposomes; however, this is the first time the Tat peptide has been shown to efficiently transport a polymer bound drug to the cytosol by a nonendocytotic pathway. These systems hold great potential, due to the immense utility of water soluble polymers as drug carriers, mainly attributed to their ability to alter the biodistribution and reduce nonspecific toxicity of low molecular weight anticancer drugs. Though the lack of cell specificity of the Tat peptide makes its applicability universal, it is this very property of the Tat peptide that also causes it to be disadvantageous. The use of water-soluble polymers which allow the facile attachment of targeting moieties such as carbohydrates and antibodies may well render a Tat containing conjugate selectively biorecognizable to a specific cell population resulting in a change in both its uptake and distribution. Further, the binding of nonimmunogenic polymers to antibodies results in the decreased immunogenicity of the antibody due to steric hindrance of the polymer conjugate (1).

Although further investigations are warranted, these results suggest that the development of polymer–Tat based cytoplasmic delivery systems, especially for gene and antisense therapy, which combine the advantages of macromolecules and exploit the unique transport capabilities of the Tat peptide, will be beneficial.

#### ACKNOWLEDGMENT

We thank Drs. E. J. King and C. Anderson for their assistance with the confocal microscopy studies. This work was supported in part by NIH Grant CA51578 from the National Cancer Institute.

# Endosomolysis by Masking of a Membrane-Active Agent (EMMA) for Cytoplasmic Release of Macromolecules

David B. Rozema,<sup>\*,†</sup> Kirk Ekena,<sup>†</sup> David L. Lewis,<sup>†</sup> Aaron G. Loomis,<sup>†</sup> and Jon A. Wolff<sup>‡</sup>

Mirus Corporation, 505 S. Rosa Road, Madison, Wisconsin 53711, and Waisman Center, Department of Pediatrics and Medical Genetics, Medical School, University of Wisconsin—Madison, Madison, Wisconsin 53705. Received August 15, 2002; Revised Manuscript Received November 6, 2002

Endosomolysis, a critical barrier to efficient delivery of macromolecules such as nucleic acids, has been breached using a novel approach: endosomolysis by masking of a membrane-active agent (EMMA). To demonstrate the concept of EMMA, a cationic membrane-active peptide, melittin, was reversibly inhibited using a maleic anhydride derivative. At neutral pH, the lysines of melittin are covalently acylated with the anhydride, thereby inhibiting melittin's membrane disruption activity. Under acidic conditions such as those present within endosomes, the amide bond of the maleamate is cleaved, thus unmasking melittin. The active melittin can then disrupt the endosomal membrane resulting in release of biologically active molecules into the cytoplasm. This approach avoids cellular toxicity by restricting melittin's activity until it reaches the endosomal compartment. The utility of this approach was demonstrated by delivery phosphorodiamidate morpholino oligonucleotides (PMOs).

## INTRODUCTION

In the rational design of synthetic delivery vehicles for biologically active compounds and macromolecules such as nucleic acids, endosomal escape can be a critical barrier for their efficient delivery to cytoplasmic and nuclear sites of action (1–3). Endosomal escape can be enabled by the use of liposomes that hypothetically fuse with the endosomal membrane in a process akin to that used by enveloped viruses such as influenza (4, 5). Alternatively, nonliposomal vehicles (e.g., polymer-based systems) and nonenveloped viruses (e.g., adenoviruses) must escape from endosomes by disrupting their membranes (termed endosomolysis) (6). Despite some advances, our understanding of endosomal release and ability to synthetically enhance it remain at a rudimentary level.

Both viral and synthetic processes for accomplishing endosomal release often rely upon the changing environment of the endosome and/or lysosome to trigger either membrane fusion or disruption (7, 8). Endosomal acidification is frequently exploited to facilitate escape, given that as the endosome matures into a lysosome, the pH progressively drops to less than 5 (9–11). The pH gradient between cytoplasm and endosome causes endosomolytic monoamines such as chloroquine to concentrate within endosomes and destroy the pH gradient (12). The pH-sensitive amines within polyamines such as polyethyleneimine also play a role in endosomal release (13–15). For some liposome-based systems, pH-sensitive groups, typically carboxylic or amino groups, have been incorporated into lipids that undergo phase transitions upon protonation (4, 16). Peptides and synthetic polymers containing protonable groups have been modeled after viral sequences to become more amphipathic and membrane active in acidic environments (17–19). By limiting membrane activity to acidic vesicles, effects on the

plasma membrane and thereby cellular toxicity are attenuated.

The use of protonation to effect membrane disruption is beset with a potential conundrum. Endosome disruption by a pH-sensitive agent will destroy the pH gradient, which may reverse the membrane activity of the endosomolytic agent. As a consequence, the endosome membrane could reseal before the macromolecule diffuses out of the endosome, thereby limiting delivery. To avoid the swift reversibility of the protonation-based membrane active agents, we have developed an irreversible process that relies upon chemical bond cleavage to unmask a peptide's endosomolytic activity. The use of linkages that are labile within the endosomal or lysosomal milieu has previously been used in liposomes or for coupling drugs with carriers (4, 7, 20, 21). We chose to work with the cationic peptide melittin that contains several lysines required for its membrane activity and to use maleic anhydrides to reversibly modify the  $\epsilon$  amino groups of the lysine residues. Maleic anhydrides react with amines to form pH-labile amides, called maleamic acids, that are cleaved when the carboxylic group becomes protonated (22). A series of cyclic, maleic anhydride derivatives were evaluated for their ability to reversibly inhibit melittin (Figure 1A). Citraconic anhydride had previously been used to reversibly modify the primary amine of dioleoylphosphatidylethanolamine, but this reagent was not effective for our purposes (21). A previously unstudied maleic anhydride derivative, 2-propionic-3-methylmaleic anhydride (termed CDM for carboxylated dimethyl maleic acid), was synthesized to incorporate two design features that were found to be required: disubstitution of the maleic anhydride to increase pH-lability and an additional carboxylic acid to inhibit membrane activity of the peptide.

## MATERIALS AND METHODS

### Maleic Anhydride Derivatives and Synthesis of 2-Propionic-3-methylmaleic Anhydride (Carboxydimethylmaleic Anhydride or CDM). 2-Propionic-3-

**Figure 1.** (A) Maleic anhydride and maleamate derivatives: maleic R<sub>1</sub> and R<sub>2</sub> = H, dimethyl maleic R<sub>1</sub> and R<sub>2</sub> = CH<sub>3</sub>, citraconic R<sub>1</sub> or R<sub>2</sub> = H and R<sub>2</sub> or R<sub>1</sub> = CH<sub>3</sub>, *cis*-aconitic R<sub>1</sub> or R<sub>2</sub> = H and R<sub>2</sub> or R<sub>1</sub> = CH<sub>2</sub>CO<sub>2</sub>H, and 2-propionic-3-methylmaleic (CDM) R<sub>1</sub> or R<sub>2</sub> = CH<sub>3</sub> and R<sub>2</sub> or R<sub>1</sub> = C<sub>2</sub>H<sub>4</sub>CO<sub>2</sub>H. (B) Synthesis of 2-propionic-3-methylmaleic anhydride (CDM): a Horner–Emmons reaction between dimethyl-2-oxoglutarate and triethyl-2-phosphonopropionate, followed by saponification of the ester groups.

methylmaleic anhydride was synthesized according to a published procedure (23). To a suspension of sodium hydride (0.58 g, 25 mmol) in 50 mL anhydrous tetrahydrofuran was added triethyl-2-phosphonopropionate (7.1 g, 30 mmol). After evolution of hydrogen gas had stopped, dimethyl-2-oxoglutarate (3.5 g, 20 mmol) in 10 mL anhydrous tetrahydrofuran was added and stirred for 30 min. Water, 10 mL, was then added, and the tetrahydrofuran was removed by rotary evaporation. The resulting solid and water mixture was extracted with 3 × 50 mL ethyl ether. The ether extractions were combined, dried with magnesium sulfate, and concentrated to a light yellow oil. The oil was purified by silica gel chromatography elution with 2:1 ether:hexane to yield 4 g (82% yield) of pure triester. The 2-propionic-3-methylmaleic anhydride was then formed by dissolving of this triester into 50 mL of a 50/50 mixture of water and ethanol containing 4.5 g (5 equiv) of potassium hydroxide. This solution was heated to reflux for 1 h. The ethanol was then removed by rotary evaporation, and the solution was acidified to pH 2 with hydrochloric acid. This aqueous solution was then extracted with 200 mL ethyl acetate, which was isolated, dried with magnesium sulfate, and concentrated to a white solid. This solid was then recrystallized from dichloromethane and hexane to yield 2 g (80% yield) of 2-propionic-3-methylmaleic anhydride (CDM).

Citraconic, *cis*-aconitic, dimethylmaleic, and succinic anhydrides were purchased from Aldrich.

**Quantification of Amines by TNBS.** To determine the amine content of a sample, 50–200 nmol of amine is added to a 0.5 mL solution of 100 mM Borax solution containing 0.4 mM 2,4,6-trinitrobenzenesulfonic acid (TNBS) (Sigma). Fifteen minutes later the absorbance of the solution was measured at 420 nm. The amount of amine may be calculated by the absorbance of a solution of known amine concentration.

**Acylation of Poly-L-lysine (PLL) with CDM, Dimethylmaleic, Succinic, Citraconic, and *cis*-Aconitic Anhydrides and Assessment of Charge Density.** To a solution containing 200 μg PLL (MW 34 000 from Aldrich), 2 mg HEPES, and 0.4 mg NaOH in 100 μL water was added 0.4 mg of CDM, dimethylmaleic, suc-

cinic, or citraconic anhydride in 20 μL ethanol with rapid vortexing. For *cis*-aconitic anhydride, there was a substantial amount of hydrolyzed anhydride present in the sample; therefore, 2 mg of anhydride, 12 mg of HEPES, and 2.4 mg of NaOH were used. By TNBS assay there was no detectable amount of amine upon acylation under these conditions.

The charge density of these polyanions was determined by adapting a technique used for assessing DNA condensation (24, 25). A compacted, interpolyelectrolyte complex is formed when the polyanions (PLL completely reacted with the anhydrides) are mixed with fluorescein-labeled PLL. The compaction causes the fluorescein residues on PLL to be in closer proximity and self-quench, which enables the condensation state and by inference the effective charge density of the polyanions to be conveniently determined. To measure the condensation of PLL by acylated PLL, 10 μg of fluorescein-labeled PLL was placed in 0.5 mL of 5 mM HEPES buffer at pH 7.8. The fluorescence intensity of this solution was measured (excitation at 495 nm, emission at 530 nm). A 1 μg sample of acylated PLL (weight based on the starting weight of PLL, not on the weight of acylated PLL) was added to the fluorescein-labeled PLL, and the fluorescence intensity was again measured. This was repeated until the decrease in fluorescence intensity ceased. The amount of acylated PLL needed to quench fluorescein–PLL to the maximum degree was assumed to be point at which an equal amount of polyanion was added to the polycation.

**Acylation of Melittin with CDM, dimethylmaleic, Citraconic, and *cis*-Aconitic Anhydrides.** To a solution containing 200 μg melittin, 500 μg HEPES, and 100 μg NaOH in 20 μL water was added 100 μg of CDM, dimethylmaleic, or citraconic anhydride in 50 μL ethanol with rapid vortexing. For *cis*-aconitic anhydride 250 μg of anhydride, 1.25 mg of HEPES, and 250 mg of NaOH were used. By TNBS assay there was no detectable amount of amine upon acylation under these conditions.

**Fluorescein Labeling of PLL.** To a solution of PLL (10 mg) in 1 mL 10 mM K<sub>2</sub>CO<sub>3</sub> was added 0.4 mg of fluorescein isothiocyanate (0.02 functional eq). After 2 h, the polymer was placed into dialysis tubing (12 000 MW cutoff) and dialyzed for 72 h against 3 × 2 L deionized

water. The polymer was then removed from the tubing, and the water was removed by lyophilization. The yield of the reaction was estimated to be 50% by measurement of the absorbance of fluorescein-labeled PLL at 494 nm in a solution of 10 mM  $\text{NaHCO}_3$  using the extinction coefficient  $77\,000\text{ M}^{-1}\text{cm}^{-1}$  (Molecular Probes).

**Synthesis of Fluorescein-PEG.** A 100 mg sample of monoamine PEG (MW 5000, Shearwater) was dissolved in 1 mL of dimethylformamide. To this solution was added  $3.5\text{ }\mu\text{L}$  of diisopropylethylamine and 8 mg of fluorescein isothiocyanate. After 1 h, the PEG was precipitated by addition of 10 mL of diethyl ether. The PEG was then dissolved in 5 mL of water and purified by size exclusion chromatography using a  $30 \times 150\text{ mm}$  column of sephadex G10 (Sigma) eluting with water.

**Kinetics of Acid-Catalyzed Cleavage of Maleamylated Glycylalanine.** CDM, dimethyl maleic, and citraconic modified glycylalanine (GA, from Sigma) were synthesized by addition of  $400\text{ }\mu\text{g}$  of CDM, citraconic, or dimethylmaleic anhydride in  $20\text{ }\mu\text{L}$  of ethanol to a solution of  $200\text{ }\mu\text{g}$  of GA and 2.4 mg of HEPES base in  $44\text{ }\mu\text{L}$  of water. The solutions were mixed by rapid vortexing. The acylated peptide was acidified by addition of  $0.8\text{ }\mu\text{L}$  glacial acetic acid and  $10\text{ }\mu\text{L}$  of 1 M sodium acetate to bring the pH to 5.0. At various times,  $10\text{ }\mu\text{g}$  aliquots were removed and added to 0.5 mL of 100 mM  $\text{NaHCO}_3$  solution containing 0.4 mM TNBS. Fifteen minutes later the absorbance of the solution was measured at 420 nm. A plot of  $\ln[1 - (A_t/A_0)]$  as a function of time was a straight line whose slope is  $-k$ , the rate constant for the cleavage reaction, where  $A_t$  is the absorbance at time  $t$  and  $A_0$  is the absorbance of unmodified GA.

For *cis*-aconitic modification of GA, 3-fold more anhydride, base, and acid were used to synthesize and cleave the acylated peptide.

**Hemolysis Assay.** The membrane activity of polymers and peptides was measured using a red blood cell (RBC) hemolysis assay (26). Porcine whole blood was isolated in heparin-containing vacutainers. The RBC's were isolated by centrifugation at 500 RCF for 5 min. They were washed three times with 100 mM dibasic sodium phosphate at the desired pH and resuspended to the initial volume. The desired pH phosphate buffer was obtained by acidification of a dibasic sodium phosphate stock with HCl. (Buffers made from mixing of mono- and dibasic phosphate lysed red blood cells at acidic pH.) A  $20\text{ }\mu\text{L}$  sample of the washed RBC suspension, which is approximately  $10^8$  cells (26), was added to 500  $\mu\text{L}$  of phosphate buffer. To this solution was added various amounts of peptide or polymer. The samples were incubated for 1.5 h in a  $37^\circ\text{C}$  incubator. They were then spun for 1 min at 15 000 RCF. Lysis was determined by measuring the absorbance of the supernatant at 541 nm. Percent hemolysis was calculated assuming 100% lysis to be the absorbance of hemoglobin released upon addition of deionized water; all sample absorbances had the absorbance of buffer alone subtracted.

**Fluorescein-PEG Delivery Assay.** HeLa (human epitheloid) cells were grown in Dulbecco's Modified Eagle's Medium (DMEM, Cellgro, Herndon, VA) containing 10% fetal bovine serum (Hyclone Laboratories, Logan, Utah) in a humidified incubator at  $37^\circ\text{C}$  with 5%  $\text{CO}_2$  atmosphere. Cells were plated in 6-well culture dishes containing untreated glass coverslips at a density of  $1.0\text{--}1.5 \times 10^5$  cells/well and incubated for 24–48 h. Media were replaced with 1.0 mL DMEM containing 1.0 mg fluorescein-PEG3000 either with or without  $400\text{ }\mu\text{g}$  CDM-melittin. Cells were then incubated for 10 min at

$37^\circ\text{C}$ , washed once with warm  $37^\circ\text{C}$  DMEM, and incubated for an additional 35 min in DMEM containing 10% bovine serum. Cells were then washed three times with PBS (Sigma), fixed for 30 min at  $4^\circ\text{C}$  in PBS + 4% formaldehyde (Sigma), and washed three times in PBS. Coverslips were mounted onto glass slides for fluorescent microscopy. Images of the samples were collected by confocal microscopy on a Zeiss LSM510 confocal microscope (Zeiss, Germany) using a  $63\times$  oil plan apo objective with NA 1.4. Similar methods were used with 1 mg/mL of fluorescein-dextran (10 kDa, purchased from Molecular Probes).

To assay or cellular toxicity,  $2\text{ }\mu\text{L}$  of saturated solution propidium iodide in water was added to cells in 3 mL PBS after 35 min incubation in DMEM. After 3 min, the PBS solution was removed and cells were washed and fixed as described above. To study the effect of a proton pump inhibitor on the release of fluorescein-PEG, the cells were incubated with 200 nM bafilomycin A, while the cells were loaded with fluorescein-PEG and during their incubation in the presence of DMEM. The cells were then washed and fixed as described above. No diffuse cytoplasmic staining was observed for cells incubated with bafilomycin A.

**Oligonucleotide Delivery Assay.** HeLa Luc/705 cells (Gene Tools, Philomath OR) were grown under conditions used for HeLa cells. The cells were plated in 24-well culture dishes at a density of  $3 \times 10^6$  cells/well and incubated for 24 h. Media were then replaced with 1.0 mL DMEM or 1.0 mL DMEM containing 10% FBS. To these samples was added 2.5 nmol PMO (CCT CTT ACC TCA GTT ACA ATT TAT A, Gene Tools, Philomath, OR) with or without 2.5 or 5.0 nmol CDM-melittin, citraconylated melittin, or *cis*-aconitylated melittin. The cells were incubated for 4 h in a humidified, 5%  $\text{CO}_2$  incubator at  $37^\circ\text{C}$ . The medium was then replaced with DMEM containing 10% fetal bovine serum. The cells were then incubated for an additional 48 h. The cells were then harvested and the lysates were then assayed for luciferase expression as previously reported using a Lumat LB 9507 (EG&G Berthold, Bad-Wildbad, Germany) luminometer (27).

## RESULTS AND DISCUSSION

Synthesis of a carboxylic acid-containing derivative of dimethylmaleic anhydride(CDM). Two features of maleic anhydride derivatives were systematically evaluated. The first was the degree of substitution at the unsaturated carbon-carbon bond since it has been shown that the greater amount of substitution increases pH-lability (28, 29). The parent anhydride, maleic anhydride, has no substitution and forms the most stable maleamic acid (Figure 1). Citraconic and *cis*-aconitic-derived maleamic acids have one substitution and are more pH-labile. Maleamic acids derived from disubstituted dimethyl maleic anhydride are the most pH-labile (30). The second parameter evaluated was the effect of the addition of a carboxylate-containing group, which increases charge and water solubility. The *cis*-aconitic anhydride has such a carboxylic acid group. To complete the series and have a disubstituted anhydride with an additional carboxylic acid group, CDM was synthesized via a Horner-Emmons reaction between dimethyloxoglutarate and triethyl-2-phosphonopropionate, followed by saponification of the ester groups (Figure 1B) (23).

**Acylation of a Polyamine with Cyclic Anhydrides and the Effect on Charge Density.** To confirm the ability of the anhydrides to modify a polyamine and to

**Figure 2.** The quenching of fluorescein-labeled PLL upon addition of PLL modified with succinic anhydride ( $\nabla$ ), dimethylmaleic anhydride ( $\bullet$ ), CDM anhydride ( $\circ$ ), citraconic ( $\blacksquare$ ), or *cis*-aconitic anhydride ( $\square$ ).

evaluate the effect of acylation on the charge of the amines, the cyclic anhydrides were reacted with the polyamine PLL. The effect of acylation on the charge of the modified polyamine is important, given that the membrane activity of melittin is presumably dependent on its positive charge (*vide infra*). After reaction of PLL with succinic, citraconic, *cis*-aconitic, dimethylmaleic, and CDM anhydrides, the TNBS assay indicated that there was complete conversion of the  $\gamma$ -amines of PLL to carboxylates. The charge density of these polyanions was determined by assessing their ability to condense cationic, fluorescein-labeled PLL (24). At slightly basic pH, 1–1.2 functional equiv of succinylated PLL is required to condense PLL, which is estimated from our observation that 10–12  $\mu\text{g}$  of succinylated PLL is required to fully quench 10  $\mu\text{g}$  of fluorescein-labeled PLL (Figure 2). Similarly, 1–1.3 equiv of citraconylated PLL and 1.5 equiv of *cis*-aconitylated PLL, which has two carboxylate groups per repeating unit, are required to condense PLL. In contrast, PLL that is modified with dimethylmaleic anhydride requires ca. 20 equiv to condense PLL. Similarly, the charge density of CDM-modified PLL is roughly one charge per two carboxylates. It appears that the distal carboxylate of CDM anhydride adds charge to the modified polymer while the carboxylate of the anhydride contributes very little charge to the polyanion. This deficiency of effective charge density for dimethylmaleamates may be due to a hydrogen bond interaction between the amide proton and the carboxylate of the dimethylmaleamylate group. Another hypothesis is that the steric bulk of the two methyl groups prevents any interaction. The reported  $\text{pK}_a$  of the carboxylate of dimethylmaleamylate is 4.2 (28), and the  $\text{pK}_a$  of citraconylates is 3.2. These values suggest that the carboxylate is not hydrogen bonded to the amide proton because one would expect that a hydrogen bond between the carboxylate and amide proton would *decrease*, not increase the  $\text{pK}_a$  of dimethylmaleamylate. Whatever the reason for dimethylmaleamate's apparent lack of charge density, these results indicate that CDM can modify the amines of lysine, thereby converting a positive charge into a negative one.

**The Acylation of the Dipeptide Glycylalalanine and the Kinetics of Cleavage.** The rates of acid-catalyzed cleavage of the maleamates were evaluated using the dipeptide glycylalalanine (GA) (Figure 3). GA was chosen because it (1) contains one amine group, which simplifies kinetics, and (2) contains a carboxylate distant from the amine, which keeps the peptide soluble in the assay conditions without greatly affecting the  $\text{pK}_a$  of the amine. The rate of maleamate cleavage was studied

**Figure 3.** The cleavage of maleamic acid modifications of the glycylalalanine dipeptide modified with dimethylmaleic ( $\bullet$ ), CDM ( $\circ$ ), citraconic ( $\blacksquare$ ), or *cis*-aconitic anhydride ( $\square$ ).

by addition of the modified peptides to a pH 5 solution, and at various times the cleavage reaction was quenched by addition to a pH 9 solution containing TNBS. As expected, the disubstituted maleamic acids cleave much more rapidly than monosubstituted maleamic acids (Figure 3) (29). At early time points, the reverse reaction is negligible, and the reaction can be treated as unimolecular; but at later time points, the reverse reaction between amine and anhydride affects the concentration of amine, and the reaction is no longer strictly unimolecular. Data points where the reaction is less than 50% complete can be fitted to the equation  $\ln[1 - (A_t/A_0)] = -kt$ , where  $A_t$  is the absorbance at time  $t$  and  $A_0$  is the absorbance of PLL that was not modified by anhydride. We calculated rate constants of  $0.4 \text{ min}^{-1}$  for dimethylmaleamic acid cleavage and  $0.3 \text{ min}^{-1}$  for the cleavage of CDM modified GA, which correspond to half-lives of 1.5 and 2 min, respectively. Similar measurements of the reversal of citraconic and *cis*-aconitic modification revealed much slower cleavage kinetics with an approximate half-life of 300 min.

**Acylation of the Membrane Disruptive Peptide Melittin.** To investigate the effect of acylation on the activity of membrane-active, cationic peptides, we chose melittin. Melittin is a 26-residue peptide from bee venom (GIGAILKVLATGLPTLISWIKNKRKQ from the little honey bee), which is highly cytotoxic and hemolytic (31). Many synthetic analogues of melittin have been studied to determine which residues are important for membrane disruptive ability (17). The lysine at position 7 has been shown to be important for hemolytic activity (32). This importance of lysine 7 and the presence of four other amine groups, from three lysines and the amino terminus, suggest that regulating these amino groups could control the activity of melittin.

To test this hypothesis, we acylated melittin at pH 7.5 with two molar equiv, relative to the four lysine residues with succinic, *cis*-aconitic, dimethylmaleic, citraconic, and CDM anhydrides. Modification by all of the anhydrides except dimethylmaleic anhydride resulted in a complete loss of membrane activity as measured by red blood cells lysis. Measurement of amine content by TNBS revealed that the inactivation of melittin by dimethylmaleic anhydride modification was not the result of incomplete amine acylation. A possible explanation for the activity of dimethylmaleamylated melittin is the lack of effective charge for dimethylmaleamates. As we observed that dimethylmaleamylated PLL possessed very little charge density, we would expect that dimethylmaleamylated melittin would not be entirely inhibited from interacting with the anionic cellular membrane.

**Figure 4.** The return of melittin hemolytic activity at various times after incubation of maleamic-modified melittin at pH 5.0, for dimethylmaleic- (●), CDM- (○), citraconic- (■), or *cis*-aconitic-anhydride- (□) modified melittin.

**Restoration of Membrane Activity of Melittin upon Acidification.** To test whether the reversibility of the acylation reaction restores membrane activity, melittin modified with CDM, citraconic, or *cis*-aconitic anhydride was incubated at pH 5. At various times, the acidification was stopped by addition to pH 7.5 phosphate buffer and the membrane disruptive ability of each sample was measured by the addition of red blood cells. The membrane activity for CDM-melittin returned to 100% within 25 min (Figure 4). Analysis of the kinetics of the return of activity using an analysis method similar to that used for the TNBS assay (plotting of  $\ln[1 - (A_t/A_0)]$  as a function of time to determine the slope,  $-k$ ) revealed a rate constant of  $0.07 \text{ min}^{-1}$ , or a half-life of 10 min for CDM-melittin. The half-life for the restoration of melittin's activity is roughly 4 times longer than the half-life of cleavage. This increase suggests that most, if not all, of the CDM groups must be cleaved from melittin for it to be active. Despite this delay for the return of activity, these results suggest that the new reagent CDM is able to reversibly inhibit melittin's membrane activity in a time frame consistent with endocytosed materials' transit to late endosomes (11).

As one would expect from the kinetics for the cleavage of monosubstituted maleamic acids, the cleavage of citraconic and *cis*-aconitic anhydride modifications of melittin were much slower (Figure 4). Incubation of *cis*-aconitylated melittin at pH 5 for 27 h resulted in only a 30% return in activity, and citraconylated melittin had only a 50% return of activity. Analysis of the kinetics of

the cleavage of *cis*-aconityl modified melittin reveals a rate constant of  $0.015 \text{ h}^{-1}$  or a half-life of 47 h, while citraconylated melittin has a half-life of 24 h. The difference between modification by *cis*-aconitic and citraconic anhydrides may be due to the charge upon modification. As mentioned previously, *cis*-aconitic modification results in two carboxylate groups, while citraconic modification results in only one carboxylate group.

**Release of Fluorescein-Labeled Polyethylene Glycol from the Endocytic Compartment by CDM-Melittin.** To assess the ability of CDM-melittin to function as an endosomolytic agent, its ability to facilitate release of fluorescein-labeled poly(ethylene glycol) (PEG) from endosomes was examined (Figure 5). Similar assays have been used to examine the endosomolytic properties of viruses (33). Cells were incubated with  $1 \text{ mg/mL}$  fluorescein-PEG  $\pm 400 \text{ } \mu\text{g/mL}$  modified melittin for 10 min at  $37^\circ\text{C}$ . After this pulse, cells were washed and chased for an additional 35 min at  $37^\circ\text{C}$  in DMEM + 10% bovine serum. In the absence of CDM-melittin, the fluorescein-PEG had a punctuate appearance, indicative of localization in endosomes and/or lysosomes (Figure 5A). In contrast, when CDM-melittin was included, there was diffuse fluorescence throughout the cell, indicating release of fluorescein-PEG from internal endosomes/lysosomes (Figure 5B). Addition of *cis*-aconitic modified melittin resulted in the punctate fluorescence from the endocytosis of the fluorophore (Figure 5C), just as in the absence of melittin. The persistence of a punctate endosomal signal in the CDM-modified melittin indicates that organelle rupture was not 100% efficient. Similar results were observed when fluorescein-labeled 10kDa dextran was used as the marker molecule (data not shown). In addition, bafilomycin A, an inhibitor of endosomal acidification, inhibited release of the fluorescein-PEG (data not shown).

Visual inspection indicated that  $400 \text{ } \mu\text{g/mL}$  of CDM-melittin had no apparent cytopathic effect, whereas  $10 \text{ } \mu\text{g/mL}$  unmodified melittin completely destroyed the cells in less than 10 min. Additionally, propidium iodide staining was used to provide a more sensitive indication of cellular toxicity (34). In the cells exposed to CDM-melittin and after the 10 min wash,  $\sim 1\%$  of the cells showed nuclear staining with propidium iodide, which is similar to control samples (data not shown). Thus, CDM modification of melittin enabled endosomal release while substantially reducing melittin's cellular toxicity.

**Delivery of Oligonucleotide.** To assay the ability of CDM-modified melittin to aid in the delivery of a biologi-

**Figure 5.** Confocal fluorescent photomicrographs showing the sub-cellular distribution of endocytosed PEG-fluorescein in HeLa cells without any melittin(A), with CDM-modified melittin(B), or with *cis*-aconitic modified melittin(C). Settings were identical for all three pictures.

**Figure 6.** The effect of 2.5 nmol of maleamate modified melittin on PMO delivery as measured by their induction of luciferase expression in a HeLa cell line stably transformed with the luciferase gene containing an intron with a mutant splice site. The values are normalized to cells treated with PMO alone and represent the means of four separate experiments. The error bars encompass entire range of induction. Data presented for PMO with CDM-melittin (white bar), *cis*-aconitylated melittin (black bar), and citraconylated melittin (striped bar).

cally active molecule, we chose to study the delivery of phosphorodiamidate morpholino oligonucleotides (PMOs) (35, 36). These agents exert their effects by steric hindrance mechanisms and can be used to block translation or splicing of a target RNA (37–39). PMOs are uncharged nucleotide analogues in which a six-membered morpholine ring is substituted for ribose and an uncharged phosphorodiamidate linkage replaces the phosphodiester linkage (40). Like PEG and dextran, oligonucleotides are internalized by endocytosis (8) and are unable to diffuse across cell membranes (41, 42).

The most common method for delivery of anionic oligonucleotides is the use of cationic lipids (43, 44) and polymers (45). However, to use these strategies for the delivery of uncharged oligonucleotides, such as PMO's, they must first be complexed with a complimentary strand of anionic oligonucleotide to form a charged complex. Two other methods for delivering PMOs, scrape-loading and syringe-loading, both involve physically damaging cells to create transient lesions in the plasma membrane (37) and do not give consistent results.

To assay the delivery of PMO by CDM-melittin, we used a commercially available HeLa cell line that carries an integrated luciferase gene with a mutant splice site (39). This mutant splice site results in production of a mRNA coding for a truncated inactive luciferase protein. Blocking this splice site with an oligonucleotide enables expression of the full-length active enzyme. Thus, the luciferase activity in this cell line is directly proportional to the amount of PMO released from the endosomal compartment.

Co-incubation of 2.5  $\mu$ M blocking PMO with 2.5  $\mu$ M CDM-melittin resulted in 5–12-fold increase in luciferase expression above incubation with PMO alone (Figure 6, white bar). The CDM-melittin facilitated induction was comparable to the induction we obtained using scrape-loading. Neither *cis*-aconitylated nor citraconylated melittin resulted in any increase in PMO delivery (Figure 6, black and striped bars respectively), supporting our hypothesis that these modifications are too stable to aid in endosome disruption.

The presence of 10% serum decreased the amount of delivery observed for CDM-modified melittin and increased the amount of peptide required for optimal delivery. For example, incubation of 2.5 nmol PMO with 5.0 nmol CDM-modified melittin resulted in a 4–5-fold increase in luciferase production. As observed in the absence of serum, citraconylated and *cis*-aconitylated

melittin did not increase the delivery of PMO in the presence of serum.

## CONCLUSIONS

The research presented in this report is a demonstration of the concept of endosomolysis by masking of a membrane-active agent (EMMA). This study demonstrates the ability of a new chemical reagent, CDM, to reversibly inhibit the membrane active peptide melittin and enable endosomal release. Melittin is only representative of the many membrane active compounds whose activity can be potentially controlled in order to deliver impermeable compounds. CDM modification could also be used to reversibly inhibit other amine-containing molecules, including membrane-active peptides or polymers. Further studies are in progress to incorporate the CDM modification and CDM-melittin into a variety of synthetic delivery systems for the delivery of oligonucleotides, plasmid DNA and other membrane impermeable drugs.

Delivery of the morpholino-based oligonucleotide by CDM-modified melittin relies on the co-endocytosis of oligonucleotide and melittin. This event is possible in the relatively high concentration of the culture dish, but is impossible in vivo. In order for CDM-based EMMA to facilitate delivery in vivo, the masked membrane-active agent must be associated, with the compound to be delivered. This association may occur by covalent attachment of the membrane-active agent to the compound to be delivered or noncovalent attachment via electrostatic interaction, for example in DNA-polycation complexes. Studies are in progress to attach compounds to be delivered to the masked endosomolytic agent.

## ACKNOWLEDGMENT

The authors would like to thank Lori Higgs for the synthesis of melittin. We would also like to thank the National Institute of Standards and Technology for financial support through Advanced Technology Program (ATP).

Received August 23, 2002

Photodynamic therapy (PDT) is a promising therapeutic modality for treatment of solid tumors. In this study, third-generation aryl ether dendrimer porphyrins (DPs) with either 32 quaternary ammonium groups (32(+)-DPZn) or 32 carboxylic groups (32(-)-DPZn) were evaluated as a novel, supramolecular class of photosensitizers for PDT. DPs showed a different cell-association profile depending on the positive or negative charge on the periphery, and both DPs eventually localized in membrane-limited organelles. In contrast, protoporphyrin IX (PIX), which is a hydrophobic and relatively low molecular weight photosensitizer used as a control in this study, diffused through the cytoplasm except the nucleus. Confocal fluorescent imaging using organelle-specific dyes indicated that PIX induced severe photodamage to disrupt membranes and intracellular organelles, including the plasma membrane, mitochondrion, and lysosome. On the other hand, cells treated with DPs kept the characteristic fluorescent pattern of such organelles even after photoirradiation. However, notably 32(+)-DPZn achieved remarkably higher  $^1\text{O}_2$ -induced cytotoxicity against LLC cells than PIX. Furthermore, both dendrimer porphyrins had far lower dark toxicity as compared with PIX, demonstrating their highly selective photosensitizing effect in combination with a reduced systemic toxicity.

## INTRODUCTION

Molecular nanomeric-scaled devices prepared through chemical process have recently been recognized to be useful for high-throughput screening, molecular diagnosis, and targeting therapy (*1*). In particular, dendrimers, the three-dimensional tree-like branched macromolecules, have received intense attention especially in the field of drug and gene delivery (*1–5*). On the basis of the delivery of modern organic synthetic chemistry, dendrimers having intriguing structures can be tailored in size, functional peripheral groups, and inner cavity for incorporation of a variety of molecules. Such custom-made dendrimers offer the design of novel types of delivery systems used for nanomedicines, with controlled interaction with cells and biological compounds. We have recently reported extensively on dendrimer porphyrins in which a porphyrin chromophore is spatially isolated by the aryl ether dendrimer framework (Figure 1) (*6–9*). The dendrimer porphyrins can transport absorbed energy to the porphyrin center over relatively large distance via the dendritic architecture, thereby mimicking the antenna complex and bacteriochlorophyll photo-

system (*8, 9*). On the other hand, a series of porphyrin compounds is known to effectively produce highly toxic singlet oxygen ( $^1\text{O}_2$ ) through excitation by light of a characteristic wavelength, and some are being used as photosensitizers for photodynamic therapy (PDT). Consequently, dendrimer porphyrins may have a potential as a novel type of photosensitizer used for PDT.

PDT is a topical and promising method for the localized treatment of solid tumors, and an increasing number of the photosensitizers are presently being explored in the preclinical and clinical study (10–15). However, most of them cause toxic side effects such as prolonged skin photosensitivity due to lack of the specificity to tumors (16). The efficiency of photosensitizers in situ is most likely to be dependent on their local accumulation and specific cellular uptake in the tumor site, stimulating research toward the development of water-soluble and efficient in vivo sensitizer–delivery system with a high potential to target specific organs (17–20). Notably, the higher molecular weight of the dendrimer porphyrins are promising in this regard, since macromolecular compounds can preferentially accumulate in solid tumor due to the enhanced permeability of tumor vascular endothelium and the lack of functional lymphatic drainage in the tumor tissue, known as the so-called enhanced permeability and retention (EPR) effect (21, 22). In addition, being different from low molecular weight photosensitizers currently in clinical use which exhibit nonspecific intracellular distribution, the dendrimer porphyrins with the relatively large size and three-dimensional structure are expected to be internalized in membrane-limited organelles, thereby achieving controlled localization in the intracellular compartment. Further, modification of the periphery of dendrimers with various ligands, including charged groups, sugars, and peptides, may open the way to design molecular-targeted PDT to accomplish highly selective death of tumorous cells with minimal side effects to the normal tissue. Here, we report for the first time the feasibility of dendrimer porphyrins with positive or negative charged groups on their periphery as an effective photosensitizer with little nonspecific, dark toxicity for PDT.

## MATERIALS AND METHODS

**Photosensitizers.** The synthesis and characterization of the ionic dendrimer porphyrins as given in Figure 1 have been reported previously (6–8). The third-generation aryl ether dendrimer with a Zn–porphyrin center and 32 positively charged  $(\text{C}(\text{O})\text{N}(\text{H})(\text{CH}_2)_2\text{N}^+\text{Me}_3)$  groups on its periphery and third-generation aryl ether dendrimer with a Zn–porphyrin center and 32 negatively charged  $(\text{COO}^-)$  groups on its periphery are abbreviated to 32(+)DPZn and 32(–)DPZn, respectively (Figure 1). The protoporphyrin IX (PIX, 8,13-divinyl-3,7,12,17-tetramethyl-21H,23H-porphine-2,18-dipropionic acid) (Aldrich Chemical Co., Inc., U.S.A.) was used as a control photosensitizer in this study.

**Evaluation of Singlet Oxygen Quantum Yield.** The singlet oxygen quantum yield was measured via direct observation of the near-infrared emission at 1268 nm, corresponding to the  $\text{O}_2(^1\Delta_g) \rightarrow \text{O}_2(^3\Sigma_g^-)$  transition (23). The experimental setup consists of Ar laser equipment (Innova 70–4; Coherent Inc., U.S.A.) and a near-infrared Ge detector (model 403HS; Applied Detector Co., U.S.A.) cooled by liquid nitrogen, connected to the exit slit of the monochromator (model CT10; JASCO, Japan) with a blaze wavelength at 1250 nm to minimize the grating loss. An IR-80 cutoff filter with 0% transmittance at less than 750 nm and 35% transmittance at 800 nm was placed at the entrance slit of the monochromator. A collecting lens focused the monochromator output onto the detector crystal. The Ar laser output at 514.5 nm was chopped with 800 Hz by an acousto-optic modulator (A-160; HOYA, Japan) operated by a driver (110-DS; HOYA, Japan). The signal output from the Ge detector was fed into a model 124A lock-in amplifier via a model 116

preamplifier (both from E.G. & G. Princeton Applied Research, U.S.A.) and synchronized with the internal reference signal of the lock-in amplifier. The signal output from the lock-in amplifier was fed to an XY recorder, and the emission spectrum was recorded by scanning the grating with a monitor. To minimize photobleaching, the solution was circulated at 4 mL/min using a peristaltic pump through a quartz flow cell ( $3 \times 3$  mm). MeOD was used as the solvent. Solutions were bubbled with pure  $\text{O}_2$  for 1 min before measurement.

Molar absorption coefficients at 514.5 nm were determined in MeOD using a JASCO UV/VIS apparatus (model: Ubest-series V-550).

**Quantitative Analysis of Photosensitizers Associated with the Cells.** Quantification of the amount of dendrimers or PIX associated with Lewis Lung Carcinoma (LLC) cells at 4 or 37 °C was performed by utilizing the fluorescence of PIX at 630 nm (excitation at 400 nm) and of 32(+)DPZn and 32(–)DPZn at 600 nm (excitation at 430 nm). Following exposure to dendrimers or PIX for 30 min, 3 h, and 8 h, the cells were washed three times with sterile PBS, harvested after treated with trypsin–EDTA solution, and then dissolved in 20% SDS solution prior to fluorescence measurement ( $n = 3$ ). Fluorescent measurement was performed by JASCO spectrofluorometer FP-777 (Tokyo, Japan).

**Confocal Microscopy.** For confocal microscopy, LLC cells were cultured onto fibronectin (from bovine plasma, Itoham Foods, Inc., Japan)-coated sterile 35 mm glass-base dishes (Iwaki Glass, Japan). The cells were then incubated with each photosensitizer. In the case of dendrimer porphyrins, the cells were coinocubated with Tex-Red dextran (Molecular Probes, U.S.A.) as a neutral endocytosis marker (24). At definite time intervals, the cells were washed two times with sterile PBS, followed by confocal microscopy observation. Confocal microscopy was conducted using LSM 510 (Carl Zeiss Co., Ltd., Germany) at excitation wavelengths of 458 nm (Ar laser) for dendrimers and 543 nm (He–Ne laser) for Tex-Red dextran.

**Photoirradiation and Cell Viability Assay.** The cytotoxicity of each photosensitizer in vitro was assessed against LLC cells. In the darkened room, photosensitizers with different concentration in medium (Dulbecco's modified eagle's medium (DMEM) + 10% Fetal Bovine Serum (FBS)) were added to cell solutions in 96-well culture plates ( $n = 4$ ). After a defined incubation time (30 min, 3 h, and 8 h) at either 4 or 37 °C, the photosensitizers were removed, and then the plates were photoirradiated for 10 min with broad-band visible light using a Xenon lamp (150 W) equipped with a filter passing light of 377–700 nm (Estimated incident light irradiance: 150 mW/cm<sup>2</sup>). The viability of photoirradiated and nonphotoirradiated cells was evaluated by using the mitochondrial respiration via the 3-(4,5-dimethyl thiazol-2-yl)-2,5-diphenyltetrazolium bromide cleavage assay (MTT) following incubation for 24 h after photoirradiation.

**Detection of Photodamage by Fluorescent Probes.** Photodamaged sites in the cell were detected by three different fluorescent probes, Rhodamine 123 (Rh123; excitation 450–490 nm, emission 520–600 nm), 1-(4-trimethylammoniumphenyl)-6-phenyl-1,3,5-hexatriene iodide (tma-DPH; excitation 330–380 nm, emission 420–550 nm) (Dojindo Laboratories, Inc., Japan), and LysoTracker Red DND-99 (LysoTracker; excitation 577 nm, emission 590 nm) (Molecular Probes, U.S.A.), which is used for the staining of the mitochondrion, plasma membrane, and lysosome, respectively, in the living cell (25). Twenty minutes after irradiation, control or photo-

damaged cells on fibronectin-coated sterile 35 mm glass-base dishes were incubated with 10  $\mu\text{g}/\text{mL}$  Rh123 for 10 min or 25  $\mu\text{M}$  LysoTracker for 40 min at 37  $^\circ\text{C}$  before the observation. To detect the plasma membrane photo-damage, a drop of tma-DPH in dimethylformamide (DMF) (0.5 mg/mL) was added to control or photodamaged cells detached from the culture dish by cell scraper 20 min after irradiation. Fluorescent images were acquired using confocal microscopy (LSM 510, Carl Zeiss Co, Germany).

## RESULTS

### Quantum Yield for Singlet Oxygen Production.

To compare the singlet oxygen quantum yield, direct observation of the  $\text{O}_2(^1\Delta_g) \rightarrow \text{O}_2(^3\Sigma_g^-)$  transition at 1270 nm ((0,0) vibronic band) was performed for PIX, 32(+)-DPZn, and 32(-)-DPZn in MeOD excited by Ar laser light bundle of 514.5 nm with 300 mW output power. The emission intensity was linear with output power over the range of at least 0–300 mW. Figure 2 presents the near-

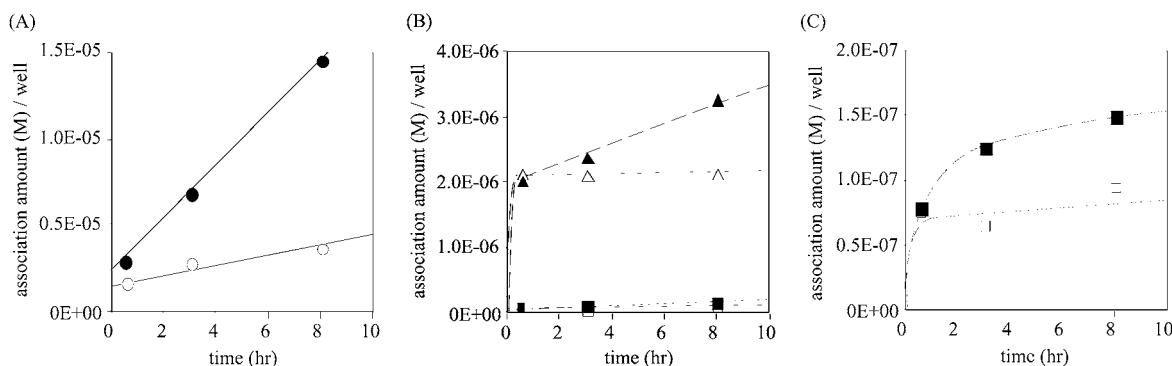

infrared singlet oxygen luminescence emission spectrum of the photosensitizers in MeOD. The linear relation between the emission intensity and the concentration of photosensitizers in the range of this measurement was confirmed for Rose Bengal, which was used as a reference. The emission efficiency defined as the molar ratio of the  $^1\text{O}_2$  emission intensity to the absorption coefficient at 514.5 nm of each photosensitizer is listed in Table 1. Small differences in the ratio of the  $^1\text{O}_2$  emission intensity to the absorption coefficient ( $I/\epsilon$ ) were observed between PIX and the dendrimer porphyrins. The observation that PIX and both dendrimers have similar singlet oxygen quantum efficiencies gave basis to directly compare the effects of 3D architecture and surface groups on the photodynamic activity of these sensitizers.

### Amount of Cellular Associated Photosensitizers.

The time-dependent association of PIX and dendrimers with Lewis Lung Carcinoma (LLC) cells at different temperature (4 or 37  $^\circ\text{C}$ ) was evaluated from their fluorescence and shown in panels A and B, respectively, of Figure 3. The amount of PIX associated with the cells increased linearly with the exposure time for both 4 and 37  $^\circ\text{C}$ ; yet the slope is remarkably steeper for the latter condition (Figure 3A). The association profile of 32(+)-DPZn comprised two-phases: the first temperature-independent rapid association accomplished within 30 min, and the subsequent slow association particularly observed at 37  $^\circ\text{C}$  (Figure 3B). 32(-)-DPZn showed a similar trend to 32(+)-DPZn, although the associated amount was about one-order of magnitude lower (Figure 3B,C).

**Intracellular Localization.** The intracellular localization of dendrimers in LLC cells was observed by confocal microscopy. Figure 4 shows the fluorescent image of PIX after incubation with LLC cells for 3 h at 37  $^\circ\text{C}$ . Diffuse PIX fluorescence was present throughout the cell except for the nuclei, which is consistent with the intracellular distribution of in situ biosynthesized PIX in  $\Delta^5$ -aminolevulinic acid (ALA)-based PDT, as previously reported by Madsen et al. (13).

Confocal fluorescent images of Texas-Red dextran (red fluorescence) and 32(+)-DPZn (green fluorescence) after incubation with LLC cells for 3 h at 37 $^\circ\text{C}$  are shown in panels A and B, respectively, of Figure 5. Texas-Red dextran, which is known to be internalized by endocytosis leading to long time location in a lysosomal vesicle, was used as a marker molecule (24). The cellular nuclei appeared not fluorescent for both Texas-Red dextran and 32(+)-DPZn, indicating their localization in the extra-nuclear region of the intracellular compartment. Texas-Red dextran revealed the tiny dotted fluorescence around the perinuclear region, resulting from localization in

**Figure 3.** Amount of photosensitizers associated with LLC cells as a function of incubation time (○: PIX(4  $^\circ\text{C}$ ); ●: PIX(37  $^\circ\text{C}$ ); △: 32(+)-DPZn(4  $^\circ\text{C}$ ); ▲: 32(+)-DPZn(37  $^\circ\text{C}$ ); □: 32(-)-DPZn(4  $^\circ\text{C}$ ); ■: 32(-)-DPZn(37  $^\circ\text{C}$ )).

**Figure 4.** Confocal images of PIX in LLC cells after incubation of 3 h at 37 °C.

**Figure 5.** Confocal images of Texas-Red dextran (A) and 32(+)DPZn (B) in LLC cells after incubation of 3 h at 37 °C.

lysosomes (Figure 5A), and 32(+)DPZn showed a similar fluorescent image. The superposition of both fluorescent images revealed that 32(+)DPZn partially colocalized with Texas-Red dextran, suggesting that 32(+)DPZn is likely to be internalized via endocytosis, followed by localization in membrane-limited organelles such as lysosomes. 32(−)DPZn showed subcellular localization similar to that of 32(+)DPZn (data not shown).

**In Vitro PDT Effect.** The viability of LLC cells upon photoirradiation was evaluated by MTT assay and determined as a function of the concentration and the exposure time of photosensitizers, PIX, 32(+)DPZn, and 32(−)DPZn. In this assay, photosensitizers were incubated with LLC cells for a definite time period (30 min, 3 h, and 8 h), and nonassociated photosensitizers were removed prior to photoirradiation. The cellular viability upon photoirradiation indicates the in vitro photodynamic (PD) effect ( $^1\text{O}_2$ -induced toxicity). Panels A and B of Figure 6 illustrate the PD effect for LLC cells

**Figure 6.** The viability of LLC cells treated with PIX (●), 32(+)DPZn (▲), and 32(−)DPZn (■) after photoirradiation and at incubation times of 30 min (A) or 8 h (B).

**Table 2.** The in Vitro PDT Effect ( $^1\text{O}_2$ -Induced Toxicity) of PIX, 32(+)DPZn, and 32(−)DPZn in LLC Cell Line<sup>a</sup>

		IC <sub>50</sub> (μM)		IC <sub>50</sub> (4 °C)/ IC <sub>50</sub> (37 °C)
		4 °C	37 °C	
PIX	30 min	2.48	1.84	1.34
	3 h	1.02	0.980	1.04
	8 h	1.33	0.503	2.64
P32(+)	30 min	0.0986	0.0469	2.10
	3 h	0.0330	0.0280	1.18
	8 h	0.0237	0.0250	0.95

	8 h	38.7	5.76	6.72

<sup>a</sup> All data were presented by 50% inhibitory concentration (IC<sub>50</sub>) (unit: μM).

incubated with an increasing concentration of PIX (circle), 32(+)DPZn (trigon), and 32(−)DPZn (square) for 30 min (A) and 8 h (B), respectively. Obviously, the PD effect observed decreased in the order of 32(+)DPZn, PIX, and 32(−)DPZn. Table 2 summarizes 50% inhibitory concentration (IC<sub>50</sub>) of each photosensitizer at which fifty percent of tumor cells survive after photoirradiation, calculated from the cell viability–concentration curve (Figure 6). At 37 °C with 30 min and 8 h incubation, respectively, 32(+)DPZn has 39 and 20 times lower IC<sub>50</sub> values than PIX and 763 and 230 times lower IC<sub>50</sub> values than 32(−)DPZn, indicating a remarkably high PD efficiency of 32(+)DPZn. Notably, 32(+)DPZn achieved an extremely high PD effect even after a short exposure period (30 min), whereas the PD effect of 32(−)DPZn was low and appeared in a time-dependent manner particularly at 37 °C, where appreciable decrease in IC<sub>50</sub> value by increasing temperature was observed. On the other hand, significant differences in IC<sub>50</sub> between 4 and 37 °C were not observed for 32(+)DPZn, especially for the sample with prolonged incubation time, but were observed for 32(−)DPZn, as can be concluded from Table 2. It should be noted that the level of endocytotic activity of cells is greatly diminished at 4 °C.

**Dark Toxicity.** It is of primary importance to evaluate the dark toxicity (inherent toxicity) of photosensitizers in long time exposure from the standpoint of their application in vivo. Therefore, each photosensitizer, PIX, 32(+)DPZn, and 32(−)DPZn, was examined in terms of IC<sub>50</sub> values without photoirradiation after 72 h exposure in a dark room, and the results are shown in Table 3. 32(+)DPZn and 32(−)DPZn, respectively, exhibited 113- and 157-fold lower dark toxicity than PIX, indicating the remarkably high light-induced toxicity of dendrimer porphyrins, especially for 32(+)DPZn.

**Figure 7.** Photodamage from PIX and 32(+)DPZn in LLC cells as detected by three fluorescent probes: Rh123(A–C), LysoTracker (D–F), and tma-DPH (G–I). Control cells with photoirradiation alone are shown in panels A, D, and G, cells photodamaged with PIX in panels B, E, and H, and cells photodamaged with 32(+)DPZn in panel C, F, and I.

**Table 3.** Dark Toxicity of PIX, 32(+)DPZn, and 32(–)DPZn in LLC Cell Line after Incubation of 72 h at 37 °C

	PIX	P32(+)	P32(–)
IC <sub>50</sub> (μM)	0.200	22.6	31.3

**Photodamaged Sites in the Cell.** Control and photodamaged cells were stained with Rh123, LysoTracker, and tma-DPH to detect the mitochondrial, lysosomal, and plasma membrane photodamage, respectively. In this experiment, LLC cells were incubated with each photosensitizer at the concentration of 10-fold IC<sub>50</sub> for a definite time period (30 min and 3 h) at 4 or 37 °C prior to photoirradiation. Note that the fluorescent patterns of every probe in control cells were not altered by photoirradiation alone.

Fluorescent images of Rh123, LysoTracker, and tma-DPH-stained LLC cells are shown in panels A–C, D–F, and G–I, respectively, of Figure 7. Irradiated control cells without incubated photosensitizers showed spotted fluorescence of Rh123 and LysoTracker corresponding to the mitochondrion and lysosome, respectively (Figure 7A,D). The fluorescence of tma-DPH was mainly present at the cell surface (Figure 7G). After photodamage by PIX, diffuse fluorescence of Rh123 and LysoTracker (Figure 7B,E) and penetration of tma-DPH into submembrane

loci (Figure 7H) were detected, suggesting a disruption of mitochondrion, lysosome, and plasma membrane, respectively. On the other hand, photodamage by 32(+)DPZn seemed to induce no substantial change in the characteristic fluorescent pattern of each probe, except that a small portion of LysoTracker fluorescence became diffuse and the number of spotted fluorescence of Rh123 evidently decreased (Figure 7C,F,I). Photodamage by 32(–)DPZn rendered the fluorescent pattern of LysoTracker diffusive in small part similar to 32(+)DPZn but kept the characteristic fluorescent pattern of each probe, as observed in control cells (data not shown).

## DISCUSSION

32(+)DPZn and 32(–)DPZn aryl ether dendrimer zinc porphyrins both absorb light at 415, 434 (Soret bands), and 559 nm (Q-band) and emit fluorescent light at 610 and 660 nm. Due to their well-defined three-dimensional shape, which is morphologically trying to mimic biological light-harvesting antennae, they are of interest as artificial antennae for large distance energy transfer. Recently it has been shown that the efficiency of photoinduced energy transfer to the porphyrin core is enhanced via the rigid dendritic architecture (8, 9). The encapsulation of the reactive porphyrin center into a dendritic architecture

was also expected to have additional interesting properties, like the possibility to influence the interactions of the ionic groups on the periphery with biocomponents. The above considerations initiate our interest to investigate the potential of porphyrin dendrimers as photosensitizers for PDT. We have chosen third-generation water soluble ionic dendrimers which have an interesting combination of their size ( $\sim 5$  nm), surface charge, and water solubility (7).

The time-dependent profile of 32(+)DPZn association with LLC cells comprised two distinct phases: first, temperature-independent rapid association accomplished within 30 min, followed by temperature-dependent slow association (Figure 3B). The first rapid association appears to correspond to 32(+)DPZn adsorption to the negatively charged plasma membrane through electrostatic interaction, and the second phase, which is apparent at 37 °C, is likely to be internalization of dendrimers by adsorptive endocytosis. Note that the size of dendrimer ( $\sim 5$  nm) is obviously too large to diffuse through the plasma membrane. On the other hand, 32(-)DPZn showed a very low initial adsorption, which is less than 1/10 of the 32(+)DPZn adsorption. The slow and small increase in the associated amount after the initial adsorption was only observed at 37 °C (Figure 3C), suggesting that 32(-)DPZn is taken up by fluid-phase endocytosis. Both dendrimers internalized into the cells finally appear to localize in endosomal compartments because they colocalized with Tex-Red dextran, a fluid-phase endocytic marker (Figure 5). The PD effect ( $^1\text{O}_2$ -induced cytotoxicity) at 37 °C of 32(+)DPZn was 230 times higher than that of 32(-)DPZn (Table 2), while the associated amount of 32(+)DPZn was estimated to be only 22–25 times higher than that of 32(-)DPZn (Figure 3B), illustrating the higher PD efficiency of 32(+)DPZn compared to 32(-)DPZn. Because both compounds have similar efficiencies of singlet oxygen production, difference in the photoinduced cytotoxicity cannot solely be attributed to the different internalized amounts. The difference in the efficiency of PD effect between 32(+)DPZn and 32(-)DPZn should be due to the different interactions of both compounds with cellular components. 32(+)DPZn is likely to adsorb strongly with negatively charged membrane components, for example, glycoproteins, through electrostatic interactions, whereas negatively charged 32(-)DPZn seems not to be in a close contact with membrane components due to electrostatic repulsion. Consequently, the photodamage to the plasma membranes may be more vigorous for 32(+)DPZn as compared to 32(-)DPZn and may cause lipid peroxidation, protein cross-linking, and loss of ionic homeostasis (26–29). Further, the photodamage to the lysosomal membranes may cause release of hydrolases into the cytoplasm (30). The direct possible interaction of dye radicals with biocomponents can be excluded in the present case because the dendrimers have a relatively dense 3D structure in which the dye molecule (porphyrin) is protected by aryl ether dendrons. Thus, it is likely that only singlet oxygen or other reactive oxygenic species are responsible for the PD effect of dendrimer porphyrins. Singlet oxygen has a quite short lifetime, and the diffusion distance of  $^1\text{O}_2$  is estimated to be less than 10 nm (10). Nevertheless, the 3D structure of dendrimers with the size of 5 nm appears not to be a barrier for the  $^1\text{O}_2$ -induced PD effect, as 32(+)DPZn showed a remarkably high cytotoxicity upon photoirradiation.

The protoporphyrin (PIX) used as a control in this study is one of primitive but effective photosensitizers well-studied by many research groups and is a component

of protoheme (28, 29, 31–33). Excessive levels of PIX in circulating red blood cells cause erythropoietic protoporphyria, leading to cutaneous photosensitivity (33). The PIX, which is rather unpolar and only slightly soluble in water, may penetrate into cells through the plasma membrane by simple diffusion (Figure 3A) and partitions into the plasma as well as subcellular membrane components, including the mitochondrial, lysosomal, endoplasmic reticulum, and nuclear membranes (31, 32). Indeed, PIX showed a diffuse pattern of fluorescence throughout the cell except the nuclei. It seems that the mitochondrion is most likely susceptible to the PIX-induced photodamage (32), since PIX can be ligands for the mitochondrial peripheral benzodiazepine receptor (PBR) (10). The reason many PD efficient photosensitizers are hydrophobic appears to be because the plasma as well as subcellular membranes are critical sites for the  $^1\text{O}_2$ -induced photodamage to the cells (25, 27, 33, 34). Worth noting is that 32(+)DPZn showed a 20 times higher PD effect than PIX (Table 2) even though the former cell association after 8 h incubation was 4.5 times lower (Figure 3A,B). These results suggest that 32(+)-DPZn has a markedly enhanced efficiency of PD effect even compared with PIX, which should be explained by the their different localization in the plasma and subcellular membranes such as plasma membrane proteins, including transporters, ion channels, enzymes or cytoskeleton, lipids, etc. (26, 27, 35), as well as the differences in photodamaged sites in the organelles in the cells (25, 30, 31, 33, 34, 36, 37). Kochevar et al. demonstrated that the photodamaged sites and functions vary with the localization or distribution of the dye molecules in the cell membranes (27). PIX is known to accumulate primarily in the lipophilic compartments of the cell membranes (31, 32), while 32(+)DPZn appears to interact electrostatically with cell membranes, leading to different localization and/or distribution on the membranes as compared to PIX. Dendrimer porphyrins with a size of 5 nm are likely too large to penetrate into the cytoplasm, so that their internalization does occur in membrane-limited organelles (Figure 5). Therefore, the PD effect of 32(+)DPZn may also be different from that of low molecular weight photosensitizers with a cationic charge, which have been shown to localize selectively within mitochondria leading to efficient cell death (10). Furthermore, 32(+)DPZn may overcome the drawback of low molecular weight, cationic photosensitizers, as they clear very rapidly from tumor tissues (38, 39). Macromolecules retain in tumor tissue at higher levels due to the EPR effect (21, 22). Recently, several studies have demonstrated that nucleic acid compounds can be an alternative potential target of  $^1\text{O}_2$ -induced photodamage (40, 41). However, this mechanism seems to be unlikely for the PD effect of 32(+)DPZn because, as seen in Figure 5, fluorescence of 32(+)DPZn was hardly detectable in cellular nuclei. Although the exact molecular targets of 32(+)DPZn are an issue to be clarified in future, it is apparently important to control the intracellular disposition of the dye molecules based on the nature of the interaction forces to achieve an efficient PD effect.

Photodamage by 32(+)DPZn maintained the characteristic structure of membrane and intracellular organelles (the plasma membrane, mitochondria, and lysosomes), whereas such organelles were severely photodamaged by PIX (Figure 7). Thus, the question is raised how photodamage by 32(+)DPZn nevertheless leads to the most efficient cell death. In this regard, the number of spotted fluorescence of the mitochondrion marker Rh123 decreased due to photodamage by 32(+)DPZn even

after incubation of 30 min (Figure 7C). The fluorescent intensity of Rh123 is known to be correlated with the amount of adenosine triphosphate (ATP) in the cell (42). Therefore, photodamage by 32(+)-DPZn may have clipped the ATP production in the cell, resulting in the efficient cell death. In general, the eliminated ATP production is characteristic for necrosis or caspase-independent programmed cell death (43, 44) (oncosis (45)). Similar necrosis-like cell death was previously observed when the plasma membrane was targeted as the photodamaged site (25, 34, 46). It was suggested that such necrotic process could be induced by photodynamically stimulating some critical targets on the plasma membrane, which results in a delayed or arrested apoptotic signaling pathway. The target sites are thought to be transporters, ion channels, or lipids rather than direct disruption of the outer cell membrane (25, 34, 46). This hypothesis appears to be consistent with our observation that the efficient PD-induced cell death combined with extremely low dark toxicity and the maintained characteristic organella structure after photoirradiation of 32(+)-DPZn-treated LLC cells. However, the mechanism of necrosis-like cell death following photodamage to the plasma membrane remains to be studied. Elucidation of the PD mechanism of dendrimer-based photosensitizers is ongoing in our laboratory.

PIX exhibited remarkably high dark toxicity after prolonged incubation of 72 h (Table 3). On the other hand, both dendrimers, 32(+)-DPZn and 32(-)-DPZn showed extremely low dark toxicity even after 72 h incubation. Upon prolonged incubation, PIX tends to localize largely in the mitochondrial membrane (32), causing mitochondrial dysfunction. Further, it can diffuse to every other organelle in the cytoplasm as shown in Figure 4 (13, 33). The high dark toxicity of PIX may result from such complexity in the intracellular localization. In contrast, the extremely low dark toxicity of dendrimer porphyrins may result from the distinctive intracellular disposition characteristics due to their relative large size and anionic or cationic periphery. Note that a low dark toxicity is one of the important criteria for assessing the usefulness of photosensitizers because unwanted toxicity to normal tissues is one of the major side effects in clinical PDT (33). The low dark toxicity of 32(+)-DPZn is consistent with previous results obtained for cationic dendrimers used for gene transfection, which are known to have lower inherent cytotoxicity than other cationic linear polymers (5). The inherent low toxicity of dendrimers may originate from their monodispersed spherical nature as compared with conventional synthetic polymers having a three-dimensional configuration as well as chemical heterogeneity. Thus, the dendrimers are of great interest as the materials for drug delivery system (DDS).

The porphyrin dendrimers used in this study have a maximum optical absorption at approximately 559 nm (Q-band), which has only limited tissue penetration efficiency. Therefore, the development of dendrimers having increased absorbance of light in the higher wavelength region may be desirable for clinical use. In this regard, synthesis of dendrimers encapsulating a metallo-phthalocyanine, which has an optical absorption at 675 nm where the light can penetrate the tissues approximately 2 times deeper than Photofrin (630 nm) (18), is in principle feasible in our laboratory (47). Alternatively, two-photon excitation by using near-infrared lasers may have great potential for dendrimer porphyrin-based PDT of diseases in the deeper tissue (e.g., brain tumors) (48). The possibility of two photon absorption is known to depend linearly on the intrinsic

two-photon cross section of the compounds,  $\delta$ , and quadratically on the incident light intensity (48). Although the two-photon cross section of molecules is typically small compared with one-photon absorption, neodymium: YAG (Nd:YAG) laser emitting at 1,064 nm or tunable solid state lasers generating far-red/near-infrared light could significantly increase the possibility of two photon absorption of the compounds due to high laser output (49).

On the other hand, substituting peripheral ionic groups of dendrimers with alternative ligands to target particular types of tumor cells is likely a key to performing the most efficient PDT (36, 50). This has wide-reaching implications for achieving efficient cell type-specific PDT because it will enable the active dose of dyes administered to the patients to be reduced. The development of appropriate in vivo carrier system of 32(+)-DPZn is of primary importance for systemic PDT of solid tumor with suppression of side effects (17–20). The desirable properties of such in vivo carrier system are (i) improved water-solubility, (ii) specific accumulation in tumor, (iii) safety to the body, and (iv) prompt excretion from the body following PDT. To achieve these requirements, we have developed poly-ion complex (PIC) micelles entrapping dendrimer porphyrins in their core through the self-association of ionic dendrimer porphyrins with oppositely charged poly(ethylene glycol) PEG–poly(amino acid) block copolymers (51). In this way, PIC micelle carriers of dendrimer porphyrins, surrounded by a hydrophilic palisade of PEG strands, were prepared. As previously reported, several types of polymeric micelles with PEG shell were demonstrated to accumulate effectively and specifically in solid tumor (52–54). Thus, we expect PIC micelles with dendrimer porphyrins in the core may hold a promise for tumor-directed targeting of photosensitizers, and research in this direction is now ongoing in our laboratory.

#### ACKNOWLEDGMENT

The authors like to thank Ms A. Ryu, Kose Co. for assisting with the singlet oxygen quantum efficiency measurements. This work was supported in part by Core Research for Evolutional Science and Technology (CREST), Japan Science and Technology Corporation (JST).

# Non-Natural Cell Surface Receptors: Synthetic Peptides Capped with N-Cholesterylglycine Efficiently Deliver Proteins into Mammalian Cells

Scott E. Martin and Blake R. Peterson\*

Department of Chemistry, The Pennsylvania State University, 152 Davey Lab, University Park, Pennsylvania 16802. Received September 5, 2002; Revised Manuscript Received October 9, 2002

Protein toxins such as shiga toxin and cholera toxin penetrate into cells by binding small molecule-based cell surface receptors localized to cholesterol and sphingolipid-rich lipid raft subdomains of cellular plasma membranes. Molecular recognition between these toxins and their receptors triggers endocytic protein uptake through endogenous membrane trafficking pathways. We report herein the synthesis of functionally related non-natural cell surface receptors comprising peptides capped with N-cholesterylglycine as the plasma membrane anchor. The peptide moieties of these receptors were based on high-affinity epitopes of anti-hemagglutinin antibodies (anti-HA), anti-Flag antibodies, and a moderate-affinity *Strep* Tag II peptide ligand of the streptavidin protein from *Streptomyces avidini*. These non-natural receptors were directly loaded into plasma membranes of Jurkat lymphocytes to display peptides from lipid rafts on the cell surface. Molecular recognition between these receptors and added cognate anti-HA, anti-Flag, or streptavidin proteins resulted in rapid clathrin-mediated endocytosis; fluorescent target proteins were completely internalized within 4–12 h of protein addition. Analysis of protein uptake by epifluorescence microscopy and flow cytometry revealed intracellular fluorescence enhancements of 100-fold to 200-fold (10  $\mu$ M non-natural receptor) with typically >99% efficiency. This method enabled intracellular delivery of a functional *Escherichia coli*  $\beta$ -galactosidase enzyme conjugated to Protein A from *Staphylococcus aureus*. We termed this novel delivery strategy “synthetic receptor targeting”, which is an efficient method to enhance macromolecular uptake by decorating mammalian cells with chemically defined synthetic receptors that access the molecular machinery controlling the organization of cellular plasma membranes.

## INTRODUCTION

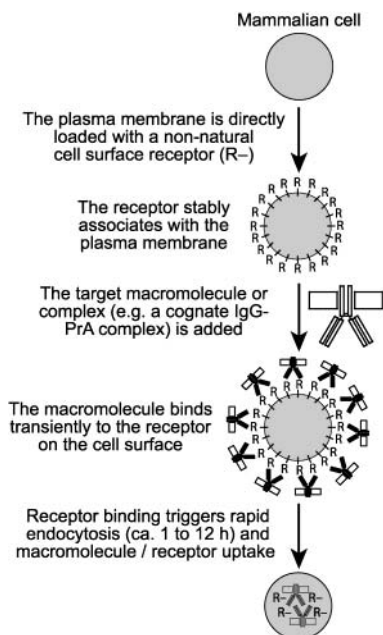

The hydrophobic character of cellular plasma membranes effectively seals the inner machinery of cells away from many molecules in the extracellular environment. Typically only moderately hydrophobic compounds of low molecular weight undergo rapid passive diffusion across low-polarity cellular membranes; macromolecules such as proteins and DNA generally require specific active transport mechanisms to access the cell interior (1). To circumvent this obstacle, many methods have been developed to enhance the cellular uptake of poorly permeable molecules (2–9). Many such methods involve covalent or noncovalent modification of macromolecules with polymers, lipids, or other agents that favorably alter the chemical properties of macromolecular cargo. In particular, peptides that mediate membrane translocation comprise an important class of oligomeric delivery vectors (2). However, the molecular mechanisms underlying many cellular delivery systems are not yet well enough understood to consistently and efficiently deliver macromolecules to desired targets in diverse cell lines. Hence, improved delivery systems with well-defined molecular mechanisms of action are needed in basic cell biology, tumor therapy, and genetic therapy.

Mammalian cells internalize nutrients and other macromolecular entities through the active transport mechanism of endocytosis (10, 11). This mechanism typically

involves recognition of molecules by plasma-membrane-associated receptors, clustering of receptor–ligand complexes, and invagination of these regions of the plasma membrane to form intracellular vesicles. These vesicles fuse to form organelles termed endosomes that are directed to compartments for degradation or recycling of internalized contents. Under certain conditions, endosomal contents can also be released into the cytosol (10, 11). Endocytosis is a mechanism of cellular penetration employed by many viruses and toxins such as shiga toxin from *Shigella dysenteriae* and cholera toxin from *Vibrio cholerae* (12). These toxins are members of the AB<sub>5</sub> family of protein toxins (13) that penetrate into mammalian cells by binding of the toxin to small molecule cell surface receptors such as the glycosphingolipid Gb3 (shiga toxin receptor) and ganglioside GM1 (cholera toxin receptor). These low molecular weight receptors are sphingolipids that comprise tri- or pentasaccharide headgroups linked to the lipid ceramide (N-acyl sphingosine). These receptors reside in sphingolipid-rich lipid raft subdomains of cellular plasma membranes. Lipid rafts are composed of cholesterol packed with sphingolipids in a liquid ordered phase (14–17), and these subdomains are key elements involved in the control of numerous signal transduction pathways (18). Although both shiga toxin and cholera toxin penetrate into cells (12) primarily through the mechanism of clathrin-mediated endocytosis (19), the precise interactions that link these toxins to clathrin through their receptors and the role played by lipid rafts in this process are not yet well understood (20, 21).

**Figure 1.** Delivery of macromolecules to cells by synthetic receptor targeting. Non-natural cell surface receptors directly loaded into cellular plasma membranes enable delivery of cognate macromolecules through endogenous membrane trafficking pathways.

**Figure 2.** Structures of previously reported non-natural cell surface receptors.

Our laboratory is investigating a novel macromolecular delivery system termed here as "synthetic receptor targeting" (Figure 1). This method employs non-natural cell surface receptors such as compounds **1** and **2** (Figure 2) based on lipids that insert into cellular plasma membranes. These receptors comprise derivatives of  $\beta$ -cholesterylamine linked to protein-binding motifs including fluorescein (22) and biotin (23). These compounds functionally mimic natural small-molecule receptors such as glycosphingolipid Gb3 or ganglioside GM1 by persistently associating with lipid raft subdomains of cellular plasma membranes. For example, the cholesterylamine-derived fluorescent probe **1** is primarily plasma-membrane-associated even 16 h after addition to living cells (22). However, as shown in Figure 1, binding of cognate proteins such as immunoglobulins (IgGs) or streptavidin to these plasma membrane-anchored small molecules rapidly triggers clathrin-mediated endocytosis of the receptor-protein complex (22, 23). This approach is conceptually related to elegant studies of metabolic cell surface engineering that display non-natural functional groups such as ketones and azides on cell surfaces (24–27). These ketones and other functional groups can

**Figure 3.** Structures of non-natural receptors based on N-( $\beta$ )-cholesteryl-glycine-capped peptides.

be incorporated into diverse glycolipids and glycoproteins on cells by accessing endogenous pathways of oligosaccharide biosynthesis with engineered monosaccharide precursors (28–30).

We describe here three novel non-natural small-molecule receptors (Figure 3, **3–5**) that deliver proteins into Jurkat lymphocytes. These receptors comprise protein-binding peptides capped with N-cholesteryl-glycine. As shown in Figure 3, peptide derivatives **3** and **4** are membrane-anchored antigens designed to bind commercially available anti-hemagglutinin (anti-HA) and anti-Flag IgGs. Peptide **5** is a derivative of the previously reported *Strep* Tag II peptide, which is a ligand of the streptavidin protein from *Staphylococcus aureus* (31). We report that receptors **3–5** dramatically enhance endocytic uptake of cognate proteins by mammalian cells, and this approach can deliver functional enzymes such as  $\beta$ -galactosidase conjugated to Protein A from *Staphylococcus aureus*.

## EXPERIMENTAL PROCEDURES

**General.** Chemical reagents and solvents were obtained from Aldrich, Alfa Aesar, Fluka, or VWR Scientific. Media and antibiotics were obtained from Gibco BRL. Streptavidin Alexa Fluor 488 (SA488), Cholera toxin Alexa Fluor 594, Protein A Alexa Fluor 488 (PrA488), and Lysotracker Red were purchased from Molecular Probes. Protein A- $\beta$ -galactosidase (PrA- $\beta$ -Gal), chlorpromazine, sucrose, methyl- $\beta$ -cyclodextrin, rabbit anti-Flag IgG, and rabbit anti-HA IgG were obtained from Sigma. Fmoc-protected amino acids, coupling reagents, and Rink Amide MBHA resin (75–150  $\mu$ m, 0.7 mmol/g) were purchased from Novabiochem. Analytical and semipreparative HPLC analysis/purifica-

**Scheme 1. General Strategy for Synthesis of Peptides Capped with N-( $\beta$ )-Cholesterylglycine**

tion employed a Hewlett-Packard HP 1100 instrument with StableBond C18 columns (analytical column: 300 SB-C18, 4.6 mm  $\times$  25 cm, 1 mL/min flow rate; semi-preparative column: 300 SB-C18, 9.4 mm  $\times$  25 cm, 3 mL/min flow rate) using a gradient from 9:1:0.001 ddw/CH<sub>3</sub>CN/TFA to 0.9:9.1:0.001 ddw/CH<sub>3</sub>CN/TFA over 40 min. Peptide mass spectrometry was obtained on a Perseptive Voyager DE-STR MALDI-TOF instrument. Epifluorescence micrographs were captured through a Zeiss Fluor (100 $\times$ ) objective by a Zeiss Axiocam digital camera interfaced to a Zeiss Axiovert S100TV microscope. Images were processed with Adobe Photoshop 5.0.

**Control and Fluorescent Peptides.** Two peptides were synthesized as C-terminal carboxamides to provide nonmembrane binding competitors. Peptide **6** sequence, YPYDVPDYA; peptide **7**, GDYKDDDDK. Biotin provided the soluble streptavidin competitor. Two peptides were synthesized as C-terminal carboxamides for fluorescence polarization assays. Peptide **8**, Fluor-GYPYDVPDYA; peptide **9**, Fluor-GDYKDDDDK. Fluor = fluorescein-5(6)-carboxamidohexanoamide. Peptide sequences are listed in single letter amino acid codes.

**Peptide Synthesis.** Peptides were synthesized with an Advanced Chemtech FBS-357 automated batch-mode synthesizer. Peptide synthesis employed standard N $\alpha$ -Fmoc methodology with *tert*-butyl ester, *tert*-butyl ether, *tert*-butyl carbamate, and methyltrityl side chain protection. Deprotection of Fmoc carbamates on Rink Amide MBHA resin (50 mg, 35  $\mu$ mol) was effected by the addition of 30% piperidine in DMF (2  $\times$  1 mL for 5 min followed by 1 mL for 20 min). N $\alpha$ -Fmoc amino acids were coupled as previously described (32). Peptide precursors to **3–5** were capped with the cholesteryl moiety by coupling with the nosyl-protected N-( $\beta$ )-cholesterylglycine (**10**, Scheme 1) prepared as previously reported (22). Peptides were capped with **10** by sequential addition of the following reagents in DMF: **10**/HOBT (250  $\mu$ L, 0.5 M of each component), followed by PyBOP (250  $\mu$ L, 0.5 M) and DIEA (500  $\mu$ L, 0.5 M). The resin was subsequently agitated for 1 h at 23  $^{\circ}$ C. This coupling step was repeated, and all amines were acylated as evidenced by Kaiser test. Deprotection of the nosyl sulfonamide was effected by treatment with K<sub>2</sub>CO<sub>3</sub> (70 mg) and thiophenol (25 mg) in DMF (2 mL) for 16 h. Fluorescent peptides **8** and **9** were synthesized with 23 mg of Rink Amide MBHA

**Table 1. Analytical Data for Peptides 3–9**

resin (16  $\mu$ mol). After N $\alpha$ -Fmoc deprotection of the N-terminal amino acid of resin-bound precursors to peptides **8** and **9**, fluorescein-5(6)-carboxamidohexanoic acid succinimidyl ester (12 mg, 24  $\mu$ mol in 500  $\mu$ L of DMF) and DIEA (500  $\mu$ L, 0.5 M in DMF) were added with shaking for 16 h at 23  $^{\circ}$ C. Cleavage of peptides from the resin and side chain deprotection employed TFA/H<sub>2</sub>O/TIS (1 mL, 95:2.5:2.5) for 1 h. Peptides were purified by reverse-phase HPLC to >90% homogeneity, and peptides were analyzed by MALDI-TOF mass spectrometry as shown in Table 1.

**Flow Cytometry.** Analyses were performed with a Beckman-Coulter XL-MCL benchtop flow cytometer equipped with a 15 mW air-cooled argon-ion laser. Fluorescence detection was derived from excitation at 488 nm, splitting the emission with a 550 nm dichroic and long pass filter, and optical filtering through 530/30-nm band-pass filter. Forward-scatter (FS) and side-scatter (SSC) dot plots afforded cellular physical properties of size and granularity that allowed gating of living cells. After gating, 10 000 cells were counted.

**Confocal Microscopy.** Sequential scans were performed on an Olympus FV300 laser scanning confocal microscope fitted with a UplanFl objective (100 $\times$ ). Alexa Fluor 488 was excited with a 488 nm Argon ion laser, and emitted photons were collected through 510 nm LP and 530 nm SP filters. Excitation of Alexa Fluor 594 employed a 543 nm HeNe laser and a 605 nm BP filter.

**Antibody Uptake Assays.** Human Jurkat T lymphocytes were maintained in Roswell Park Memorial Institute (RPMI) 1640 media supplemented with Fetal Bovine Serum (FBS, 10%), penicillin (100 units/mL), and streptomycin (100  $\mu$ g/mL). Receptors **3–5** were dissolved in dimethyl sulfoxide (DMSO), which was diluted with media to yield a final DMSO concentration of 1%. For antibody/PrA488 uptake assays, Jurkat cells ( $5 \times 10^6$ ) were incubated with receptors **3–5** at 37  $^{\circ}$ C for 1 h, washed with media (2  $\times$  0.5 mL), and resuspended in media (490  $\mu$ L). To these cells was added a mixture of antibody (2.7  $\mu$ g) and PrA488 (0.5  $\mu$ g) in phosphate buffered saline (PBS, 10  $\mu$ L, pH 7.4). This protein mixture was preincubated at 23  $^{\circ}$ C for 1 h prior to addition to cells. Cells were maintained at 37  $^{\circ}$ C for 12 h. Cells were then washed with media (1  $\times$  0.5 mL), incubated with the appropriate free peptide (100  $\mu$ M, **6** or **7**) in media (2  $\times$  0.5 mL  $\times$  30 min) to compete away any noninternalized protein, washed with media (1  $\times$  0.5 mL), resuspended in media (0.75 mL), and analyzed by flow cytometry.

**Cellular Uptake of Protein A- $\beta$ -Galactosidase (PrA- $\beta$ -Gal).** The antibody/PrA- $\beta$ -Gal uptake assays employed Jurkat cells ( $5 \times 10^6$ ) incubated with receptor **3** (10  $\mu$ M) at 37  $^{\circ}$ C for 1 h. The cells were washed with media (2  $\times$  0.5 mL) and resuspended in media (490  $\mu$ L). A mixture of rabbit anti HA antibody (2.7  $\mu$ g) and PrA- $\beta$ -Gal (4  $\mu$ L, 0.3 units) in PBS (10  $\mu$ L, pH 7.4) was incubated at 23  $^{\circ}$ C for 1 h and then added to the cells treated with **3**. Cells were maintained at 37  $^{\circ}$ C for 12 h, washed with media (1  $\times$  0.5 mL), and incubated with free

HA peptide in media ( $100\ \mu\text{M}$ ,  $3 \times 0.5\ \text{mL} \times 30\ \text{min}$ ) to competitively displace any plasma membrane-bound protein. Uptake of PrA- $\beta$ -Gal was detected by incubation with fluorescein di-( $\beta$ -D-galactopyranoside) in media ( $1\ \text{mM}$ ,  $2\%$  DMSO) for  $30\ \text{min}$  at  $37\ ^\circ\text{C}$ . After this incubation, cells were washed with media ( $1 \times 1\ \text{mL}$ ), resuspended in media ( $0.75\ \text{mL}$ ), and analyzed by flow cytometry.

**Streptavidin Uptake Assay.** Receptors **3–5** were dissolved in DMSO and diluted with media to yield a final DMSO concentration of  $1\%$ . Jurkat cells ( $5 \times 10^6$ ) were incubated with receptors **3–5** at  $37\ ^\circ\text{C}$  for  $1\ \text{h}$ , washed with media ( $2 \times 0.5\ \text{mL}$ ), and resuspended in media ( $198\ \mu\text{L}$ ). To these cells was added streptavidin Alexa Fluor 488 (SA 488,  $2\ \mu\text{g}$ ), and cells were maintained at  $37\ ^\circ\text{C}$  for  $4\ \text{h}$ . Cells were washed with media ( $1 \times 0.5\ \text{mL}$ ), followed by media containing biotin ( $50\ \mu\text{M}$ ,  $1\%$  DMSO,  $2 \times 0.5\ \text{mL}$ ) as a nonmembrane binding competitor to displace any noninternalized protein. The cells were washed again with media ( $1 \times 0.5\ \text{mL}$ ) and resuspended in media ( $0.75\ \text{mL}$ ) for analysis by flow cytometry.

**Inhibition of Uptake Experiments.** Receptor **3** ( $1\ \mu\text{M}$ ) was subjected to the uptake assay with an antibody/PrA 488 incubation time of  $4\ \text{h}$ .

**Depletion of Cellular Cholesterol with Methyl- $\beta$ -Cyclodextrin (CD).** Cells were suspended in PBS (pH 7.4) containing BSA ( $1\ \text{mg/mL}$ ) and CD ( $10\ \text{mM}$ ) for  $30\ \text{min}$  prior to the protein uptake assay, and BSA ( $1\ \text{mg/mL}$ ) was included in subsequent assay media.

**Treatment with Hypertonic Sucrose.** Cells were suspended in media containing sucrose ( $400\ \text{mM}$ ) for  $1\ \text{h}$  prior to the protein uptake assay, and sucrose ( $400\ \text{mM}$ ) was included in subsequent assay media.

**Treatment with Chlorpromazine.** Cells were suspended in media containing chlorpromazine ( $100\ \mu\text{M}$ ) for  $1\ \text{h}$  prior to the protein uptake assay, and chlorpromazine ( $100\ \mu\text{M}$ ) was included in subsequent assay media.

**Fluorescence Polarization Assays.** Apparent binding constants for rabbit anti-HA and anti-Flag IgGs were determined by fluorescence polarization measurements with a Packard Fusion microtiterplate reader utilizing a  $485\ \text{nm}$  excitation filter and a  $535\ \text{nm}$  fluorescence polarization emission filter. All fluorescence polarization experiments employed black 384 well plates (Costar) with a fixed concentration of **8** or **9** ( $10\ \text{nM}$ ) in PBS (pH 7.4,  $40\ \mu\text{L}$ ). Fluorescent peptides **8** and **9** were equilibrated with cognate antibodies for  $10\ \text{min}$  prior to fluorescence polarization measurements. Dissociation constants were calculated by nonlinear regression with a one-site binding model (GraphPad Prism 3 software). Errors reflect calculated standard errors of the mean.

## RESULTS AND DISCUSSION

**Design and Synthesis of Non-Natural Cell Surface Receptors.** Receptors **3** and **4** were designed on the basis of known short peptide epitopes of anti-HA (epitope sequence: YPYDVPDYA) (**33**) and anti-Flag (epitope sequence: DYKDDDDK) IgGs (**34**). Receptor **5** was designed from the previously reported *Strep* Tag II peptide (sequence: SNWSHPQFEK), which is a moderate affinity ( $K_d = 72\ \mu\text{M}$ ) peptide ligand of the protein streptavidin (SA) (**31**).

To examine hypothetical geometries of receptors **3** and **5** bound to cognate proteins, models of molecular complexes interacting with a model membrane were constructed (Figure 4). These models employed X-ray crystal structures of a peptide-bound anti-HA Fab fragment

**Figure 4.** Molecular models of proteins (ribbon diagrams) bound to Macromodel-minimized peptidic receptors (CPK models) inserted into a model lipid raft (CPK models). (A) Model of anti-HA/PrA bound to **3**. (B) Model of SA bound to **5**.

(PDB# 1FRG) (**33**) and *Strep* Tag II-bound SA (PDB# 1KL5) (**35**). The anti-HA model was embellished by inclusion of the invariant Fc fragment from an X-ray structure of IgG2a (PDB# 1IGT) (**36**) and the structure of a Fc-bound fragment of PrA (PDB# 1FC2) (**37**). Model construction involved modification of the X-ray structure of the anti-HA epitope peptide and the SA-bound *Strep* Tag II peptide by addition of a flexible glycine residue appended to the peptide N-terminus, which was further capped with N-( $3\beta$ )-cholesteryl glycine (**22**). The model cholesteryl glycine-Gly moiety was minimized with the Macromodel (v. 6.5) (**38**) Amber\* force field prior to attachment to the bound peptide ligands of cognate proteins (Figure 4). WebLab ViewerLite (Molecular Simulations Inc., v. 3.2) was employed to display the complexes. The model membrane bilayer was constructed to mimic the composition of a lipid raft subdomain composed of cholesterol packed with sphingomyelin in the outer leaflet and cholesterol packed with saturated phosphatidylserine in the inner leaflet (Figure 4) (**17**). These modeling studies suggested that a glycine linker between the protein-bound peptides and N-( $3\beta$ )-cholesteryl glycine would be sufficient to enable complete insertion of the bound steroid into the model membrane. The length of linker between the steroid and protein ligand has been shown to be critical in structurally related systems (**23**).

Receptors **3–5** were synthesized as shown in Scheme 1. The peptide precursors were synthesized and capped with a previously reported nosyl-protected N-( $3\beta$ )-cholesteryl glycine (**10**) (**22**). The nosyl protecting group was removed on solid phase with deprotonated thiophenol prior to cleavage of peptides from the solid support. Analogous control peptides **6** and **7** were synthesized lacking the N-cholesteryl glycine moiety to serve as non-membrane binding competitors. Because the affinities of rabbit anti-HA and rabbit anti-Flag IgGs have not been previously reported, fluorescent peptides **8** and **9** were

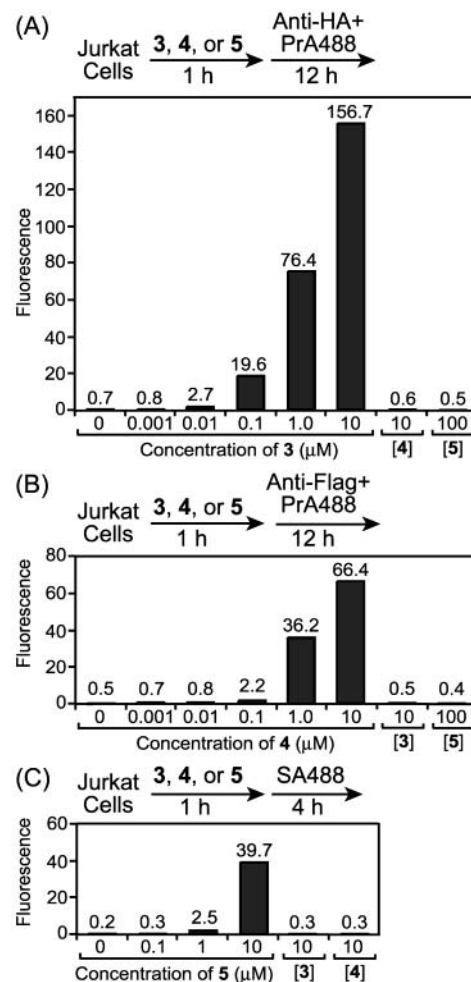

**Figure 5.** Determination of apparent dissociation constants ( $K_d$ ) of anti-HA and anti-Flag IgGs by quantification of the fluorescence polarization of peptides **8** and **9**.

**Figure 6.** Differential interference contrast (DIC) and epifluorescence micrographs of Jurkat lymphocytes treated with receptor **3** ( $10\ \mu\text{M}$ ), anti-HA, and green fluorescent PrA488. Fluorescence excitation (Ex.) and emission (Em.) wavelengths (nm) are explicitly shown.

synthesized as analogues of **3** and **4** that substitute the N-cholesteryl-glycine moiety with a fluorescein derivative to enable determination of peptide affinities by fluorescence polarization (FP) measurements (39). As shown in Figure 5, quantification of FP values as a function of IgG concentration yielded apparent  $K_d$  values of  $311 \pm 64\ \text{nM}$  for the anti-HA-binding peptide **8** and  $39 \pm 15\ \text{nM}$  for the anti-Flag-binding peptide **9**. In these experiments, the concentration of the fluorescent tracer peptide was fixed at  $10\ \text{nM}$ .

**Uptake of Proteins by Mammalian Cells Bearing Non-Natural Cell Surface Receptors.** Initial qualitative analysis of protein uptake mediated by receptors **3**–**5** employed epifluorescence microscopy. As shown in Figure 6, Jurkat lymphocytes treated with receptor **3** for 1 h followed by addition of anti-HA and green fluorescent PrA (PrA488) as a probe exhibited bright fluorescence at the cellular periphery within 10 min of protein addition. This peripheral fluorescence was localized to the plasma membrane of practically 100% of viable cells as compared with fluorescent plasma membrane probes such as the fluorescent analogue **1** (22, 40). After 12 h of protein treatment, the fluorescence was observed in defined compartments in the cell interior, indicating that the protein complex was internalized (Figure 6). Cells treated with receptor **4** followed by anti-Flag IgG/PrA488 or

**Figure 7.** Analysis of dose-dependent cellular uptake of proteins by flow cytometry. Each bar represents the median fluorescence of 10 000 living cells.

treated with receptor **5** followed by SA488 showed highly similar patterns of cellular fluorescence (data not shown).

To quantitatively examine this uptake process, dose-dependent effects on intracellular fluorescence were measured by flow cytometry. Because flow cytometry cannot distinguish membrane-associated from intracellular fluorescence, cells were extensively washed with soluble competitor peptides ( $100\ \mu\text{M}$ ) or biotin ( $50\ \mu\text{M}$ ) prior to analysis to displace any noninternalized protein. As shown in Figure 7A, pretreatment of cells with **3** for 1 h followed by addition of anti-HA and PrA488 for 12 h dramatically enhanced intracellular fluorescence with significant effects observed at concentrations of **3** as low as  $100\ \text{nM}$ . The intracellular fluorescence of cells pretreated with  $10\ \mu\text{M}$  **3** was enhanced by over 200-fold compared with cells treated with the anti-HA/PrA488 complex alone. This effect on anti-HA/PrA488 specifically required receptor **3**; no uptake of this complex was mediated by receptors **4** or **5** (Figure 7A). However, receptor **4** efficiently and specifically mediated the dose-dependent uptake of anti-Flag/PrA488 with over a 100-fold enhancement of intracellular fluorescence at  $10\ \mu\text{M}$  (Figure 7B). Furthermore, green fluorescent streptavidin (SA488) was specifically internalized by receptor **5**, which enhanced uptake by over 100-fold at  $10\ \mu\text{M}$  (Figure 7C).

**Non-Natural Cell Surface Receptors Direct Cognate Proteins to Lipid Rafts and Effect Protein Uptake via Clathrin-Mediated Endocytosis.** The biotin-derived “streptaphage” receptor (**2**) was previously

**Figure 8.** Analysis of inhibition of protein uptake and protein subcellular localization. (A) Uptake of anti-HA/PrA488/3 measured by flow cytometry in the presence of inhibitors of clathrin-mediated endocytosis. (B) Confocal laser scanning microscopy of cells treated with **3** for 1 h followed by anti-HA/PrA488 and red fluorescent Alexa fluor-594 Cholera toxin B subunit for 5 min. White arrows illustrate colocalization of green and red fluorescence.

shown to mediate uptake of streptavidin by targeting this protein to lipid rafts and promoting clathrin-mediated endocytosis (23). To examine the mechanism of uptake of structurally related receptors **3–5**, protein uptake under conditions that block clathrin-mediated endocytosis was examined (Figure 8A). Cells treated with hypertonic sucrose exhibit defects in clathrin-coated lattices (41), and these conditions were found to diminish receptor **3**-mediated uptake of anti-HA/PrA488 measured by flow cytometry. In addition, the cationic amphiphatic drug chlorpromazine disrupts the assembly/disassembly of clathrin associated with coated pits and endosomes (42), and this drug inhibited protein uptake. Furthermore, depletion of cellular cholesterol by treatment with methyl- $\beta$ -cyclodextrin to disrupt lipid rafts (43) blocked protein uptake. These results indicate that lipid rafts may be important for this process, and protein uptake mediated by receptors **3–5** is most likely controlled by a clathrin-mediated endocytosis mechanism.

To examine the localization of proteins binding to non-natural receptors in cellular plasma membranes, cells were treated with **3** followed by addition of anti-HA/PrA488 and red fluorescent cholera toxin B subunit. Cholera toxin binds ganglioside GM1 in lipid rafts and provides a probe of these membrane subdomains. As shown in Figure 8B, confocal laser scanning microscopy revealed a heterogeneous distribution of anti-HA/PrA488/3 in plasma membranes of Jurkat lymphocytes. Moreover, this complex extensively colocalized with cholera toxin, indicating that receptor **3** mediates protein association with lipid rafts.

**Non-Natural Receptor-Mediated Delivery of Functional  $\beta$ -Galactosidase into Cells.** Functional enzymes such as caspases (9), ribonuclease (44), and horseradish peroxidase (45) have been delivered into cells by a variety

**Figure 9.** Flow cytometry of Jurkat lymphocytes treated with receptor **3**, anti-HA IgG, and PrA- $\beta$ -galactosidase.

of carrier mechanisms and are under investigation as components of antitumor agents. To investigate whether a synthetic cell surface receptor might enable delivery of a functional enzyme into mammalian cells, uptake of a commercially available Protein A- $\beta$ -galactosidase conjugate (PrA- $\beta$ -Gal) was examined. As shown in Figure 9, Jurkat lymphocytes were treated with receptor **3** and the anti-HA/PrA- $\beta$ -Gal conjugate. Cells were treated with a fluorescent substrate of  $\beta$ -galactosidase, and fluorescence was analyzed by flow cytometry. These experiments revealed that receptor **3** engendered a ca. 9-fold enhancement of median cellular fluorescence compared with identically treated cells in the absence of receptor **3**. Under these conditions, this fluorescence enhancement was detected in 75% of the treated cells (Figure 9). This result established that non-natural cell surface receptors such as **3** can deliver at least transiently functional enzymes into cells.

## CONCLUSION

We describe three novel non-natural cell surface receptors (**3–5**) that enable dose-dependent uptake of specific macromolecules by mammalian cells. These compounds comprise peptides capped with N-(3 $\beta$ )-cholesteryl glycine, which is a mimic of cholesterol that can stably integrate into cellular plasma membranes of mammalian cells (22, 23). Addition of cognate IgGs or streptavidin proteins to cells displaying these non-natural cell surface receptors triggers endocytic protein uptake through endogenous membrane trafficking pathways.

Proteins delivered through this "synthetic receptor targeting" approach can span a wide range of affinities for non-natural cell surface receptors. For example streptavidin can be delivered to cells by surface display of either very high affinity biotin (100 fM) (23) or the modest affinity Strep Tag II peptide (receptor **5**, ca. 72  $\mu$ M). However, the magnitude of delivery of streptavidin is ca. 6.5-fold greater with the high-affinity biotin-derived receptor **2** compared with the modest-affinity receptor **5**. Despite these vast affinity differences, similarities in the magnitude of delivery may relate to the high effective concentration of non-natural receptors on cell surfaces and the multivalent nature of cell surface recognition by bivalent IgGs and tetrameric streptavidin. Interestingly, the higher affinity anti-Flag receptor **4** ( $K_d \sim 39$  nM) delivered 2.4-fold less IgG/PrA complex than the lower

**Figure 10.** Model of a plasma membrane raft segment containing the non-natural receptors **3–5** and the natural receptor ganglioside GM1.

affinity anti-HA receptor **3** ( $K_d \sim 311$  nM). This result may relate to the highly acidic nature of the Flag epitope peptide, which has been shown to diminish the affinity of fusion proteins for cellular plasma membranes (34).

The non-natural receptors described herein appear to associate with lipid raft subdomains of cellular plasma membranes as evidenced by colocalization with cholera toxin on cell surfaces, and these receptors cause proteins to penetrate into cells by clathrin-mediated endocytosis. In this regard, as shown in a model of a lipid raft in Figure 10, these compounds functionally mimic natural cell surface receptors such as ganglioside GM1, which resides in lipid rafts and enables the cellular penetration of cholera toxin through endocytic uptake mechanisms. Given that non-natural cell surface receptors can be used for the delivery of functional enzymes of high molecular weight such as *E. Coli*  $\beta$ -galactosidase (tetramer  $\sim 540$  000 Da) (46) conjugated to Protein A ( $\sim 42$  000 Da) and bound to IgGs ( $\sim 150$  000 Da), this “synthetic receptor targeting” approach may have potential applications in tumor therapy by enabling the delivery of lethal enzymes into tumor cells. This approach may also facilitate studies in other areas requiring the delivery of macromolecules into mammalian cells including basic cell biology, genetic therapy, and immunology.

# Preparation of Bioconjugates by Solid-Phase Conjugation to Ion Exchange Matrix-Adsorbed Carrier Proteins

G. Houen,<sup>\*,†</sup> D. T. Olsen,<sup>†</sup> P. R. Hansen,<sup>‡</sup> K. B. Petersen,<sup>†</sup> and V. Barkholt<sup>§</sup>

Department of Research and Development, Statens Serum Institut, Artillerivej 5, DK-2300 Copenhagen, Denmark, Department of Chemistry, Royal Veterinary and Agricultural University, Thorvaldsensvej 40, DK-1871 Frederiksberg, Denmark, and BioCentrum-DTU, Biochemistry and Nutrition, Technical University of Denmark, DK-2800 Lyngby, Denmark. Received October 8, 2002; Revised Manuscript Received October 23, 2002

A solid-phase conjugation method utilizing carrier protein bound to an ion exchange matrix was developed. Ovalbumin was adsorbed to an anion exchange matrix using a batch procedure, and the immobilized protein was then derivatized with iodoacetic acid *N*-hydroxysuccinimid ester. The activated protein was conjugated with glutathione, the conjugation ratio determined by acid hydrolysis, and amino acid analysis performed with quantification of carboxymethyl cysteine. Elution of conjugates from the resin by a salt gradient revealed considerable heterogeneity in the degree of derivatization, and immunization experiments with the eluted conjugates showed that the more substituted conjugates gave rise to the highest titers of glutathione antibodies. Direct immunization with the conjugates adsorbed to the ion exchange matrix was possible and gave rise to high titers of glutathione antibodies. Conjugates of ovalbumin and various peptides were prepared in a similar manner and used for production of peptide antisera by direct immunization with the conjugates bound to the ion exchanger. Advantages of the method are its solid-phase nature, allowing fast and efficient reactions and intermediate washings, and the ability to release conjugates from the solid phase under mild conditions.

## 1. INTRODUCTION

Sequence-specific peptide antibodies are important tools for protein chemistry, histochemistry, cytochemistry, and immunology. Such antibodies are fairly easily prepared, but most peptides require conjugation to a carrier protein in order to elicit high titers of antibodies. The same applies to hapten antibodies, which are also valuable reagents in immunoassays, histochemistry, and cytochemistry.

Peptides and haptens may be conjugated in solution to the carrier protein using various condensing agents (e.g., carbodiimides) or homo- and heterobifunctional cross-linking reagents such as glutaraldehyde, SPDP,<sup>1</sup> iminothiolane, and others (Briand et al., 1985; Regemortel et al., 1988; Carter, 1994). In relation to this, it has been shown that preactivation of the carrier proteins followed by conjugation may have some advantages, including increased stereochemical control of the reaction (Houen and Jensen, 1995).

Solid-phase synthesis of peptides directly on carrier proteins has also been described, but the properties of the resulting conjugates were found to be unsuitable for routine use (Hansen et al., 1993). Solid-phase conjugation to carrier proteins preadsorbed to aluminum hydroxide was developed by Houen et al. (1997) as a method for producing well defined conjugates, which simultaneously incorporated an adjuvant as the solid phase. The adjuvant-carrier-peptide particles thus produced were found to

elicit high titers of specific peptide antibodies. However, the physical strength of the interaction between carrier protein and aluminum hydroxide is very sensitive to pH and to the ionic strength and composition of the buffers used for washing and conjugation, making it essential to carefully control these parameters during all steps. For this reason we have further explored the principle of solid-phase conjugation, and here we describe a procedure for solid-phase conjugation to ion exchange matrix-adsorbed carrier proteins and immunization with the conjugates. This method has the added advantage of allowing elution of the conjugates for analysis of the conjugation ratios and for separation of conjugates with different conjugation ratios. We believe this method will be useful for preparation and analysis of a wide range of bioconjugates.

## 2. MATERIALS AND METHODS

**2.1. Reagents.** Glycine, urea, trishydroxymethylaminomethane (Tris), dithiothreitol (DTT), iodoacetic acid, ovalbumin, phenol, dithiodipropionic acid, *ortho*-phthalaldehyde (OPA), diethanolamine, *p*-nitrophenyl phosphate tablets, 5-bromo-4-chloro-3-indolyl phosphate/nitro blue tetrazolium tablets, bromophenol blue, and bovine serum albumin (BSA) were from Sigma (St. Louis, MO). Methanol, NaCl, CH<sub>3</sub>COOH, CH<sub>3</sub>COONa, HCl, NaHCO<sub>3</sub>, Na<sub>2</sub>CO<sub>3</sub>, Na<sub>2</sub>HPO<sub>4</sub>, NaH<sub>2</sub>PO<sub>4</sub>, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, Pyronin G, Tween 20, and acetonitrile were from Merck (Darmstadt, Germany). Glutathione (reduced and oxidized) was from Boehringer (Mannheim, Germany). Tris-glycine gels (12% and 4–20%) were from NOVEX (San Diego, CA). GELCODE Blue Stain Reagent was from Pierce (Rockford, IL). Sodium dodecyl sulfate (SDS) was from BDH (Poole, Dorset, England). Prestained low molecular weight standard proteins, acrylamide, bisacrylamide, ammonium persulfate, *N,N,N,N*-tetramethylethylenediamine,

<sup>1</sup> Abbreviations: Fmoc, 9-fluorenylmethyloxycarbonyl; SPDP, *N*-hydroxysuccinimidyl-3-(2-pyridyldithio)-propionate

and DEAE cellulose were from Bio-Rad (Hercules, CA). Q Sepharose High Performance (HP), DEAE Sephadex, CNBr Sepharose were from Pharmacia (Uppsala, Sweden). Nitrocellulose (NC) membranes (0.2  $\mu$ m) were from Schleicher & Schuell (Dassel, Germany). Milli Q water equipment was from Millipore (Bedford, MA).

Iodoacetic acid *N*-hydroxysuccinimid ester was synthesized according to Hampton et al. (1976).

Peptides were made by solid-phase synthesis using Fmoc protection and diisopropylcarbodiimide/1-hydroxybenzotriazol activation (Chang and White, 2000).

Rabbit immunoglobulins against glutathione conjugated to BSA using divinylsulfone were produced as described (Houen and Jensen, 1995).

**2.2. Amino Acid Analysis.** Amino acid analysis was carried out as described by Barkholt and Jensen (1989). In short, samples were hydrolyzed in 6 M HCl, 0.05% phenol, 0.05% dithiodipropionic acid for 24 h at 110 °C, dried in vacuo, redissolved, and analyzed by ion exchange chromatography with postcolumn OPA derivatization.

**2.2. SDS-PAGE.** SDS-PAGE was performed according to Laemmli (1970) and Studier (1973) using precast 12% or 4–20% Tris-glycine gels following the prescriptions of the manufacturer. Electrophoresis was performed for about 90 min at 150 V using Tris-glycine running buffer (25 mM Tris, 192 mM glycine, 0.1% sodium dodecyl sulfate, pH 8.3).

Coomassie Brilliant Blue staining was performed using GELCODE stain reagent. The gel was washed three times for 5 min in milli Q water, followed by staining for 1 h or overnight with GELCODE Blue Stain Reagent, and finally washed with milli Q water.

**2.3. Immunoblotting.** SDS-PAGE gels were electroblotted overnight (0.1 mA/cm<sup>2</sup>) to nitrocellulose membranes using a semi-dry apparatus (Bio-Rad) and 2.5 mM Tris, 19.2 mM glycine, pH 8.3, 20% EtOH as transfer buffer. Membranes were pre-blocked in 50 mM Tris, pH 7.5, 1% Tween 20, 0.3 M NaCl (TTN), and incubated with primary antibodies (mouse or rabbit sera) diluted in TTN. After 1 h incubation the membrane was washed three times for 5 min in TTN and incubated 1 h with alkaline phosphatase-conjugated rabbit immunoglobulins against mouse immunoglobulins or goat immunoglobulins against rabbit immunoglobulins. After washing in TTN three times for 5 min, the membranes were developed with BCIP/NBT (one tablet per 10 mL water).

**2.4. Conjugation to Activated Ion Exchange Matrix-Adsorbed Ovalbumin.** Ten milliliters of ion exchange matrix was washed in 0.1 M sodium phosphate, pH 8.8, and then in 10 mM sodium phosphate, pH 9.0. The matrix was then incubated with 10 mL ovalbumin (25 mg/mL) overnight at 4 °C on a rotator. The matrix was washed three times in 10 mM sodium phosphate, pH 9.0, with intermittent centrifugations. The washed matrix was resuspended with 10 mL sodium phosphate, pH 9.0, and 1 mL of iodoacetic acid *N*-hydroxysuccinimide (10 mg/mL DMF) was added. After incubation 1 h at 4 °C on a rotator, the matrix was washed three times in 10 mM sodium phosphate, pH 8, with intermittent centrifugations. The washed matrix was resuspended with 10 mL sodium phosphate, pH 8.0, and then incubated with glutathione (1 mg/mL) for 1 h or peptides (0.1 mg/mL) overnight at 4 °C. Finally, the matrix was washed three times in 10 mM sodium phosphate, pH 8, with intermittent centrifugations.

**2.5. Elution of Conjugates from Ion-Exchange Resins.** The ion exchange matrix with glutathione-conjugated ovalbumin (10 mL) was packed in a column (16 mm diameter) washed with 10 mM sodium phos-

**Figure 1.** Schematic presentation of the principle of solid-phase conjugation to ion exchange matrix-adsorbed carrier proteins. IAAOSu: iodoacetic acid *N*-hydroxysuccinimid ester.

phate, pH 8, and eluted with a linear gradient of NaCl in the same buffer (0–1 M over 200 min; flow, 1 mL/min).

**2.6. ELISA.** Antigens were diluted 1:1000 and coated in wells of microtiter plates using 50 mM sodium carbonate, pH 9.6, as coating buffer. The wells were washed three times for 5 min with TTN and incubated for 1 h with primary antibodies diluted 1:1000 in TTN. After washing in TTN three times for 5 min, the wells were incubated 1 h with alkaline phosphatase-conjugated secondary antibodies (rabbit immunoglobulins against mouse immunoglobulins or goat immunoglobulins against rabbit immunoglobulins) diluted 1:2000 in TTN. The wells were washed three times for 5 min in TTN and developed with pNPP (1 tablet (15 mg) per 15 mL 1 M diethanolamine, 0.5 mM MgCl<sub>2</sub> pH 9.8). Absorbances were read at 405 nm with background subtraction at 690 nm.

**2.7. Immunizations.** Ion exchange matrix-adsorbed conjugates were washed three times in water, and eluted conjugates were dialyzed three times against water. They were then mixed with an equal volume Al(OH)<sub>3</sub> before immunization. Mice were immunized intraperitoneally or subcutaneously with 100  $\mu$ L. Rabbits were immunized subcutaneously with 1 mL. In some experiments aluminum hydroxide was substituted with Freund's complete adjuvant for the first immunization and Freund's incomplete adjuvant for the following immunizations. The titer of a serum was defined as the dilution giving half-maximal response when analyzed by ELISA.

### 3. RESULTS

To determine the feasibility of solid-phase carrier protein activation and peptide conjugation, we initially compared immobilization of ovalbumin on three ion exchange matrixes in combination with iodoacetic acid *N*-hydroxysuccinimide ester activation and subsequent conjugation of glutathione using batch procedures for all steps (Figure 1, Table 1). As illustrated in Figure 1, this procedure takes advantage of the immobilization of proteins on ion exchange matrixes at low ionic strength. This allows the protein to be manipulated by solid-phase methods, and it allows the resulting conjugate to be

**Table 1. **Figure 2.** Elution of glutathione-IAA-ovalbumin conjugates from Q Sepharose HP after solid-phase activation of ovalbumin with iodoacetic acid *N*-hydroxysuccinimid ester (1 mg/mL) and conjugation of glutathione (1 mg/mL). The protein profile (A280), the reactivity with an antiserum against glutathione (A405), and the conjugation ratio between glutathione and ovalbumin as determined by amino acid analysis are shown.

eluted from the ion exchange matrix by increasing the ionic strength. As shown in Table 1, and in agreement with the capacities of the matrixes, the highest amounts were immobilized on Q Sepharose High Performance (HP) (about 20 mg/mL settled matrix) and the lowest amounts on DEAE cellulose. The average conjugation ratios (the number of glutathione molecules covalently bound to each ovalbumin molecule) as determined by amino acid analysis were almost equal for the ion exchange matrix-bound ovalbumin conjugates and reached a value of about 9 on Q Sepharose HP.

Immunization of mice with the ion exchange matrix-bound conjugates showed that essentially equal titers of ovalbumin antibodies were elicited, whereas the average titers for glutathione antibodies ranged from 300 for DEAE Sephadex to about 2000 for Q Sepharose HP (Table 1).

To analyze the extent of conjugation further, we immobilized ovalbumin on 30 mL Q Sepharose HP anion exchange matrix, activated the immobilized protein with iodoacetic acid *N*-hydroxysuccinimid ester and derivatized 10 mL immediately with glutathione. The rest was frozen at 20 °C for later derivatization. The glutathione-derivatized resin was then packed in a column and subjected to elution with a salt gradient (Figure 2). As expected, this revealed a broad elution pattern reflecting a heterogeneous distribution of conjugated molecules. Analysis with an antiserum against glutathione (Houen and Jensen, 1995) showed the lowest reactivity in the

28	0.1	3.80		

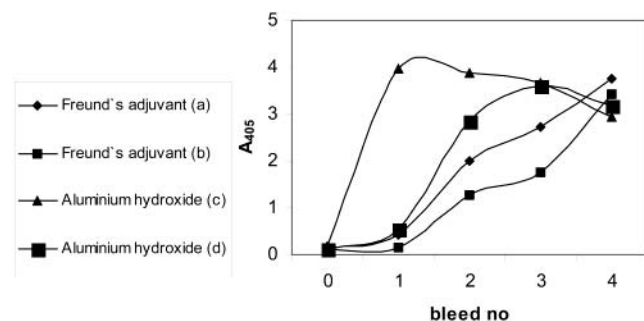

early eluting fractions and increasing reactivity at the end of the elution profile. This reflects that ovalbumin molecules with more glutathione conjugated are more negatively charged (for each lysine activated one positive charge is lost, and for each glutathione molecule conjugated one negative charge is gained). Amino acid analysis of selected fractions confirmed this and revealed the actual conjugation ratios (Table 2), which ranged from 0.22 to 7.02. Compared to the average conjugation ratio in Table 1, these values are somewhat lower, which is due to the use of less iodoacetic acid *N*-hydroxysuccinimid ester in the activation step (1 mg/30 mg ovalbumin vs 1 mg/10 mg ovalbumin). SDS-PAGE analysis and immunoblotting of selected fractions from the elution are shown in Figure 3. These analyses correspond to the elution pattern, showing a relatively large amount of protein early in the chromatogram with an electrophoretic mobility corresponding to nonconjugated ovalbumin and with a low reactivity with the glutathione antiserum. Fractions eluting later in the chromatogram showed a more heterogeneous electrophoretic mobility pattern and reacted stronger with the antiserum. Immunization of mice with selected fractions representing low (fraction 10), intermediate (fraction 18), and high (fraction 24) conjugation ratios induced antibodies against glutathione for the two latter fractions (Table 2), while no antibodies against glutathione were induced by the essentially nonconjugated fraction. The highest titers of glutathione antibodies were achieved with the fraction containing the more substituted conjugate, whereas the titers for ovalbumin antibodies were highest for the fractions with the lowest conjugation ratios. For one particular mouse, immunized with the highly conjugated fraction, the level of ovalbumin antibodies was remarkably low, while the glutathione antibody titer reached a level of almost 6000.

Immunization of rabbits with a pool of fractions (15–25) representing the more substituted conjugates showed that high titers of glutathione antibodies were rapidly induced. Aluminum hydroxide adjuvant was more effective than Freund's adjuvant since the antibody levels increased faster (Figure 4).

Thawing of the frozen iodoacetic acid *N*-hydroxysuccinimid ester-activated matrix and derivatization with glutathione revealed a lower average conjugation ratio, showing that freezing leads to inactivation of some of the reactive iodine groups. Similarly, in situ activation of ion exchange matrix-immobilized carrier protein packed in a column and conjugation by recirculation of reagents was attempted but was found to be inferior to batch activation and conjugation, presumably due to the absence of stirring, which is important for heterogeneous reactions (results not shown).

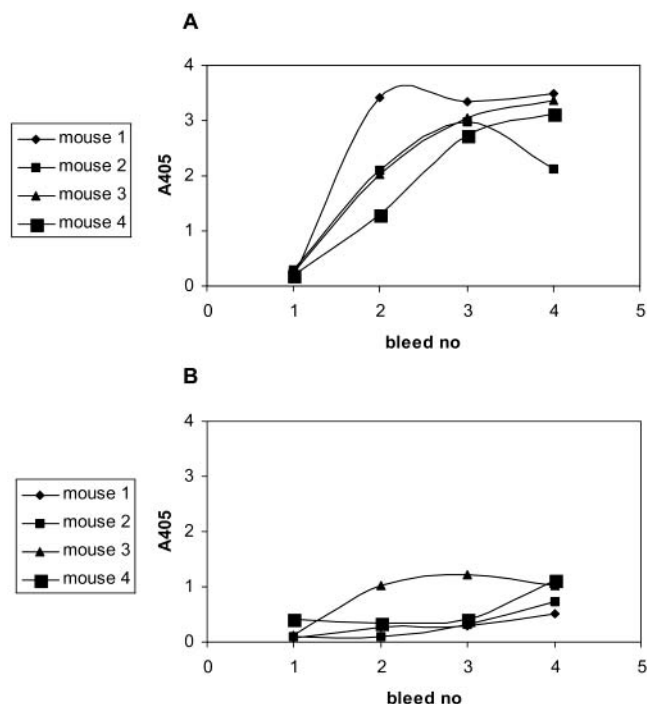

**Figure 3.** Analysis of eluted conjugates from Figure 2 by SDS-PAGE (A) and by immunoblotting (B) with an antiserum against glutathione. M: molecular weight marker proteins.

**Figure 4.** Time course for induction of antibodies against glutathione in rabbits immunized with eluted glutathione-ovalbumin conjugates using aluminum hydroxide (a, b) or Freund's adjuvant (c, d).

Conjugation of various peptides (1 mg/mL), with N- or C-terminally added cysteines, to ion exchange matrix-adsorbed ovalbumin was carried out using the batch procedure. Conjugation ratios of 1–2 were found by amino acid analysis. The conjugation ratios were lower for the synthetic peptides than for glutathione because lower concentrations were used. However, immunization of mice with the peptide-ovalbumin conjugates bound to Q Sepharose HP showed induction of antibodies, although different peptides were not equally immunogenic (Figure 5). As seen in Figure 5A, the conjugate of ovalbumin and peptide CGHEKEGFMEAEQC bound to

**Figure 5.** Antibody levels in mice immunized with Q Sepharose HP-immobilized ovalbumin conjugates of the following peptides (one letter amino acid code): (A) CGHEKEGFMEAEQC, (B) CADQLDPIYVAYNM.

Q Sepharose HP induced antibodies in all four mice reaching titers of 1:1600, whereas the conjugate of ovalbumin and peptide CADQLDPIYVAYNM bound to Q Sepharose HP was less immunogenic and only induced low titers of antibodies ( $\leq 1:200$ ).

#### 4. DISCUSSION

In this study we have shown that a carrier protein can be immobilized on an ion exchange matrix, activated with iodoacetic acid *N*-hydroxysuccinimid ester and then conjugated with glutathione or peptides containing a cysteine residue. The resulting conjugates could be eluted from the matrix for use in immunization experiments but the matrix-immobilized conjugates could also be used directly for immunization. Immunization of mice with eluted glutathione-ovalbumin conjugates showed that the more substituted conjugates elicited the highest titers of glutathione antibodies, and immunization experiments with matrix-bound peptide-ovalbumin conjugates revealed varying degrees of peptide antibody induction depending on the peptide.

Compared to previously described methods such as peptide synthesis directly on carrier proteins (Hansen et al., 1993), preactivation of carrier proteins in solution (Houen and Jensen, 1995), or preactivation of carrier proteins adsorbed to aluminum hydroxide (Houen et al., 1997), the present method is more versatile and easier to carry out. Peptide synthesis on proteins results in highly substituted conjugates with low solubility and requires simultaneous synthesis of the peptide itself for binding studies and absorption experiments. Preactivation of carrier proteins in solution with heterobifunctional reagents (eg., iodoacetic acid *N*-hydroxysuccinimid ester) is an efficient way of achieving conjugation to specific groups in haptens and peptides (eg., cysteine SH group), but this method requires extensive dialyses in order to remove activation reagents. Preactivation of carrier proteins adsorbed to aluminum hydroxide substitutes

dialysis for reagent removal with washing-centrifugation steps and therefore incorporates the advantages of solid-phase chemistry. This procedure, however, has the disadvantage that aluminum hydroxide is sensitive to variations in pH, and that the aluminum hydroxide-carrier interactions are rather weak and therefore sensitive to low concentrations of salt even at physiological pH. Adsorption of the carrier protein on ion exchange matrixes is much more robust compared to aluminum hydroxide, since the matrix itself is very stable and since the ionic interactions involved are strong. Furthermore, elution of the conjugates may be easily achieved by a salt gradient.

Compared to conjugation methods using homobifunctional reagents for cross-linking of carrier and peptide/hapten, the use of preactivation and heterobifunctional cross-linking reagents provides for better conjugation ratios and lower degrees of multimeric aggregate formation. When this is combined with solid-phase technology, which has proven its efficacy in peptide and oligonucleotide synthesis, the conjugation procedures can be carried out with optimal convenience, speed, and control of the conjugations. For this purpose, we have explored the use of ion exchange matrixes as the solid support in bioconjugate preparations, and we find that this is currently the optimal choice with respect to convenience, speed, stability, robustness, and versatility. Compared to the use of aluminum hydroxide as the solid support, ion exchange matrixes have the drawback of being less effective as adjuvants, and it may therefore be desirable to add aluminum hydroxide or another adjuvant prior to immunization. However, for several conjugates we observed efficient induction of antibodies without addition of adjuvant (results not shown), indicating that the matrix-bound conjugates are capable of activating a sufficient immune response.

In conclusion, we have developed a convenient and robust solid-phase conjugation method, which will be useful in preparation of many types of bioconjugates. Future investigations could therefore be aimed at incorporating the adjuvant into the solid-phase matrix or linking it through ionic interactions. Also, the combination of an affinity matrix and an immobilized ligand will offer protection of the ligand binding site during subse-

quent conjugations. Elution of the conjugate afterwards should provide a functional conjugate.

# Reversible Biotinylation Phosphoramidite for 5'-End-Labeling, Phosphorylation, and Affinity Purification of Synthetic Oligonucleotides

Shiyue Fang<sup>†,§</sup> and Donald E. Bergstrom<sup>\*,†,§</sup>

Department of Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, Indiana 47907 and Walther Cancer Institute, Indianapolis, Indiana 46208. Received October 14, 2002

A fluoride/amine-cleavable phosphoramidite designed for biotinylation, phosphorylation, and affinity purification of synthetic oligonucleotides was synthesized and coupled efficiently to the 5'-end of DNA on a solid-phase automatic synthesizer. The two hydroxyl groups of diethyl bis(hydroxymethyl)malonate were used to link biotin and the 5'-end of DNA together through a diisopropylsilyl acetal functionality and a phosphate ester group, respectively. The DNA was cleaved from solid support and fully deprotected by treating with a mixture of MeNH<sub>2</sub> (~40%) and NH<sub>4</sub>OH (~29%) (1:1, v/v, 65 °C, 30 min), and the linkage between biotin and DNA was found completely stable under these conditions. The biotinylated full-length DNA was efficiently attached to NeutrAvidin coated microspheres and failure sequences and other impurities were simply removed by washing with buffer and water. The microspheres were then treated with HF/pyridine/THF (rt, 1 h) and MeNH<sub>2</sub> (~40%, rt, 15 min) sequentially to yield high quality full-length 5'-end phosphorylated unmodified DNA as revealed by HPLC analysis. It is anticipated that this method will find applications in areas that require efficient isolation of 5'-end phosphorylated DNA from a complex mixture.

## INTRODUCTION

The high affinity between biotin and streptavidin or avidin (association constant 10<sup>15</sup>/M) has been widely used as a means to label DNA and RNA (1), and as a result, chemical biotinylation of these biopolymers has received considerable attention (2–9). For some applications, reversible biotinylation may be required in order to regenerate unmodified DNA/RNA that can be biochemically or biologically processed. For 5'-end reversibly biotinylated DNA/RNA, after cleavage, both 5'-end non-phosphorylated and 5'-end phosphorylated DNA/RNA are required to meet different applications. For the former purpose, Gildea and co-workers reported an acid-labile biotinylation phosphoramidite (8). For the latter purpose, Rothschild and co-workers reported a photocleavable biotinylation phosphoramidite (9). Although they successfully applied their methods for affinity purification of synthetic oligonucleotides, Gildea's method requires a challenging and inconvenient reagent synthesis, and in Rothschild's method, formation of thymine–thymine photodimer under UV irradiation is a concern (10–12). We recently reported a fluoride-cleavable biotinylation phosphoramidite for 5'-end-labeling, affinity purification of synthetic oligonucleotides (13). In this method, non-phosphorylated unmodified DNA was obtained after removal of the biotin tag. Complementary to this method, we describe here a reversible biotinylation phosphoramidite that on removal of the biotin tag affords 5'-end phosphorylated unmodified DNA.

## MATERIALS AND METHODS

**General.** All reactions were performed under a blanket of dry argon. Reagents and solvents available from commercial sources were used as received unless otherwise noted. Tetrahydrofuran was distilled from a Na/benzophenone ketyl. Acetonitrile was distilled over CaH<sub>2</sub>. Acetone was dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>, and the supernatant was used directly. Thin-layer chromatography (TLC) was performed using Sigma-Aldrich TLC plates, silica gel on aluminum 60F-254, 200 μm thickness. Flash column chromatography was performed using 'Baker' silica gel (40 μm). NMR spectra were obtained using a 250 or 500 MHz Bruker spectrometer. Chemical shifts (δ) are reported relative to CHCl<sub>3</sub> (δ = 7.27 ppm for <sup>1</sup>H and 77.23 ppm for <sup>13</sup>C) or triphenyl phosphate (δ = 0.00 ppm for <sup>31</sup>P). Infrared spectra were recorded on a Nicolet FTIR spectrophotometer. High-resolution mass spectra were obtained on a Finnigan Mat 95XL spectrometer. UltraLink Immobilized NeutrAvidin (slurry in water, approximately 50% v/v, containing 0.02% sodium azide; pore size, 1000 Å; particle size, 50–80 μm; biotin-binding capacity, ~0.08 μmol biotin/mL gel) was purchased from Pierce. Aqueous MeNH<sub>2</sub> (~40%) and NH<sub>4</sub>OH (~29%), HF/pyridine (HF, ~70%; pyridine, ~30%), diethyl bis(hydroxymethyl)malonate and Me<sub>3</sub>SiOMe were purchased from Aldrich Inc. Diisopropylchlorosilane was purchased from Gelest Inc. Succinic ester linked DMTr-dT-lcaa-CPG (pore size 1000 Å), (2-cyanoethyl)-[2,2-bis(ethoxycarbonyl)-3-(4,4'-dimethoxytrityloxy)propyl-1]-N,N-diisopropylphosphoramidite and 5'-DMTr, 2-cyanoethyl phosphoramidites: benzoyl-dA, isobutryl-dG, acetyl-dC, and dT were purchased from Glen Research Inc. PBS buffer: 136.9 mM NaCl, 2.7 mM KCl, 10.1 mM Na<sub>2</sub>HPO<sub>4</sub>, 1.8 mM KH<sub>2</sub>PO<sub>4</sub>, adjusted to pH 7.0 with HCl. HPLC: C-18 reverse phase column (100 Å, 250 × 4.6 mm for analysis, 250 × 10.0 mm for preparation, Varian

Analytical Instruments); solvent A: 0.1 M triethylammonium acetate, 5% acetonitrile; solvent B: 90% acetonitrile; profiles were generated by detection of the absorbance of DNA at 260 nm using two linear gradient solvent systems: Gradient A: solvent B (0–45%) in solvent A over 60 min at flow rates of 1 mL/min (analysis) and 3 mL/min (preparation); Gradient B: solvent B (0–20%) in solvent A over 60 min at a flow rate of 1 mL/min (analysis). In all cases, gradient A was used unless otherwise noted.

**Biotin Diethyl Bis(hydroxymethyl)malonate Conjugate 2.** A one-necked round-bottomed flask was charged with biotinyl alcohol **1** (605 mg, 0.93 mmol), synthesized following procedures described previously (13), and imidazole (63 mg, 0.93 mmol) and flushed with Ar. DMF (2 mL) and diisopropylethylamine (498  $\mu$ L, 2.79 mmol) were added via syringe. After the mixture was cooled to 0 °C, diisopropyldichlorosilane (252  $\mu$ L, 1.40 mmol) was added via syringe in one portion. The light yellow solution was stirred at 0 °C for 1 h and at rt for 4 h and then added to a solution of diethyl bis(hydroxymethyl)malonate (500 mg, 2.20 mmol) and imidazole (126 mg, 1.86 mmol) in DMF (2 mL) via syringe very slowly (over 45 min). After being stirred at 0 °C for 5 h, the reaction mixture was partitioned between CH<sub>2</sub>Cl<sub>2</sub> (30 mL  $\times$  5) and 5% citric acid (50 mL). The organic phase was washed with brine (30 mL) and dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>. Removal of volatile components gave a light yellow residue, which was purified by flash column chromatography (3.0  $\times$  12 cm, SiO<sub>2</sub>, 19:1, CH<sub>3</sub>Cl/CH<sub>3</sub>OH). The highest UV active spot (the major one) on TLC ( $R_f$  = 0.5; 9:1, CH<sub>3</sub>Cl/CH<sub>3</sub>OH) was easily isolated, giving **2** (Scheme 1) as a white foam (839 mg, 92%): IR (thin film, cm<sup>-1</sup>)  $\nu$  3318, 2954, 2864, 1739, 1652, 1555, 1040; <sup>1</sup>H NMR (CDCl<sub>3</sub>, 500 MHz)  $\delta$  0.88–1.01 (m, 14H), 1.24–1.27 (m, 12H), 1.32 (s, 9H), 1.47–1.53 (m, 2H), 1.65–1.85 (m, 6H), 2.18–2.31 (m, 4H), 3.03–3.10 (m, 2H), 3.25 (dt, 1H,  $J$  = 7.4, 4.7 Hz), 3.38–3.50 (m, 4H), 3.54–3.56 (m, 4H), 3.60 (s, 4H), 4.14–4.27 (m, 9H), 5.22–5.24 (m, 1H), 6.37 (t, 1H,  $J$  = 5.5 Hz), 6.58 (t, 1H,  $J$  = 5.3 Hz), 7.39 (d, 2H,  $J$  = 8.5 Hz), 7.57 (d, 2H,  $J$  = 8.5 Hz); <sup>13</sup>C NMR (CDCl<sub>3</sub>, 500 MHz)  $\delta$  13.4, 14.2, 17.7, 27.8, 29.8, 30.5, 31.3, 32.0, 35.1, 35.6, 38.4, 39.2, 39.5, 40.0, 55.2, 57.5, 61.6, 61.7, 61.8, 62.7, 70.0, 70.1 (X 2), 70.3, 73.8, 124.7, 129.1, 131.9, 155.1, 156.3, 169.2, 170.2, 173.3, 174.2. HRMS (ESI, M + H<sup>+</sup>) Calcd for C<sub>48</sub>H<sub>81</sub>N<sub>4</sub>O<sub>13</sub>SSi 981.5290, found 981.5295.

**Biotin Diethyl Bis(hydroxymethyl)malonate Conjugate Phosphoramidite 3.** To a solution of **2** (715 mg, 0.72 mmol) in dry acetonitrile (2 mL) were added 2-cyanoethyl-*N,N,N,N*-tetraisopropylphosphoramidite (264  $\mu$ L, 0.80 mmol) and 1*H*-tetrazole (0.45 M in acetonitrile, 1.68 mL, 0.76 mmol) sequentially. After stirring at rt for 3 h, some white precipitate formed. The reaction was quenched with NaHCO<sub>3</sub> (5%, 50 mL), and the mixture was extracted by CH<sub>2</sub>Cl<sub>2</sub> (30 mL  $\times$  5). The organic phase was dried over anhydrous Na<sub>2</sub>SO<sub>4</sub>, solvents were removed under reduced pressure, and the residue was purified by flash column chromatography (3.0  $\times$  10 cm, SiO<sub>2</sub>, 7:3:0.5, CHCl<sub>3</sub>/THF/Et<sub>3</sub>N), giving **3** as a white foam (520 mg, 61%):  $R_f$  = 0.5 (7:3:0.5, CHCl<sub>3</sub>/THF/Et<sub>3</sub>N); <sup>1</sup>H NMR (CDCl<sub>3</sub>, 250 MHz)  $\delta$  0.91–1.07 (m, 14H), 1.14–1.18 (m, 12H), 1.22–1.29 (m, 12H), 1.32 (s, 9H), 1.41–1.51 (m, 2H), 1.65–1.82 (m, 4H), 2.16–2.34 (m, 4H), 2.60 (t, 2H,  $J$  = 6.8 Hz), 3.04–3.06 (m, 2H), 3.21–3.26 (m, 1H), 3.40–3.48 (m, 4H), 3.52–3.61 (m, 8H), 3.76–3.82 (m, 2H), 4.05–4.25 (m, 11H), 5.19–5.22 (m, 1H), 6.28 (t, 1H,  $J$  = 5.5 Hz), 6.39 (t, 1H,  $J$  = 5.3 Hz), 7.39 (d, 2H,  $J$  = 8.0 Hz), 7.57 (d, 2H,  $J$  = 8.3 Hz); <sup>31</sup>P NMR (CDCl<sub>3</sub>, 250 MHz)  $\delta$  166.36.

**Biotinyl Oligonucleotide 4, Synthesis, Cleavage, Deprotection, and HPLC Analysis.** The oligonucleotide was synthesized on an ABI DNA/RNA synthesizer at 1  $\mu$ mol scale, using the following 5'-DMTr, 2-cyanoethyl phosphoramidites: benzoyl-dA, isobutyryl-dG, acetyl-dC and dT. The manufacturer recommended synthetic cycles were used except that **3** (0.1 M in acetonitrile) was coupled for 15 min. The CPG was dried under nitrogen flow and then divided into two portions (0.52  $\mu$ mol, 0.48  $\mu$ mol). To the 0.52  $\mu$ mol portion in a screw-capped 5-mL vial was added NH<sub>4</sub>OH (~29%, 200  $\mu$ L) and methylamine (~40%, 200  $\mu$ L), and the resulting suspension was heated to 65 °C for 30 min. After being cooled to -20 °C, the supernatant was taken out, and the CPG was washed with water (200  $\mu$ L  $\times$  5). The supernatant and water washes were combined and dried on a SpeedVac. The residue was redissolved in 1.0 mL water, of which 10  $\mu$ L was diluted to 100  $\mu$ L, and 50  $\mu$ L was analyzed by HPLC to generate trace a (Figure 1). From the 1.0 mL solution was taken out a 100  $\mu$ L portion and dried on a SpeedVac. The residue was suspended in dry THF (200  $\mu$ L) in an Eppendorf tube, 30  $\mu$ L of HF/pyridine was added via pipet. The mixture was vortexed for 1 min and then

**Figure 1.** HPLC traces of (a) crude oligonucleotide **4**, containing failure sequences. (b) HF/pyridine-treated crude **4**. (c) HF/pyridine- and aqueous methylamine-treated crude **4**. (d) Unbiotinylated failure sequences left after treating crude **4** with NeutrAvidin gel. (e) Affinity-purified oligonucleotide **7**. (f) Authentic **6**. (g) Authentic **6** and HF/pyridine-treated crude **4**. (h) Authentic **7** and affinity-purified **7**. (i) Authentic **7**. (j) Authentic **7** and affinity-purified **7** eluted with solvent gradient B. (k) Authentic **8** and affinity-purified **7** eluted with solvent gradient B.

allowed to stand at rt for 1 h with occasional shaking. The excess fluoride ion was quenched with Me<sub>3</sub>SiOMe (500  $\mu$ L) by gentle shaking at rt for 30 min. Volatile components were removed on a SpeedVac, the residue was dissolved in 500  $\mu$ L water, and 50  $\mu$ L was analyzed by HPLC to generate trace **b** (Figure 1). From the 1.0 mL solution was taken out another 100  $\mu$ L portion, which was treated with HF/pyridine and Me<sub>3</sub>SiOMe exactly as described above. To the resulting residue was added MeNH<sub>2</sub> (~40%, 200  $\mu$ L), the mixture was gently shaken at rt for 15 min and then dried on a SpeedVac. The residue was dissolved in 500  $\mu$ L water, and 50  $\mu$ L was analyzed by HPLC to generate trace **c** (Figure 1). The coupling efficiency of **3** was estimated to be more than 81% by comparing the area of the peak with retention time near 43 min to that of the major peak near 15 min in trace **a** (Figure 1).

**Affinity Purification and HPLC Analysis.** Another 100  $\mu$ L was taken out from the above-described 1.0 mL solution of crude oligonucleotide **4**, dried on a SpeedVac, redissolved in 300  $\mu$ L of PBS buffer, and incubated with UltraLink Immobilized NeutrAvidin gel (0.5 mL gel, 1.0 mL gel slurry), which was washed with PBS buffer (300  $\mu$ L  $\times$  3), for 1 h at rt with gentle shaking (it is important to handle the gel gently, otherwise, gel material may leak, and recovery yield of full-length DNA may be low). The mixture was centrifuged, the supernatant removed, and the gel washed with PBS buffer (300  $\mu$ L  $\times$  2). The supernatant and PBS buffer washes were combined, dried on a SpeedVac, redissolved in 500  $\mu$ L water, and 100  $\mu$ L was analyzed by HPLC to generate trace **d** (Figure 1). The gel was further washed with PBS buffer (500  $\mu$ L  $\times$  3) and water (500  $\mu$ L  $\times$  3), dried by washing with dry acetone (500  $\mu$ L  $\times$  3) and THF (500  $\mu$ L  $\times$  3), and then suspended in THF (300  $\mu$ L). To the suspension was added HF/pyridine (30  $\mu$ L), and the mixture was incubated at rt for 1 h with gentle shaking. The excess fluoride ion was quenched with Me<sub>3</sub>SiOMe (500  $\mu$ L, rt, 30 min), the mixture was centrifuged, and the supernatant was removed. The gel was washed with THF (300  $\mu$ L  $\times$  2) and then incubated in MeNH<sub>2</sub> (~40%, 500  $\mu$ L) at rt for 15 min. The mixture was centrifuged, the supernatant obtained, and the gel washed with water (300  $\mu$ L  $\times$  8).

The supernatant and water washes were combined and dried on a SpeedVac. The residue was redissolved in water (1.5 mL), and 100  $\mu$ L was analyzed by HPLC to give trace **e** (Figure 1). The recovery yield of full-length 5'-end phosphorylated DNA **7** (see Scheme 2 for structure) was estimated to be 72% by comparing the area of the peak in trace **e** to that in trace **a** with a retention time of near 43 min. The presence of the 5'-phosphate group on **7** was supported by HPLC analysis through coinjection of authentic **6** (authentic samples were synthesized as described below) with the sample used to generate trace **b** (trace **g**, Figure 1). Coinjection of the affinity purified **7** with authentic **7** gave trace **h** (Figure 1). Coinjection of affinity purified **7** with the nonphosphorylated authentic sample HOACAGTGACTOH (**8**) eluting with solvent gradient A, however, gave a single peak (HPLC trace not shown). To resolve affinity purified **7** and authentic **8**, solvent gradient B was used, and HPLC trace **k** was generated. Coinjection of affinity purified **7** with authentic **7** under these conditions gave trace **j**. The identity of affinity purified **7** was also confirmed by MALDI mass spectrum analysis of the failure sequences and full-length **7** (**14**). The samples, which were used to generate HPLC traces **d** and **e**, were desalted by Sep-Pac cartridge independently according to the reported procedure and analyzed separately (**14**). The failure sequences gave the following peaks: 2718.4 for (HO-TCAGTGACA-OH - H)<sup>-</sup> calcd 2721.9, 2405.7 for (HO-TCAGTGAC-OH - H)<sup>-</sup> calcd 2408.7, 2117.7 for (HO-TCAGTGA-OH - H)<sup>-</sup> calcd 2119.5, 1804.3 for (HO-TCAGTG-OH - H)<sup>-</sup> calcd 1806.3, 1476.5 for (HO-TCAGT-OH - H)<sup>-</sup> calcd 1477.1, 1173.2 for (HO-TCAG-OH - H)<sup>-</sup> calcd 1172.8, 844.9 for (HO-TCA-OH - H)<sup>-</sup> calcd 843.6, 531.0 for (HO-TC-OH - H)<sup>-</sup> calcd 530.4. The affinity purified **7** gave a peak of 2804.8 for (HO-TCAGTGACA-OPO<sub>3</sub>H<sub>2</sub> - H)<sup>-</sup> calcd 2801.9.

**Synthesis and Purification of Authentic Oligonucleotides **6**, **7**, and **8**.** Oligonucleotide **6** and **7** were synthesized independently on an ABI DNA/RNA synthesizer at 1  $\mu$ mol scale, using the following 5'-DMTr, 2-cyanoethyl phosphoramidites: benzoyl-dA, isobutyryl-dG, acetyl-dC and dT; and (2-cyanoethyl)[2,2-bis(ethoxycarbonyl)-3-(4,4'-dimethoxytrityloxy)propyl-1]-*N,N*-diiso-

## Scheme 2

propylphosphoramidite. Manufacture recommended synthetic cycles were used. Cleavage/deprotection was performed by  $\text{NH}_4\text{OH}$  (~29%) and  $\text{MeNH}_2$  (~40%) (1:1, v/v) at 65 °C for 15 min. Following the procedure described by Guzaev (15), trityl-on reverse phase preparative HPLC purification, detritylation gave **6** (HPLC trace f, Figure 1); removal of the 5'-end diethyl bis(hydroxymethyl)malonate moiety gave **7** (HPLC trace i, Figure 1). Authentic **8** was synthesized following a procedure described previously (13).

## RESULTS AND DISCUSSION

We recently reported the design and synthesis of a fluoride-cleavable phosphoramidite for 5'-end biotinylation and affinity purification of synthetic oligonucleotides (13). The biotinylated structure obtained by such a method after cleavage of the oligonucleotide from solid support and ammonia deprotection is illustrated in Figure 2 (**9**). The diisopropylsilyl acetal linkage, which connects the biotin moiety and the 5'-OH of the synthetic oligonucleotide through a tertiary hydroxide group, was found completely stable under certain postsynthetic DNA cleavage/deprotection conditions. However, this linkage can be readily broken by treating with HF/pyridine under mild conditions to yield unmodified DNA carrying a free 5'-OH. In 1995, Guzaev and co-workers described an approach that used the dimethoxytrityl protected diethyl bis(hydroxymethyl)malonate phosphoramidite for chemical phosphorylation of oligonucleotides at the 5'-terminus (15). The structure of DNA obtained by their method is also shown in Figure 2 (**10**). The DMTr-protected diethyl bis(hydroxymethyl)malonate moiety that is linked to the 5'-OH of DNA through a phosphodiester group is stable under common amino cleavage/deprotection conditions.

This property is useful for purification of synthetic DNA by reverse phase HPLC. After purification and removal of the DMTr group, the 5'-end phosphate group is released by briefly treating with aqueous amine under mild conditions. On the basis of these two reports, we reasoned that substitution of the DMTr group in **10** by the diisopropylsilyl acetal functionality linked to biotin as in **9** would provide a simple method for reversible biotinylation and phosphorylation of DNA. This led to design of the reversible biotinylation phosphoramidite **3** (Scheme 1). The new linkage between DNA and biotin, like **9** and **10**, should be stable under certain postsynthetic DNA cleavage/deprotection conditions. Removal of the silyl acetal group by treating with fluoride ion should generate the same species as treating **10** with acid, and 5'-end phosphorylated DNA should be produced in the presence of aqueous amine under mild conditions.

Synthesis of the phosphoramidite **3** is shown in Scheme 1. The biotinyl tertiary alcohol **1** was prepared according to procedures described previously (13). The tertiary hydroxyl group of **1** was first silylated by diisopropylchlorosilane in DMF in the presence of diisopropylethylamine (2 equiv) and imidazole. This solution was added to a solution of diethyl bis(hydroxymethyl)malonate and imidazole in DMF via syringe very slowly to avoid possible deformylation of the hydroxymethylmalonate under basic conditions, and **2** was obtained as a white foam in excellent yield. The biotinyl alcohol **2** was then phosphorylated under a slightly acidic conditions following Guzaev's procedure to give **3** (61%) (15).

The biotinyl oligonucleotide **4** (Scheme 2) was synthesized on an automatic DNA/RNA synthesizer according to standard synthetic cycles. The following 5'-DMTr, 2-cyanoethyl phosphoramidites were used: benzoyl-dA,

Figure 2.

isobutyryl-dG, acetyl-dC and dT, and in the last cycle, **3** (0.1 M in acetonitrile) was coupled for 15 min. Protection of C with an acetyl group allowed fast cleavage/deprotection of the DNA by treating with MeNH<sub>2</sub> (~40%)/NH<sub>4</sub>-OH (~29%) (1:1, v/v, 65 °C, 30 min) (16, 17). The 4-tertiary butyl benzoyl protecting group on biotin was also removed under these conditions, giving the diisopropylsilyl acetal linked biotinyl oligonucleotide **4** as the product (13). Analysis by HPLC generated *trace a* (Figure 1); the major peak with a retention time near 43 min should be the biotinylated oligonucleotide **4** (Scheme 2). A portion was treated with HF/pyridine, followed by quenching the excess fluoride ion by methoxytrimethylsilane (18), dried, redissolved in water, and analyzed by HPLC to give *trace b* (Figure 1); the major peak with a retention time near 20 min should be **6** (Scheme 2). The peaks with retention time around 15 min in *traces a* and *b* should be failure sequences and other impurities. Another portion was treated similarly with HF/pyridine, followed by methoxytrimethylsilane, but was then further incubated in aqueous MeNH<sub>2</sub> (~40%) at room temperature to give the 5'-end phosphorylated unmodified oligonucleotide **7** (Scheme 2) (15). As expected, HPLC analysis (*trace c*, Figure 1) indicated that the major peaks in *traces a* (retention time ~43 min) and *b* (retention time ~20 min) was replaced by a peak near 15 min. Comparison of *traces a* with *b* and *c* indicates that the linkage between biotin and the 5'-end of DNA is completely stable under these postsynthetic DNA cleavage/deprotection conditions. The coupling efficiency of phosphoramidite **3** was estimated to be 81% by comparing the area of the peak in *trace a* with a retention time of near 43 min to that of the largest peak with retention time near 15 min.

To demonstrate application of this biotinylation strategy, the crude oligonucleotide **4**, contaminated by failure sequences and other impurities (see *trace a*, Figure 1), was then purified by NeutrAvidin-coated microsphere-mediated affinity purification. Because the failure sequences and other impurities do not contain biotin, incubation of the crude product with the microsphere followed by washing with buffer should leave only the biotinylated full-length **4** on the solid phase. In practice, crude **4** was incubated with the microspheres in PBS buffer at room temperature for 1 h. After being centrifuged, the supernatant was removed and analyzed by HPLC (*trace d*, Figure 1). The major peak in *trace a* (retention time ~43 min) disappeared in *trace d*, showing the high efficiency of binding **4** to the NeutrAvidin-coated microspheres. The microspheres were then further washed with buffer and water, dried by washing with anhydrous acetone and THF, and then suspended in dry THF. The cleavage reagent HF/pyridine was added, incubated at room temperature, followed by quenching excess fluoride ion by methoxytrimethylsilane to give **6** (Scheme 2). The mixture was centrifuged and the supernatant removed. The gel was washed with THF and incubated at room temperature in aqueous MeNH<sub>2</sub> (~40%) to remove the diethyl bis(hydroxymethyl)malonate moiety and generate 5'-end phosphorylated **7** (15). After centrifugation, the supernatant was obtained, and the gel was washed with water. The supernatant and water washes were combined, dried on a SpeedVac, redissolved in water, and analyzed by HPLC to give *trace e* (Figure 1). As can be seen, the full-length, 5'-end phosphorylated DNA **7** is very pure. The recovery yield of **7** by this purification method was estimated by comparing the area of the peak in *trace e* (Figure 1) with that in *trace a* with a retention time of near 43 min, and it was 72%. To confirm the identity of **7**, authentic samples of **6** and **7** were prepared

following the published procedure (15). We first confirmed the structure of **6** by coinjection of the sample used to generate HPLC *trace b* with authentic **6** to give *trace g*. The identity of **7** was confirmed by coinjection of affinity purified sample with authentic **7**, whereupon only one peak was observed (*trace h*, Figure 1). However, when we coinjected affinity purified **7** with nonphosphorylated authentic sample HOACAGTGACTOH (**8**), prepared according to procedures described previously (13), a single peak was also observed (HPLC trace not shown). To resolve affinity purified **7** and authentic **8**, the solvent gradient B was used, and HPLC *trace k* was generated, which had two peaks. To make certain the affinity purified **7** and authentic **7** were also identical under these conditions, they were also coinjected for HPLC analysis, eluting with solvent gradient B; as expected, a single peak was observed (*trace j*). The identity of **7** was also conveniently confirmed by MALDI mass spectrum analysis of the failure sequences and full-length **7** (samples used to generate HPLC *traces d* and *e*, respectively), because the failure sequences were easily enriched after efficient separation from the full-length biotinylated **4** (14).

In conclusion, we designed and synthesized a novel reversible biotinylation, phosphorylation phosphoramidite, and successfully used it to biotinylate and phosphorylate the 5'-end of DNA on an automatic synthesizer. We demonstrated the use of this method by application in affinity purification of a synthetic oligonucleotide. The full-length biotinylated DNA was efficiently attached to NeutrAvidin-coated microspheres by brief incubation, and failure sequences and other impurities were removed by simple washing with buffer and water. High quality full-length 5'-end phosphorylated DNA was recovered by brief treatments with fluoride ion and aqueous amine, sequentially. The procedure is simple, and the recovery yield is high. We anticipate that this method will find applications in areas that require efficient isolation of 5'-end phosphorylated DNA from complex mixtures.

Received March 8, 2002;

Revised Manuscript Received July 18, 2002

Formation of  $\beta$ -amyloid plaques in Alzheimer's disease is initiated by intermolecular contact of the 5-amino acid sequence, KLVFF, in  $\beta$ -amyloid peptides ranging in size from 40 to 43 residues. Through optimization of binding avidity using structure/function studies, we have found that the retro-inverso peptide, ffvlk, binds artificial fibrils made from  $A\beta^{1-40}$  with moderate affinity ( $K_d = 5 \times 10^{-7}$  M). Conjugates having two copies of this peptide, whether connected by a long poly(ethylene glycol) (PEG) spacer or just two amino acids, display about 100-fold greater affinity for fibrils. Placing six copies of ffvlk on a branched PEG resulted in a 10 000-fold greater affinity ( $K_d = 1 \times 10^{-10}$  M) than the monomer peptide. This increased affinity was accompanied by more effective inhibition of the thioflavin T fluorescence signal, which correlates with neurotoxicity of plaques and fibrils. We propose that conjugates bearing several copies of ffvlk may be useful as diagnostic and therapeutic agents for Alzheimer's disease.

## INTRODUCTION

In Alzheimer's disease (AD), the brain is characterized by diffuse atrophy, especially of the cortex and hippocampus, and by the presence of senile plaques, the hallmark of AD. The plaques are complex extracellular lesions composed of a central deposition of  $\beta$ -amyloid peptide. Genetic, neuropathological, and biochemical evidence has shown that these deposits of  $\beta$ -amyloid peptide play an important role in the pathogenesis of AD (Glenner et al., 1984; Master et al., 1985; Selkoe, 1994).  $\beta$ -Amyloid ( $A\beta$ ) peptide refers to a 39–43 amino acid peptide derived from the amyloid precursor protein (APP) by proteolytic processing (Figure 1). Both the  $A\beta^{1-40}$  and  $A\beta^{1-42}$  amyloid peptides are components of the deposits of amyloid fibrils found in brain tissue of AD patients.  $A\beta^{1-42}$  is believed to play a more important role in the early stage of fibril formation and to have a seeding effect, thus being more "amyloidogenic" than  $A\beta^{1-40}$ . The fibril formation process is proposed to have two phases, nucleation followed by extension. The nucleation phase requires unfavorable, rate-limiting association steps from monomers. Once the nucleus of aggregated monomers has been formed, further addition of monomers becomes thermodynamically favorable, resulting in rapid extension of amyloid peptides into fibrils and then plaques (Harper and Lansbury, 1997).

**Figure 1.** Partial sequence of APP770. The  $\beta$ -amyloid peptide,  $A\beta^{1-43}$ , is shown in bold;  $A\beta^{1-40}$  would have the three amino acids, IAT, truncated from the C-terminus. The motif of  $A\beta$  that is the initial contact site in fibril formation is underlined.

Finding an inhibitor of the proteolytic process that is believed to excise the  $\beta$ -amyloid peptide from APP has been suggested as an approach to plaque elimination (Esler and Wolfe, 2001). Alternatively, plaque elimination could involve blocking or reversing the process of  $A\beta$  monomer aggregation into amyloid fibrils and plaques. This latter approach does not necessarily require a complete blockade, but is based on the hypothesis that aggregated  $A\beta$  in its disordered form is not neurotoxic. The fact that  $A\beta$  is also produced in normal people indicates that there may be certain functions associated with it (Haass et al., 1992; Seubert et al., 1992). Therefore, preventing  $A\beta$  from forming highly ordered amyloid fibrils and then plaques, rather than interfering with its synthesis and proteolytic processing, may be preferable as a therapeutic strategy.

The earliest studies on the aggregation process were done by Hilbich et al. (1992). They identified the critical region of  $A\beta$  involved in amyloid fibril formation by substituting the hydrophobic amino acids in  $A\beta$  by more hydrophilic amino acids and testing the effects of these changes. Their results showed that the hydrophobic core at residues 17–20 of  $A\beta$ , LVFF, is crucial for the formation of the  $\beta$ -sheet structure and the amyloid properties of  $A\beta$ . The  $A\beta^{1-40}$  analogues, where the amino acids in 17–20 are substituted by more hydrophilic amino acids, are still able to bind to full length  $A\beta^{1-40}$ . Further-

more, they were reported (Hilbich et al. 1992) to inhibit fibril formation in vitro, and therefore these analogues were suggested as therapeutic reagents for AD.

Similarly, Tjernberg et al. (1996) first synthesized the 31 possible decamers (corresponding to amino acid residues 1–10 through 31–40) of the  $A\beta^{1-40}$  molecule on a cellulose membrane matrix. The  $A\beta$  fragments capable of binding full length  $A\beta$  were identified by radioligand binding. A series of overlapping peptides, representing a region located in the central part of  $A\beta$  ( $A\beta^{9-18}$  to  $A\beta^{13-22}$ ), displayed prominent binding to  $A\beta^{1-40}$ .  $A\beta^{11-20}$ , which comprises the center of the binding region, was selected for further studies of the structural requirements for binding. This peptide, as well as N- and C-terminally truncated fragments, were synthesized and tested. It was found that the shortest peptide still displaying consistently high  $A\beta$  binding capacity had the sequence KLVFF (corresponding to  $A\beta^{16-20}$ ). This result agreed with Hilbich et al. (1992). This peptide was studied by microscopy and was found to be able to interfere with fibril formation in vitro. Having shown that the short peptide KLVFF can bind to  $A\beta$  and disrupt ordered fibril formation, Tjernberg et al. (1997) showed that peptide KLVFF binds stereospecifically to the homologous sequence in  $A\beta$ , i.e.,  $A\beta^{16-20}$ . Also, molecular modeling suggested that association of the two homologous sequences leads to the formation of an atypical antiparallel  $\beta$ -sheet structure stabilized primarily by interaction between the Lys, Leu, and Phe residues. The self-recognition property of the peptide, KLVFF, without any additional amino acids, has recently been confirmed (Watanabe et al., 2001).

On the basis of these results, Ghanta et al. (1996) presented an approach to the design of inhibitors of  $A\beta$  toxicity. In their strategy, a recognition element, which interacts specifically with  $A\beta$ , is combined with a disrupting element, which alters  $A\beta$  aggregation pathways. They synthesized a peptide composed of residues 15–25 of  $A\beta$ , designed as the recognition element, linked to an oligolysine disrupting element. This inhibitor does not alter the apparent secondary structure of  $A\beta$  nor prevent its aggregation; rather, it causes changes in aggregation kinetics and higher order structural characteristics of the aggregate. In addition to its influence on the physical properties of  $A\beta$  aggregates, the inhibitor completely blocks  $A\beta$  toxicity to PC-12 cells. These results suggest that formation of disordered aggregates rather than complete blockade of amyloid fibril formation might be sufficient for abrogation of toxicity.

Many peptide fragments, homologous to the  $\beta$ -amyloid peptide, have been synthesized and tested, and they can block the orderly aggregation of the  $\beta$ -amyloid peptide. For example, Soto et al. (1998) designed small peptides to interfere with the development of  $\beta$ -sheet structures. Their so-called ' $\beta$ -sheet breaker', a pentapeptide with partial homology to the  $\beta$ -amyloid peptide, was shown to be capable of preventing  $\beta$ -amyloid fibril formation and disassembling preformed fibrils in vitro when a 20-fold excess of inhibitor peptide was used. However, specific binding to plaques was not shown. More recently, a peptidase-resistant congener based on the KLVFF motif, having *N*-methyl amino acids at alternate positions, was shown to prevent ordered fibril formation (Gordon et al., 2001). Although interesting, the ability of these  $\beta$ -sheet breakers to oppose the accumulation of toxic plaques has been demonstrated only in model in vitro systems. To be useful therapeutically, these inhibitory compounds must be able to cross the blood–brain barrier (BBB). Furthermore, there must be specificity in the ability of the proposed inhibitory compounds to recognize aggregates

of  $\beta$ -amyloid peptide, rather than bonding and disrupting  $\beta$ -sheet structures in unrelated proteins.

We now present results that address the issues of target specificity, in addition to  $\beta$ -sheet disruption. Our research focuses on the design of multifunctional conjugates. We are using branched PEG as a scaffold and the peptide motif, KLVFF, as the plaque recognition element for preparing diagnostic and therapeutic agents for AD. Studies are presented on a PEG–peptide conjugate that cannot only bind to  $\beta$ -amyloid plaques much more avidly than those described above, but also can efficiently disrupt ordered  $\beta$ -sheet formation.

## MATERIALS AND METHODS

**Synthesis of Conjugates.** Peptides were synthesized manually by solid phase, Fmoc chemistry using reagents from Bachem and other commercial sources. Note that capital letters refer to the L-isomer, whereas lower case letters refer to the D-isomer. To prepare the tandem dimer peptide,  $\alpha$ -Fmoc (fluorenylmethoxycarbonyl),  $\epsilon$ -Mtt (methoxytrityl)-Lys was placed at the C-terminus. The Fmoc group was removed by treating the resin with 20% piperidine, and Fmoc- $\beta$ -alanine was coupled. After piperidine followed by 1% trifluoroacetic acid deprotection, the dimer peptide was produced by continuing the synthesis in the normal manner. Thus, the tandem dimer comprised two identical sequences, fvlk, joined at their C-termini by a Lys- $\beta$ -Ala spacer. A different dimer was produced by coupling KLVFF to  $\alpha,\omega$ -di-*N*-hydroxysuccinimide-PEG (Shearwater Polymers, Huntsville, AL). Peptides were cleaved from the resin and deprotected using 90% trifluoroacetic acid, 5% thioanisole, 3% ethanedithiol, and 2% anisole. After purification by reverse-phase HPLC, molecular weights were determined by MALDI-TOF mass spectrometry (Perkin-Elmer) and found to be within 1 Da of the predicted value. Unless otherwise indicated, all peptides have a free N-terminus and an amidated C-terminus. Peptide concentration was determined by absorbance at 260 nm using a standard solution of phenylalanine for calibration.

The PEG conjugate of the retro-inverso peptide, ckffvlk (Scheme 1), was prepared from eight-arm-branched amino-PEG, 10 kDa total molecular weight (Shearwater Polymers). In this process, two biotin residues were appended to PEG via amide bond formation, as quantitated by the fluorescamine reaction (Udenfriend et al., 1972). This assay measures primary amines, and coupling two out of eight amino groups gives a decrease of 25% in the fluorescence signal of an aliquot compared with an aliquot of the original reaction mixture.

**Binding to Fibrils.** The dissociation constant ( $K_d$ ) for each peptide and for the PEG conjugate with preformed fibrils was determined by Scatchard plot analysis (Scatchard, 1949). This method is necessary when one of the binding components (fibrils) is a solid and cannot be expressed in units of concentration. The  $A\beta^{1-40}$  (Quality Control Biochemicals) was dissolved in phosphate-buffered saline (PBS) with 0.05% sodium azide to form a clear solution (0.5 mg/mL, 0.1 mM). The solution was shaken for 3 days to allow fibrils to form. The preformed fibrils were checked visually, and an aliquot of each fibril suspension was checked for  $\beta$ -amyloid quality by the ThT assay (see below). Fibrils are considered to be highly representative of  $\beta$ -amyloid plaques in the brain.

The peptides and conjugates to be tested were labeled with either fluorescein isothiocyanate or [ $^3$ H]acetic anhydride for quantitation. Labeled peptide that bound fibrils was separated from unbound labeled peptide by

**Scheme 1. Multipetide Conjugate Synthesis**

ultrafiltration. Furthermore, the molecular weight cutoff of the ultrafilter was sufficiently high to permit even the largest nonfibrillar conjugates to pass through. In a typical binding assay, the total volume was 400  $\mu\text{L}$ . In each Centricon filter unit (100 kDa cutoff), 50  $\mu\text{L}$  of a preformed fibril suspension (0.5 mg/mL) and 50  $\mu\text{L}$  of peptide or conjugate solutions of various concentrations, typically diluted down from 0.1 mM, were added. PBS solution was used to adjust the total volume to 400  $\mu\text{L}$ . After incubation at room temperature with gentle shaking, some of the original mixture was taken, and the fluorescence or the radioactivity was measured to determine total peptide concentration. Then the mixture was centrifuged for 5 min at 5000 rpm at room temperature. The fluorescence or the radioactivity of the ultrafiltered permeate was measured to determine the free (unbound) peptide concentration. Then the ratio of bound concentration/free concentration was plotted against the bound concentration. The  $K_d$  was calculated from the slope of the linear plot. For Scatchard analysis of binding of conjugates to monomer peptide, the biotinylated conjugate was immobilized on streptavidin-coated plates.

**Thioflavin T Assay.** The benzothiazole dye, thioflavin T (ThT), is a classical amyloid stain for senile plaques containing  $\text{A}\beta$  in AD brain.  $\text{A}\beta^{1-40}$  was dissolved in HPLC grade DMSO to yield a clear stock solution (10 mg/mL). Before use, the solution was centrifuged for 10 min at 12 000 rpm to remove potential fibril formed during storage. In a typical ThT assay, the test sample (peptide or peptide conjugate) was diluted serially into PBSA (PBS with 0.05% sodium azide). Then 95  $\mu\text{L}$  of such diluted test sample solution was mixed with 5  $\mu\text{L}$  of  $\text{A}\beta^{1-40}$  stock solution in a 1.5 mL polypropylene tube. The mixtures were shaken vigorously at room temperature for 2 days. Then, 500  $\mu\text{L}$  of 12  $\mu\text{M}$  ThT solution in sodium phosphate buffer pH 6.0 was added. The tubes were vortexed briefly. The mixture was left standing at room temperature for 30 min. Then fluorescence was measured at excitation

and emission wavelengths of 450 and 482 nm, respectively. The fluorescence was plotted against the molar ratio of test sample to  $\text{A}\beta^{1-40}$ .

**RESULTS**

**Binding Properties.** The goal of these experiments was to maximize the avidity of interaction with amyloid plaques while preserving the natural KLVFF motif. Fibrils made similarly to our procedure are commonly used to represent amyloid plaques in the brain. According to the Scatchard equation, the data form a straight line in which the slope is the negative reciprocal of the dissociation constant. The various peptides and peptide-PEG conjugates and their binding avidity to preformed fibrils are summarized in Table 1. Note the relative standard deviation of about 30% for the prototype peptide, KLVFF (Table 1), when evaluating the data.

Peptide KLVFF is the natural sequence of residues 16–20 from  $\text{A}\beta$ , the nucleation site for peptide aggregation. Peptide ffvfk is a retro-inverso peptide, made of all D-amino acids and having the reverse of the natural sequence. Peptide ffvkk is the retro-inverso peptide with one extra lysine at the C-terminus. That extra lysine provides an additional positive charge that might increase the avidity of the peptide for binding to fibrils. Peptide FLKVF is a control peptide having a scrambled sequence. We confirmed that the binding to preformed fibrils is sequence specific since the control peptide has much lower affinity than does KLVFF. We also found that the retro-inverso peptides ffvk and ffvkk both have slightly higher affinity (2–3-fold lower dissociation constants) with  $\beta$ -amyloid fibrils than does the natural KLVFF (Table 1; Figure 2A) peptide. More importantly, these retro-inverso peptides are made of all D-amino acids and are resistant to protease digestion in vivo.

A PEG conjugate containing two copies of the prototype fibril-binding peptide had a dissociation constant ( $K_d$ ) that was 100-fold lower than the free peptide, KLVFF. The tandem dimer peptide (Table 1), having two closely spaced copies of the retro-inverso peptide, gave a  $K_d$  of the same magnitude as the peptide-PEG-peptide conjugate having one peptide appended at either end of the polymer chain. The markedly increased avidity of both dimer peptides for preformed fibrils suggested that increasing the number of  $\text{A}\beta$ -derived peptides on a single polyvalent carrier molecule might even further increase the binding strength. Therefore, we tested the fibril-binding ability of a hexameric conjugate of the retro-inverso peptide, ckffvfk, on a branched PEG carrier. The conjugate  $\text{PEG}_{10\text{kDa}}(\text{biotin})_2(\text{ckffvfk})_6$  was made for this purpose. The PEG used in this conjugate was branched PEG of molecular weight 10 kDa with eight primary amines used for attaching other components. The  $K_d$  for binding of this hexameric peptide conjugate to fibrils was determined to be  $1.1 \times 10^{-10}$  M (Figure 2B), which is 4 orders of magnitude higher avidity than the single peptide. Thus, we have found the means to increase binding avidity by using multiple interactions between the "ligand" and the "receptor" molecules (i.e., the peptide conjugate and the fibril, respectively).

Besides binding to plaques, inhibitor peptides could hypothetically interfere with plaque formation by binding to monomer or oligomeric  $\text{A}\beta$  peptides before they have a chance to form  $\beta$ -sheets. To test this possibility, the target was monomeric  $\text{A}\beta^{1-40}$  instead of fibrils. The tandem dimer peptide was found to bind  $\text{A}\beta^{1-40}$  moderately ( $K_d = 1.7 \mu\text{M}$ ), while the hexameric peptide conjugate had about 10-times greater avidity ( $K_d = 0.16 \mu\text{M}$ )

**Table 1. Summary of  $K_d$  Values Determined by Scatchard Plot**

binding compound	binding target	$K_d$ ( $\mu$ M)	$R^2$ <sup>b</sup>
KLVFF (prototype)	preformed fibrils	$1.1 \pm 0.3^a$	0.998
ffvlk (retro-inverso)	preformed fibrils	0.50	0.973
ffvlkk	preformed fibrils	0.33	0.985
FLKVF (scrambled)	preformed fibrils	52	0.997
PEG-(KLVFF) <sub>2</sub> (dimer)	preformed fibrils	$1.0 \times 10^{-2}$	0.917
(ffvlk) <sub>2</sub> ( $\beta$ A)k (tandem dimer)	preformed fibrils	$1.3 \times 10^{-2}$	0.910
PEG <sub>10k8a</sub> (biotin) <sub>2</sub> (ckffvlk) <sub>6</sub>	preformed fibrils	$1.1 \times 10^{-4}$	0.980
tandem dimer	fluorescein-A $\beta^{1-40}$ monomer	1.7	0.980
PEG <sub>10k8a</sub> (biotin) <sub>2</sub> (ckffvlk) <sub>6</sub>	fluorescein-A $\beta^{1-40}$ monomer	0.16	0.862
ffvlk	biotinylated tandem dimer	1.8	0.973

<sup>a</sup> Standard deviation for three analyses done on different days. Scatchard plot was done on triplicate samples at each concentration in one experiment for each of the other binding compounds. <sup>b</sup> Correlation coefficient.

**Figure 2.** Scatchard plot analysis of binding to preformed fibrils. Panels A and B are for the peptide, KLVFF, and the conjugate PEG(ckffvlk)<sub>6</sub>(biotin)<sub>2</sub>, respectively. Both peptides have a free N-terminus and an amidated C-terminus. The peptides were labeled using tritiated acetic anhydride. Triplicate samples were analyzed at each concentration within the same experiment.

for the A $\beta^{1-40}$  peptide (Table 1). By having six copies of the binding peptide present in each conjugate, there is a 10-fold greater binding (relative to the dimeric peptide) when the target is monomer peptide. In contrast, when the target is fibrils, there is a 100-fold difference between the dimeric and hexameric binding peptides. However, binding constants alone are not predictors of in vivo antiplaque activity.

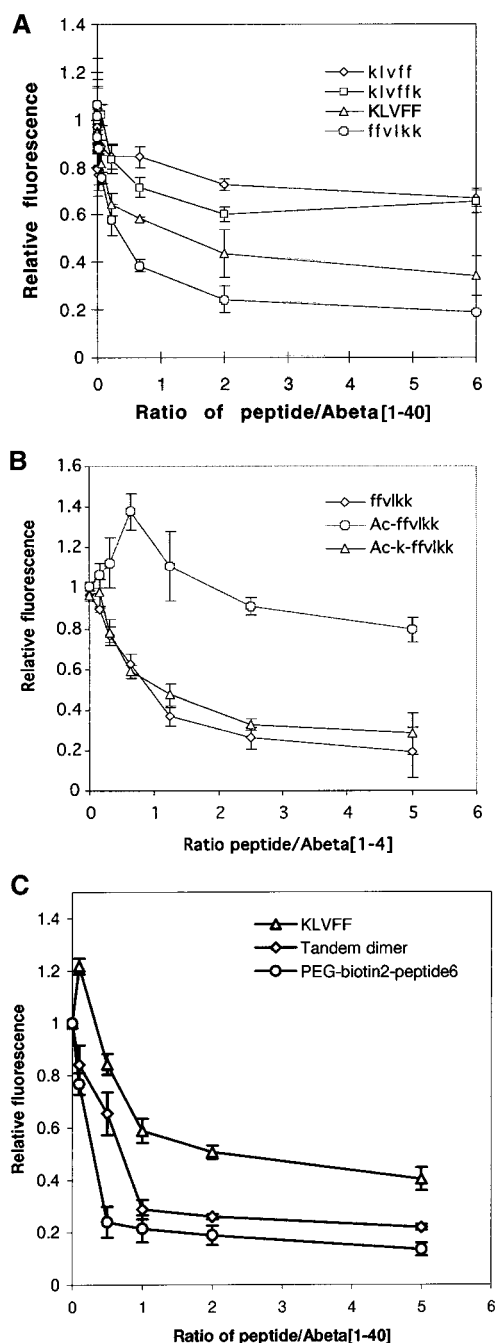

Specificity of binding was tested by measuring the binding to preformed fibrils in the presence of a large excess of serum albumin. That is, if some form of the KLVFF peptide were to be used clinically, would albumin interfere with binding to fibrils? Not only is albumin the most abundant protein in blood, but it is known to bind hydrophobic substances, such as the anticancer drug,

**Figure 3.** Specificity of binding. Binding of [<sup>3</sup>H]-PEG(ckffvlk)<sub>6</sub>(biotin)<sub>2</sub> to preformed fibrils was done in the presence and absence of bovine serum albumin. The percent nonspecific binding to albumin was essentially independent of concentration of conjugate. Triplicate samples were analyzed at each concentration within the same experiment.

camptothecin (Mi et al., 1995). As seen in Figure 3, there was about a 60% decrease in binding of the six-peptide conjugate across the entire dosage range in the presence of bovine serum albumin at 10 mg/mL. In this assay, the amount of A $\beta^{1-40}$  peptide was only 0.017 mg/mL, about 600-fold lower than albumin. Indeed, the amount of six-peptide conjugate tested was as low as 0.01 nM ( $10^{-14}$  mol/mL), which is on the order of 0.01 ng/mL or 1 part per trillion of albumin. Thus, the pharmacokinetic result of this interaction might be to extend the in vivo half-life of the KLVFF-related peptides and conjugates. Albumin does not appear to sequester the binding peptide conjugate in an inactive form.

**Inhibition of Ordered Fibril Formation.** While the Scatchard plot is a good way to evaluate a peptide or conjugate by determining the  $K_d$  for binding to preformed fibrils, it does not provide information on inhibition of ordered fibril formation, as opposed to disordered aggregation. ThT binds rapidly and specifically to the antiparallel  $\beta$ -sheet fibrils formed from synthetic A $\beta^{1-40}$ , but it does not bind to monomer or oligomeric intermediates (LeVine, 1993). A $\beta$  in the  $\beta$ -amyloid fibrils in senile plaque is arranged in a highly ordered, condensed antiparallel  $\beta$ -sheet structure, and neuronal toxicity is attributed to this structural characteristic. That is, an amorphous aggregate of amyloid peptide is not neurotoxic, while a highly ordered, condensed antiparallel  $\beta$ -sheet structure is neurotoxic. For this reason, completely preventing the aggregation of A $\beta$  may not be necessary for achieving a therapeutic effect. It has been shown that the fluorescence in the ThT assay is correlated with both neurotoxicity and with the aggregation morphology being highly ordered (Ghanta et al., 1996).

**Figure 4.** Thioflavin T assays for inhibition of ordered fibril formation. The monomer peptide,  $A\beta^{1-40}$ , was incubated with each test sample for 2 days to determine inhibition of ordered fibril formation. Amorphous aggregates are observed as low fluorescence intensity, while well-ordered fibrils are observed as high fluorescence signal. Each of panels A, B, and C depict the concentration curves for several variations in the KLVFF motif done at the same time. Triplicate samples were analyzed at each concentration within the same experiment.

The inhibitory effect of the various peptides and conjugates in preventing ordered fibril formation, as monitored by the ThT assay, is presented in Figure 4. While peptide KLVFF and retro-inverso ffvlkk show an inhibitory effect in reducing the fluorescence signal, corresponding to preventing ordered fibril formation, inverso peptides klvff and klvfk were found to be relatively ineffective at all concentrations (Figure 4A). This result confirmed that the effect on ordered aggregation of  $A\beta^{1-40}$  by KLVFF analogues is specific with respect to both sequence and three-dimensional structure. The

**Figure 5.** Kinetics of fibril formation. A fresh solution of  $A\beta^{1-40}$  (0.1 mM), spiked with fluorescein-labeled  $A\beta^{1-40}$ , was incubated with or without an inhibitor peptide (0.5 mM). Samples were centrifuged at either 2 or 24 h, and peptide content in the pellet (if present) and supernatant were measured by fluorescence. Results are the average data from two separate experiments.

effect on ordered aggregation of  $A\beta^{1-40}$  by the positive charge at the N-terminus of the retro-inverso peptide, ffvlk, was examined using the *N*-acetylated peptide, *N*-acetyl-ffvlkk; there was no suppression of ThT fluorescence even at a 6-fold excess of the hexapeptide. However, an extra lysine residue in the peptide, *N*-acetyl-kffvlkk, which restored a positive charge at the N-terminus, was able to inhibit the ThT fluorescence identically to the retro-inverso hexapeptide, ffvlkk (Figure 4B). Indeed, there was actually an increase in ThT fluorescence with *N*-acetyl-ffvlkk. In a repeat experiment with *N*-acetyl-ffvlkk, this increase was qualitatively reproducible, including the large variability in the fluorescence signal (Figure 4B).

The tandem dimer retro-inverso peptide was found to be much more effective in preventing ordered fibril formation than the prototype peptide, KLVFF, or any of the monomer peptides, as indicated by both the amount of fluorescence reduction in the ThT assay and the relative amount needed for inhibition (Figure 4C). The conjugate  $PEG_{10k8a}(biotin)_2(peptide)_6$  was even more effective in preventing the ThT signal (Figure 4C). Indeed, the six-copy conjugate is about 3 times more potent than the dimer when expressed per mole of peptide subunit, as in Figure 4C, but 9 times more potent when expressed per mole of conjugate molecule. That is, maximal inhibition is attained at a ratio of one inhibitor peptide per three  $A\beta^{1-40}$  peptides in the context of the conjugate, but at a 1:1 ratio in the tandem dimer form of the same retro-inverso peptide.

**Other Studies.** Experiments were done to determine if the peptides or conjugates can disaggregate preformed fibrils. Preformed fibrils were incubated with peptides or conjugates at different ratios for 3 days at room temperature. Then the ThT assay was done to quantify the amount of ordered fibrils remaining after treatment. None of the peptides or peptide conjugates were able to break preformed fibrils under these conditions, according to the ThT assay (data not shown).

The kinetics of aggregation of  $A\beta^{1-40}$  was also monitored in the absence and presence of inhibitory peptides.  $A\beta^{1-40}$  was incubated under conditions typically used to prepare fibrils, normally taking 2–3 days to complete. Since the transition from a soluble to an insoluble form of  $A\beta^{1-40}$  was at about 15 h (data not shown), the experimental samples were spun down at either 2 or 24 h to observe any change in the kinetics of aggregation. As shown in Figure 5, all of the  $A\beta^{1-40}$  peptide was in

the supernatant at 2 h, while all was in the pellet at 24 h, in agreement with the transition occurring at 15 h. However, in the presence of either the dimer or the six-copy conjugate inhibitor, all of the  $A\beta^{1-40}$  appeared in the pellet after only 2 h. On the basis of the ThT assay (Figure 4C), this increased kinetics results in nonordered aggregates rather than highly ordered beta-sheet structures, in agreement with Ghanta et al. (1996). Essentially the same conclusion, that a decrease in the rate of aggregation (i.e., transition time going from 30 to 43 h) of  $A\beta$  increased the tendency to form  $\beta$ -amyloid plaques, was drawn in studies on the Flemish variant, Ala<sup>692</sup>Gly, which results in early onset AD (Walsh et al., 2001).

## DISCUSSION

This work confirms and extends the structure/function studies on  $A\beta$  fibrils of the peptide motif, KLVFF. We show that the retro-inverso analogue, fflvk, is preferable for use as a target recognition element. Not only does it have a 2-fold greater affinity for fibrils, but it is composed of peptidase-resistant D-amino acids. According to the ThT assay, a positively charged group at the N-terminus is essential in order to inhibit ordered fibril formation. Furthermore, this work demonstrates the cooperative effect that multiple copies of the KLVFF motif can have on the binding to fibrils and the aggregation of  $A\beta^{1-40}$  into fibrils. Two different dimers displayed 100-fold stronger avidity than their respective monomers for fibrils. In one dimeric form, (KLVFF)-PEG-(KLVFF), the two copies of the L-amino acid binding peptide were linked by a long, flexible PEG chain. In the other dimeric form, the two copies of the retro-inverso peptide, fflvk, were linked by just a pair of amino acids. The synergistic effect is so substantial that a six-copy conjugate of the retro-inverso peptide, kfflvk, can bind preformed fibrils 10 000-times more avidly than does the monomer peptide. Furthermore, the multicopy conjugates block the formation of well ordered fibrils from monomer  $A\beta$  peptide. Thus, the KLVFF motif might be useful not only as a target recognition element, but also as a  $\beta$ -sheet breaker.

The concept of increased avidity due to multivalent interactions is certainly not new. For example, combining multiple weak but specific receptor-ligand interactions was recently illustrated by Mourez et al. (2001). Using phage display libraries directed to the heptameric cell-binding subunit of anthrax toxin, they selected a peptide sequence, synthesized that peptide, and appended multiple copies to a flexible polymer. This polyvalent inhibitor was able to block toxin action in an animal model. Similarly, we showed the relationship between the number of copies of the macrophage chemoattractant peptide, *N*-formyl-Met-Leu-Phe-OH, and macrophage receptor avidity, being 1000-fold stronger with the eight-copy versus the single-copy PEG adducts (Pooyan et al., 2002).

In this study, the biotin groups were included in the hexameric conjugate for future use as a reporter for a quantitative ELISA or for a qualitative tissue stain. Recently, we have described the ability of an appended biotin group to impart oral bioavailability to a fragment of the HIV-1-encoded Tat protein (Ramanathan et al. 2001a). The permeability across the intestinal barrier was even greater for PEG conjugates comprising as many as eight copies of the Tat peptide (Ramanathan et al. 2001b). Indeed, the membrane-penetrating properties of Tat peptide and other small cationic peptides has been documented by several laboratories, as reviewed by

Fischer et al. (2001). Since delivery of plaque-binding compounds across the blood-brain barrier (BBB) might be a requirement for a diagnostic or therapeutic agent for AD, the presence of biotin or another transport ligand might be important for clinical applications. However, recent results (DeMattos et al., 2002) suggest that a therapeutic or diagnostic agent, comprising a monoclonal antibody against  $A\beta$  peptide in their studies, can be useful when administered peripherally. Apparently, the pools of soluble plaque-forming  $A\beta$  peptide in the central nervous system and in the periphery are in equilibrium, implying that  $A\beta$  is able to cross the BBB. Injection of their antibody was shown to produce a "sink" effect, drawing soluble  $A\beta$  from the brain into the bloodstream (DeMattos et al., 2002). This could remove  $A\beta$  from the brain, potentially halting or even reversing plaque formation. The antibody results suggest that even if the multivalent conjugates described above do not cross the BBB, they may be useful for diagnosis and treatment of AD.

Research Services, Harry S. Truman Memorial Veterans' Hospital, Columbia, Missouri 65201, and Departments of Internal Medicine and Radiology, University of Missouri—Columbia School of Medicine, Columbia, Missouri 65211. Received April 24, 2002; Revised Manuscript Received July 15, 2002

Bombesin (BBN), a 14 amino acid peptide, is an analogue of human gastrin releasing peptide (GRP) that binds to GRP receptors (GRPr) with high affinity and specificity. The GRPr is overexpressed on a variety of human cancer cells, including prostate, breast, lung, and pancreatic cancers. The specific aim of this study was to develop  $^{99m}\text{Tc}$ -radiolabeled BBN analogues that maintain high specificity for the GRPr in vivo. A preselected synthetic sequence via solid-phase peptide synthesis (SPPS) was designed to produce  $\text{N}_3\text{S}-\text{BBN}$  ( $\text{N}_3\text{S}$  = dimethylglycyl-L-seryl-L-cysteinylglycinamide) conjugates with the following general structure:  $\text{DMG-S-C-G-X-Q-W-A-V-G-H-L-M}(\text{NH}_2)$ , where the spacer group,  $\text{X}$  = 0 (no spacer),  $\omega\text{-NH}_2(\text{CH}_2)_2\text{COOH}$ ,  $\omega\text{-NH}_2(\text{CH}_2)_4\text{COOH}$ ,  $\omega\text{-NH}_2(\text{CH}_2)_7\text{COOH}$ , or  $\omega\text{-NH}_2(\text{CH}_2)_{10}\text{COOH}$ . The new BBN constructs were purified by reversed phase-HPLC (RP-HPLC). Electrospray mass spectrometry (ES-MS) was used to characterize the nonmetalated BBN conjugates.  $\text{Re(V)}-\text{BBN}$  conjugates were prepared by the reaction of  $\text{Re(V)}\text{gluconate}$  with  $\text{N}_3\text{S-X-BBN}[7-14]\text{NH}_2$  ( $\text{X}$  = 0 carbons,  $\beta\text{-Ala}$  ( $\beta$ -alanine), 5-Ava (5-aminovaleric acid), 8-Aoc (8-aminooctanoic acid), and 11-Aun (11-aminoundecanoic acid)) with gentle heating.  $\text{Re}-\text{N}_3\text{S-5-Ava-BBN}[7-14]\text{NH}_2$  was also prepared by the reaction of  $[\text{Re(V)}\text{dimethylglycyl-L-seryl-L-cysteinylglycinamide}]$  with 5-Ava-BBN[7–14] $\text{NH}_2$ . ES-MS was used to determine the molecular constitution of the new  $\text{Re(V)}$  conjugates. The  $^{99m}\text{Tc}$  conjugates were prepared at the tracer level by each the prelabeling, post-conjugation and pre-conjugation, postlabeling approaches from the reaction of  $\text{Na}^{99m}\text{TcO}_4$  with excess  $\text{SnCl}_2$ , sodium gluconate, and corresponding ligand. The  $^{99m}\text{Tc}$  and  $\text{Re(V)}$  conjugates behaved similarly under identical RP-HPLC conditions. In vitro and in vivo models demonstrated biological integrity of the new conjugates.

## INTRODUCTION

Detection and treatment of cancers using radiopharmaceuticals that selectively target cancers in human patients has been employed for several decades (1–10). There is accelerated interest in developing new radiolabeled drugs due to the emergence of more sophisticated biomolecular vectors that exhibit high affinity and specificity for in vivo targeting of tumors. Several types of targeting agents are being developed and have been investigated, including monoclonal antibodies and other immuno-derived fragments and assemblies and receptor-avid peptides (11–15). The potential utility of using radiolabeled receptor-avid peptides to formulate site-directed radiopharmaceuticals is readily exemplified by the radiolabeled conjugates of octreotide and analogues that bind to cancer cells that overexpress somatostatin receptors (16–21).  $^{111}\text{In}$ -DTPA-octreotide (Octreoscan, Mallinckrodt Medical Inc.) is available for routine use in patients,<sup>16</sup> and other derivatized forms are currently

being developed as anti-cancer radiolabeled diagnostics and therapeutics (16–21).

Bombesin (BBN), a 14 amino acid peptide, is an analogue of human gastrin releasing peptide (GRP) that binds to GRP receptors with high affinity and specificity (22–24). GRP receptors have been shown to be overexpressed on several types of cancer cells including prostate, breast, lung, and pancreatic cancers (22–24). Since BBN agonistically binds to GRP receptors on cancer cells and may function as an autocrine or paracrine growth stimulator, a great deal of work has been devoted to development of BBN or GRP analogues that are antagonists as potential agents for inhibition and control of GRP-expressing tumors (23, 24). These antagonists are designed to competitively inhibit endogenous GRP binding to GRP receptors and reduce the rate of cancer cell proliferation (23, 24). Treatment of cancers using these nonradioactive antagonists requires chronic injection regimens using large quantities of the drug.<sup>25</sup> In designing receptor-avid radiopharmaceuticals for use as diagnostic or therapeutic agents, it is important that the drug not only exhibit cancer-specific in vivo targeting and acceptable pharmacokinetic properties, but it must be available as high specific activity products and exhibit long-term residualization in the tumor (26–28).

The synthesis and characterization of radiolabeled BBN or GRP analogues has been reported by several groups (26–35). Several of these analogues, labeled with radioiodine and radiometals, have been shown to bind

**Figure 1.** Structures of DMG-S-C-G-X-Q-W-A-V-G-H-L-M-NH<sub>2</sub>, where the spacer group, X = 0 (no spacer),  $\omega\text{-NH}_2(\text{CH}_2)_2\text{COOH}$ ,  $\omega\text{-NH}_2(\text{CH}_2)_4\text{COOH}$ ,  $\omega\text{-NH}_2(\text{CH}_2)_7\text{COOH}$ , or  $\omega\text{-NH}_2(\text{CH}_2)_{10}\text{COOH}$ .

selectively and avidly to GRP receptors on cancer cells, both in vitro and in vivo (26–35). The various BBN analogues studied range from structures in which the radiolabeled moiety is conjugated to the nearly full-length BBN (1–14) sequence, to where it is attached to a smaller truncated amino acid sequence comprising the GRP-receptor binding moiety (e.g., BBN[8–14]NH<sub>2</sub>). Results of studies to evaluate these conjugates demonstrate that radiolabeled BBN/GRP analogues hold important promise as cancer specific radiopharmaceuticals (26–35).

Our laboratory has focused on the design of BBN-agonist analogues in which the radiolabeled moiety (e.g., radiometal chelate) is linked either directly to the N-terminal amine group of BBN[7–14]NH<sub>2</sub> or via hydrocarbon spacer groups (Figure 1) (33–38). The length and composition of the spacer group, or tether, as well as the physio-chemical properties of the radiolabeled moiety will influence the GRP receptor binding affinity, residualization of radioactivity in cancer cells, and pharmacokinetics of the BBN conjugate (33–38). In this study, we have complexed <sup>99m</sup>Tc to a triamido-thiol (N<sub>3</sub>S) bifunctional chelating agent (BFCA). The <sup>99m</sup>Tc chelate has been conjugated to the N-terminal amine of BBN[7–14]NH<sub>2</sub>

via a limited series of hydrocarbon spacers of increasing length (i.e., 3, 5, 8, and 11 carbon atoms in length). The purpose of this study is to determine the effects of varying the length of hydrocarbon spacer groups on the in vitro binding affinity with GRP receptors expressed on human prostate PC-3 cells and their in vivo pharmacokinetics in normal CF-1 mice. It would be beneficial to formulate new <sup>99m</sup>Tc-labeled site-specific tracers since <sup>99m</sup>Tc is currently the most widely used radionuclide used for diagnostic SPECT imaging studies (39). The N<sub>3</sub>S-BFCA used to complex <sup>99m</sup>Tc is N-dimethylglycyl-L-seryl-L-cysteinyglycyl[(CH<sub>3</sub>)<sub>2</sub>-G-S-C-G], which has been shown to form a well-defined and stable complex with TcO<sup>3+</sup> (40).

#### EXPERIMENTAL SECTION

All solvents were either ACS certified or HPLC grade. All solvents were obtained from Fisher Scientific and used as received. Fmoc-amino acids, coupling agents and resins were purchased from Calbiochem-Novabiochem Corp., San Diego, CA. All other reagents were purchased from either Aldrich Chemical Co., Fisher Scientific or ACROS Chemicals. <sup>99m</sup>TcO<sub>4</sub><sup>−</sup> was obtained as the sterile

## Scheme 1

0.9% aqueous NaCl eluant solution from a  $^{99}\text{Mo}/^{99m}\text{Tc}$  generator (Mallinckrodt Medical, Inc.). Electrospray mass spectral (ESMS) Analyses were performed by SynPep Corporation, Dublin, CA.  $^{125}\text{I}$ -Tyr<sup>4</sup>-BBN was obtained from NEN Life Sciences Products, Inc., Boston, MA.

**Solid-Phase Peptide Synthesis (SPPS).** Peptide synthesis was performed on a Perkin-Elmer-Applied Biosystem Model 432 automated peptide synthesizer employing traditional Fmoc Chemistry. The reaction of HBTU activated carboxyl groups on the reactant with the N-terminal amino group on the growing peptide, anchored via the C-terminus to the resin, provided for stepwise amino acid addition. Rink Amide MBHA resin (25  $\mu\text{mole}$ ) and Fmoc-protected amino acids, with appropriate side-chain protections, and the Fmoc-protected  $\omega$ - $\text{NH}_2(\text{CH}_2)_n\text{COOH}$  compounds used as spacer groups (75  $\mu\text{mol}$ ), were used for SPPS of the nonmetalated BBN conjugates. The preselected synthetic sequence was designed to produce the  $\text{N}_3\text{S}$ -BBN conjugates with the following general structure DMG-S-C-G-X-Q-W-A-V-G-H-L-M-NH<sub>2</sub>, where the spacer group, X = 0 (no spacer),  $\omega$ - $\text{NH}_2(\text{CH}_2)_2\text{COOH}$ ,  $\omega$ - $\text{NH}_2(\text{CH}_2)_4\text{COOH}$ ,  $\omega$ - $\text{NH}_2(\text{CH}_2)_7\text{COOH}$ , or  $\omega$ - $\text{NH}_2(\text{CH}_2)_{10}\text{COOH}$  (See Figure 1 for structures of these  $\text{N}_3\text{S-X-BBN}[7-14]\text{NH}_2$  conjugates). The final products were cleaved by a standard procedure using a cocktail containing thioanisole, water, ethanedithiol and trifluoroacetic acid in a ratio of 2:1:1:36 and precipitated into methyl-*tert*-butyl ether. The crude peptides were purified by HPLC and the solvents removed on a SpeedVac concentrator. Typical yields of the crude peptides were 80–85%. ES-MS was used in order to determine the molecular constitution of the  $\text{N}_3\text{S-X-BBN}[7-14]\text{NH}_2$  conjugates.

**HPLC Purification and Analysis.** HPLC analyses and purification of all peptide conjugates and their metal complexes were performed on a Waters 600E instrument equipped with a Varian 2550 variable absorption detector, a Packard Radiometric 150 TR flow scintillation analyzer or a sodium iodide crystal radiometric detector, and an Eppendorf TC-50 column temperature controller and Hewlett-Packard HP3395 integrator. HPLC solvents consisted of H<sub>2</sub>O containing 0.1% trifluoroacetic acid

**Table 1. Mass-Spectral Analyses and IC<sub>50</sub> (IC<sub>50</sub>*nM*(SD), *n* = 3) Determination of the Peptide Series and Re Conjugates**

peptide/ conjugate	calculated mass	actual mass	IC <sub>50</sub> (PC-3)
Re-0	1471.7	1472.4	3.97(1.07)
Re-3	1542.8	1543.6	0.67(0.21)
Re-5	1570.8	1571.4	1.00(0.20)

Re-11	1655.0	1655.6	1.50(0.26)

(Solvent A) and acetonitrile containing 0.1% trifluoroacetic acid (Solvent B). A Phenomenex Jupiter C-18 (5  $\mu\text{m}$ , 4.6  $\times$  250 mm) column was used with a flow rate of 1.5 mL/min. The HPLC gradient system begins with a solvent composition of 95% A and 5% B and follows a linear gradient of 30% A:70% B from 0 to 25 min, and 30% A:70% B to 5% A:95% B from 25 to 30 min.

**$^{99m}\text{Tc}$ - and Re- $\text{N}_3\text{S-X-BBN}[7-14]\text{NH}_2$  Conjugate Synthesis.** The  $\text{N}_3\text{S-X-BBN}[7-14]\text{NH}_2$  analogues were labeled with  $^{99m}\text{Tc}$  and Re using pre-conjugation, post-transmetalation from  $^{99m}\text{Tc(V)}$ <sup>41</sup> or Re(V)-gluconate<sup>42</sup> synthons, respectively (Scheme 1). Preparation of Re(V)-gluconate was performed as previously described.<sup>42</sup> In brief, the preparation of the Re(V) conjugates was performed by addition of excess Re(V)-gluconate solution to a solution of  $\text{N}_3\text{S-X-BBN}[7-14]\text{NH}_2$ . Each mixture was heated for 2h at 60 °C. After incubation of the resulting solutions at room temperature, the Re- $\text{N}_3\text{S-X-BBN}[7-14]\text{NH}_2$  complexes were purified by RP-HPLC. Each of the new complexes were peak-collected and evaporated to dryness. ES-MS analysis was used to determine the molecular constitution of the new Re conjugates (Table 1). For  $^{99m}\text{Tc}$ , this method involved preparation of a stannous gluconate stock solution by mixing 20 mg  $\text{SnCl}_2$  in 1 mL ultrapure deoxygenated water. Twenty microliters of this stock solution was mixed with 1.0 mL of a 13 mg/mL sodium gluconate solution. To 100  $\mu\text{L}$  of this solution was added 500  $\mu\text{L}$  of an isotonic saline solution containing approximately 370 MBq of  $^{99m}\text{TcO}_4^-$  and 50  $\mu\text{g}$  of the  $\text{N}_3\text{S-X-BBN}[7-14]\text{NH}_2$  conjugate.<sup>10,30,40</sup> After incubation of the resulting solution at room temperature, the  $^{99m}\text{Tc}-\text{N}_3\text{S-X-BBN}[7-14]\text{NH}_2$  complexes were puri-

**Scheme 2**

fied by RP-HPLC and the peaks collected into a 1 mL solution of 0.02 M sodium phosphate buffered saline at pH 7.4, containing 0.1 mg of bovine serum albumin (BSA). Prior to use of the purified conjugates for in vitro GRP receptor binding and in vivo biodistribution studies, the residual acetonitrile was evaporated from the solution under a stream of nitrogen. These  $^{99m}\text{Tc}$ - $\text{N}_3\text{S}$ - $\text{X}$ -BBN[7-14] $\text{NH}_2$  conjugates were of high specific activity as the  $\text{N}_3\text{S}$ - $\text{X}$ -BBN[7-14] $\text{NH}_2$  analogues eluted approximately 1 min prior to the corresponding metalated  $^{99m}\text{Tc}$ - $\text{N}_3\text{S}$ - $\text{X}$ -BBN[7-14] $\text{NH}_2$  conjugates.

$^{99m}\text{Tc}$ - $\text{N}_3\text{S}$ -5-Ava-BBN[7-14] $\text{NH}_2$  was also synthesized by the prechelat post-conjugation approach, as was  $\text{Re}$ - $\text{N}_3\text{S}$ -5-Ava-BBN[7-14] $\text{NH}_2$  (Scheme 2). The  $^{99m}\text{Tc}$ - $\text{N}_3\text{S}$  bifunctional chelate (BFC) was prepared by transchelation from  $^{99m}\text{Tc(V)}$ -gluconate similar to the method described earlier. The  $\text{Re}$ - $\text{N}_3\text{S}$  BFC was prepared by trans-metalation of  $\text{Re(V)}$  to the  $\text{N}_3\text{S}$ -BFCA from the  $[\text{ReO}_2(\text{en}_2)]\text{Cl}$  ( $\text{en}$  = ethylenediamine) synthon using a method previously reported (40).  $\text{ReO}$ - $\text{N}$ -dimethylglycyl-L-seryl-L-cysteinyl-glycine ( $\text{ReO}$ - $\text{N}_3\text{S}$ -BFCA) was provided by Resolution Pharmaceuticals (Toronto, Canada).

The C-terminal carboxy group on both the  $^{99m}\text{Tc}$ - and  $\text{Re}$ - $\text{N}_3\text{S}$ -BFCA were converted to the corresponding tetrafluoro-phenyl (TFP) ester precursors. To produce the  $\text{Re}$ - $\text{N}_3\text{S}$ -TFP precursor, 0.011 g (0.02 mmol) of  $\text{Re}$ - $\text{N}_3\text{S}$ -BFCA was dissolved in 500  $\mu\text{L}$  of deionized water with gentle stirring. To this solution was added 7 mg of TFP (0.042 mmol) in 500  $\mu\text{L}$  of acetonitrile, followed by addition of 7 mg (0.044 mmol) of  $N,N$ -dicyclohexylcarbodiimide. The reaction mixture was heated gently for 2 h. Synthesis of  $\text{Re}$ - $\text{N}_3\text{S}$ -5-Ava-BBN[7-14] $\text{NH}_2$  was performed by dissolving 0.011 g ( $0.11 \times 10^{-5}$  moles) of  $\text{N}_3\text{S}$ -5-Ava-BBN[7-14] $\text{NH}_2$  in a water/acetonitrile mixture (50:50) with gentle stirring, followed by addition of 1.8 mL of 0.2N  $\text{NaHCO}_3$ . The crude  $\text{Re}$ - $\text{N}_3\text{S}$ -TFP solution was added to this solution and the reaction mixture was heated at 60  $^\circ\text{C}$  for 2 h. The progress of the reaction was incrementally followed by RP-HPLC (Figure 2). The HPLC purified  $\text{Re}$ - $\text{N}_3\text{S}$ -5-Ava-BBN[7-14] $\text{NH}_2$  product was analyzed by ES-MS ( $m/z$  for  $(\text{M}+\text{H})^+$  was found to be 1570.0; calculated 1569.9).

The  $^{99m}\text{Tc}$ - $\text{N}_3\text{S}$ -5-Ava-BBN[7-14] $\text{NH}_2$  product was prepared by the same procedure (Scheme 1), however, the HPLC purified  $^{99m}\text{Tc}$ - $\text{N}_3\text{S}$ -BFCA reagent was present at tracer levels when reacted with excess TFP to produce the  $^{99m}\text{Tc}$ - $\text{N}_3\text{S}$ -TFP precursor. The progress of the reactions leading to production of the  $^{99m}\text{Tc}$ - $\text{N}_3\text{S}$ -5-Ava-BBN-

**Figure 2.** HPLC elution profile of  $\text{ReO}$ - $\text{N}_3\text{S}$ -5-Ava-BBN[7-14] $\text{NH}_2$  and reaction intermediates (prechelate, post-conjugation labeling method).

**Figure 3.** HPLC elution profile of  $^{99m}\text{TcO}$ - $\text{N}_3\text{S}$ -5-Ava-BBN[7-14] $\text{NH}_2$  and reaction intermediates (prechelate, post-conjugation labeling method).

[7-14] $\text{NH}_2$  product was also incrementally monitored by HPLC (Figure 3).

$^{99m}\text{Tc}$ - and  $\text{Re}$ - $\text{N}_3\text{S}$  BFCs and their respective TFP-activated esters reveal the presence of two readily identifiable peaks for each chelate reflecting the presence of *syn*- and *anti*-isomers<sup>40</sup> (Figures 2 and 3). The final  $^{99m}\text{Tc}$ - and  $\text{Re}$ - $\text{N}_3\text{S}$ -5-Ava-BBN[7-14] $\text{NH}_2$  conjugates, which eluted at retention times of 14.32 and 14.33 min, respectively, are single Gaussian peaks (Figures 2 and 3) which are expected to include both the *syn*- and *anti*- $\text{N}_3\text{S}$ -BFCA conjugates which are not resolvable by this HPLC elution method.  $^{99m}\text{Tc}$ - $\text{N}_3\text{S}$ -5-Ava-BBN[7-14] $\text{NH}_2$  and  $\text{Re}$ - $\text{N}_3\text{S}$ -5-Ava-BBN[7-14] $\text{NH}_2$ , synthesized by each the preformed chelate method and the post-conjugation transmetalation approach, produce  $^{99m}\text{Tc}/\text{Re}$  species that

have identical HPLC retention times (i.e., approximately 14.3 min).  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava}-\text{BBN}[7-12]$  was also synthesized. This analogue has both the C-terminal Leu<sup>13</sup> and Met<sup>14</sup> deleted and is expected to exhibit neither agonist nor antagonist binding to GRP receptors (43–44).

**In Vitro Cell Binding Studies.** In vitro GRP receptor binding affinities and specificities of the BBN conjugates were assessed utilizing displacement cell-binding assays using  $^{125}\text{I}-\text{Tyr}^4\text{-BBN}$  as the GRP receptor specific radioligand with PC-3 human prostate cancer cells (ATCC, Manassas, VA) by a method previously described.<sup>22</sup> Briefly, the PC-3 cells were grown in HAM's F-12K media supplemented with 7% fetal calf serum. The  $3 \times 10^4$  PC-3 cells were suspended in 300  $\mu\text{L}$  RPMI 1640 media at pH 7.4 containing 2.4 mg/mL HEPES, 0.1  $\mu\text{g}/\text{mL}$  Bacitracin, and 2 mg/mL BSA. They were incubated at 37 °C (5%  $\text{CO}_2$ ) for 40 min in the presence of approximately 20,000 cpm of  $^{125}\text{I}-\text{Tyr}^4\text{-BBN}$  and increasing concentrations of the  $\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$  conjugates or the  $\text{Re}-\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$  conjugate ranging from  $10^{-11}\text{M}$  to  $10^{-5}\text{M}$ . After incubation, the reaction medium was centrifuged (1 min, 8000 rpm) and aspirated and the cells washed three times with media. The radioactivity bound to the cells was counted in a Packard Riastar gamma counting system. The percent  $^{125}\text{I}-\text{Tyr}^4\text{-BBN}$  bound to the cells was plotted versus increasing concentration of the BBN-[7-14] $\text{NH}_2$  conjugates to determine the specific  $\text{IC}_{50}$  values (Table 1,  $n = 3$ ). The degree of specific  $^{99m}\text{Tc}-\text{N}_3\text{S}-\text{X}-\text{BBN}$  analogue binding to the GRP receptors expressed on PC-3 cells was determined by incubating approximately 0.01–0.02  $\mu\text{Ci}$  of each  $^{99m}\text{Tc}$  analogue with  $3 \times 10^4$  PC-3 cells in the absence of displacing BBN[7-14] $\text{NH}_2$  ligands and in the presence of  $10^{-5}\text{M}$  of the corresponding  $\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$  analogue.

**Internalization Studies.** In vitro studies were performed to determine the efficiency of internalization of  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava}-\text{BBN}[7-14]\text{NH}_2$  (Scheme 2) and the degree of residualization of  $^{99m}\text{Tc}$  in the cells as a function of time. These studies were performed by a method similar to that described by Rogers et al. (28). In short,  $3 \times 10^4$  PC-3 cells were suspended in RPMI 1640 media at pH 7.4 containing 2.4 mg/mL HEPES, 0.1  $\mu\text{g}/\text{mL}$  Bacitracin and 2 mg/mL BSA in the presence of approximately 20 000 cpm  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava}-\text{BBN}[7-14]\text{NH}_2$  (3) for a period of 40 min at 37 °C (5%  $\text{CO}_2$ ). After incubation, the reaction medium was centrifuged (1 min, 8000rpm) and aspirated, and cells were washed with the incubation media. The percent of  $^{99m}\text{Tc}$  cell-associated activity were determined as a function of time (in the incubating medium at 37 °C). The percentage of  $^{99m}\text{Tc}$  activity trapped in the cells was determined after removing  $^{99m}\text{Tc}$  activity bound to the surface of the cells by washing with a pH 2.5 (0.2 M acetic acid and 0.5 M NaCl) buffer at 10, 20, 30, 60, and 90 min ( $n = 3$ ) following the washing with incubation media (Figure 5). A control study with  $^{125}\text{I}-\text{Tyr}^4\text{-BBN}$  was performed using the same method (Figure 6).

**Biodistribution of  $^{99m}\text{Tc}-\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$  Analogues in Normal Mice.** Normal CF-1 mice (average weight 20–25 g) were used for the biodistribution studies (Tables 2–5). The pH of the HPLC-purified  $^{99m}\text{Tc}-\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$  solutions was adjusted to physiological conditions using a 0.01 M phosphate buffer (pH 7.4). Aliquots (80–100  $\mu\text{L}$ ) of the labeled peptide solution (55–75 kBq) were injected into each animal via the tail vein. Tissues and organs were excised from the sacrificed animals 30 min, 1 h, and 4 h post-injection (p.i.). The organs and tissue were weighed and the

**Figure 4.** Typical  $\text{IC}_{50}$  cell-binding studies of  $\text{ReO}-\text{N}_3\text{S}-5\text{-Ava}-\text{BBN}[7-14]\text{NH}_2$  in human prostate (PC-3) cancerous cells ( $\text{IC}_{50} = 1.0 \pm 0.2\text{nM}$ ). Each point is an average of three separate values.  $\text{IC}_{50}$  values from the best-fit line from four separate studies with each conjugate were used to calculate the means and respective standard deviations reported in Table 1.

**Figure 5.** Efflux determination of  $^{99m}\text{TcO}-\text{N}_3\text{S}-5\text{-Ava}-\text{BBN}[7-14]\text{NH}_2$  in human prostate (PC-3) cancerous cells.

activity was counted in a NaI counter. The percent-injected dose per organ and the percent-injected dose per gram were calculated. The % ID in whole blood was estimated assuming a blood volume of 6.5% of the total body weight. Receptor blocking studies were also carried out where excess BBN was administered to animals prior to injection of  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava}-\text{BBN}[7-14]\text{NH}_2$ . In these studies, each animal received a subcutaneous injection of 1 mg of BBN dissolved in 100  $\mu\text{L}$  of the solvent mixture of saline/acetonitrile/DMF (90:5:5) 35 min prior to the injection of  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava}-\text{BBN}[7-14]\text{NH}_2$ . Control (unblocked) animals received an injection of 100  $\mu\text{L}$  of the solvent mixture without BBN 35 min prior to the injection of  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava}-\text{BBN}[7-14]\text{NH}_2$ . The animals were sacrificed 30 min post-injection and the tissues removed, weighed, and counted as previously described.

<sup>a</sup> %ID in blood was estimated assuming the whole blood volume to be 6.5% of the total body weight.

The biodistribution of  $^{99m}\text{Tc}$ -N<sub>3</sub>S-5-Ava-BBN[7-12] analogue, which does not bind with high affinity to GRP receptors, was also determined at 1 h p.i.

## RESULTS

The N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> (Figure 1) conjugates were conveniently synthesized by SPPS. The yields of the HPLC purified conjugates were approximately 50%. ES-MS analyses were consistent with the molecular weights calculated for each conjugate.

Figure 4 shows an example of the displacement binding of  $^{125}\text{I}$ -Tyr<sup>4</sup>-BBN from GRP receptors expressed on PC-3 cells as a function of increasing concentrations of the metalated N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> conjugate, Re-N<sub>3</sub>S-5-Ava-BBN[7-14]NH<sub>2</sub>. In the absence of competitors, approximately 5% of the  $^{125}\text{I}$ -Tyr<sup>4</sup>-BBN was bound to the cells after 40 min incubation. In the presence of 10<sup>-5</sup> M cold Tyr<sup>4</sup>-BBN, <10% of the  $^{125}\text{I}$ -Tyr<sup>4</sup>-BBN activity was bound to the cells relative to the absence of cold ligand. This demonstrates that >90% of the  $^{125}\text{I}$ -Tyr<sup>4</sup>-BBN associated with the cells corresponds to specific GRP receptor binding.

The IC<sub>50</sub> values obtained for the series of ReO-N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> conjugates are summarized in Table 1. These results show that the metalated N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> derivatives with 3-, 5-, and 8-carbon spacers (i.e., X = ω-NH<sub>2</sub>(CH<sub>2</sub>)<sub>2</sub>COOH, ω-NH<sub>2</sub>(CH<sub>2</sub>)<sub>4</sub>COOH and ω-NH<sub>2</sub>(CH<sub>2</sub>)<sub>7</sub>COOH) exhibit IC<sub>50</sub> values in the single direct nanomolar range which are lower than derivatives containing the 0- and 11-carbon spacers. The IC<sub>50</sub> for N<sub>3</sub>S-5-Ava-BBN[7-12], the analogue with deletion of Leu<sup>13</sup> and Met<sup>14</sup>, is >10<sup>-6</sup> M. The IC<sub>50</sub> for ReO-N<sub>3</sub>S-5-Ava-BBN[7-14]NH<sub>2</sub> is 1.0 nM.

Radiolabeling of the N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> series of chelates with  $^{99m}\text{Tc}$  was performed by the pre-conjugation post-labeling approach using  $^{99m}\text{Tc}$ (V) gluconate as the synthon (40). The yields of the  $^{99m}\text{Tc}$ -N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> conjugates ranged from 90% to 95%.  $^{99m}\text{Tc}$ -N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> products were purified by RP-HPLC to produce the respective  $^{99m}\text{Tc}$  conjugates in high radiochemical purity (RCP). The  $^{99m}\text{Tc}$ (metalated) conjugates eluted 1 min later than the corresponding nonmetalated N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> reactants, making it possible to collect the  $^{99m}\text{Tc}$  N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> conjugates as high specific activity products. The HPLC chromatograms in Figures 2 and 3 show the elution profiles of the prechelated  $^{99m}\text{Tc}$  and Re reactants and the final  $^{99m}\text{Tc}$ - and Re-N<sub>3</sub>S-5-Ava-BBN[7-14]NH<sub>2</sub> products. These figures also show that both the Re- and  $^{99m}\text{Tc}$ -N<sub>3</sub>S-5-Ava-BBN[7-14]NH<sub>2</sub> species coelute at 14.3 min retention times.

Specific binding of all of the  $^{99m}\text{Tc}$ -N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> conjugates to GRP receptors expressed on PC-3 cells was demonstrated following incubation (40min) of 3 × 10<sup>4</sup> PC-3 cells with high specific activity  $^{99m}\text{Tc}$  analogues. In the absence of the corresponding nonmetalated analogue, approximately 3–6% of the  $^{99m}\text{Tc}$  activity was associated with the PC-3 cells. In contrast, if 10<sup>-5</sup> M of the corresponding unlabeled N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> conjugate or BBN(1-14) is present during the 30 min incubation, less than 0.5% of the  $^{99m}\text{Tc}$  activity is cell associated.

Figure 5 summarizes the results of studies to assess the degree of trapping (or internalization) of the  $^{99m}\text{Tc}$ -N<sub>3</sub>S-5-Ava-BBN[7-14]NH<sub>2</sub> in PC-3 cells. The total  $^{99m}\text{Tc}$  activity associated with the cells after the 40 min incubation was measured following washing the cells with the pH 7.4 incubation media. After washing these cells with the pH 2.5 buffer to remove surface bound  $^{99m}\text{Tc}$  activity, approximately 84% remained trapped by the cells (Figure 5). Results of measurements at 10, 20, 30, 60, and 90 min show that the majority of activity remains trapped by the PC-3 cells, with approximately 70% of the  $^{99m}\text{Tc}$  activity associated with the cells at  $t = 0$  remaining residualized at 90 min. Thus, at 90 min, approximately 83% of the activity remains residualized when normalized to the 84% trapped in the cells at  $t = 0$ . The same studies, when performed with  $^{125}\text{I}$ -Tyr<sup>4</sup>-BBN, show that after a 40 min incubation of PC-3 cells with  $^{125}\text{I}$ -Tyr<sup>4</sup>-BBN, nearly 100% of the cell-associated  $^{125}\text{I}$  activity is internalized (Figure 6). Furthermore, efflux of radioactivity is comparable to that of the  $^{99m}\text{Tc}$  conjugate. Therefore, incorporation of the  $^{99m}\text{Tc}$ -N<sub>3</sub>S chelate onto BBN[7-14]NH<sub>2</sub> has little or no effect on the internalization properties of the  $^{99m}\text{Tc}$  conjugate in GRP receptor-specific PC-3 cells. The binding of these radioligands to PC-3 cells is receptor-specific since the addition of 10<sup>-5</sup> M of the corresponding unlabeled BBN analogues essentially eliminated the uptake of radioactivity by these cells. Furthermore, incubation of  $^{99m}\text{Tc}$ -N<sub>3</sub>S-5-Ava-BBN[7-14]NH<sub>2</sub> and  $^{125}\text{I}$ -Tyr<sup>4</sup>-BBN with MDA-MB-438 human breast cancer cells, a cell line that exhibits no measurable GRPr expression, showed no significant uptake or internalization of the radioligand.

**Biodistribution of  $^{99m}\text{Tc}$ -N<sub>3</sub>S-BBN[7-14]NH<sub>2</sub> Conjugates.** Tables 2 and 3 summarize the results of the biodistribution studies in normal CF-1 mice at 1 h post-intravenous injection for the series of  $^{99m}\text{Tc}$ -N<sub>3</sub>S-X-BBN[7-14]NH<sub>2</sub> conjugates. As the hydrocarbon chain length of the spacer group, X, increases from 0 to 11, the % ID cleared by the renal-urinary pathway decreases. There is no significant uptake or retention in the stomach

indicating that there is minimal, if any, in vivo dissociation of  $^{99m}\text{Tc}$  from these ligands to produce  $^{99m}\text{TcO}_4^-$ . Pancreatic uptake of this series of conjugates at 1 h p.i. shows considerable variability, with the highest value associated with the three-carbon conjugate (Tables 2 and 3). As the tethering moiety is lengthened beyond three carbons, the uptake in normal pancreas decreases. There is retention of the  $^{99m}\text{Tc}$  activity localized in the pancreas; however, there is some efflux. For example, for the  $^{99m}\text{Tc}-\text{BBN}$  analogue where  $\text{X} = \text{NH}_2(\text{CH}_2)_4\text{COOH}$  (5-Ava), the percent  $^{99m}\text{Tc}$  activity retained in the pancreas at 1 and 4 h, relative to  $^{99m}\text{Tc}$  activity localized in that organ at 30 min is approximately 75% and 35%, respectively. Tables 4 and 5 summarize the results of the biodistribution studies in normal CF-1 mice at 30 min, 1 h, and

4 h post-intravenous injection for the  $^{99m}\text{Tc}-\text{N}_3\text{S}-5-\text{Ava}-\text{BBN}[7-14]\text{NH}_2$  conjugate. There is  $4.22 \pm 0.81\%$  ID/gm retained in the kidneys at 30 min p.i., but in all cases, the  $^{99m}\text{Tc}$  activity in the kidneys decreases to a level at 4 h p.i., which is approximately 35% of that observed at 30 min p.i. The  $^{99m}\text{Tc}-\text{N}_3\text{S}-5-\text{Ava}-\text{BBN}[7-12]$  analogue with the Leu<sup>13</sup> and Met<sup>14</sup> deletion does not bind to GRP receptors and shows no significant accumulation in pancreatic tissue. Blocking studies in which high levels of cold BBN[1–14] was administered 35 min prior to the  $^{99m}\text{Tc}$  ligands, reduced the % ID/gm uptake/retention in the pancreas at 30 min p.i. by a factor of 8–10, demonstrating the in vivo specificity of these analogues for GRP-receptor expressing cells.

## DISCUSSION

Considerable efforts have been made by several research groups to identify structural features of BBN-analogues that produce binding and stability properties necessary for in vivo targeting of GRP receptor expressing cancers (43–48). Insights gained from these research efforts can provide the basis for designing radiolabeled conjugates of BBN derivatives that maintain high GRP receptor-binding affinities. The W-A-V-G-H-L sequence BBN[8–13] has been shown to be a sequence that is directly involved in a specific high-affinity binding interaction with GRP receptors (44, 49). Modifications or a deletion at position 14 (i.e., the position normally occupied by methionine Met<sup>14</sup>) is an important factor in determining whether or not the derivative will possess antagonistic or agonistic properties (23, 45, 47, 48). Minor structural variations (e.g., reduction of the Leu<sup>13</sup>–Met<sup>14</sup> peptide bond or cyclization of Met<sup>14</sup> on the BBN analogue structure) can confer agonist or antagonist properties (44, 47, 50). While the vast majority of research with BBN analogues has been devoted to the development of antagonists, BBN[8–14]NH<sub>2</sub> is an example of a truncated BBN[1–14] sequence that will form conjugates that frequently bind GRP receptors as agonists (34, 43, 44).

The strategy used in designing the limited series of  $^{99m}\text{Tc}-\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$  derivatives was to covalently link the  $^{99m}\text{Tc}-\text{N}_3\text{S}$  chelate via a spacer group to the BBN[8–14]NH<sub>2</sub> binding sequence (32). Previous studies demonstrated that the inclusion of Gln<sup>7</sup> in linking radiometal chelates to BBN[8–14]NH<sub>2</sub> was beneficial in reducing renal retention of  $^{105}\text{Rh}-\text{S}_4-\text{BBN}$  analogues and is compatible with maintaining high GRP receptor binding affinity (15, 35). For these reasons, the various hydrocarbon spacer groups used in this study were linked to the BBN[8–14]NH<sub>2</sub> receptor binding sequence via the Gln<sup>7</sup> residue (Figure 1).

Since the Re–N<sub>3</sub>S-5-Ava-BBN[7–14]NH<sub>2</sub> and  $^{99m}\text{Tc}-\text{N}_3\text{S}-5-\text{Ava}-\text{BBN}[7-14]\text{NH}_2$  conjugates each have a 14.3

min retention time by RP-HPLC (Figures 2 and 3), it can be deduced that both the Re and  $^{99m}\text{Tc}$  conjugates have the same structure. These results provide evidence that  $^{99m}\text{Tc}$  is present as the  $^{99m}\text{TcO}-\text{N}_3\text{S}$  chelate, attached via the spacer groups to the BBN[7–14] $\text{NH}_2$  GRP receptor binding sequence. These results are consistent with previous studies which show that  $^{99m}\text{Tc}(\text{V})$  precursors react with  $\text{N}_3\text{S}$  ligand systems to form stable chelates that contain the mono-oxo- $\text{Tc}(\text{V})$  (i.e.,  $\text{TcO}^{3+}$ ) core, as do the corresponding Re(V) chelates (40). Complexation of  $\text{ReO}^{3+}$  and  $\text{TcO}^{3+}$  with these types of  $\text{N}_3\text{S}$  ligands results in deprotonation of two amide groups to produce metal chelate structures that have an overall neutral charge (40). The observation that  $^{99m}\text{TcO}-\text{N}_3\text{S}-5\text{-Ava-BBN}[7-14]\text{NH}_2$  is formed in high yields by transchelation from  $^{99m}\text{Tc}$ -gluconate (Scheme 1), and, coelutes with  $^{99m}\text{TcO}-$  and  $\text{ReO}-\text{N}_3\text{S}-5\text{-Ava-BBN}[7-14]\text{NH}_2$  conjugates synthesized by the preformed chelate route demonstrates the feasibility of producing well defined  $^{99m}\text{Tc}-\text{N}_3\text{S}-\text{BBN}[7-14]\text{NH}_2$  chemical entities via the post conjugation labeling method. These results are consistent with previous studies that utilized other  $\text{N}_3\text{S}$  bioconjugates to formulate  $^{99m}\text{Tc}(\text{V})\text{O}$ -labeled radiopharmaceuticals in high specific activities using similar labeling approaches (40, 41).

In vitro binding studies with the  $\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$  analogues demonstrate that derivatives where the spacer group, **X**, comprises a 3-, 5-, and 8-carbon tether (i.e.,  $\beta$ -Ala, 5-Ava and 8-Aoc), produce derivatives that have high GRP-receptor binding affinities (i.e.,  $\text{IC}_{50} < 10 \text{ nM}$ ) (Table 1). In the absence of a spacer group and with an 11-carbon (11-Aun) tether, the  $\text{IC}_{50}$  values increase (Table 1). This is similar to the results obtained with analysis of  $^{105}\text{Rh}-\text{S}_4-\text{X}-\text{BBN}[7-14]\text{NH}_2$  constructs (35). These data, therefore, indicate that the most promising analogues of this design, for in vivo targeting of cells expressing GRP receptors, are those with **X** = 3–8 carbon atoms.

Maximizing residualization of radioactivity in tumors after binding of the activity is an important factor in optimizing the diagnostic and/or therapeutic efficacy of radiotracers (1, 36, 51). Results of studies with  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava-BBN}[7-14]\text{NH}_2$  show that most of the  $^{99m}\text{Tc}$  activity associated with the PC-3 cells is not surface bound and is not lost from the cells by incubation in pH 2.5 buffer (Figure 5). Furthermore, there is only minimal efflux of  $^{99m}\text{Tc}$  activity from the cells for at least 90 min. These results indicate that residualization of  $^{99m}\text{Tc}$  activity results from GRP receptor-mediated endocytosis of  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava-BBN}[7-14]\text{NH}_2$  with subsequent trapping of activity. Similar studies with  $^{125}\text{I}-\text{Tyr}^4\text{-BBN}$  demonstrate that GRP receptor mediated trapping and efflux of  $^{125}\text{I}$  radioactivity is comparable to that of the  $^{99m}\text{Tc}$  conjugate (Figure 6).

Internalization of both the  $^{125}\text{I}$  and  $^{99m}\text{Tc}-\text{BBN}$  analogues can be attributed to their agonistic binding to GRP receptors (26, 28, 36, 44). GRP receptors are 7-TMS-G-protein coupled receptors which are capable of internalizing the agonist-receptor complex (48, 49, 52, 53). Since the BBN[7–14] $\text{NH}_2$  receptor binding sequence is consistent with agonistic binding, GRP receptor mediated endocytosis of the  $^{99m}\text{Tc}-\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$  constructs used in this study is not unexpected. The specific intracellular trapping mechanism of the  $^{99m}\text{Tc}$  activity in these PC-3 cells is not understood. It is likely that following internalization of  $^{99m}\text{Tc}-\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$ , that lysosomal proteases degrade the  $^{99m}\text{Tc}-\text{BBN}$  conjugate to peptide fragments.<sup>54,55</sup> The fragments to which  $^{99m}\text{Tc}$  remain attached would be the chemical species that are residualized in the cell for extended

periods. Further work is needed to identify the structure of the  $^{99m}\text{Tc}$  fragments to help elucidate the trapping mechanisms. Efflux of  $^{125}\text{I}$  activity (Figure 6), on the other hand, is expected, as lysosomal breakdown of the  $^{125}\text{I}-\text{Tyr}^4$ -containing peptides results in the production of free  $^{125}\text{I}$  tyrosine, which is exported from the lysosome and the cell by specific transport pathways (55–57). The degree of efflux for the  $^{125}\text{I}-\text{Tyr}^4\text{-BBN}$  species does occur at a slightly more rapid rate than that of the corresponding  $^{99m}\text{Tc}$  conjugate (Figures 5 and 6).

Results from the biodistribution studies, where **X** = 0–11 carbons, are summarized in Tables 2 and 3. These data, along with the data acquired from in vitro cell binding assays, suggest that those  $^{99m}\text{Tc}-\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$  conjugates, where **X** = 3–8, are the most promising candidates for further in vivo evaluation. It is interesting to note that with this limited series of  $^{99m}\text{Tc}-\text{BBN}$  conjugates, the 3-carbon spacer ( $\beta$ -Alanine) analogue exhibits the highest localization in the pancreas at 1 h p.i. As the length of the spacer increases, there is a decline in pancreatic uptake (Tables 2 and 3). The reasons for this observation are not clear. However, this relationship may result from the higher degree of plasma protein binding of the  $^{99m}\text{Tc}-\text{BBN}$  analogues as their hydrophobicity increases. As plasma protein binding increases, the availability of the respective  $^{99m}\text{Tc}$  analogue for binding to the GRP expressing cells in the pancreas possibly decreases.

Results from biodistribution studies with  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava-BBN}[7-14]\text{NH}_2$  in normal CF-1 mice at 30 min, 1 h, and 4 h p.i. are summarized in Tables 4 and 5. This  $^{99m}\text{Tc}$  conjugate clears efficiently from the blood with only  $0.34 \pm 0.12 \text{ ID}$  remaining in the blood at 1 h p.i. (Table 3).  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava-BBN}[7-14]\text{NH}_2$  clears by each the hepatobiliary and renal/urinary pathways. Retention in the kidneys is significant (i.e.,  $2.89\% \pm 0.67\%$  and  $1.53\% \pm 0.31\% \text{ ID/g}$  at 1 and 4 h, respectively, Table 4) but is less than the level of retention in that organ reported for several other radiolabeled peptides and proteins.<sup>12</sup> Uptake and retention of  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava-BBN}[7-14]\text{NH}_2$  in the pancreas is high (i.e.,  $13.8\% \pm 1.62\%$  and  $6.05\% \pm 0.28\% \text{ ID/g}$  at 1 and 4 h p.i., respectively, Table 4). The observation that the uptake of this  $^{99m}\text{Tc}$  conjugate in the pancreas is reduced to  $2.10\% \pm 0.80\% \text{ ID/g}$  at 0.5 h p.i., when the animals were administered 1 mg of BBN 35 min prior to injection of the radiotracer, demonstrates the high specificity of  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava-BBN}[7-14]\text{NH}_2$  for in vivo targeting of the GRP receptor expressing cells in this organ. The high pancreas-to-blood and pancreas-to-muscle ratios that are maintained at  $\geq 4 \text{ h p.i.}$  (Table 4) is a reflection of the high GRP binding affinity of this  $^{99m}\text{Tc}-\text{BBN}$  analogue and its receptor-mediated transport to promote intracellular trapping. While retention of  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava-BBN}[7-14]\text{NH}_2$  is extended, washout of  $^{99m}\text{Tc}$  activity from the organ occurs over time with  $1.36\% \pm 0.27\% \text{ ID}$  remaining at 4 h p.i. in comparison to  $3.19\% \pm 0.35\% \text{ ID}$  at 1 h p.i. (Table 2). For this reason, the pancreas to blood and pancreas-to-muscle ratios at 4 h are not significantly different than those at 1 h p.i.

## CONCLUSION

The results of this study demonstrate that the  $^{99m}\text{Tc}-\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$  construct provides flexibility for designing  $^{99m}\text{Tc}$ -labeled conjugates that retain high in vitro and in vivo specificity targeting of GRP receptor expressing cells. In this particular instance, it was shown that the length of the hydrocarbon spacer group can be

varied from at least 3–8 carbon atoms in length without comprising agonistic binding affinity to GRP receptors. These findings, coupled with previous reports, show that there is a significant degree of bulk tolerance when attaching radiometals via the N-terminal end of the BBN[8–14] $\text{NH}_2$  sequence (31–35). The potential clinical utility of the  $^{99m}\text{Tc}-\text{N}_3\text{S}-\text{X}-\text{BBN}[7-14]\text{NH}_2$  constructs as cancer specific imaging agents was recently demonstrated by Van de Weile et al. (10, 30) in human patients with either prostate or breast cancer. Their studies showed that  $^{99m}\text{Tc}-\text{N}_3\text{S}-5\text{-Ava}-\text{BBN}[7-14]\text{NH}_2$  localizes in tumors with high specificity producing good tumor-to-normal tissue uptake ratios and high-quality SPECT images (10, 30). To design improved radiolabeled synthetic BBN analogues for diagnostic or therapeutic applications, it is essential to devote more effort to better understand the structurally sensitive mechanisms involved in the binding of these derivatives to GRP receptors and subsequent residualization of the radiotracer in cancer cells.

#### ACKNOWLEDGMENT

This material is the result of work supported with resources and the use of facilities at the Harry S. Truman Memorial Veterans' Hospital, Columbia, MO 65201, and the University of Missouri-Columbia School of Medicine Departments of Radiology and Internal Medicine, Columbia, MO 65211. This work was also funded in part by grants from the American Cancer Society (RPG-99-331-01-CDD), the National Cancer Institute (DHHS-RO1-CA72942), the National Institute of Health (DHHS-1P20-CA86290), and Resolution Pharmaceuticals Inc., Mississauga, Ontario, Canada. The University of Missouri holds a patent on the bombesin agonists cited in this paper.

University of Turku, Department of Biotechnology, Tykistökatu 6 A, FIN-20520, Turku, Finland. Received June 14, 2002; Revised Manuscript Received October 30, 2002

A majority of current immunoassays rely on capturing a specific analyte on a solid phase to allow the separation of the bound analyte from nonbound components. Streptavidin-coated microtitration plates are widely used for immobilization of capturing antibodies, since they provide a generic surface for immobilization of any biotinylated molecule and preserve biomolecule activity much better than direct passive adsorption. Our trials to further improve the properties of the plates resulted in a development of a modified plate, which has higher binding capacity than currently used control plate. The modified coat was prepared by cross-linking streptavidin chemically prior to adsorption onto the microtitration well surfaces. The binding capacities of the plates were measured with biotinylated, europium-labeled molecules and labeled antigen. The immunoassay performance of the plates was studied with noncompetitive, sandwich-type assays of prostate specific antigen (PSA) and human chorionic gonadotropin (hCG). The maximum immobilization capacity of the modified plate was up to 2.5 times higher than that of the control plate. The higher binding capacity was especially emphasized with small-size molecules. The modified high capacity plate increased the linear ranges of the immunoassays and thus delayed the high-dose hook effect. At high antigen concentrations the signal increased up to 59%, and at the conventional linear ranges of the assays, the increase was up to 29%. We conclude that the modified coating method will be valuable for the future miniaturized systems, where high immobilization capacity is needed at limited areas.

## INTRODUCTION

Most of the presently used immunoassays utilize binding of a specific antigen or antibody on a solid phase followed by the removal of nonbound analyte and the sample matrix by extensive washing procedure (1). Commonly used solid phases are 96-well microtitration plates or single wells prepared of polystyrene. For the immunoassay purposes, the microtitration well surfaces are precoated with capturing protein like antibody to allow analyte immobilization. However, direct adsorption of antibodies on the plastic surface may destroy the functional sites to even less than one-tenth of the original activity (2–4). These studies have shown also that the protein activity could be preserved when the capturing antibody was immobilized as a secondary layer over a primary coated layer such as via streptavidin–biotin linkage. Therefore, streptavidin-coated wells are preferred to antibody or antigen coated wells. In addition, streptavidin-coated wells provide a universal immobilization surface for any biotinylated molecule and therefore tedious optimization of adsorption conditions for a number of different antibodies or antigens could be avoided. Generally, the streptavidin–biotin technology provides a valuable tool in clinical diagnostics (5) like immobilization of the molecules on the solid phases or signal amplification (6, 7). Therapeutic applications of biotin–streptavidin use are, e.g., delivery of drug molecules to pretargeted cancer cells (8, 9).

Streptavidin, like its counterpart hen egg-white avidin, is a tetrameric protein consisting of four identical subunits each about 14 kDa in size. These proteins are known for their ability to bind biotin very tightly (10, 11). Unlike avidin, streptavidin is from microbial source;

it is produced by the bacteria *Streptomyces avidinii*. In diagnostic applications streptavidin is preferred to avidin due to reduced nonspecific binding which is because of lower isoelectric point and lack of carbohydrate moieties. Biotin, also known as vitamin H, is a small molecule (MW = 244) with a double-ring structure and a carboxyl acid side chain. The side chain can be extended with different linker molecules and active groups enabling chemical coupling of biotin to other molecules. The coupling can be done under gentle conditions (12), and the biological activity of protein is thus well preserved. The biotin–streptavidin interaction is nearly irreversible since the binding affinity ( $K_a$ ) in liquid phase is about  $2.5 \times 10^{13} \text{ M}^{-1}$  (13). However, decreased affinity (around  $10^8$ – $10^{10} \text{ M}^{-1}$ ) was shown between biotinylated macromolecule and solid-phase adsorbed streptavidin (14). This may be due to partial rupture of the critical binding sites and adoption of stiff conformation upon adsorption and attachment on the solid phase. Nevertheless, the binding tightness is still strong enough to separate the biotinylated molecules from nonbiotinylated ones in the immunoassays.

The influence of the solid phase is significant in noncompetitive, two-site immunoassays (1). The binding capacity of the surface must be high enough to provide a real reagent excess, wide dynamic range without high-dose hook effect, and rapid kinetics. Nonspecific binding must be negligible in order to acquire the highest possible assay sensitivity. It is also evident that correct orientation of the immobilized antibody has a significant role (15, 16). Besides immunoassays, streptavidin surfaces are used for nucleic acid assays to immobilize biotinylated oligonucleotide probes or biotinylated amplification products (17). The immobilization of oligonucleotides directly on the plastic surface is often complicated, since they are too small in size for proper passive adsorption to take

place. Nucleic acid amplifications usually utilize a large excess of biotinylated primers, and therefore detection of the products at streptavidin wells requires a large number of binding sites.

Dissolving streptavidin in appropriate buffer and subsequent plain passive adsorption into the microtitration wells usually results in quite poor coating densities and low binding capacities. Therefore, the advantageous effect of streptavidin–biotin immobilization to the features of immunoassays may be abolished by the poor quality of the primary streptavidin coat. Some trials have been made to improve the coats. High-capacity plates have been prepared by coupling streptavidin to hydrophobic proteins prior to adsorption or by immobilizing streptavidin on biotinylated macromolecule coats (18, 19). We introduce here a simple method to prepare streptavidin-coated plates having improved binding capacities. The method relies on the chemical cross-linking of streptavidin prior to the routine coating procedure. The properties of the high-capacity plate were compared to the control plate coated without pretreatment of streptavidin. These types of the wells are widely used, and this is the way a number of commercial plates are still prepared. The properties of the plates were studied in different capacity tests and in noncompetitive, sandwich-type immunoassays.

#### MATERIALS AND METHODS

**Coating Procedure.** Streptavidin was obtained from BioSpa, Società Prodotti Antibiotici (Milan, Italy). Lyophilized protein was dissolved in pure water (Milli-Q) 10 mg/mL and stored frozen in aliquots. Maxisorp™ microtitration plates in C12-strips or single well formats were from Nunc A/S (Roskilde, Denmark). The normal coating procedure for streptavidin, the preparation of the control plate, is briefly described below. Streptavidin was diluted in the coating buffer (100 mM Na<sub>2</sub>HPO<sub>4</sub>/50 mM citric acid, pH 5.0) to the final concentration 5.0 µg/mL. Then 200 µL of the coating solution was dispensed into each well, giving 1 µg streptavidin per well. The plates were closed in a humidified box and incubated overnight at +35 °C. Then the plates were washed in a DELFIA Platewash (Perkin-Elmer Life Sciences, Turku, Finland) with DELFIA Wash Solution supplemented with Tween 20 (Merck, Hohenbrunn, Germany) to the final concentration 0.05%. After washing, 250 µL of saturation solution (50 mM Tris-HCl, pH 7.0; 150 mM NaCl; 0.05% NaN<sub>3</sub>; 0.2% bovine serum albumin and 6% D-sorbitol) was added per well. The plates were saturated overnight at +25 °C. The saturation solution was aspirated and the plates were dried (+35 °C, relative humidity < 5%) for 2 h. Finally the plates were packed with moisture adsorbent and stored dry at +4 °C.

The procedure leading to the high-capacity, modified plate included a pretreatment step prior to addition of streptavidin into the coating buffer. A reaction mixture was prepared, containing 2 mg/mL streptavidin, 10 mM NaH<sub>2</sub>PO<sub>4</sub>/Na<sub>2</sub>HPO<sub>4</sub> (pH 7.0), 150 mM NaCl, and 1.0% glutaraldehyde (J. T. Baker, Deventer, The Netherlands). The mixture was incubated 2 h at +4 °C. The excess glutaraldehyde was removed by purifying the reaction in gel filtration through NAP-5 and NAP-10 columns or PD-10 column (Amersham Biosciences AB, Uppsala, Sweden). The cross-linked glutaraldehyde–streptavidin (GA–SAv)<sup>1</sup> was eluted in TSA buffer (50 mM Tris-HCl, pH 7.75; 150 mM NaCl; 0.05% NaN<sub>3</sub>). The streptavidin concentration of the eluate was determined in a Bradford dye-binding assay following the instructions of the kit

supplier (Bio-Rad Laboratories, Hercules, CA). Originally dissolved streptavidin was used as a reference standard. GA–SAv was then diluted in the coating buffer (5.0 µg/mL), and the coating was proceeded according to the procedure described above.

**Size-Exclusion Chromatography of Cross-Linked Streptavidin.** GA–SAv was analyzed and fractionated in a preparative size-exclusion chromatography through Superose 12 HR 10/30 column driven by ÄKTA explorer system (both from Amersham Biosciences AB). An aliquot of completed cross-linking reaction mixture (before purification through NAP-columns) was injected into the column through a 2.0 mL sample loop, followed by isocratic elution in buffer consisting of 50 mM Tris-HCl (pH 8.40) and 0.05% NaN<sub>3</sub> with flow rate 0.5 mL/min. The purification was monitored at 280 nm, and 0.5 mL fractions were collected in an automatic fraction collector. Molecular weight calibration standards of Gel filtration calibration kits (Amersham Biosciences AB) were run separately in identical conditions. The protein concentrations of the fractions were determined with the Bradford method as above.

On the basis of absorbance and protein concentration profiles, adjacent fractions from the appropriate sites were combined to give three pools representing different molecular sizes. An aliquot from each pool was coated on the microtitration plates as described above.

**MALDI-TOF Mass Spectrometric Analyses.** Bound proteins were eluted from ZipTip C<sub>4</sub> reverse-phase matrix (Millipore, Bedford, U.S.A.) in 2.5% formic acid (Rathburn Chemicals, Walkerburn, Scotland), 50% acetonitrile (Rathburn Chemicals), and 10 mg/mL sinapinic acid (Sigma-Aldrich, Steinheim, Germany) to the sample plate. Perseptive Biosystems (Framingham, MA) Voyager DE-PRO mass spectrometer with a pulsed nitrogen laser at 337 nm was operated in a linear mode. The instrument operated at a 25 kV accelerating potential. At least 120 scans were collected for data acquisition. For calibration we used lysozyme (Sigma-Aldrich) and bovine serum albumin (Sigma-Aldrich).

**Biotinylation and Labeling.** The immobilization capacities of the streptavidin-coated plates were measured with molecules bearing both biotin moieties and europium (Eu) chelates as measurable labels. A monoclonal intact antibody H117 (20) was biotinylated with an isothiocyanate derived active biotin, BITC (21). The biotinylation was performed with an 80-fold molar excess (500 µM) of BITC in 50 mM carbonate buffer (pH 9.8). After 4 h incubation at room temperature the biotinylated antibody was separated from noncoupled BITC through NAP-5 and NAP-10 columns. The biotinylated antibody was labeled with an isothiocyanate-activated fluorescent Eu chelate, 2,2',2'',2'''-[[4-[(4-isothiocyanatophenyl)ethynyl]pyridine-2,6-diyl]bis(methylenenitrilo)]tetrakis(acetic acid) (22). The labeling was performed with a 20–40-fold molar excess (125–250 µM) of activated Eu chelate in 50 mM carbonate buffer (pH 9.8). After overnight incubation at +25 °C the biotinylated and labeled antibody (Bio-H117–Eu) was separated from noncoupled chelate in a Superdex 200 HR 10/30 column (Amersham Biosciences AB). The antibody was eluted in TSA buffer, and the fractions containing the purified labeled antibody were pooled. The protein concentration

<sup>1</sup> Abbreviations: BITC, biotin isothiocyanate; DELFIA, dissociation-enhanced lanthanide fluoroimmunoassay; GA–SAv, glutaraldehyde pretreated streptavidin; hCG, human chorionic gonadotropin; MS, mass spectrometry; PSA, prostate specific antigen; SAv, streptavidin.

of the pool was determined by measuring absorbance at 280 nm. Eu contents of the pool was measured by preparing a dilution series of the solution in DELFIA Enhancement Solution and measuring time-resolved fluorescence in a Victor 1420 multilabel counter (Perkin-Elmer Life Sciences) after 30 min shaking. A dilution series of europium standard calibrator was run together with the sample. The labeling degree (Eu chelates/antibody molecule) was calculated on the basis of measured Eu and protein concentrations.

We used also horse skeletal muscle myoglobin (Sigma-Aldrich) and biotinylated peptide for the capacity measurements. Those represented smaller molecular weights (myoglobin  $\approx$  17 000 Da and peptide = 1672 Da) than the intact antibody ( $\approx$ 160 000 Da). Myoglobin (Mb) was biotinylated, labeled, and purified as described above. The protein concentration of the purified, pooled Bio-Mb-Eu solution was determined in the Bradford assay using originally dissolved myoglobin as a reference standard. The labeling degree was calculated based on the measured Eu and protein concentrations. The biotinylated and Eu-labeled peptide (Bio-Eu-peptide) was purchased from Perkin-Elmer Life Sciences. The peptide consisted of 11 amino acids and its molecular weight was 1672. The peptide bore two Eu chelates ([2-(4-isothiocyano-benzyl)]diethylenetriaminetetraacetic acid), described by Mukkala et al. (23).

**Production and Purification of Recombinant Fab Fragment.** Hybridoma cell line H117 was previously (24) cloned as a recombinant Fab fragment. It contains an engineered five amino acid long Thr-Ser-Cys-Ala-Ala peptide at C-terminus of the Fd chain. Fab fragments were expressed to periplasmic space of *Escherichia coli* in a 5-L BioFlo3000 fermentor (New Brunswick Scientific, New Jersey) and purified with osmotic shock, Streamline SP (75 mL in Streamline25 column) expanded bed adsorption chromatography and finally 5 mL HiTrap Protein G affinity column (all from Amersham Biosciences AB). Unpaired cysteine in C-terminal peptide was used for site-specific biotinylation with 3-(N-maleimido-propionyl) biocytin (Sigma-Aldrich), and the biotinylated fraction was collected using 5 mL monomeric avidin column (SoftLink avidin resin, Promega, Madison, USA).

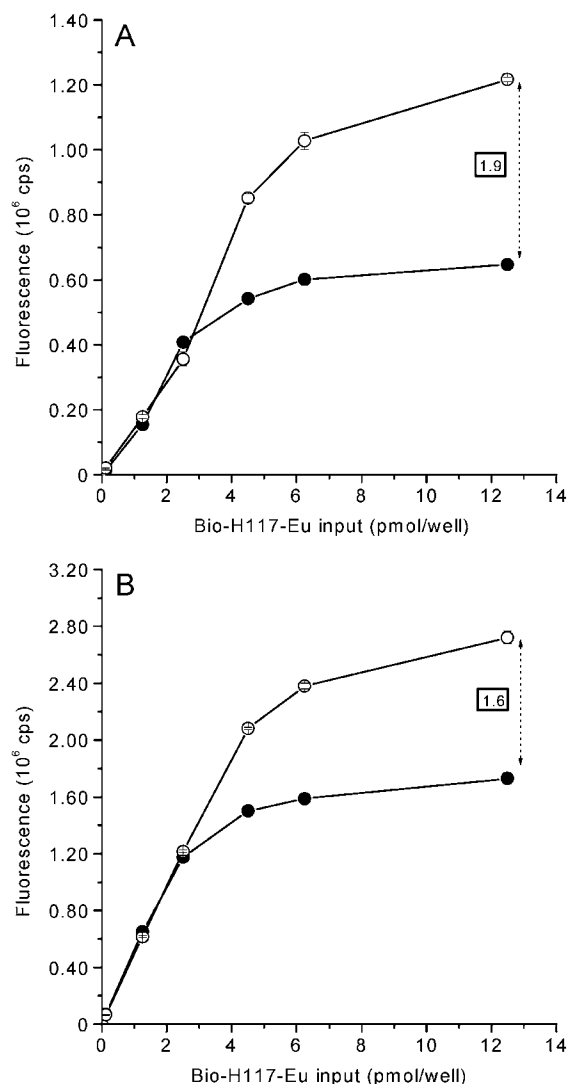

**The Determination of the Binding Capacities of the Coated Wells.** Dilution series of Bio-H117-Eu or Bio-Mb-Eu were prepared in Assay Buffer (Perkin-Elmer Life Sciences) shortly before use. One hundred microliters of each dilution was added into four replicate wells of streptavidin-coated microtitration plates, giving 0.125–12.5 pmol protein inputs per well. The plates were sealed with tape and shaken for 1 h in the DELFIA Plateshake and washed six times with DELFIA Wash solution (5 mM Tris-HCl, pH 7.75; 154 mM NaCl; 0.1% Germall II<sup>+</sup>; 0.005% Tween20) in the Platewash. The plates were dried at +65 °C air blow for 3 min and were cooled to the room temperature for 10 min. The time-resolved fluorescence signal was measured from the bottom of the dried wells in the Victor counter. For this surface readout measurement the measurement focus was custom-adjusted close to the bottom of the well. An area of a few square millimeters in the bottom of the well becomes excited and measured. After the surface readout measurement, the plates were passed to the conventional dissociation enhancement (DELFA) measurement. Two hundred microliters of Enhancement Solution was added into each well, and the time-resolved fluorescence was measured in the Victor counter after 30 min shaking. Known amounts of europium calibrators were measured

parallel. A standard curve was derived and the Eu concentrations of the wells containing immobilized Bio-Eu-molecules were calculated. Since the label degrees of the molecules were known, the actual immobilized quantities of Bio-Eu-molecules (pmol/well) could be calculated.

The capacity test utilizing successive incubations with free biotin and Bio-Eu-peptide was performed as follows. D-Biotin (Sigma-Aldrich) was first dissolved in 1 M NaOH and diluted in the Assay Buffer to give a 11.9 mM stock solution from which the work dilutions containing up to  $2.5 \times 10^{13}$  molecules (41.5 pmol) D-biotin per 200  $\mu$ L were prepared. Two hundred microliters of each dilution was added into four replicate wells of the streptavidin-coated plates. The plates were shaken at room temperature for 1 h and washed twice in the Platewash. Bio-Eu-peptide was diluted in Assay Buffer and 200  $\mu$ L of the dilution was added into each well giving 0.17 pmol peptide input per well. After 1 h shaking the wells were washed six times, and Enhancement Solution was added. Time-resolved fluorescence was measured in Victor counter after 5 min shaking.

For the antigen-binding capacity test, biotinylated intact antibody H117 or site-specifically biotinylated recombinant Fab fragments of that were diluted in Assay Buffer and immobilized in streptavidin-coated wells during a 30 min shaking. Four hundred nanograms of Bio-H117 and two hundred nanograms of Bio-Fab per well were used. Prostate-specific antigen (PSA) standard was a kind gift from Professor Hans Lilja (Lund University, Malmö, Sweden). PSA was labeled with Eu chelate (22) as described above. A dilution series of Eu-PSA was prepared in Assay Buffer, and 30  $\mu$ L of each dilution (5–500 ng Eu-PSA) was added into the wells harboring the immobilized Bio-H117 or Bio-Fab fragments. The reaction was incubated 40 min at +30 °C in iEMS incubator shaker (LabSystems, Helsinki, Finland). The plates were then washed six times, Enhancement Solution was added, and time-resolved fluorescence was measured in Victor after five minutes shaking.

**Immunoassays. Prostate Specific Antigen.** Four hundred nanograms of Bio-H117 (in 50  $\mu$ L Assay Buffer) were added into streptavidin coated wells. The plates were shaken for 1 h at the room temperature in the Plateshake and washed twice in the Platewash. A series of PSA antigen standard dilutions (0.19–5000  $\mu$ g/L) were prepared in 7.5% TSA-BSA (50 mM Tris-HCl, pH 7.75; 150 mM NaCl; 0.05% NaN<sub>3</sub>; 7.5% bovine serum albumin). Ten microliters of each standard dilution was added into the wells containing immobilized Bio-H117. The tracer antibody 5F7 was produced at our department as characterized by Nurmikko et al. (25). The antibody 5F7 was labeled with the fluorescein Eu chelate (22) as described above. Eu-5F7 was diluted in Assay Buffer and 20  $\mu$ L of the dilution containing 200 ng antibody was added to each well shortly after the addition of the standard dilutions. The plates were shaken 30 min at room temperature, followed by washing six times. Enhancement Solution was added (200  $\mu$ L), and the signal was measured in Victor after 30 min shaking. In the other PSA assay, recombinant Fab fragment of H117 antibody (produced as described above) was used as capturing antibody instead of intact Bio-H117. The assay was run as above, except that the amount of Bio-Fab used for the immobilization in the first step was 600 ng/well, and the tracer antibody Eu-5F7 was used 800 ng/well to provide sufficient reagent excess to satisfy increased binding capacity.

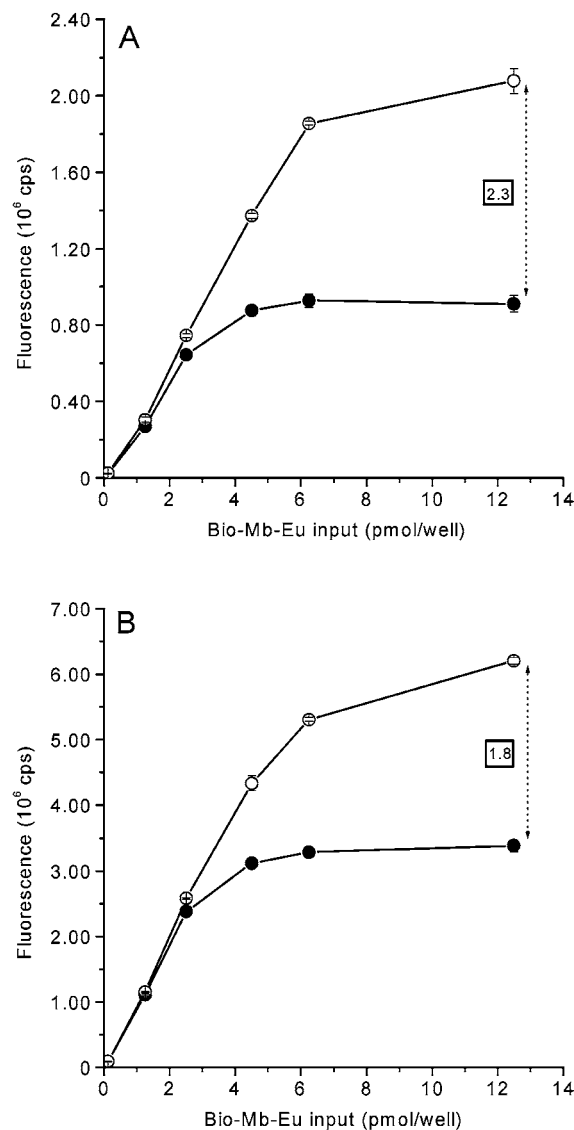

**Figure 1.** The capacities of the streptavidin-coated plates measured with a biotinylated, Eu-labeled antibody Bio-H117-Eu. The signal was measured either with a surface readout method from the dried bottom of the well (A) or with dissociation enhancement (DELFA) method (B). The filled symbols (●) denote the control plate and the open symbols (○) the GA-SAv plate. The error bars indicate the within-assay standard deviations of four replicate wells.

*Human Chorionic Gonadotropin (hCG).* Biotinylated monoclonal antibody Bio-E27, hCG standards, and tracer antibody Eu-8D10 were from Perkin-Elmer Life Sciences. Four hundred nanograms of Bio-E27 was used for immobilization into streptavidin-coated microtitration wells in 50  $\mu$ L Assay Buffer. The hCG standard dilutions including 2–80 000 units per liter hCG (1 U/L corresponds to about 0.1  $\mu$ g/L) were prepared in 7.5% BSA-TSA. Shortly after the addition of the standard dilution, 300 ng/well of Eu-8D10 was added in 20  $\mu$ L Assay Buffer. The plates were shaken 30 min at +36 °C in iEMS incubator shaker and washed six times. The signal measurement was run as described above for the surface readout method.

## RESULTS

**The Immobilization Capacities of the Streptavidin-Coated Plates.** The binding capacities of the plates measured with Bio-H117-Eu are shown in Figure 1. The GA-SAv plate shows up to 1.9 times higher signal than the control plate when the surface readout mea-

**Figure 2.** The capacities of the streptavidin-coated control plate (●) and GA-SAv plate (○) measured with a biotinylated Eu-labeled myoglobin, Bio-Mb-Eu. The signal was measured either with a surface readout method from the dried bottom of the well (A) or with dissociation enhancement (DELFA) method (B). The error bars indicate the within-assay standard deviations of four replicate wells.

surement was used and up to 1.6 times higher signal with dissociation enhanced (DELFA) method. The surface readout method measures only a certain area in the bottom of the well, while the latter method rather represents an integrated signal of the total coated area. The capacity curves of Bio-Mb-Eu measurement are shown in Figure 2. Compared to the control plate, the GA-SAv plate presented 2.3-fold increase in signal with surface readout and 1.8-fold increase in DELFA method. It was noted that as the size of the immobilized detection molecule decreased the differences between the control and GA-SAv plates increased, which most probably indicates less steric hindrance in the case of Bio-Mb-Eu. The actual immobilized quantities were calculated from the DELFA signals and were found to be 2.2 and 3.6 pmol for Bio-H117-Eu and 2.8 and 5.2 pmol for Bio-Mb-Eu at the control well and GA-SAv well, respectively.

The results of the capacity test based on the successive incubations with D-biotin and Bio-Eu-peptide are shown in Figure 3. The measured fluorescence signals

**Figure 3.** The capacities of the plates as measured in the D-biotin test. D-Biotin was first immobilized in the wells, and the unoccupied sites were detected with biotinylated, Eu-labeled peptide (Bio-Eu-peptide). The capacities of the control plate (●) and GA-SAv plate (○) can be read at the lower turn-points of the curves. The error bars indicate the within-assay standard deviations of the replicate wells.

**Table 1. The Capacities of the Control Plate and the GA-SAv Plate to Immobilize Different Biotinylated Molecules**

biotinylated molecule	MW	capacity (pmol/well)	
		control plate	GA-SAv plate
intact antibody (IgG)	160 000	2.2	3.6
myoglobin	17 000	2.8	5.2
peptide (direct immob.)	1672	3.8	8.3
D-biotin/peptide	1672	13	30

were compared to the maximum signal measured from the zero wells (no D-biotin input), and the percentage values were calculated. The capacities of the plates were estimated at the lower turn-points of the curves. The capacity of the control plate was  $0.8 \times 10^{13}$  molecules (13 pmol), that of the modified plate  $1.8 \times 10^{13}$  molecules (30 pmol), and the difference between the plates thus 2.3. It was noted that the signal level did not reach close to zero but stayed around 20% of the maximum signal despite large excess of D-biotin used. We assume that some of the bound D-biotin dissociated out of the surface and thus the method overestimates the binding capacities. The binding capacities of the wells in the case when Bio-Eu-peptide was immobilized direct (like Bio-H117-Eu and Bio-Mb-Eu above) were 3.8 pmol for the control well and 8.3 pmol for the GA-SAv well. Table 1 summarizes the binding capacities of the control and GA-SAv plates as measured with different biotinylated molecules.

Figure 4 compares the capacities of immobilized biotinylated intact antibody (Bio-H117) or biotinylated Fab fragment (Bio-Fab) to bind cognate Eu-labeled PSA antigen. Changing from Bio-H117 to Bio-Fab resulted in around 1.8-fold increase in the binding capacity. Immobilizing Bio-Fab in the GA-SAv well resulted in 1.9-fold more increase in the binding capacity. Thus, combining Bio-Fab with high capacity GA-SAv plate altogether resulted in 3.5-fold increase compared to the case of intact antibody immobilized in the control well.

**Size-Exclusion Analysis and Fractionation of Cross-Linked Streptavidin.** The elution profile of cross-linked streptavidin is shown in Figure 5. Under the

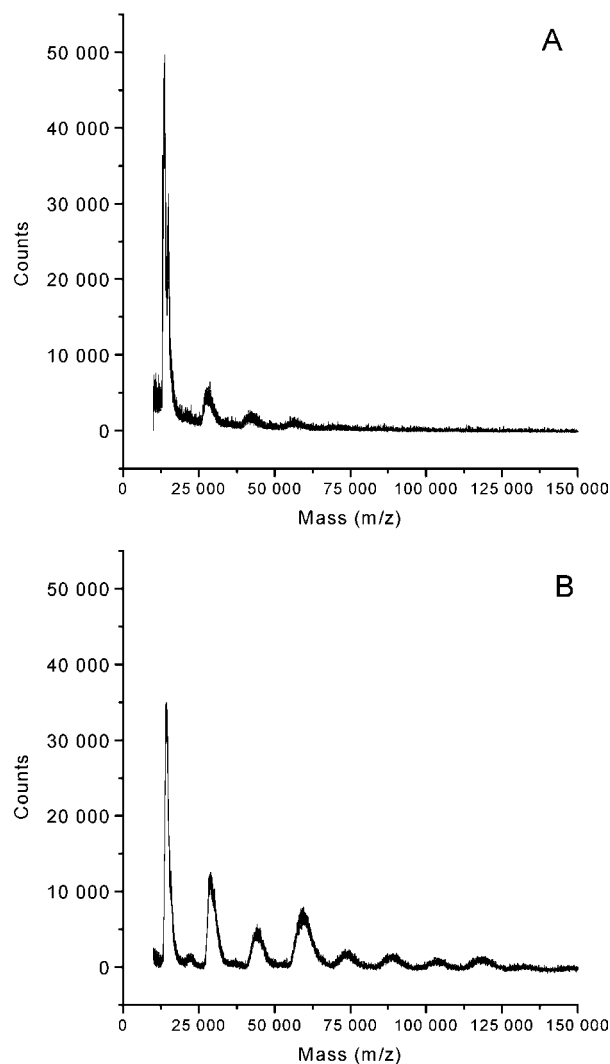

**Figure 4.** Antigen-binding capacities of the intact antibody (● and ○) and Fab fragments (▲ and △) at the control plate (filled symbols) or GA-SAv-plate (open symbols). The error bars indicate the within-assay standard deviations of the replicate wells.

**Figure 5.** Elution profiles of cross-linked streptavidin (straight line) and BSA as a molecular weight marker (dashed line). The fractionation of GA-SAv was performed in a Superose 12-gel filtration column. The profile represents molecular weights extending from around 200 to 25 kDa. The locations of the adjacent fractions combined to three pools are shown with bars.

described conjugation conditions (+4 °C, 2 h, 2 mg/mL SAv), the reaction resulted in a mixture of products ranging in molecular weights from around 25 to around 200 kDa. The exact determination of the highest molecular weights turned out to be inaccurate, since those eluted quite close to the column void volume determined with Blue Dextran 2000 from the calibration kit. The peak representing free glutaraldehyde appeared at an elution volume of 21 mL. The first one of the pooled fractions represented molecular weights from 95 to 200 kDa, the second 65 to 85 kDa, and the third 45 to 55 kDa. Prolonged incubation of the conjugation reaction at the room temperature increased the proportion of larger molecular weight products slightly. A considerable change was noted when protein concentration in the conjugation reaction was increased from 2 to 4 mg/mL. This resulted in an almost complete cross-linking; i.e., only one peak

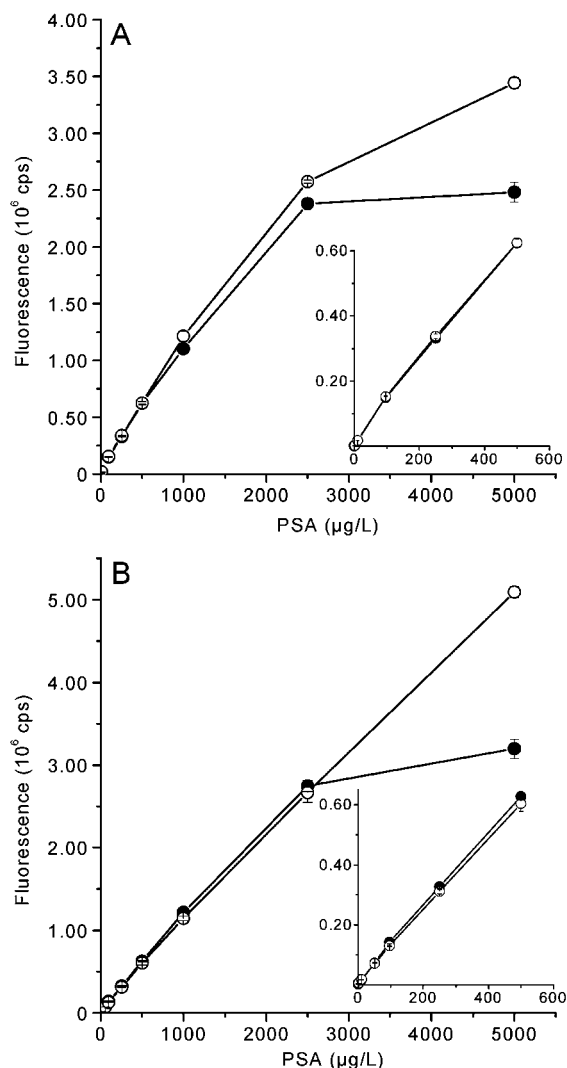

**Figure 6.** Mass spectra of streptavidin. Native streptavidin (A) is mainly found as monomeric form ( $m/z$  13 140) while di-, tri-, and tetrameric forms are hardly present. Glutaraldehyde-treated streptavidin (B) is stabilized over native streptavidin and up to octameric subunit compositions are found.

appeared representing the largest conjugate sizes (data not shown).

The binding capacities of the wells coated from the three pools of cross-linked, fractionated streptavidin (see Figure 5) did not exceed that coated from nonfractionated mixture. The immobilization capacities of the pools 1 and 2 were 80% and pool 3 around 50% of a nonfractionated, total mixture. The capacity of the pool 3 was close to the control plate. Neither the coated wells prepared from the cross-linking reaction with 4 mg/mL protein concentration introduced improved capacity compared to the 2 mg/mL reaction but the capacities were equal or slightly decreased (data not shown).

**Analysis of Mass Spectrometry Results.** Streptavidin from *Streptomyces avidinii* is synthesized as a 183 amino acids long precursor. After cleavage of a 24 aa long signal sequence, mature 159 aa long streptavidin (calculated mass 16 490 Da) is released. It undergoes proteolytic digestions, and finally a core streptavidin of 127 aa is formed. Monomeric core streptavidin has an expected molecular mass of 13 270 daltons (10), and thus calculated mass for tetrameric core streptavidin (native existence) is 53 080 daltons. For non-glutaraldehyde-treated streptavidin (Figure 6 A), we found four peaks

**Figure 7.** The standard curves of the PSA-assays. Either biotinylated intact antibody (A) or a recombinant Fab fragment of the antibody (B) was used as the immobilized capturing agent. The filled symbols (●) denote the assays run at the control plate and open symbols (○) at the GA-SAv plate. The inset graphs show the standard curve ranges up to 500 µg/L. The error bars show the within-assay standard deviations of four replicate wells.

corresponding to mono- (13 140 Da) to tetrameric streptavidin masses (56 782 Da). Monomeric peak dominated in the results. Glutaraldehyde treatment increased di- to tetrameric streptavidin peak intensities 2- to 10-fold. Also, new peaks differing in size at average intervals of 14 880 Da appeared clearly up to size 118 152 Da, which presumably corresponds to a dimer of streptavidin (Figure 6 B).

**PSA Immunoassay.** Figure 7 A shows the standard curves of PSA immunoassays with the intact Bio-H117 antibody immobilized as the capturing antibody. The figure shows that the assay performed at the high-capacity GA-SAv plate has improved high-dose hook efficiency; i.e., the hook is avoided, or it tends to appear at higher antigen concentrations. The background signals were 637 cps at the control plate and 937 at the GA-SAv plate. The detection limits of the assays (background + 3 × SD) were 0.191 µg/L at the control plate and 0.239 µg/L at the GA-SAv plate. Figure 7 B shows the standard curves of the assays utilizing recombinant Bio-Fab immobilized as the capturing agent. This assay clearly shows the potential of the high capacity GA-SAv

**Figure 8.** The standard curves of the hCG-assays at the control plate (●) and GA-SAv plate (○). The inset graph shows the range of the assay up to 20 000 U/L. The error bars show the within-assay standard deviations of four replicate wells.

plate since excellent linearity of the assay extends at least up to 5000  $\mu\text{g/L}$ , while the standard curve at the control plate declines earlier. Because nonoptimal excess amounts of the labeled tracer antibody had to be used to satisfy increased capacities, the background signals tended to increase and thus lower detection limits of these assays were 0.795  $\mu\text{g/L}$  at the control plate and 0.717  $\mu\text{g/L}$  at the GA-SAv plate.

**hCG Immunoassays.** The standard curves of the hCG immunoassays, measured by surface readout method, are shown in Figure 8. The assay shows improved linearity and higher binding capacities of the GA-SAv plate. Since hCG concentration in pregnancy can be as high as 200 000 IU/L or above, it is essential to have high binding capacity and improved linearity to avoid the high-dose hook effect. The background signals were 1782 at the control plate and 1876 at the GA-SAv plate. The detection limits of the assays were 4.5 U/L at the control plate and 4.2 U/L at the GA-SAv plate. The hCG assay was also run at the GA-SAv plates coated from the pools of fractionated cross-linking reactions. No improvement in linearity or binding capacity was obtained compared to the nonfractionated mixture (data not shown), as would have been expected also on the basis of the Bio-Mb-Eu capacity test.

**Reproducibility and Storage Stability.** Thirteen separate batches of GA-SAv plates were coated independently of each other. The coated plates were collected together, and the capacities of the plates were measured with Bio-Mb-Eu. The CV% values within one coated batch varied from 0.6% to 4.3%. The batch to batch CV% values varied from 10.0% to 14.3%.

The stability of one batch of GA-SAv-coated plates was followed several months. The plates were stored in separate sealed boxes with moisture adsorbent at +4 °C after coating. One plate at a time was taken out and the capacity was measured with Bio-Mb-Eu using low input (1.25 pmol/well) and high input (12.5 pmol/well). Figure 9 shows the results of the assays measured during those 225 days of storage. A slight increase (19%) in the signal level was noted when measured with low amount of Bio-Mb-Eu but a slight drop (6%) when measured with 12.5 pmol Bio-Mb-Eu.

**Figure 9.** The storage stability of the GA-SAv plate. Bio-Mb-Eu was used to measure the capacities of GA-SAv plates after different storage periods. The measurements were performed either with 1.25 (●) or 12.5 pmol/well (○) inputs. The storage stability was followed up to 225 days. The error bars indicate the standard deviations of the replicate wells.

## DISCUSSION

The streptavidin-coated plates allow an immobilization of any biotinylated molecule and thus provide flexibility for the solid phase assays compared to the antibody- or antigen-coated plates. Streptavidin-coated plates are widely used in clinical diagnostics and there are numbers of manufacturers. Though the plates are widely used, the optimal coating conditions are based more or less on experimental optimization and the adsorption mechanisms are not well understood, as is the case for proteins in general. Also, the influence of the solid phase on the immunoassay performance is often underestimated.

We presented a preparation of high-capacity streptavidin-coated microtitration plate with a convenient and cost-effective method. The properties of the plates were characterized in terms of binding capacities and immunoassay performance. The capacity increased considerably compared to the control plate but the size of the immobilized biotinylated molecule affected the difference, a result that is quite obvious from steric point of view. Furthermore, surface readout measurement gave larger differences between the plates than dissociation enhancement method. Probably adsorption to the bottom of the well was thus favored in GA-SAv coating, which is promising for the future surface measurement applications. Taking into account the different molecular sizes and measurement methods, we can deduce that the maximum binding capacity of the GA-SAv plate is at least 2–2.5-fold higher than that of the control plate.

Fractionation of GA-SAv by gel filtration and coating from pooled peaks showed that the largest molecular weight products are mainly responsible for the increased capacities, but none of the fractions alone exceeded the capacities of a nonfractionated mixture. It shows that a range of molecular sizes is needed in order to achieve the highest performance. The fractionation also showed products that were smaller in size than a native streptavidin consisting of four identical subunits. A reason may be that some element in conjugation process had partially dissociated tetrameric structure to smaller units from which the cross-linking and building of the larger species was started. On the other hand, our gel filtration runs with native, nontreated streptavidin showed that some

of the original protein had dissociated to subunit dimers and thus peaked at around 25–30 kDa.

The MALDI-TOF mass spectrometry results of non-treated streptavidin showed a dominance of the peak corresponding to one subunit of streptavidin. Most probably the tetrameric structure, held together by non-covalent interactions, was disrupted to subunits by intensive laser radiation. The MALDI-TOF results of GA-SAv showed peaks representing larger sizes, which were multiples of one subunit size. The existence of the peak corresponding to one subunit confirmed that the conjugation did not go to completion in the conditions we used for cross-linking.

Noncompetitive reagent excess immunoassays are widely used to assay clinical analytes demanding high sensitivity, wide dynamic range, speed, and robustness. Minimal nonspecific binding, even background signal and high slope of the standard curve result in sensitive assays having low detection limits. The high-dose hook effect, caused by blocking of all antibody binding sites before sandwich formation, can be avoided or shifted to higher concentrations by increasing the number of binding sites for antigen. Our immunoassay results showed that the hook performance could be improved with high capacity solid phases. The influence of the high capacity plates to the assay sensitivities was insignificant, since the standard curves worked quite equally in the "conventional" linear ranges of the assays at both types of plates. In that area, the capacity of the control plate was high enough to immobilize the required quantity of the biotinylated antibody to give optimal binding of the antigen. It must be considered that the actual quantities of the antigens we used were quite low since small sample volumes (10  $\mu$ L per well) were used. The GA-SAv coating protocol is likely to be important when the solid phases are reduced in area as in spots or in chip technologies. In these cases a considerable high density of the coat at the unit area is required to give enough binding capacity.

A large increase in antigen binding capacity was obtained when Fab fragments were immobilized in GA-SAv plates (Figure 4). This shows clearly how dramatic the influence is of steric hindrance caused by the large size of the intact antibody. Large antibody molecules mask the streptavidin binding sites on the surface and therefore full potential of the GA-SAv plates is not available. In the Bio-Fab-based PSA-assay (Figure 7 B), we did not reach such improvement in assay performance as would have been expected on the basis of labeled antigen-binding assay. There are at least two reasons for that. First, the actual antigen amounts were quite small as discussed above. Second, we had to use intact whole size antibody as the tracer and this rises again the influence of steric factors. There was not a proper recombinant Fab fragment of any appropriate tracer antibody available.

Nonspecific binding of the labeled antibody causes increase in the assay background signal (wells with zero standard), and especially background variation impairs the lower detection limit. The immunoassays run at the GA-SAv plate showed none or up to some 1.5–2-fold increase in background signals, but as the variation kept quite constant, the detection limits were only slightly affected. A higher degree of nonspecific binding is usually obvious when there are larger amounts of coated proteins or immobilized antibodies present. It must be anyhow considered that the background values and the effects of the solid phase may vary between the assays of different analytes, and even within one analyte if different batches of antibodies are used.

In principle, the assay equilibrium should be reached faster (kinetics improved) as more antigen binding sites are introduced and therefore high-capacity plates provide potential for faster kinetics. Our hCG and PSA assays had quite fast kinetics (equilibration at  $\leq 30$  min) in the optimized assay conditions, but no substantial improvement in kinetics beyond that point was noted when control plates were replaced to GA-SAv plates. The assays utilized well-selected antibody–antigen pairs that allowed fast kinetics as such. The effect of the solid-phase capacity may have become more remarkable in the case of slower-reacting antibodies.

## CONCLUSIONS

We have developed a modified streptavidin coating method, which leads to surfaces having high binding capacity for immobilization of biotinylated molecules. The method relies on a chemical cross-linking of streptavidin prior to the routine coating procedure. The treatment was also upscaled and tested in pilot production facilities. The maximum binding capacity of the modified plate increased up to 2.5 times compared to the control plate.

The high-capacity surface increased the linear ranges of the sandwich-type immunoassays and improved the high-dose hook performance. Especially biotinylated Fab fragments immobilized in GA-SAv plate resulted in considerable increase in antigen binding capacities. Some of the potential of the high-capacity plates was masked by steric factors caused by the large size of the immobilized antibody. Furthermore, the coated area of a microtitration well is quite large, and the total binding capacity of low capacity plates is considered adequate for many purposes. We anticipate that the benefits of the GA-SAv coatings will be more evident when reduced surface areas are combined with small biotinylated antibody fragments.

## ACKNOWLEDGMENT

The study was financially supported by the National Technology Agency of Finland (TEKES) and InnoTrac Diagnostics Oy. We thank Mrs Pirjo Laaksonen for technical assistance.

Curie, 75231-Paris Cedex, France. Received July 3, 2002; Revised Manuscript Received October 28, 2002

Gadolinium-chelating cationic lipids have been synthesized to obtain lipoplexes with MRI contrast properties. These compounds were designed to follow the biodistribution of synthetic DNA for gene delivery by nuclear magnetic resonance imaging. The lipid MCO-I-68 was synthesized, and chelate complexes with gadolinium were formed and characterized in terms of physicochemical and DNA binding properties. The transfection activity of MCO-I-68-Gd/DNA complexes was assayed in vitro on NIH 3T3. Different formulations of the product were tested. When up to 5% of the gadolinium lipid complexes were co-formulated with the cationic lipid RPR120535 used as a reference, the transfection levels were maintained as compared to RPR120535 alone. To date, only a liposomal formulation of a gadolinium–cationic lipid chelate without DNA had been observed using magnetic resonance imaging. In vivo intratumoral administration of MCO-I-68-Gd/DNA lipoplexes to tumor model led to an important increase of the NMR signal. It was demonstrated that the new complexes also acted as transfection carriers when they were formulated from liposomes.

## INTRODUCTION

The different self-assembling systems presented since the pioneering works of Felgner (1) on nonviral approaches for gene delivery have explored the nature and geometry of the cationic moiety, the type of lipid, the biodegradability properties, the controlled release of DNA from complexes, and the introduction of some targeting elements (2–3). During the last five years, a great effort has been devoted to the elucidation of the physicochemical properties of the different cationic lipid/DNA complexes (named lipoplexes). Moreover, it seems increasingly crucial to develop efficiently tissue-targeted lipoplexes, taking advantage of the growing number of tissue targeting molecules emerging from phage libraries (4) and other selection technologies.

Histological processing commonly monitors visualization of gene expression in opaque tissues. Noninvasive techniques such as PET (positron emission tomography),  $\gamma$  cameras, and SPECT (single-photon emission tomography) operate in the range of cubic millimeters or larger. Magnetic resonance imaging (MRI) provides an alternative to these technologies and its use for noninvasive visualization of gene delivery complexes is an exciting emerging technique (5–9). In particular, it was studied with contrast agents whose activity depends of an enzymatic process (7–8). With the aim to follow the biodistribution of lipoplexes and correlate their transfecting ability with in vivo biodistribution, we present

here a new strategy based on magnetic resonance imaging using gadolinium-chelating cationic lipid associated to DNA.

Our approach included the design and synthesis of a new building block precursor of DTPA in which the carboxylic acids in DTPA are protected as *tert*-butyl esters and only one of them remains free for coupling to the cationic lipid. This synthesis could be accomplished using a solid-phase methodology. This precursor was coupled to a free amino group placed in the side chain of the protected cationic lipid backbone to result in the desired cationic lipid bearing a gadolinium-complexing moiety as side chain.

## EXPERIMENTAL PROCEDURES

**General.** <sup>1</sup>H NMR spectra were recorded on Bruker 300 and 600 MHz spectrometers. Samples were dissolved in CDCl<sub>3</sub> or CD<sub>3</sub>OD. Chemical shifts are in parts per million relative to TMS internal standard.

We have performed a complete NMR analysis of the final product MCO-I-68, including <sup>1</sup>H NMR recorded with an Avance DMX 600 Bruker (2D, COSY, and HOHAHA methods, *t* = 40ms) and <sup>13</sup>C NMR (heteronuclear 2D techniques HMQC and HMBC with a delay of 3.45 and 60 ms, respectively, in the reverse mode).

Analytical and preparative HPLC were performed on Waters HPLC system equipped with a 717-plus autosampler, a 600-controller pump, a 996-photodiode array detector with tunable wavelength set at 220 nm, and a fraction collector Gilson 202. Mobile phases were (A) H<sub>2</sub>O (0.1%TFA) and (B) MeCN (0.08% TFA). Separation conditions are as follows. *Analytical.* Method A: column C18 Vydac-218TP-54, gradient H<sub>2</sub>O/MeCN, 3 min [80/20], 3–25 min [0/100], 25–50 min [0/100], 51min [80/20]; flow, 1 mL/min. Method B: Column BU-300 aquapore Butyl 7 m, 30 × 4.6 mm from Perkin-Elmer,

<sup>§</sup> University of Verona.

gradient H<sub>2</sub>O/MeCN, 3 min [80/20], 3–25 min [0/100], 25–35 min [0/100], 36 min [80/20]; flow, 1 mL/min. Method C: Column BU-300 aquapore Butyl 7 m, 30 × 4.6 mm, 3 min [100/0], 3–20 min [50/50], 20–30 min [0/100], 30–40 min [0/100], 41 min [100/0]; flow, 1 mL/min. Preparative. Method D: column C<sub>4</sub> Vydac-214TP1022, 250 × 26 mm gradient H<sub>2</sub>O/MeCN, 3 min [60/40], 3–10 min [38/62], 10–15 min [34/66], 15–20 min [30/70], 20–30 min [60/40]; flow, 10 mL/min.

Fluorescence measurements were carried out on a Jobin-Yvon Spex fluoromax-2 spectrofluorimeter (Longjumeau, France). The size distribution of the liposomes and the lipoplexes was determined by dynamic light scattering using a coulter N4 Plus particle sizer (Coulter, Margency, France). Solid supports were purchased from Nova-Biochem (Switzerland), polyamine, and other reagents and solvents from Aldrich. Solvents for HPLC were purchased from Merck (Germany), and DOPE was purchased from Avanti Polar Lipids, Inc. (Alabaster, AL).

**Solid-Phase Synthesis of Protected DTPA Harboring a Single Free Carboxylate (1).** 2-Chloro trityl chloride resin (2 g, 1.5 mmol) was placed in a solid phase synthesis flask, and DCM was added, followed by bromoacetic acid (1.43 g, 10.3 mmol) and DIEA (4 mL). The flask was placed into a motor flask shaker and was shaken overnight at room temperature. MeOH was added as capping reagent, and the reaction was left for 10 additional minutes; the solution was filtered, and the resin was washed alternatively using DCM and <sup>3</sup>PrOH (×3) and finally MeOH (×2) and then dried.

Diethylenetriamine (29.4 mmol, 10 equiv) was dissolved in DCM, added to the flask containing the bromoacetyl resin, and agitated for 4 h. The solvent was filtered, and the resin was washed by alternating between DCM and <sup>3</sup>PrOH (×3), distilled water (×2), and again DCM and <sup>3</sup>PrOH (×2). The Kaiser test (90 °C) was positive. The resin was then washed with DMF (×2). *tert*-Butyl bromoacetate (5.2 mL, 35.3 mmol) and TEA (6.9 mL, to pH 7–8 on wet pH paper) were dissolved in DMF and added to the flask shaker containing the resin. The reaction was left overnight at room temperature under shaking. The solvent was filtered, and the resin was washed with <sup>3</sup>PrOH and distilled water. Additional washings were performed alternating between DCM and <sup>3</sup>PrOH (×3), then MeOH (×2), and finally ether (×1) and dried under vacuo. The Kaiser test was negative. The resin was washed with 20 %TEA in DCM (×2) and alternatively with DCM and <sup>3</sup>PrOH (×3) and then MeOH (×1) and removed to a round-bottomed flask equipped with a magnetic stirrer. A solution composed of DCM and trifluoroethanol in ratio of 2:1 was added and stirred for 2 h at room temperature. The solution was filtered and the resin washed with DCM. The organic fractions were collected and evaporated to give the expected product 0.81 g (89%). <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub> δ in ppm): 1.45–1.48 (36H, s, *t*-Bu), 2.95–3.05 (8H, m, NCH<sub>2</sub>CH<sub>2</sub>NCH<sub>2</sub>CH<sub>2</sub>N), 3.45 (4H, s, NCH<sub>2</sub>COO-*t*-Bu), 3.53 (2H, s, NCH<sub>2</sub>COO-*t*-Bu), 3.54 (2H, s, NCH<sub>2</sub>COO-*t*-Bu), 3.56 (2H, s, NCH<sub>2</sub>COOH). HPLC analysis *t*<sub>R</sub> = 17.14 min (analytical method A). HRMS: calcd for C<sub>30</sub>H<sub>55</sub>N<sub>3</sub>O<sub>10</sub>, 618.3965; found [M + H<sup>+</sup>], 618.3982.

**Synthesis of [(Boc)NH(CH<sub>2</sub>)<sub>2</sub>]<sub>2</sub>N(CH<sub>2</sub>)<sub>2</sub>N(Boc)-CH<sub>2</sub>CO-Lys(Z)-ditetradecylamide (2).** Ditetradecylamine (1 g, 2.4 mmol) was dissolved in DCM. TEA (1 mL, 7.3 mmol) was added until the solution reached pH 8. BOC-Lys (Z)-OH (0.93 g, 2.4 mmol) was dissolved in DCM and added to the flask. Then PyBOP coupling reagent (1.3 g, 2.4 mmol) was added. The reaction mixture was stirred at room temperature for 3 h. The reaction was

followed to completion by TLC (EtOAc:Hex 1:1, ninhydrin). The DCM was then removed under reduced pressure. EtOAc was added and the organic layer was washed with aq. KHSO<sub>4</sub> (×3), aq. NaHCO<sub>3</sub> (×3), brine (×3), dried over MgSO<sub>4</sub>, filtered, and evaporated to give 1.76 g (93.3%). TFA (6 mL) was added to the flask-containing product (2). The solution was stirred for 1.5 h at room temperature. The TFA was removed under reduced pressure using ether in order to removed excess of TFA to give 1.48 g (96.9%). This product was used without further purification. H-Lys(Z)-ditetradecylamide (1 g, 1.5 mmol) was dissolved in DCM. The BOC-protected mono functionalized polyamine obtained as previously reported (12) (0.76 g, 1.5 mmol) was then added. TEA was added until the mixture showed pH 8 and then the PyBOP (0.78 g, 1.5 mmol). The reaction mixture was stirred at room temperature for 4 h. The coupling was followed using TLC (EtOAc:chloroform 3:1, ninhydrin) to completion. The DCM was removed under reduced pressure, and EtOAc was added. The organic layer was washed with aq. KHSO<sub>4</sub> (×3), aq. NaHCO<sub>3</sub> (×3), brine (×2), and dried over MgSO<sub>4</sub>, filtered, and evaporated, and the product was chromatographed on silica gel (EtOAc:chloroform 3:1) to give 0.63 g (36.4%). This intermediate was used without further purification.

**Synthesis of [NH<sub>3</sub><sup>+</sup>(CH<sub>2</sub>)<sub>2</sub>]<sub>2</sub>N(CH<sub>2</sub>)<sub>2</sub>NH<sub>2</sub><sup>+</sup> CH<sub>2</sub>CO-Lys(DTPA)-ditetradecylamide (MCO-I-68).** Product 2 (0.6 g, 0.5 mmol) was dissolved in EtOH. Pd/C 10% (0.6 g) was added, and H<sub>2</sub> gas was bubbled continuously into the reaction solution. The reaction was followed by TLC (EtOAc:chloroform 3:1, ninhydrin, and fluorescamine) to completion after 1 h. MeOH was added and the reaction solution was filtered and evaporated to give 0.43 g (82%) of the desired product.

The crude [BocNH(CH<sub>2</sub>)<sub>2</sub>]<sub>2</sub>N(CH<sub>2</sub>)<sub>2</sub>N(Boc)CH<sub>2</sub>CO-Lys-ditetradecylamide (0.4 g, 0.4 mmol) was dissolved in DCM, and TEA was added until the mixture showed pH 8. A solution of product 1 (0.4 g, 0.64 mmol) in DCM was added; then BOP (0.25 g, 0.56 mmol) was used as coupling reagent. The reaction was followed by TLC (EtOAc:chloroform 3:1, ninhydrin, and fluram) to completion (overnight). The DCM was evaporated, and EtOAc was added. The organic layer was washed with aq. NaHCO<sub>3</sub> (×3), brine (×2), dried over MgSO<sub>4</sub>, filtered, and evaporated to give 0.67 g (99.2% of crude product). TFA was added, and the solution was stirred at room temperature for 1.5 h. The TFA was evaporated, and the crude was purified by preparative HPLC according to method D. The appropriate fractions were pooled and lyophilized to afford pure product, 0.22 g (48.5%). <sup>1</sup>H NMR (600 MHz, CD<sub>3</sub>OD δ in ppm): 0.9 (6H, CH<sub>3</sub>), 1.3–1.35 (44H lipid CH<sub>2</sub>'s), 1.36 (2H, COCHCHCH<sub>2</sub>), 1.4–1.6 (2H, NCH<sub>2</sub>CH<sub>2</sub>(CH<sub>2</sub>)<sub>11</sub>CH<sub>3</sub>), 1.54 (2H, NCH<sub>2</sub>CH<sub>2</sub>(CH<sub>2</sub>)<sub>11</sub>CH<sub>3</sub>), 1.6–1.8 (4H, COCHCH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>NH), 2.8 (4H, N(CH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub>)<sub>2</sub>), 2.8–2.9 (4H, HNCH<sub>2</sub>CH<sub>2</sub>N), 3.14 (2H, CONHCH<sub>2</sub>(CH<sub>2</sub>)<sub>3</sub>CH), 3.16–3.48 (2H, CONCH<sub>2</sub> lipid), 3.2–3.3 (4H, N(CH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub>)<sub>2</sub>), 3.21 (2H, CONCH<sub>2</sub>lipid), 3.3 (8H, HO<sub>2</sub>CCH<sub>2</sub>N-(CH<sub>2</sub>CH<sub>2</sub>N)<sub>2</sub>), 3.37 (1H, CHCON), 3.64 (2H, (CH<sub>2</sub>CH<sub>2</sub>)<sub>2</sub>NCH<sub>2</sub>CO<sub>2</sub>H), 3.72 (2H, Lys-NHCO-CH<sub>2</sub>NCH<sub>2</sub>CO<sub>2</sub>H), 3.74 (4H, N(CH<sub>2</sub>CO<sub>2</sub>H)<sub>2</sub>), 3.84–3.9 (2H, Lys-NHCOCH<sub>2</sub>N), 3.92–4.09 (2H, HNCH<sub>2</sub>CO NH).

HPLC analysis  $t_R = 17.14$  min (analytical method B) and  $t_R = 25.38$  min (analytical method C). MS analysis: calcd for  $\text{C}_{56}\text{H}_{110}\text{N}_{10}\text{O}_{11}$ , 1098; found  $[\text{MH}^+]$ , 1099.

**Preparation of the Chelate Complex (MCO-I-68-Gd).** MCO-I-68 (33 mg, 30  $\mu\text{mol}$ ) was dissolved in  $\text{H}_2\text{O}$ , the pH was adjusted to 5–6.5, and  $\text{GdCl}_3 \cdot 6\text{H}_2\text{O}$  (52 mg, 150  $\mu\text{mol}$ ) was added. The mixture was stirred overnight and then dialyzed over  $\text{H}_2\text{O}$ . After filtration on sephadex G25, the compound was lyophilized. Electrospray mass spectrometry confirmed the mass of the expected product: calcd for  $\text{C}_{56}\text{H}_{107}\text{N}_{10}\text{O}_{11}$  ( $\text{MH}^+$ ), 1254.78; found, 1254.8.

**Preparation of MCO-I-68-Gd/DOPE Liposomes.** MCO-I-68-Gd (3.7 mg, 3  $\mu\text{mol}$ ) was dissolved in sterile water (150  $\mu\text{L}$ ) by heating at 30 °C. Dioleoylphosphatidylethanolamine (DOPE, 2.2 mg, 3  $\mu\text{mol}$ ) was added to the solution and the mixture was sonicated for an hour (Laboratory Supplies Co., Inc., model G112sp1t). When all the co-lipid had been incorporated, 150  $\mu\text{L}$  of  $\text{H}_2\text{O}$  was added to get a 10 mM solution. Integrity of the lipid MCO-I-68-Gd after sonication was checked by mass spectrometry. Peaks compatible with calculated DOPE (744) and MCO-I-68-Gd (1254) were found. Mean size of the particles was measured at 160 nm by dynamic light scattering.

**Preparation of MCO-I-68-Gd as Micelles.** MCO-I-68-Gd (3.7 mg, 3  $\mu\text{mol}$ ) was dissolved in sterile water (300  $\mu\text{L}$ ) by heating at 30 °C. Mean size of the particles was measured at 110 nm by dynamic light scattering.

**Preparation of Liposomes of RPR120535/DOPE/MCO-I-68-Gd.** The cationic lipid RPR120535 (5.3 mg, 5  $\mu\text{mol}$ ) was dissolved in a DOPE chloroform solution (373  $\mu\text{L}$ , 10 g/L, 5  $\mu\text{mol}$ ). A solution of MCO-I-68-Gd was added to get 1% and 5% of the gadolinium lipid incorporated as compared to the cationic lipid (0.05 and 0.25  $\mu\text{mol}$ , respectively). The solvent was removed via rotary vacuum evaporation resulting in the formation of a thin film, which was hydrated at 4 °C in  $\text{H}_2\text{O}$ . Slow vortex and sonication of the film lead to particles sizing 100–300 nm.

**Preparation of the Lipoplexes.** For size measurements, complexation, and in vitro experiments, lipoplexes were formed by mixing volume to volume 8  $\mu\text{g}$  DNA (200  $\mu\text{g}/\text{mL}$  plasmid pCMV-luc+, pCOR plasmid) with different charge ratio of MCO-I-68-Gd, formulated as micelles or liposomes, in 5% glucose/20 mM NaCl.

For in vivo experiments, 25  $\mu\text{L}$  (7.5 mM) liposome or micelle of MCO-I-68-Gd were mixed with 25  $\mu\text{L}$  DNA (400  $\mu\text{g}/\text{L}$  in 5% glucose, 20 mM NaCl).

**Fluorescence Studies.** Complexes were prepared as described above. Ethidium bromide (3  $\mu\text{L}$ , 1 mM) was added to the lipoplexes, and fluorescence was read at 590 nm upon a 260 nm excitation wavelength with 5 nm slit width.

**In Vitro Transfections.**  $5 \times 10^4$  NIH 3T3 cells were seeded in 24-well plates in Dubelcco Modified Eagle Medium (DMEM) at 37 °C, in 5%  $\text{CO}_2$ . After 24 h, cells were washed twice with 0.5 mL of serum free medium and then supplemented with 0.5 mL of medium ( $\pm$  serum). Plasmid DNA (1  $\mu\text{g}/\text{well}$ ) containing the luciferase gene under the dependency of the cytomegalovirus (CMV) immediate early promoter purified according to standard procedure was mixed with 0.5, 1.5, and 6 nmol of cationic lipid per  $\mu\text{g}$  DNA in 75 mM NaCl. For each condition a triplicate determination was performed. Extemporaneous prepared complexes were added dropwise to the cells in the medium  $\pm$  serum. After 2 h of transfection, fetal calf

serum was added to a 10% final concentration in the wells free of serum. The cells were then incubated at 37 °C for an additional period of 24 h, then the medium removed, the cells washed with PBS and lysed with 100  $\mu\text{L}/\text{well}$  of passive lysis buffer (Promega, Madison, WI) for 30 min at RT. Protein concentration of cell extracts was determined using the Bradford protein assay kit (Bio-Rad). Luminescence was measured using a luminometer (Multilabel counter 1420 Victor, EG&G Wallac) equipped with a co-injector that delivered 80  $\mu\text{L}$  of luciferase substrate into 20  $\mu\text{L}$  of cells extracts. The indicated luciferase activity corresponds to the ratio between the detected light unit and the protein amount.

**Animals.** Nude mice were bilaterally implanted in the subcutaneous tissue of the flanks with fragments of human lung tumor NCIH-1299. Human tumors have been used because they develop slowly and with less necrosis than murine tumors. As the cationic lipid has no targeting group, injection in the blood flow leads to a wide dispersion in the body, so that the low gadolinium concentration is not sufficient to expect an increasing of the MRI signal. As our purpose was the validation of the DNA/lipid cationic/gadolinium complex as a lipoplex imaging agent, we have tested the distribution of the lipoplex after direct injection into the tumoral mass. After 4–6 weeks from implant, tumors were large enough (about 1 cm in diameter) to be injected with lipoplex. The mice were anaesthetized with aqueous chloral hydrate (8 mg in 100  $\mu\text{L}$  of  $\text{H}_2\text{O}$ ) administrated intraperitoneally. Then, 50  $\mu\text{L}$  of the lipoplex (formulated as MCO-I-68-Gd/DNA or MCO-I-68-Gd/DOPE/DNA) was injected locally in one of the two tumors, the other contralateral tumor being a control. Experiments were performed with 25 mice (12 injected with micelles and 13 with liposomes).

In each mouse, imaging was performed after 4 h, 24 h, 48 h, 72 h, 8 days, and 10 days from the lipoplex injection. Before each imaging sequence, the animals were anesthetized with an intraperitoneal injection of pentobarbital (2.4 mg in 400  $\mu\text{L}$  of water).

For transfection measurements, the animals were euthanased 1, 2, 3, or 10 days after injection, and the tumors were removed and homogenized in 1 mL of PLB (Promega, Madison, WI). After centrifugation at 3000 g for 20 min at 4 °C, luciferase was assessed on 10  $\mu\text{L}$  supernatant, using a luminometer (Multilabel counter 1420 Victor, EG&G Wallac).

**MRI Experiments.** Magnetic Resonance images were acquired using a Bruker AMX300 spectrometer equipped with a mini-imaging accessory (RF probe 38 mm, gradient strength 0.5 G/cm/A). A spin-echo sequence was used to obtain T1 weighted MR images ( $\text{TE}/\text{TR} = 10/500$  ms;  $\text{NEX} = 6$ ). Typically, a FOV of  $3 \times 3$  cm with a slice thickness of 1 mm was used with a  $256 \times 256$  matrix data. Sixteen consecutive transverse slices, and then eight sagittal slices through the tumor were acquired.

## RESULTS AND DISCUSSION

**Synthesis of Gadolinium Cationic Lipids.** According to previously reported results (9) using DTPA dianhydride as precursor, our attempts to synthesize MCO-I-68 failed to give good yields of the desired product, since the second anhydride function reacted with another equivalent of the amino-free lipopolyamine to result in a dimeric molecule containing two lipid units linked through a DTPA diamide spacer (Figure 1).

To develop our integrated imaging approach, it was necessary to use large quantities of the Gd-cationic lipid. Therefore, we decided to use a protected DTPA harboring

**Figure 1.** Attempts to use DTPA anhydride to obtain MCO-I-68.

a single free carboxylic acid precursor. To our surprise, there are only two methods to obtain the desired DTPA harboring a single free carboxylic acid. In one of them, the building block is obtained by biodegradation of a single methyl ester using an esterase to form a DTPA protected with methyl esters in small quantities (10). This approach is complicated and necessitates the final deprotection by basic ester hydrolysis.

The second approach is a seven-step process for obtaining DTPA *tert*-butyl esters with a free carboxylic acid at one extremity (11). This tedious multistep process prompted us to propose the simplified and versatile method presented here. The approach is based on our previous works for the synthesis of protected monofunctionalized polyamines using solid support techniques (12–13). In those works, we have taken advantage of the dilution effect induced by the coupling of an alkylating agent to a solid support, which prevents polyalkylation when treating a polyamine with the solid supported alkylating agent. Thus, we have attached bromoacetic acid to chlorotriethyl resin and reacted the solid supported bromide with an excess of free diethylenetriamine. In a second step, the supported polyamine was reacted with excess *tert*-butyl-bromoacetate under basic conditions to afford the protected DTPA. Finally, the product was cleaved from the solid support using mild acidic conditions (trifluoroethanol) to prevent *tert*-butyl ester deprotection, thus resulting in the desired DTPA building block **1** with a single free carboxylic acid (see Figure 2).

Unlike our previous works using spermine as polyamine, we did not observe any of the symmetric free carboxymethylene DTPA product which could have been obtained, in theory, by the reaction between the central secondary amine of the diethylenetriamine and the solid supported bromoacetyl group. This is probably mainly due to the statistical ratio of 1/2 secondary/primary amines in diethylenetriamine, contrary to the 1/1 ratio in the case of spermine. This, together with small steric and inductive effects favoring the reaction of the primary amine, results in the absence of the symmetric product. The advantage of this new method is that no isolation of intermediates is necessary. Thus, product **1** is obtained rapidly without needing any purification step. (Figure 2).

**Figure 2.** Synthesis of asymmetrically protected DTPA building block **1**. (a) Diethylisopropylamine  $\text{CH}_2\text{Cl}_2$  overnight, (b) diethylenetriamine  $\text{CH}_2\text{Cl}_2$ , 4 h, and (c) *tert*-butyl-bromoacetate triethylamine overnight then trifluoroethanol/ $\text{CH}_2\text{Cl}_2$ , 1 h.

The lipopolyamine precursor was obtained by coupling of previously reported protected building block tris-aminoethylcarboxymethylene to a preformed H-Lys(Z)-ditetradecylamide (13). After deprotection of the Lys side chain of product **2** by hydrogenolysis, product **1** was coupled with the free amino group of the obtained product **3** using regular peptide coupling techniques to give **4**.

The final product was obtained after exhaustive deprotection of **4** using trifluoroacetic acid (see Figure 3). The cationic lipid MCO-I-68 was fully characterized using two different HPLC gradients, multidimensional NMR, and high-resolution mass spectroscopy. The gadolinium ion was complexed to the DTPA moiety of the lipid as previously described (9).

The excess of  $\text{GdCl}_3 \cdot 6\text{H}_2\text{O}$  was removed via subsequent dialysis and gel filtration to remove all traces of toxic  $\text{GdCl}_3 \cdot 6\text{H}_2\text{O}$ . The full conversion of MCO-I-68 to MCO-I-68-Gd was checked by electrospray mass spectroscopy. (See Figure 3).

**Physicochemical Characterization of DNA/MCO-I-68-Gd Complexes.** Dilution of MCO-I-68-Gd in water gave a micellar suspension. The cationic polyamine moiety of this lipid allowed to form MCO-I-68-Gd/DNA lipoplexes by direct mixing of the micelles with DNA. Liposomes were prepared by direct mixing of the gadolinium lipid with a co-lipid.

The lipid chains of the widely used dioleoylphosphatidylethanolamine (DOPE), and the gadolinium lipid or-

**Figure 3.** Synthesis of MCO-I-68 and its complex with gadolinium.

ganized together under liposome type of structures when both lipids were sonicated together, as described in materials and methods and in (9). On the other hand, the usual way of preparing liposomes via formation of a film under vacuum elimination of CHCl<sub>3</sub> did not allow us to form homogeneous liposomal structures. Lipoplexes (MCO-I-68-Gd/DOPE/ DNA) were then formed by diluting different amounts of the preformed liposomes with a constant amount of DNA.

The ability of MCO-I-68-Gd as micelles or liposomes to complex DNA and to form small particles was studied. The size of lipoplexes obtained either by association of micelles to DNA or by association of liposomes to DNA was evaluated by dynamic light scattering experiments (Figure 4). Results are represented as a function of the ratio of positive charges (MCO-I-68-Gd) to negative charges (DNA Phosphate) equivalents, considering that the MCO-I-68-Gd compound carried three positive charges.

Complexes, formulated either from micelles or liposomes, exhibit comparable size for the different studied charge ratio (MCO-I-68-Gd/DNA) studied. Moreover, the characteristics of lipoplexes are similar to those previously observed with lipopolyamine RPR120535 (14). We found that, when lipoplex self-assembly is formed with negative charges in excess (charge ratio MCO-I-68-Gd/DNA < 1), lipoplexes are colloidally stable and exhibit a small size around 110 nm when starting from micelles and 150 nm when starting from liposomes. Aggregation (size > 1  $\mu$ m) occurs at lipid/DNA ratio between 1 and 2, corresponding to charge neutrality of the complexes. As the amount of cationic lipid was increasing relative to the DNA, colloidally stable 100 nm size particles are obtained. We also carried out fluorescence experiments in order to estimate DNA entrapment into the lipoplexes. Intercalation of ethidium bromide between the free DNA base pairs gives a fluorescent signal taken as 100%. When DNA is complexed with the cationic lipids, the ethidium bromide signal decreases due to its exclusion from DNA. This allows monitoring the percentage of compacted DNA. Figure 4 shows the diminution of fluorescence depending on the degree of DNA complexation. Fluorescence level decreases to 50% or 60% for

**Figure 4.** Size of the lipoplexes and ethidium bromide residual fluorescence in function of the charge ratio lipid/DNA ( $\pm$ ). Open circles represent the size of the lipoplexes, measured by dynamic light scattering. Full squares represent complexation of DNA, measured by emission fluorescence (100% = complete intercalation in absence of cationic lipid).

micelle or liposome-based lipoplexes, respectively. This is less than what had been previously observed with

**Figure 5.** Lipoplexes were loaded on a 0.8% agarose gel at the different DNA complexation zone identified in Figure 2. Free DNA was loaded on the first well as a control. Then mixtures of MCO-I-68-Gd/DNA at the lipid/DNA charge ratio 0.4, 1.1, 2.5, 4, and 6 were loaded either when starting from liposomes (A) or micelles (B).

RPR120535 (13), thus suggesting incomplete DNA compaction or association to lipoplexes. However, MCO-I-68-Gd/DNA lipoplexes did not migrate on agarose gel electrophoresis (Figure 5). Thus, it appeared in both liposome and micelle-based lipoplexes that a charge ratio of 2.5 was enough to get a full DNA complexion. Nevertheless, the ethidium bromide test indicates a lower affinity of the MCO-I-68-Gd lipid for DNA as compared to the RPR120535 lipopolyamine control.

**In Vitro Transfection.** The gadolinium lipid had been designed as a tracer co-lipid for MRI studies in order to follow the biodistribution of our new homemade DNA lipidic vectors. As this lipid presents the same type of structure as other cationic lipids, it should not alter in vivo lipoplex biodistribution.

Moreover, the physico-chemistry shown above indicates that this lipid behaves very closely to previously studied cationic lipids). In vitro transfection activity of MCO-I-68-Gd lipid was studied on NIH3T3 cells and compared to reference lipid RPR120535. MCO-I-68-Gd was used either alone or by co-formulation with cationic RPR120535, which represents the way this method will be used in future MRI studies. The gadolinium lipid, to be used as a co-lipid, should not modify the activity, nor reduce the efficiency of the lipid tested. The cationic lipid RPR120535 formulated with DOPE (1/1) was chosen as a reference, since it was shown that this lipid did transfect efficiently NIH 3T3 cells in absence of serum (15). We incorporated 1–5% gadolinium lipid into the cationic formulation (materials and methods) and evaluated the transfection activity of these new gadolinium-based formulations (see Figure 6).

With the MCO-I-68-Gd/DNA complex was used, transfection efficiency was reduced as compared to the

**Figure 6.** Lipid-mediated DNA transfection of NIH 3T3 cells using cationic liposomes RPR120535/DOPE, RPR120535/DOPE + 1% MCO-I-68-Gd, RPR120535/DOPE, /DOPE+5% MCO-I-68-Gd in three different charge ratio (RPR120535/DNA) 0.5, 1.5, and 6, in the presence (gray) or absence (white) of calf serum. Data are the mean of triplicate determination (error bars: SD).

RPR120535/DNA complex (not shown). This may be explained by the reduced affinity of the MCO-I-68-Gd for DNA as compared to RPR120535, as measured by ethidium bromide. Complexes formed out of MCO-I-68-Gd are likely less stable and release DNA faster than the RPR120535. On the other hand, addition of 1 and 5% of the MCO-I-68-Gd into the RPR120535/DOPE formulation did not significantly affect the DNA transfection efficiency, as compared to DNA complexed with RPR120535/DOPE, indicating that MCO-I-68-Gd does not interfere with in vitro transfection efficiency of RPR120535 (Figure 6).

**MRI Experiments.** The efficiency of a DNA delivery vehicle depends of the pharmacokinetics that determines distribution and concentration in targeted tissue. With the aim to explore the possibility of imaging a DNA transfection event, Nantz et al. (9) brought to the fore a contrast enhancement in lymph nodes after subcutaneous injection of a polymerizable lipid chelated with gadolinium. They formulated afterward this gadolinium lipid with DOTAP and DNA and showed that the lipoplex formed was able to transfect NIH 3T3 cells in vitro. However, visualization DNA complexes were not shown in those works so far.

The most important objective of this work was to design and assess a new tool visualizable in MRI for the biodistribution monitoring of cationic lipid/DNA complexes. For this purpose we have tested the ability of MCO-I-68-Gd/DNA complex to act as a MRI contrast agent and to follow lipoplex biodistribution in vivo. Imaging studies were performed after intratumoral injection of the complexes. Tumors were bilaterally implanted in the flanks of the animals, and only one tumor was injected, the contralateral one serving as a control.

Noninjected tumors appeared as multinodular masses with a thin layer of oedematous tissue at their boundary (Figure 7). The neoplastic tissue appeared as rather homogeneous nodules emitting a signal of medium intensity. Hypointense areas were visible within the mass, probably corresponding to necrotic tumoral tissue. In lipoplex injected tumor, areas of hyperintensity were visible. In some cases (2 out of 13), these areas appeared only 24 h after injection, probably because little or no exchange water with the gadolinium could occur in the injection site (Figure 8). The contrast agent diffused slowly (up to 10 days) out of the neoplastic mass, in the healthy tissue. The injection of the contrast agent labeled lipoplexes did not cause any increase of the necrosis, but both with liposomes and micelles small hemorrhages were associated to the injection site. After 24 h, the

**Figure 7.** (A) 48h after injection of the left side tumor with MCO-I-68-Gd/DOPE/ DNA complexes. Right side tumor is thenon injected tumor control. (B) 48 h after injection of the right side tumor with MCO-I-68-Gd/DNA lipoplex. Left side tumor is the noninjected tumor control.

contrast agent diffused in the surrounding neoplastic tissue, creating areas of medium intensity signal with irregular margins. However, injection site was still visible by its hyperintensity. In the cases in which a necrotic core was involved in the injection site, the diffusion of the hyperintensity signal was poor and mainly limited around the injection site. The different behavior of the complex from a mouse to another was correlated to the intern structure of the tumor. No difference could be obviously detected between micelles and liposomes. Diffusion of the hyperintensity signal reached a maximum after 52 h from injection and decreased slowly thereafter. Nevertheless, hyperintensity was still visible after 10 days (Figure 8).

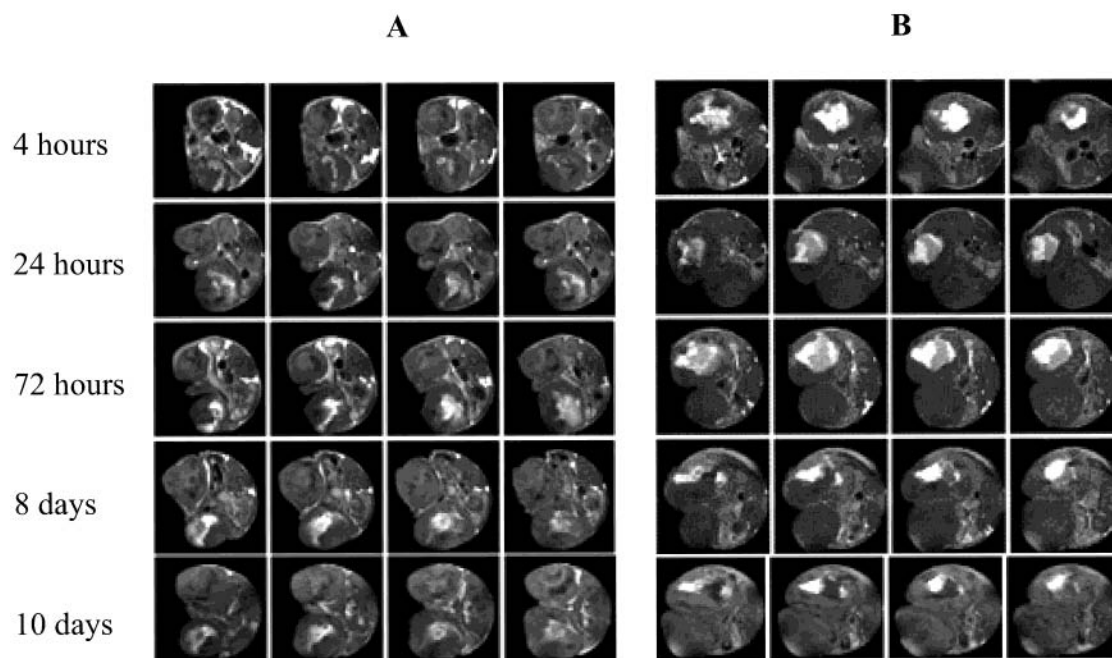

The presence of hyperintensity demonstrates that gadolinium complex interacts with water molecules and is not sequestered in small intracellular compartments (i.e., secondary lysosomes). The clearance of the gadolinium from the tumor is probably hampered by the hypovascularity of the tumoral core. The displacement of the contrast agent in the tumor could be due to both diffusive and convective movements of the interstitial fluid.

In these MR imaging experiments, the injected plasmid coded for the reporter gene luciferase, thus allowing

assaying transfection efficiency. After 1, 2, 3, and 10 days, mice were euthanased, tumors were removed, and the luciferase activity was quantified. No significant luciferase activity was detected in the tumors injected with micelle-based complexes. On the other hand, in most of the tumors injected with liposome-based lipoplexes, the luciferase activity was noteworthy although with low levels during the first 3 days. Nevertheless, as shown from the corresponding imaging, the transfection level seems to depend essentially on the possible diffusion of the complex in nonnecrotic zones. Because of the variability between the tumors observed, we could not evaluate the decrease of transfection from day 1 to day 3. No luciferase activity could be detected at day 10. This was expected, as it had been shown that cationic lipid mediated gene transfer results in a temporary transgene expression with a maximal expression after 24 h which decreases rapidly afterward (data not shown).

It should be noted that all the MRI experiments were performed using MCO-I-68-Gd to form the DNA complexes, without adding cationic lipid RPR120535. On the other hand the transfection level was lower when using MCO-I-68-Gd/DNA complexes than when diluting 1–5% MCO-I-68-Gd in a RPR120535/DOPE/DNA. Thus, we are currently working on the MRI of the co-formulated cationic lipid, which has been shown to be more efficient *in vitro*. In this way we will aim at adjusting the *in vivo* formulation so that gadolinium contrast can be observed with a lower concentration of MCO-I-68-Gd in a co-formulation, hence, increasing *in vivo* transfection and thus correlating the imaging observation to transfection.

According to the *in vivo* results, the transfection occurs only during the first 3 days after injection and is paralleled by hyperintensity at MRI examination. In the following days, there is a mismatch between hyperintensity and transfection. This mismatch seems to suggest that lipoplexes although remain in the tumor, their ability to transfect is lost. We speculate that the loss of transfection ability could arise from DNA damage; however, we cannot demonstrate this assumption to date.

**Figure 8.** Visualization of lipoplex-Gd in tumor NCIH-1299 at 4 h, 24 h, 72 h, 8 days, and 10 days after injection. (A) Lipoplexes formed from liposomes injected on left side tumor. (B) Lipoplexes formed from micelles injected on right side tumor.

## CONCLUSIONS

We have designed and applied a new tool based on in vivo magnetic resonance imaging of cationic lipid/DNA complexes. A new versatile solid phase synthesis of asymmetrically protected DTPA building block for covalent conjugation to cationic lipids has been demonstrated.

The DTPA-cationic lipid obtained was chelated with gadolinium and complexed with plasmid DNA. We have shown that these complexes display significant levels of transgene expression after in vitro transfection. Our present studies show, for the first time, that cationic lipid/DNA complexes can be observed in vivo using magnetic resonance imaging after intratumoral administration. We could visualize cationic lipid/DNA complexes and observe their distribution in the tumor area as a function of time. We have shown that lipoplexes formulated from both micelles and liposomes can be observed during long periods of time. However, transgene expression could be detected on tissue extract only when complexes were formulated as liposomes.

Overall, this technique opens the field of gene delivery to the design and the in vivo observation DNA/cationic targeted to various tissues or tumors. Works exploiting these possibilities are currently ongoing.

## ACKNOWLEDGMENT

This project was funded by Arc-en-Ciel and AFIRST Israel/France (programs of the French Ministry of Foreign Affairs and the Israeli Ministry of Sciences). Dr. Gerardo Byk is also indebted to the Marcus Center of Medicinal Chemistry and to TEVA Pharmaceuticals Inc. The imaging system was purchased with a grant of the Association pour la Recherche sur le Cancer (ARC).

DNA binding compounds, such as benzo[e] (BePI) and benzo[g] pyridoindole (BgPI) derivatives, exhibit preferential stabilization of triple helices. We report here the synthesis of a series of pyrimidine triple-helix-forming oligo-2'-deoxyribonucleotides conjugated with these molecules. BePI was coupled to the 5-position of 2'-deoxyuridine via two linkers of different sizes attached to its 11-position and placed at either the 5'-end, inside the sequence, or at both the 5'-end and the internal positions using periodate oxidation of a diol-containing oligonucleotide followed by reductive coupling with amino-linked BePI. The same BePI derivatives were also linked to the oligonucleotide chain via internucleotidic phosphorothiolate or phosphoramidate linkages. A mixture of diastereoisomers was prepared as well as separate pure Rp and Sp isomers. A BePI derivative, with two different linkers attached to its 3-position, and BgPI derivatives were also linked to the 5-position of a 2'-deoxyuridine located at either the 5'-end or inside the sequence, as well as to the  $\beta$ -anomeric position of an additional 2'-deoxyribose placed inside the sequence. The binding properties of these oligonucleotide–benzopyridoindoles conjugates with their double-stranded DNA target was studied by absorption spectroscopy.

## INTRODUCTION

Since their first description with polynucleotides by Felsenfeld et al. (1) in 1957, followed 30 years later by the discovery that they can also be formed upon binding of synthetic oligonucleotides to double-helical DNA (2, 3), nucleic acid triple helices have been the focus of considerable attention because of their possible applications in biotechnology, diagnostics, and therapeutics (for reviews, see ref 4). Short triple-stranded complexes can compete with the cellular machinery to inhibit either transcription initiation (5) or transcription elongation (6, 7). In addition, reactive triple-helix-forming oligonucleotides (TFOs) have been shown to induce targeted mutations (8, 9) and have been used to demonstrate the accessibility of the DNA target sequence in the cell nuclei (10–12). TFOs covalently linked to camptothecin, an inhibitor of topoisomerase I, have been proven to induce in vitro sequence-specific cleavage of one strand of the double-stranded DNA target by recruiting topoisomerase I (13, 14). More recently a TFO was shown to induce mutations in mice

(15). However, in many cases the stability of triple-helical complexes is not strong enough to compete efficiently with transcription activating factors or to arrest the transcription machinery. The mechanism of sequence-specific DNA triplex formation involves the formation of hydrogen bonds between the bases of the third strand and the purine bases of the double stranded DNA target. The stability of triple helices involving a natural oligo-2'-deoxyribonucleotide third strand is in most cases inferior to that of double helices. Only a few (G,A)-containing third strands form very stable complexes (16). The requirement for cytosine protonation destabilizes triplexes involving (C,T)-containing third strands under physiological conditions, especially when they contain adjacent cytosines. To increase the stability of the complexes, the third-strand oligonucleotides have to be modified. This can be achieved by modification of the oligonucleotide either at the backbone or at the base level. Another strategy consists of the covalent attachment of stabilizing agents such as groove binding ligands (17–18), peptides (19), or intercalators (20–28). The covalent attachment of intercalators at the end of the oligonucleotides has been shown to strongly stabilize triple helical complexes due to intercalation at the junction between the duplex and triplex regions along the DNA template. One example of strong stabilization of a triple helix by covalent coupling of two intercalators derivatives at both the 5' and the 3'-ends of a pyrimidine triple-helix-forming oligonucleotide has also been reported (27). The design of triple-helix-specific intercalating agents (29) has opened the possibility of stabilizing triplexes by attaching this kind of triplex-specific ligand at any site along the third strand oligonucleotide. Benzopyridoindole and Benzopy-

ridoquinoxaline derivatives have been covalently attached to either the 5'-end, via a phosphoramidate linkage, or an internal position, via an abasic site generated after *in situ* depurination followed by reductive amination of the generated aldehyde group by the amino-containing intercalator-linker derivative (24, 25). Two derivatives, a benzopyridoquinoxaline attached to the 5'-end and a benzopyridoindole attached to the internal position, notably stabilized the triple helix.

On the basis of these results and in order to further explore the possibility of increasing the stability of triplexes, we chose to covalently attach a few benzo[e] pyridoindole and benzo[g] pyridoindole derivatives to different positions of a pyrimidine third strand: the 5-position of 2'-deoxyuridine incorporated in place of thymidine at various locations inside the sequence, the  $\beta$ -anomeric position of a 2'-deoxyribose residue inserted between the second and third nucleotides of the third strand and at internucleotidic positions via a phosphorothiolate or a phosphoramidate linkage. We also chose to study the influence of the position of the linker attachment site to the intercalator as well as that of the linker size to connect the intercalator to the oligonucleotide. We report here the preparation of these oligonucleotide-BePI and oligonucleotide-BgPI conjugates and their binding properties with a complementary double-stranded DNA target sequence.

#### EXPERIMENTAL PROCEDURES

**General Methods.** All solvents used were dried, distilled, and stored as described in ref 30. All chemicals were used as obtained unless otherwise stated. Triethylamine and sodium sulfate were from Merck. Pyridine and dichloromethane were from SDS. Analytical thin-layer chromatography (TLC) was performed on precoated alumina plates (Merck silica gel 60F 254 ref. 5554). For flash chromatography, Merck silica gel 60 (70–230 mesh) (ref. 7734) or Aldrich neutral alumina oxide (150 mesh) (ref. 19,997-4) and anhydrous solvents were used. Melting points (mp, uncorrected) were measured using an Electrothermal IA 9200 melting point apparatus. NMR spectroscopy was performed on a Bruker AC 200 or AM 300WB Spectrometer.  $^1\text{H}$  chemical shifts were referenced to either residual solvent peak DMSO (2.54 ppm) or  $\text{Me}_4\text{Si}$ . Elemental analysis was performed by Service Central de microanalyses du CNRS, 91190 Gif sur Yvette, France. The results are within  $\pm 0.4\%$  of the theoretical values corresponding to the mentioned formulas. Mass analysis was performed on a Quattro II (Micromas) instrument. Oligonucleotides, including those with an internucleotidic thiophosphate group, were synthesized using cyanoethyl phosphoramidite chemistry using either a Pharmacia Gene Assembler or an Expedite Nucleic Acid Synthesis system 8909 from Perseptive Biosystems. Analysis and purification by ion-exchange chromatography were carried out on a Pharmacia FPLC with a DEAE column (8  $\mu\text{m}$ , 100 mm  $\times$  10 mm, Waters) with a linear gradient of NaCl in Tris/HCl, 25 mM buffer, pH 7, containing 10%  $\text{CH}_3\text{CN}$ . Reversed-phase chromatography analysis was performed on a 600 E System Controller equipped with a photodiode array detector Waters 990 using a Lichrospher 100 RP18 (5  $\mu\text{m}$ ) column (125 mm  $\times$  4 mm) from Merck with a linear gradient of  $\text{CH}_3\text{CN}$  in 0.1 M aqueous triethylammonium acetate, pH 7, with a flow rate of 1 mL/min. The concentration of unmodified oligonucleotides was calculated using molar extinction coefficients at 260 nm using a nearest-neighbor model (31). The extinction coefficients for oligo-2'-deoxyribonucleotide-BePI and oligo-2'-deoxyribonucleotide-BgPI conjugates

**Figure 1.** Structures of the BePI and BgPI derivatives 1–6.

were approximated by adding the experimentally determined extinction coefficient at 260 nm of the unconjugated BePI or BgPI in  $\text{H}_2\text{O}$  to the extinction coefficient for oligonucleotide  $5'\text{TTTTCTTTTC}'$  ( $\epsilon_{260} = 80\ 100\ \text{M}^{-1}\ \text{cm}^{-1}$ ). All concentrations are given on a per strand basis.

#### A. Synthesis of BePI and BgPI Derivatives 1–20.

**I. Synthesis of the BePI Derivatives 1 and 2 Involving an Amino-Containing Linker Attached to Their 11-Position.** The 11-amino-substituted benzo[e]pyridoindole derivatives 1 and 2 (Figure 1) were obtained as described in the literature (32, 33).

**II. Synthesis of the BePI and BgPI Derivatives 3–6 Involving a Carboxylated Linker (Schemes 1 and 2).** **1. 11-Chloro-3-hydroxy-8-methyl-7H-benzo[e]pyrido[4,3-b]indole 8.** To a suspension of the methoxybenzo[e]pyrido[4,3-b]indole 7 (1 g, 3.4 mmol) in 12 N hydrochloric acid (100 mL) was added benzyltriethylammonium chloride (3 g, 13 mmol). The mixture was heated at reflux under nitrogen atmosphere for 72 h. Evaporation to dryness under reduced pressure provided a solid residue, which was taken up in water (100 mL), and the pH was adjusted to 14 by 14%  $\text{NH}_4\text{OH}$ . The precipitate was collected by filtration and washed with water, dried and chromatographed on neutral alumina column with gradient of ethanol (0 to 10%) in  $\text{CH}_2\text{Cl}_2$  as eluent, giving 820 mg (86%) of **8**: mp 236  $^\circ\text{C}$  (dioxane);  $^1\text{H}$  NMR,  $\delta$  12.5 (s, 1H, NH), 9.57 (d, 1H, H-1), 8.07 (s, 1H, H-9), 7.90 (d, 1H, H-5), 7.76 (d, 1H, H-6), 7.36 (d, 1H, H-4), 7.27 (dd, 1H, H-2), 2.58 (s, 3H,  $\text{CH}_3$ -8). Anal. Calcd for  $\text{C}_{16}\text{H}_{11}\text{N}_2\text{ClO} \cdot \text{H}_2\text{O}$ : C, 63.89; H, 4.32; N, 9.31. Found: C, 63.72; H, 4.1; N, 9.22.

**2. 7-Chloro-3-hydroxy-10-methyl-11H-benzo[g]pyrido[4,3-b]indole 12.** This compound was prepared according to the procedure described above for **8** (starting from the methoxybenzo[g]pyrido[4,3-b]indole 11) in 85% yield mp 298  $^\circ\text{C}$  (acetonitrile);  $^1\text{H}$  NMR,  $\delta$  12.50 (s, 1H, NH), 9.96 (s, 1H, OH), 8.66 (d, 1H, H-1), 8.35 (d, 1H, H-6), 8.07 (s, 1H, H-9), 7.63 (d, 1H, H-5), 7.36 (d, 1H, H-4), 7.29 (dd, 1H, H-2), 2.66 (s, 3H,  $\text{CH}_3$ -10). Anal. Calcd for  $\text{C}_{16}\text{H}_{11}\text{N}_2\text{ClO} \cdot \text{H}_2\text{O}$ : C, 63.89; H, 4.32; N, 9.32. Found: C, 63.72; H, 4.63; N, 9.78.

**3. Alkylation and Hydro-Dechlorination Reactions for the Production of the O-Substituted Derivatives 9, 10, 13, and 14.** **Preparation of Ethyl 4-(7H-Benzo[e]pyrido[4,3-b]indol-3-yloxy)butanoate 9: An Example of the General Method.** A solution of ethyl 4-bromobutyrate (1.9 g; 9.7

mmol) in DMF (20 mL) was added over a 4 h period at 0 °C to the mixture of 3-hydroxybenzo[*e*]pyrido[4,3-*b*] indole **8** (2.3 g; 8.1 mmol) in DMF (60 mL) and K<sub>2</sub>CO<sub>3</sub> (5.6 g; 40 mmol). After 8 h at 0 °C, the mixture was kept under stirring at room temperature for 72 h. Water (250 mL) was added, and the mixture was extracted with ethyl acetate. Evaporation of the solvent gave a gum which was chromatographed on a silica column with a gradient of ethanol (0–1.5%) in CH<sub>2</sub>Cl<sub>2</sub> as eluent. A residue (1.77 g) was obtained, and it was submitted to hydrogenation in absolute ethanol (150 mL) in the presence of 10% palladium on activated charcoal (900 mg) and triethylamine (1.5 mL). After 48 h at room temperature, the catalyst was removed by filtration and washed with hot ethanol, and the filtrate was evaporated to dryness. To the residue was added 50 mL of water, and the pH was adjusted to 14 by 14% NH<sub>4</sub>OH. The precipitate was collected by filtration and washed with water, dried, and chromatographed on a neutral alumina column with a gradient of ethanol (0–2%) in CH<sub>2</sub>Cl<sub>2</sub> as eluent to give the titled compound **9** (1.3 g; 45%); <sup>1</sup>H NMR, δ 12.31 (s, 1H, NH), 9.87 (s, 1H, H-11), 8.94 (d, 1H, H-1), 8.54 (s, 1H, H-9), 8.18 (d, 1H, H-5), 8.04 (d, 1H, H-6), 7.82 (d, 1H, H-4), 7.63 (dd, 1H, H-2), 4.5–4.3 (m, 4H, OCH<sub>2</sub>CH<sub>2</sub> + CH<sub>2</sub>CH<sub>3</sub>), 2.86 (s, 3H, CH<sub>3</sub>-8), 2.9–2.8 (m, 2H, CH<sub>2</sub>CO), 2.4–2.3 (m, 2H, CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>), 1.46 (t, 3H, CH<sub>3</sub>CH<sub>2</sub>). Anal. Calcd for C<sub>22</sub>H<sub>22</sub>N<sub>2</sub>O<sub>3</sub>: C, 72.92; H, 6.07; N, 7.73. Found: C, 72.84; H, 5.96; N, 8.01. Similar preparation from 3-hydroxybenzopyridoindoles **8** or **12** and ethyl 4-bromobutyrate or ethyl 5-bromovalerate gave ester derivatives **10**, **13**, and **14**, respectively.

*Ethyl 5-(7H-benzo[*e*]pyrido[4,3-*b*]indol-3-yloxy)pentanoate* **10** was obtained in 47% yield; <sup>1</sup>H NMR, δ 12.07 (s, 1H, NH); 9.64 (s, 1H, H-11), 8.70 (d, 1H, H-1), 8.31 (s, 1H, H-9), 7.94 (d, 1H, H-5), 7.80 (d, 1H, H-6), 7.58 (d, 1H, H-4), 7.40 (dd, 1H, H-2), 4.2–4.0 (m, 4H, OCH<sub>2</sub>CH<sub>2</sub> + CH<sub>2</sub>CH<sub>3</sub>), 2.62 (s, 3H, CH<sub>3</sub>-8), 2.45 (t, 2H, CH<sub>2</sub>CO), 2.0–1.8 (m, 4H, OCH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>), 1.22 (t, 3H, CH<sub>3</sub>CH<sub>2</sub>). Anal. Calcd for C<sub>23</sub>H<sub>24</sub>N<sub>2</sub>O<sub>3</sub>·2 H<sub>2</sub>O: C, 70.05; H, 6.59; N, 7.10. Found: C, 70.16; H, 6.44; N, 6.92.

*Ethyl 4-(11H-benzo[*g*]pyrido[4,3-*b*]indol-3-yloxy)butanoate* **13** was obtained in 46% yield; <sup>1</sup>H NMR, δ 12.18 (s, 1H, NH), 9.24 (s, 1H, H-7), 8.67 (d, 1H, H-1), 8.3–8.2 (m, 2H, H-6+H-9), 7.68 (d, 1H, H-5), 7.54 (d, 1H, H-4), 7.38 (dd, 1H, H-2), 4.25–4.05 (m, 4H, OCH<sub>2</sub>CH<sub>2</sub> + CH<sub>2</sub>CH<sub>3</sub>), 2.67 (s, 3H, CH<sub>3</sub>-10), 2.5–2.4 (m, 2H, CH<sub>2</sub>CO), 2.2–2.0 (m, 2H, CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>), 1.23 (t, 3H, CH<sub>3</sub>CH<sub>2</sub>). Anal. Calcd for C<sub>22</sub>H<sub>22</sub>N<sub>2</sub>O<sub>3</sub>: C, 72.92; H, 6.07; N, 7.73. Found: C, 73.02; H, 6.14; N, 7.80.

*Ethyl 5-(11H-benzo[*g*]pyrido[4,3-*b*]indol-3-yloxy)pentanoate* **14** was obtained in 45% yield; <sup>1</sup>H NMR, δ 12.17 (s, 1H, NH), 9.24 (s, 1H, H-7), 8.67 (d, 1H, H-1), 8.3–8.2 (m, 2H, H-6+H-9), 7.67 (d, 1H, H-5), 7.54 (d, 1H, H-4), 7.38 (dd, 1H, H-2), 4.3–4.0 (m, 4H, OCH<sub>2</sub>CH<sub>2</sub> + CH<sub>2</sub>CH<sub>3</sub>), 2.66 (s, 3H, CH<sub>3</sub>-10), 2.45 (t, 2H, CH<sub>2</sub>CO), 1.9–1.7 (m, 4H, OCH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>), 1.22 (t, 3H, CH<sub>3</sub>CH<sub>2</sub>). Anal. Calcd for C<sub>23</sub>H<sub>24</sub>N<sub>2</sub>O<sub>3</sub>: C, 73.40; H, 6.38; N, 7.44. Found: C, 73.04; H, 6.53; N, 7.59.

**4. Saponification Reaction for the Production of the Acid Derivatives 3–6.** Preparation of 4-(7H-Benzo[*e*]pyrido[4,3-*b*]indol-3-yloxy)butanoic acid **3**: Example of the General Method. To a solution of NaOH (600 mg; 15 mmol) in water (30 mL) and ethanol (83 mL) was added the ester derivative **9** (1.0 g; 2.7 mmol), and the mixture was heated at reflux for 1 h. Evaporation to dryness under reduced pressure provided a solid residue, which was taken up in water (80 mL), and 1N HCl (15 mL) was added. The precipitate was collected by filtration and washed with water and dried, giving 900 mg (87%) of **3**;

<sup>1</sup>H NMR, δ 13.35 (s, 1H, NH), 12.20 (br.s, 1H, OH), 9.99 (s, 1H, H-11), 8.79 (d, 1H, H-1), 8.56 (s, 1H, H-9), 8.14 (d, 1H, H-5), 7.93 (d, 1H, H-6), 7.69 (d, 1H, H-4), 7.47 (dd, 1H, H-2), 4.21 (t, 2H, OCH<sub>2</sub>CH<sub>2</sub>), 2.76 (s, 3H, CH<sub>3</sub>), 2.55–2.45 (m, 2H, CH<sub>2</sub>CO), 2.2–2.0 (m, 2H, CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>). Anal. Calcd for C<sub>20</sub>H<sub>18</sub>N<sub>2</sub>O<sub>3</sub>·2.75 H<sub>2</sub>O: C, 62.58; H, 6.12; N, 7.30. Found: C, 62.41; H, 5.84; N, 7.24.

Similar preparation from ester derivatives **10**, **13**, and **14** gave acid derivatives **4**, **5**, and **6**, respectively.

*5-(7H-Benzo[*e*]pyrido[4,3-*b*]indol-3-yloxy)pentanoic acid* **4** was obtained in 98% yield; <sup>1</sup>H NMR, δ 12.89 (s, 1H, NH), 12.10 (br.s, 1H, OH), 9.84 (s, 1H, H-11), 8.75 (d, 1H, H-1), 8.45 (s, 1H, H-9), 8.06 (d, 1H, H-5), 7.88 (d, 1H, H-6), 7.64 (d, 1H, H-4), 7.44 (dd, 1H, H-2), 4.19 (t, 2H, OCH<sub>2</sub>CH<sub>2</sub>), 2.69 (s, 3H, CH<sub>3</sub>), 2.38 (t, 2H, CH<sub>2</sub>CO), 1.95–1.65 (m, 4H, OCH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>). **III. Preparation of the Activated Esters 15–18 of the BePI and BgPI Derivatives 3–6.** Compounds **3–6** individually (0.13 mmol) were placed in a round-bottomed flask, and anhydrous CH<sub>3</sub>CN (5 mL) was added. Triethylamine (0.1 mL) was added, and the reaction mixture was stirred at room temperature for 5 min and then concentrated to dryness. The process was repeated three times, and the obtained salt was dried overnight in a desiccator which was filled with argon before being opened. Dichloromethane (5 mL) triethylamine (1.1 equiv) and then pentafluorophenyltrifluoroacetate (1 equiv) were successively added. The reaction mixture became homogeneous under vigorous stirring. After 15 min stirring, silica gel TLC analysis using ethyl acetate/hexane and then CH<sub>3</sub>CN as eluent showed the formation of a new compound *R*<sub>f</sub> = 0.7–0.8 (blue-colored spot after spraying with a 2,6-dibromo-4-benzoquinone-*N*-chloroimine solution in ethanol). (Starting material *R*<sub>f</sub> = 0.) The reaction mixture was concentrated and the residue purified on a small silica gel column using an ethyl acetate/hexane (1:1, v/v) mixture and then CH<sub>3</sub>CN as eluent.

**Mass Analysis.** ESI, polarity-positive. Calcd for compound **15** C<sub>26</sub>H<sub>17</sub>N<sub>5</sub>O<sub>3</sub>F<sub>5</sub>: 500.16. Found: M + H = 501.2. **IV. Preparation of Iodoacetamido BePI Derivatives 19 and 20 from BePI Derivatives 1 and 2.** To modify the thiophosphate-containing oligonucleotides, two BePI derivatives with amino-containing linkers were transformed into activated acetamide derivatives following a previously published procedure (34). Compounds **19** and **20** were obtained as a pale yellow powder, after stirring

in hexane, with 75% yield. Silica gel TLC analysis using dichloromethane/methanol (90:10, v/v) mixture as eluent  $R_{f19} = 0.36$  (starting material  $R_f = 0$ ) and  $R_{f20} = 0.40$  (starting material  $R_f = 0$ ). Mass analysis. ESI, polarity-positive. Calcd for compound **19**  $C_{22}H_{23}N_4O_2I$ : 503.09. Found: M + H = 504.0.

**B. Synthesis of the Modified Oligo-2'-deoxyribonucleotides.** *I. Synthesis of Oligonucleotides 28–30 Containing Modified 2'-Deoxyuridine Involving a Linker Ending with cis Diol at the 5-Position.* *1. Synthesis of the Modified 2'-Deoxyuridine-Linker Derivative 27 (Scheme 3).* *3',5'-O-(Tetraisopropylidisiloxane-1,3-diyl)-5-N-(2,3-dihydroxypropyl)amino-2'-deoxyuridine 23.* To a solution of 5-bromo-2'-deoxyuridine **21** (1.58 g, 5 mmol) in anhydrous pyridine (20 mL) was added a solution of 1,3-dichloro-1,1,3,3-tetraisopropylidisiloxane (1.88 g, 6 mmol) in dry dichloromethane (10 mL) over 30 min under stirring. After 2 h of stirring at room temperature, the reaction was completed as shown by silica TLC analysis using dichloromethane/methanol (9:1, v/v) mixture as eluent ( $R_{f22} = 0.75$ ). The reaction mixture was quenched with 2 mL of methanol and the solvents removed under reduced pressure. The residue was dissolved with dichloromethane (70 mL) and washed with 5% aqueous sodium bicarbonate (3 × 70 mL). The organic phase was dried over  $Na_2SO_4$  and concentrated, and the residue was dried by coevaporation with toluene to leave a white foam. Yield 93% (2.21 g, 4.65 mmol). This product, **22**, was used in the next step without purification.

A solution of **22** (2.14 g, 4.5 mmol) and 3-amino-1,2-propanediol (4.2 g, 45 mmol) in ethanol (15 mL) was heated at 80 °C for 17 h. TLC analysis using the elution system reported above showed the formation of a new more polar product ( $R_{f23} = 0.2$ ). The solvent was evaporated under reduced pressure and the residue dissolved in ethyl acetate (50 mL) and washed with water (5 × 50 mL) to eliminate excess aminodiol. The organic solution was dried over  $Na_2SO_4$  and evaporated to dryness. Compound **23** was purified by silica gel column chromatography using dichloromethane/methanol (9:1, v/v) mixture as eluent. Yield: 76% (1.66 g, 3.42 mmol).  $^1H$  NMR ( $CDCl_3$ ),  $\delta$  ppm: 6.57 (s, 1H, H-6), 6.14 (m, 1H, H-1'), 4.55 (m, 1H, H-3'), 4.04 (m, 2H, H-4' + OH), 3.94 (t, 1H, NH), 3.78–3.60 (m, 3H, CH +  $CH_2$ ), 3.04 (d, 1H, OH), 3.00 (m, 2H, H-5', H-5''), 2.43 (m, 2H, H-2', H-2''), 2.30 (m, 2H,  $CH_2$ ), 1.09–1.06 (s, 28 H, 'Pr).

*5-N-(2,3-O-Dibenzoyloxypropyl)amino-2'-deoxyuridine 25.* To a stirred solution of **23** (1.56 g, 3.2 mmol) in anhydrous pyridine (20 mL) at 0 °C was added benzoyl chloride (1.12 mL, 1.35 g, 9.6 mmol) for 15 min, and the mixture was left under stirring for 2 h at room temperature. Methanol (2 mL) was added under cooling in an ice bath, and the resulting solution was poured into a 5% aqueous sodium bicarbonate solution (200 mL). The reaction mixture was extracted with dichloromethane (3 × 100 mL), the organic phases pooled, dried over  $Na_2SO_4$ , and concentrated to dryness, and the residue dried by coevaporation with toluene. Compound **24**, obtained as a yellow oil ( $R_{f24} = 0.85$  in the above-described TLC analysis system), was used in the next step without purification.

A solution of **24** in dry tetrahydrofuran (15 mL) was added to a 1.1 M solution of tetrabutylammonium fluoride in tetrahydrofuran (14 mL) with stirring. Silica gel TLC analysis using a dichloromethane/methanol (9:1, v/v) mixture as eluent showed complete reaction after 10 min with the apparition of a new spot ( $R_{f25} = 0.35$ ). The reaction was quenched by addition of a pyridine/methanol/water (3:1:1, v/v/v) mixture (15 mL), and a

suspension of Dowex 50W × 4-200 resin (pyridinium form) (15 g) was added in the above solvent mixture with gentle stirring. The final suspension was stirred for 0.5 h. The resin was filtered off and washed with the above-described solvent mixture (3 × 50 mL). The combined filtrates were evaporated to dryness under reduced pressure. Compound **25** was purified by silica gel column chromatography using 10% methanol in dichloromethane as eluent. Compound **25** was obtained as a white foam. Yield 72% (1.21 g, 2.30 mmol).  $^1H$  NMR ( $CDCl_3$ ),  $\delta$  ppm: 8.05–6.70 (m, 10 H, Ar-H), 5.70 (d, 1H, OH-3'), 5.30 (m, 1H, OH-5'), 3.44–3.30 (m, 3H, CH +  $CH_2$ ), 2.64 (m, 2H,  $CH_2$ ).

*5'-O-(4,4'-Dimethoxytrityl)-5-N-(2,3-O-dibenzoyloxypropyl)amino-2'-deoxyuridine-3'-O-(2-cyanoethyl)-N,N-diisopropylphosphoramidite 27.* Compound **25** (1.16 g, 2.2 mmol) was dried by coevaporation with anhydrous pyridine (3 × 10 mL), and a solution of 4,4'-dimethoxytrityl chloride (0.85 g, 2.5 mmol) in 10 mL of pyridine was added with exclusion of moisture. The reaction was quenched after 2 h by addition of methanol (1 mL), and the mixture was poured into a 5% aqueous sodium bicarbonate solution (70 mL). The crude product was extracted with dichloromethane (3 × 70 mL) and the organic phase pooled, dried over  $Na_2SO_4$ , and concentrated under reduced pressure. The residue was purified by silica gel column chromatography using a dichloromethane/methanol (98:2, v/v) mixture to give compound **26** ( $R_{f26} = 0.75$ , using the TLC analysis system described above). Yield: 90% (1.62 g, 1.98 mmol). Compound **26** (0.83 g, 1 mmol) was dried by coevaporation with anhydrous pyridine (5 mL) then with anhydrous  $CH_3CN$  (5 mL, three times) and left in a desiccator under vacuum overnight. The next day, the desiccator was filled with argon before its opening. The residue was solubilized with 1,2-dichloroethane (10 mL), and diisopropylethylamine (0.52 mL, 0.387 g, 3 mmol) was added, and then 2-cyanoethyldiisopropylchlorophosphoramidite (0.301 mL, 0.319 g, 1.35 mmol) was added dropwise under stirring at room temperature. After 15 min, silica gel TLC analysis using ethyl acetate/triethylamine mixture (95:5, v/v) mixture as eluent showed complete reaction, with the formation of two new spots corresponding to both isomers of the phosphoramidite derivative. The reaction mixture was diluted with methanol (1 mL) and after 10 min stirring concentrated to dryness. The residue was dissolved with ethyl acetate (50 mL) previously washed with a cold aqueous 10% sodium carbonate solution. The organic phase was washed with a cold 10% aqueous sodium carbonate solution (10 mL) and with cold saturated aqueous sodium chloride solution (10 mL), dried over  $Na_2SO_4$ , and concentrated to dryness. The residue was purified on a silica gel column using a ethyl acetate/triethylamine (99:1, v/v) mixture. After precipitation from hexane, compound **27** was obtained as a white powder. Yield 78% (0.8 g, 0.78 mmol).  $^1H$  NMR ( $CDCl_3$ ),  $\delta$  ppm: 7.94–6.76 (m, 23H, Ar), 6.2 (m, 1H, H1'), 5.25 (s, 1H, H-6), 4.75–3.25 (m, 5H, H-3', H-4', H-5', H-5'' + CH), 3.80 (s, 6H,  $OCH_3$ ), 3.60–3.23 (m, 8H,  $CH_2OH$  +  $CH_2OP$  +  $2CH$  +  $OCH_2$ ), 2.60–2.34 (m, 6H,  $CH_2CN$  + H-2', H-2'' + HN- $CH_2$ ), 1.17–1.12 (m, 12H, 4  $CH_3$ ).

*2. Synthesis of the Modified Oligo-2'-deoxyribonucleotides 28–30 Involving Modified 2'-Deoxyuridine Containing a Linker Ending with cis Diol (Scheme 3).* The oligo-2'-deoxyribonucleotides were assembled using classical phosphoramidite chemistry on a CPG support at a  $\mu$ mol scale. To introduce the modified 2'-deoxyuridine residue into the oligonucleotides, an automated prolonged coupling step (5 min) was used for compound **27**.

**Table 1.**  $\lambda$  Max Values for Oligo-2'-deoxyribonucleotide–BePI and Oligo-2'-deoxyribonucleotide–BgPI Conjugates, Retention Times<sup>a</sup> for the Modified Oligonucleotides 28–32 and for the Oligo-2'-deoxyribonucleotide–BePI and Oligo-2'-deoxyribonucleotide–BgPI Conjugates II–X, and  $T_m$  Values for Triplexes Formed between Various Conjugates and the Double-Stranded Target<sup>b,c</sup>

<sup>a</sup> Obtained by reversed-phase HPLC analyses, performed on a Lichrospher 100 RP18 (5  $\mu$ M) column (125 mm  $\times$  4 mm) from Merck using a linear gradient of CH<sub>3</sub>CN (12.5–31.25% over 15 min for compounds **28–32** and **I–VI**) and (8–32% over 30 min for compounds **11–12** and **VII–X**) in 0.1 M aqueous triethylammonium acetate, pH 7, with a flow rate of 1 mL/min. <sup>b</sup> In a 10 mM sodium cacodylate, pH 6, containing 100 mM NaCl and 10 mM MgCl<sub>2</sub>. <sup>c</sup> Oligonucleotide concentrations were 1  $\mu$ M of the duplex target D (with a 1/1.2 ratio of purine/pyrimidine-containing strands), and 1.5  $\mu$ M of the third strand. n.m. = not measured.

<sup>d</sup> For these conjugates a weak absorption is observed between 320 and 420 nm, and the  $\lambda_{\text{max}}$  of the UV band is slightly red-shifted as compared to the UV  $\lambda_{\text{max}}$  of other conjugates.

The average coupling efficacy was 85–95%. The deprotection step was performed by 28% aqueous ammonia treatment for 3 h at 55°C or for 18 h at 20°C. Purifications were performed either on 20% PAGE in denaturing conditions or by reversed-phase HPLC (see legend for Table 1). Oligonucleotides **28** and **29** with one modified 2'-deoxyuridine or oligonucleotide **30** with two modified 2'-deoxyuridines gave the following retention times: 6 min 10 s, 5 min 56 s, and 6 min 58 s.

**II. Synthesis of Oligonucleotides 31 and 32 Containing Modified 2'-Deoxyuridine Involving a Linker at the 5-Position Ending with an Amino Function.** Oligonucleotides **31** and **32** were obtained via phosphoramidite chemistry using the Amino-Modifier C2 dT from Glen Research. Deprotection and purification steps were performed using classical procedures. Retention times obtained by reversed-phase analysis are given in Table 1

**III. Synthesis of the Modified Oligonucleotide 43 Involving the Sugar-Linker Derivative between the Second and the Third Nucleotides.** 1. **Synthesis of the 2'-Deoxyribose-Linker Derivatives 42** (Scheme 4). *N*-Fmoc-3-aminopropan-1-ol **33**. To a 9-fluorenylmethyl chloroformate (2.058 g, 10 mmol) solution in dry ether (120 mL) was added dropwise, under stirring at 0°C, a solution of 3-amino-1-propanol (0.75 g, 20 mM) in 1,2-dichloroethane (30 mL) over 10 min. The mixture was maintained at 0°C for 20 min and then left to warm to room temperature for 20 min. Silica gel TLC analysis using a hexane/ethyl acetate (1:1, v/v) mixture as eluent showed complete reaction with a new spot ( $R_{33}$  = 0.2). The mixture was concentrated to dryness, and then dichloromethane (60 mL) was added. The organic phase was washed with H<sub>2</sub>O (15 mL, twice). The organic phase was dried over Na<sub>2</sub>SO<sub>4</sub> and then concentrated to dryness. The residue was

purified on a silica gel column using dichloromethane/methanol (99:1, v/v, then 98:2, v/v) as eluent. Yield 90% (1.62 g, 9 mmol). <sup>1</sup>H NMR (CDCl<sub>3</sub>),  $\delta$  ppm: 7.77–7.26 (m, 8H, Ar), 5.03 (s, 1H, NH), 4.43 (d, 2H,  $J$  = 6.64 Hz, O–CH<sub>2</sub>), 4.20 (t, 1H fmoc,  $J$  = 6.6 Hz), 3.64 (d, 2H,  $J$  = 5.48, CH<sub>2</sub>), 3.34 (d, 2H,  $J$  = 5.92 CH<sub>2</sub>), 1.69 (t, 2H,  $J$  = 5.64, CH<sub>2</sub>).

*1'*-Deoxy-1'-(*N*-fmoc-3-aminopropyl)-2,3,5-tri-*O*-acetyl- $\beta$ -D-ribofuranose **35**. Compound **33** (3.12 g, 10.5 mmol) and  $\beta$ -D-ribofuranose 1,2,3,5-tetraacetate **34** (3.18 g, 10 mmol) were dried overnight in a desiccator containing P<sub>2</sub>O<sub>5</sub>. The mixture was partially dissolved by addition of 1,2-dichloroethane (85 mL) and cooled to –10°C with an NaCl-ice bath, and trimethylsilyltrifluoromethanesulfonate (2.17 mL, 2.67 g, 12 mmol) was added slowly with a syringe over 10 min. The reaction mixture was stirred for 15 min at –10°C and then for 1 h at room temperature. Silica gel TLC in hexane/ethyl acetate (1:1, v/v) showed complete reaction with a new spot  $R_{35}$  = 0.46 and a side product with  $R_f$  = 0.63. The reaction mixture was cooled, pyridine (8 mL) was added, and the mixture was left to react for 15 min. The reaction mixture was then concentrated to dryness, the residue solubilized with dichloromethane (100 mL), and the organic phase washed with a 5% aqueous sodium hydrogenocarbonate solution (20 mL) and then with saturated sodium chloride aqueous solution (20 mL). The organic phase was dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated to dryness. The residue was purified on a silica gel column using a hexane/ethyl acetate mixture (60:40, v/v) then (55:45, v/v) as eluent. Yield 30% (1.7 g, 3.15 mmol).

<sup>1</sup>H NMR (CDCl<sub>3</sub>),  $\delta$  ppm: 7.76–7.25 (m, 8H, Ar), 5.22 (d, 1H,  $J$  = 3.73, H-1'), 5.13 (br s, 1H, NH), 4.38 (d, 2H,  $J$  = 6.58 O–CH<sub>2</sub>), 4.31–4.10 (m, 5H, H-3', H-4', H-5', H-5'' + C–H fmoc), 3.85–3.72 (m, 2H, CH<sub>2</sub>), 3.50–3.15 (m, 3H, CH<sub>2</sub>O, H-2'), 2.1–2.00 (m, 9H, CH<sub>3</sub>–C(O)), 1.83–1.70 (m, 2H, CH<sub>2</sub>).

*1'*-Deoxy-1'-(*N*-fmoc-3-aminopropyl)- $\beta$ -D-ribofuranose **36**. Compound **35** (2 g, 3.6 mmol) was dissolved at room temperature in a 0.1 M solution of KCN in methanol (105 mL, 3.6 mmol). After 1 h stirring, silica gel TLC analysis using hexane/ethyl acetate (1:1, v/v) mixture as eluent, showed complete reaction with a new spot  $R_{36}$  = 0.21. The solution was evaporated to dryness. The residue was solubilized with dichloromethane (80 mL) and the organic phase was washed with a 5% aqueous sodium hydrogenocarbonate solution (15 mL) and water (15 mL), dried over Na<sub>2</sub>SO<sub>4</sub>, and concentrated to dryness. The residue was purified on a silica gel column using a dichloromethane/methanol (97:3, v/v) mixture as eluent. Yield 70% (1 g, 2.52 mmol). <sup>1</sup>H NMR (CDCl<sub>3</sub>),  $\delta$  ppm: 7.77–7.24 (m, 8H, Ar), 5.8 (br s, 1H, NH), 5.3 (m, 1H, H1'), 4.36 (d, 2H,  $J$  = 3.22 Hz, O–CH<sub>2</sub>), 4.14 (m, C–H fmoc), 4.17–3.60 (m, 7H, H-3', H-4', H-5', H-5'' + 3 OH), 3.44–3.10 (m, 5H, CH<sub>2</sub>, H-2' + CH<sub>2</sub>O), 1.70–1.60 (m, 2H, CH<sub>2</sub>).

*1'*-Deoxy-1'-(*N*-fmoc-3-aminopropyl)-3,5-*O*-(tetraisopropylidisiloxane-1,3-diyl)- $\beta$ -D-ribofuranose **37**. Compound **36** (0.9 g, 2 mmol) and imidazole (0.57 g, 8 mmol) were dried by coevaporation with anhydrous pyridine (10 mL, three times) and left overnight in a desiccator containing P<sub>2</sub>O<sub>5</sub>. The residue was solubilized with anhydrous pyridine (20 mL), and 1,3-dichloro-1,1,3,3-tetraisopropylidisiloxane (0.73 mL, 0.72 g, 2.2 mmol) in 1,2-dichloromethane solution (1 mL) was added dropwise at 0°C under stirring. The reaction mixture was left to react at room temperature, under stirring, for 1 h. Silica gel TLC analysis using a hexane/ethyl acetate (1:1, v/v) mixture as eluent showed complete reaction with a new spot  $R_{37}$  = 0.75. Methanol (5 mL) was added and the stirring maintained for 15 min.

The reaction mixture was concentrated to dryness, and the residue was dissolved with dichloromethane (60 mL). The organic phase was washed with a 5% aqueous sodium hydrogenocarbonate solution (15 mL) and with water (15 mL), dried over  $\text{Na}_2\text{SO}_4$ , and concentrated to dryness. The residue was purified on a silica gel column using a dichloromethane and then a dichloromethane/methanol (98:2, v/v) mixture as eluent. Yield 85% (1.2 g, 1.7 mmol).

$^1\text{H}$  NMR ( $\text{CDCl}_3$ ),  $\delta$  ppm: 7.77–7.26 (m, 8H, Ar), 5.09 (m, 1H, H-1'), 4.92 (br s, 1H, NH), 4.52–4.49 (m, 2H, H-5', H-5''), 4.39 (d, 2H,  $J = 6.9$  Hz, O-CH<sub>2</sub>), 4.24–4.18 (m, 1H, CH-fmoc), 4.07–3.7 (m, 5H, OH, H-3', H-4' + CH<sub>2</sub>O), 3.50–3.15 (m, 3H, CH<sub>2</sub>N, H-2'), 1.76 (m, 2H, CH<sub>2</sub>), 1.15–1.03 (m, 28H,  $^i\text{Pr}$ ).

*1'-Deoxy-1'-(N-fmoc-3-aminopropyl)-2'-O-phenoxythiocarbonyl-3,5'-O-(tetraisopropylidisiloxane-1,3-diyl)- $\beta$ -D-ribofuranose 38.* Compound **37** (1.2 g, 1.8 mmol) was dried by coevaporation with anhydrous pyridine (10 mL, three times). The residue was solubilized with anhydrous pyridine (20 mL), and phenylchlorothionoformate (0.37 mL, 0.46 g, 27 mmol) was added under stirring. The reaction mixture was stirred for two additional hours. Silica gel TLC analysis using a hexane/ethyl acetate (5:2, v/v) mixture as eluent showed complete reaction with a new spot  $R_{38} = 0.55$  (starting material  $R_{37} = 0.33$ ). The reaction mixture was concentrated to dryness under vacuum and the residue dissolved with dichloromethane (60 mL). The organic phase was washed with a 5% aqueous sodium hydrogenocarbonate solution (15 mL) and with water (15 mL), dried over  $\text{Na}_2\text{SO}_4$ , and concentrated to dryness. The residue was purified on a silica gel column using a hexane:ethyl acetate (5:0.5 to 5:2, v/v) mixture as eluent. Yield 71% (1 g, 1.27 mmol).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ),  $\delta$  ppm: 7.77–7.10 (m, 8H, Ar), 5.71 (m, 1H, H-1'), 5.08 (br s, 1H, NH), 4.68–4.72 (m, 1H, H-5'), 4.40 (d, 2H,  $J = 5.61$  Hz, O-CH<sub>2</sub>), 4.26–4.19 (m, 1H, CH fmoc), 4.04–3.70 (m, 3H, H-3', H-4', H-5''), 3.56–3.14 (m, 5H, CH<sub>2</sub>O + CH<sub>2</sub>N + H-2'), 1.80–1.70 (m, 2H, CH<sub>2</sub>), 1.15–1.00 (m, 28H,  $^i\text{Pr}$ ).

*1'-Deoxy-1'-(N-fmoc-3-aminopropyl)-3,5'-O-(tetraisopropylidisiloxane-1,3-diyl)- $\beta$ -D-2'-deoxyribofuranose 39.* Compound **38** (0.8 g, 1 mmol) was coevaporated three times with dry toluene (10 mL). The residue was left in a desiccator for 3 h, which was then filled with argon before its opening. The residue was solubilized with freshly distilled toluene (over  $\text{P}_2\text{O}_5$ ). Tributyltin hydride (0.4 mL, 0.43 g, 1.5 mmol) was added at room temperature and then  $\alpha$ ,  $\alpha'$ -azaisobutyronitrile (0.05 g, 0.3 mmol). The mixture was stirred for a few min at room temperature and then refluxed for 1 h. Another amount of  $\alpha$ ,  $\alpha'$ -azaisobutyronitrile (0.03 g, 0.2 mmol) was added, and the mixture was refluxed for an additional 1 h. Silica gel TLC analysis using a dichloromethane/methanol (98:2, v/v) mixture as eluent showed complete reaction with a new spot  $R_{39} = 0.83$  (starting material  $R_f = 0.90$ ). The reaction mixture was concentrated to dryness under vacuum and the residue dissolved with dichloromethane (50 mL). The organic phase was washed with a 5% aqueous sodium hydrogenocarbonate solution (10 mL) and with water (10 mL), dried over  $\text{Na}_2\text{SO}_4$  and concentrated to dryness. The residue was purified on a silica gel column using a dichloromethane/ethyl acetate (98:2 to 96:4, v/v) mixture as eluent. Yield: 66% (0.43 g, 0.66 mmol).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ),  $\delta$  ppm: 7.77–7.28 (m, 8H, Ar), 5.23 (br s, 1H, NH), 5.03 (m, 1H, H-1'), 4.70–4.60 (m, 1H, H-5'), 4.36 (d, 2H,  $J = 6.10$  Hz, O-CH<sub>2</sub>), 4.22–4.19 (m, 1H, CH fmoc), 4.05–3.66 (m, 3H, H-3', H-4', H-5''),

3.35–3.21 (m, 4 H, CH<sub>2</sub>O + CH<sub>2</sub>N), 2.30–2.05 (m, 2H, H-2', H-2''), 1.80–1.71 (m, 2H, CH<sub>2</sub>), 1.14–0.98 (m, 28 H,  $^i\text{Pr}$ ).

*1'-Deoxy-1'-(N-fmoc-3-aminopropyl)- $\beta$ -D-2'-deoxyribofuranose 40.* Compound **39** (0.43 g, 0.66 mmol) was dried by coevaporation with  $\text{CH}_3\text{CN}$  (10 mL, three times). The residue was solubilized with anhydrous THF (6 mL), and the reaction mixture was cooled to 0 °C with an ice–water bath. Tetrabutylammonium fluoride (1.3 mL of 1.1 M solution in THF, 1.3 mmol) was added. The reaction mixture was stirred for 15 min at 0 °C. Silica gel TLC in dichloromethane/methanol (90:10, v/v) showed complete reaction with a new spot  $R_{40} = 0.44$  (starting material  $R_f = 0.88$ ). The reaction mixture was diluted with water (1 mL) and concentrated to dryness. The residue was purified on a silica gel column using a dichloromethane/ethyl acetate (98:2 to 96:4, v/v) mixture as eluent. Yield 70% (0.19 g, 0.46 mmol).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ),  $\delta$  ppm: 7.77–7.28 (m, 8H, Ar), 5.21–5.16 (m, 2H, H1', NH), 4.48–4.41 (m, 3H, H-5' + O-CH<sub>2</sub>), 4.20 (m, 1H, CH fmoc), 4.01–3.99 (m, 1H, OH), 3.84–3.54 (m, 4H, H-3', H-4', H-5'', OH), 3.47–3.24 (m, 4 H, 2 CH<sub>2</sub>), 2.23–2.07 (m, 2H, 2', 2''), 1.77–1.73 (m, 2H, CH<sub>2</sub>).

*1'-Deoxy-1'-(N-fmoc-3-aminopropyl)- $\beta$ -D-2'-deoxyribofuranose-5'-O-(4,4'-dimethoxytrityl) 41.* Compound **40** (0.070 g, 0.17 mmol) was coevaporated with anhydrous pyridine (5 mL, three times). The residue was solubilized with pyridine (5 mL), and dimethoxytritylchloride (170 mg, 0.5 mmol) was added under stirring. Silica gel TLC analysis using a dichloromethane/methanol (90:10, v/v) mixture as eluent showed complete reaction with a new spot  $R_{41} = 0.75$  (starting material  $R_f = 0.44$ ). The reaction mixture was diluted with methanol (1 mL) and after 15 min stirring concentrated to dryness. The residue was dissolved with dichloromethane (20 mL). The organic phase was washed with a 5% aqueous sodium hydrogenocarbonate solution (5 mL) and with water (5 mL), dried over  $\text{Na}_2\text{SO}_4$ , and concentrated to dryness. The residue was purified on a silica gel column using dichloromethane and then a dichloromethane/methanol (99:1, v/v) mixture as eluent. Yield 72% (0.086 g, 0.124 mmol).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ),  $\delta$  ppm: 7.76–6.78 (m, 21 H Ar), 5.11 (m, 1H, H-1'), 4.93 (br s, 1H, NH), 4.36 (d, 2H,  $J = 6.77$  Hz, O-CH<sub>2</sub>), 4.19–4.17 (m, 1H, CH fmoc), 4.0–3.98 (m, 1H, OH), 3.77–3.66 (m, 6H, H-3', H-4', H-5', H-5'' + CH<sub>2</sub>O), 3.75 (s, 6H, OCH<sub>3</sub>), 3.12–3.07 (m, 2H, CH<sub>2</sub>N), 2.17–2.02 (m, 2H, H-2', H-2''), 1.61–1.56 (m, 2H, CH<sub>2</sub>).

*1'-Deoxy-1'-(N-fmoc-3-aminopropyl)- $\beta$ -D-2'-deoxyribofuranose-5'-O-(4,4'-dimethoxytrityl)-3'-O-(2-cyanoethyl N,N-diisopropylphosphoramidite 42.* Compound **41** (0.08 g, 0.11 mmol) was dried by coevaporation with anhydrous pyridine (5 mL, twice) and then with anhydrous  $\text{CH}_3\text{CN}$  (5 mL, twice) and left in a desiccator under vacuum overnight. The next day the desiccator was filled with argon before its opening. The residue was solubilized with 1,2-dichloroethane (2 mL); then diisopropylethylamine (0.1 mL, 0.072 g, 0.55 mmol) was added, and finally 2-cyanoethyl diisopropylchlorophosphoramidite (0.040 g, 0.165 mmol) was added dropwise under stirring at room temperature. After 20 min, silica gel TLC analysis using a ethyl acetate/triethylamine (95:5, v/v) mixture as eluent showed complete reaction with the formation of a new spot  $R_{42} = 0.82$  (starting material  $R_{41} = 0.61$ ). The residue was dissolved with ethyl acetate (5 mL) previously washed with a cold aqueous 10% sodium carbonate solution. The organic phase was washed with a cold 10% aqueous sodium carbonate solution (5 mL) and with a cold saturated aqueous sodium chloride solution (5 mL), dried over  $\text{Na}_2\text{SO}_4$ , and concentrated to dryness. The

residue was purified on a silica gel column using a dichloromethane/triethylamine (99:1, v/v) mixture as eluent. The collected product was dried in a desiccator overnight, solubilized with ethyl acetate (3 mL), and precipitated in anhydrous hexane (50 mL) at  $-70^{\circ}\text{C}$ . Yield 85% (0.085 g, 0.093 mmol).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ ),  $\delta$  ppm: 7.76–6.78 (m, 21H, Ar), 5.20 (m, 1H, H1'), 5–4.90 (br s, 1H, NH), 4.34 (d, 2H,  $J = 7.04$  Hz, O–CH<sub>2</sub>), 4.27–4.16 (m, 1H, fmoc), 3.75–3.13 (m, 12H, H-3', H-4', H-5', H-5'' + 3CH<sub>2</sub> + 2CH), 3.74 (s, 6H, OCH<sub>3</sub>), 2.56 (t, 2H,  $J = 6.45$  Hz, CH<sub>2</sub>CN), 2.20–2.17 (m, 2H, H-2', H-2''), 1.65–1.63 (m, 2H, CH<sub>2</sub>), 1.17–1.12 (m, 12H, 4 CH<sub>3</sub>).

$^{31}\text{P}$  NMR ( $\text{CDCl}_3$ ),  $\delta$  ppm: 149.3–150 ppm.

**2. Preparation of the Modified Oligo-2'-deoxyribonucleotide 43 Involving the Sugar-Linker Derivative between the Second and the Third Nucleotides.** The oligo-2'-deoxyribonucleotide was assembled using classical phosphoramidite chemistry on a CPG support at a  $\mu\text{mol}$  scale. To introduce the modified 2'-deoxyribose-linker residue into the oligonucleotide, a manual coupling step (10 min) was used for compound **42**. The coupling efficacy was 85–95%. The deprotection step was performed by 28% aqueous ammonia treatment for 18 h at  $20^{\circ}\text{C}$ . Purification was performed by ion exchange chromatography on a DEAE column (8  $\mu\text{m}$ , 100 mm  $\times$  10 mm, Waters) using a linear gradient of NaCl (0 to 0.725 M over 30 min) in Tris/HCl pH 7, 25 mM buffer containing 10% MeOH. After the desalting and detritylation steps (using an 80% acid acetic treatment for 20 min), reversed-phase chromatography analyses were performed on a Lichrospher 100 RP18 (5  $\mu\text{m}$ ) column (125 mm  $\times$  4 mm) from Merck with a linear gradient of CH<sub>3</sub>CN (12.5–35% over 30 min) in 0.1 M aqueous triethylammonium acetate, pH 7, with a flow rate of 1 mL/min. One peak was obtained with  $t_{\text{R}43} = 5$  min.

**IV. Synthesis of Modified Oligonucleotides Involving One or Two Internucleotidic Thiophosphate Groups 44 and 45, Respectively.** The oligonucleotides involving one or two phosphorothioate groups were assembled using classical phosphoramidite chemistry at the  $\mu\text{mol}$  scale, except that at the site preselected for the introduction of a phosphorothioate group, the oxidation step by iodine was replaced by a sulfuration step using a 15 min treatment with a 0.5 M tetraethylthiuram disulfide solution in anhydrous CH<sub>3</sub>CN (35). The deprotection step was carried out using aqueous concentrated (28%) ammonia treatment overnight at room temperature. Purification was performed by reversed-phase chromatography or 20% PAGE in denaturing conditions. In the case of monothiophosphate, oligonucleotides were eluted as two peaks with very close retention times ( $t_{\text{R}} = 5$  min 36 s and  $t_{\text{R}} = 6$  min) corresponding to the two diastereoisomers. In the case of oligonucleotides with two phosphorothioate groups, three main peaks were observed by reversed-phase analysis (see Table 2) corresponding to the mixture of isomers. 20% PAGE analysis in denaturing conditions (Figure 7) exhibited only one band for the mixture of isomers of either the monophosphorothioate oligonucleotide **44** (lane 1) or the diphosphorothioate-containing oligonucleotide **45** (lane 4) with very close mobilities for oligonucleotides **44** and **45**.

**C. Preparation of the Oligo-2'-deoxyribonucleotide-intercalator Conjugates II–XXI. I. Base-Linked BePI Derivatized Oligo-2'-deoxyribonucleotides II–VI (Figure 2).** Diol-containing oligonucleotide **28**, **29**, or **30** (25–50 nmol) were oxidized with a 20 mM sodium periodate solution (25  $\mu\text{L}$ ) for 1 h at room temperature. The resulting aldehyde-containing oligonucleotide was

<sup>a</sup> Obtained by reversed-phase HPLC analyses, performed on a Lichrospher 100 RP18 (5 mM) Column (125 mm  $\times$  4 mm) from Merck using a linear gradient of CH<sub>3</sub>CN (12.5–31.25% over 15 min) in 0.1 M aqueous triethylammonium acetate, pH 7, with a flow rate of 1 mL/min. <sup>b</sup> Conditions used are the same as described in Table 1. <sup>c</sup> n.m. = not measured. <sup>d</sup> For these conjugates a weak absorption is observed between 320 and 420 nm and the  $\lambda_{\text{max}}$  of the UV band is slightly red-shifted as compared to the UV  $\lambda_{\text{max}}$  of other conjugates.

precipitated as cetyl trimethylammonium salt, washed with water (50  $\mu\text{L}$ ) and redissolved in methanol (50  $\mu\text{L}$ ). A solution of a BePI reagent (0.1 M in methanol) (25–50  $\mu\text{L}$ ) was then added and then sodium cyanoborohydride in a 0.5 M aqueous sodium acetate solution (1 mg in 10  $\mu\text{L}$ ), pH 5. The mixture was allowed to rest for 24 h at  $40^{\circ}\text{C}$ . Next, a 0.1 M SDS solution in methanol (10  $\mu\text{L}$ ) was added, followed by addition of water (500  $\mu\text{L}$ ). Excess BePI was extracted with *n*-butanol (3  $\times$  300  $\mu\text{L}$ ), and the oligonucleotide–BePI conjugate was precipitated with a 4% lithium perchlorate solution in acetone. PAGE analysis showed the formation of a slower migrating band with a visible fluorescence at  $\lambda = 350$  nm. The reaction yields of the reaction usually reached 60–85% as determined for the HPLC-purified oligonucleotide–BePI conjugates. Retention times are given in Table 1. The oligonucleotide–BePI conjugates **II** to **VI** were characterized by UV–visible spectroscopy.  $\lambda_{\text{max}}$  values are given in Table 1. Absorption spectra recorded between 230 and 420 nm of the oligonucleotide–BePI conjugates **II** and **VI** are shown in Figure 3A.

**II. Base-Linked BePI and Base-Linked BgPI Derivatized Oligo-2'-deoxyribonucleotides VII–X (Figure 4) and Sugar-Linked BePI and BgPI Derivatized Oligo-2'-deoxyribonucleotides XI–XIV (Figure 5).** Oligonucleotide **31**, **32**, or **43** (7 OD units) was dissolved in anhydrous DMSO

**Figure 2.** Oligo-2'-deoxyribonucleotide-BePI conjugates **II**–**VI** with linkage of the intercalators at the 5-position of a 2'-deoxyuridine residue.

**Figure 3.** Absorption spectra recorded between 230 and 420 nm of the oligo-2'-deoxyribonucleotide-BePI conjugates **II** (full line) and **VI** (dotted line) (A), oligo-2'-deoxyribonucleotide-BePI conjugate **VIII** (dotted line) and oligo-2'-deoxyribonucleotide-BgPI conjugate **IX** (full line) (B), oligo-2'-deoxyribonucleotide-BePI conjugate **XII** (full line) and oligo-2'-deoxyribonucleotide-BgPI conjugate **XIII** (dotted line) (C), and oligo-2'-deoxyribonucleotide-BePI conjugates **XV** (full line) and **XIX** (dotted line) (D).

(50  $\mu\text{L}$ ) containing diisopropylethylamine (5  $\mu\text{L}$ ). The activated ester (10 equiv) solubilized with DMSO (50  $\mu\text{L}$ ) was added. The mixture was left at room-temperature overnight. The reaction mixture was precipitated by addition of a 3% solution of lithium perchlorate in acetone. The precipitate was washed twice with acetone and solubilized with water. The residue was purified by reversed-phase chromatography on a Lichrospher 100 RP18 (5  $\mu\text{M}$ ) column (125 mm  $\times$  4 mm) from Merck with a linear gradient of  $\text{CH}_3\text{CN}$  in 0.1 M aqueous triethylammonium acetate, pH 7, with a flow rate of 1 mL/min. Retention times obtained for the purified conjugates by

reversed-phase analysis performed on the same column but using different linear gradients of  $\text{CH}_3\text{CN}$  are given in Tables 1 and 2. The oligonucleotide-BePI and oligonucleotide-BgPI conjugates **VII**–**XIV** were characterized by UV-visible spectroscopy.  $\lambda_{\text{max}}$  values are given in Tables 1 and 2. Absorption spectra recorded between 230 and 420 nm of the oligonucleotide-BePI conjugates **XIII** and oligonucleotide-BgPI conjugate **IX** are shown in Figure 3B. Absorption spectra recorded between 230 and 420 nm of the oligonucleotide-BePI conjugates **XII** and oligonucleotide-BgPI conjugate **XIII** are shown in Figure 3C.

**Figure 4.** Oligo-2'-deoxyribonucleotide-BePI and oligo-2'-deoxyribonucleotide-BgPI conjugates **VII–X** with linkage of the intercalators at the 5-position of a 2'-deoxyuridine residue.

**III. Internucleotidic Thiophosphate-Linked BePI-Derivatized Oligo-2'-deoxyribonucleotides **XV–XX**** (Figure 6). To a water solution of oligonucleotides **44** or **45** (sodium salt) (25–50 nmol) (10  $\mu\text{L}$ ) were added 15-crown 5 (2  $\mu\text{L}$ ) and methanol (50  $\mu\text{L}$ ) to obtain a homogeneous solution. A BePI reagent solution (0.1 M in methanol) (25–50  $\mu\text{L}$ ) was then added, and the mixture was allowed to rest for 48 h at 40  $^{\circ}\text{C}$ . Oligonucleotide-BePI conjugates were precipitated with a 4% lithium perchlorate solution in acetone and purified by reversed-phase chromatography. Yields of purified conjugates usually reached 50–60%. In addition 20% PAGE analysis in denaturing conditions (see Figure 7) indicated that the coupling of oligonucleotide **44** (lane 1) with the BePI derivative **1** gave a new band with lower mobility as compared to that of oligonucleotide **44**. The mobilities for oligonucleotide-BePI conjugates **XV** (lane 2) and **XVI** (lane 3) (corresponding to each stereoisomer at the phosphorus level) were similar. The coupling of oligonucleotide **45** involving two phosphorothioate groups (mixture of stereoisomers) (lane 4) with two BePI derivatives **1** (compound **XIX**) gave a new band (lane 5) with a retarded mobility as compared to those of the conjugates **XV** and **XVI**. The oligonucleotide-BePI conjugates were characterized by UV-visible spectroscopy.  $\lambda_{\text{max}}$  values are given in the Table 1. Oligonucleotide-BePI conjugates **XVII**, **XVIII**, and **XX** involving BePI derivative **2** with a longer linker were obtained and characterized as described above for the preparation of conjugates **XV**, **XVI**, and **XIX** (see Table 2). Absorption spectra recorded between 230 and

420 nm of the oligonucleotide-BePI conjugates **XV** and **XIX** are shown in Figure 3D.

**IV. Internucleotidic Phosphoramidite linked-BePI Derivatized Oligo-2'-deoxyribonucleotide **XXI**** (Figure 6). The oligo-2'-deoxyribonucleotide was assembled using classical phosphoramidite chemistry on a CPG support at a  $\mu\text{mol}$  scale except that at the site selected for the introduction of the intercalator linker residue, a coupling step using H-phosphonate chemistry was manually performed. The syntheses were performed as follows. After the assembly of the first three nucleotides, an additional detritylation step was performed. 5'-O-(4,4'-dimethoxytrityl)- $\beta$ -thymidine-3'-H-phosphonate (0.05 g, 0.056 mmol) in a pyridine/ $\text{CH}_3\text{CN}$  (50:50, v/v) mixture (0.4 mL) and pivaloyl chloride (0.02 g, 0.166 mmol) in a pyridine/ $\text{CH}_3\text{CN}$  (50:50, v/v) mixture (0.5 mL) were then added simultaneously to the trinucleotide bound to the support. After a 2.5 min reaction, the solution was removed and the support washed with an anhydrous pyridine/ $\text{CH}_3\text{CN}$  (50:50, v/v) mixture (1 mL, three times). Then BePI derivative **1** (0.135 g, 0.87 mmol) solubilized by a pyridine/ $\text{CCl}_4$  (50:50, v/v) mixture (1 mL) was added. After 1 h, the solution was removed and the support washed with an anhydrous pyridine/ $\text{CH}_3\text{CN}$  (50:50, v/v) mixture (1 mL) three times and then with anhydrous  $\text{CH}_3\text{CN}$  (1 mL) three times. The support was treated with a mixture of capping solutions used on the synthesizer (0.5 mL each) for 10 min, washed with  $\text{CH}_3\text{CN}$  (1 mL, four times), and dried. The oligonucleotide chain assembly was completed via phosphoramidite chemistry to give the fully protected

**Figure 5.** Oligo-2'-deoxyribonucleotide-BePI and oligo-2'-deoxyribonucleotide-BgPI conjugates **XI–XIV** with linkage of the intercalators at the  $\beta$ -anomeric position of a 2'-deoxyribose residue.

oligo-2'-deoxyribonucleotide bound to the support bearing the BePI derivative at the seventh internucleotidic phosphate. At the end of the chain assembly, an additional detritylation step was performed to deblock the 5'-terminal hydroxyl function. The deprotection step was completed by overnight concentrated ammonia treatment at room temperature. Purification was performed by 20% PAGE in denaturing conditions. After the desalting steps, reversed-phase chromatography analyses were performed on a Lichrospher 100 RP18 (5  $\mu$ M) column (125 mm  $\times$  4 mm) from Merck with a linear gradient of CH<sub>3</sub>CN (12.5–35% over 30 min) in 0.1 M aqueous triethylammonium acetate, pH 7, with a flow rate of 1 mL/min.

**V.  $T_m$  Measurements by UV Absorption Experiments.** UV melting curves were obtained using a UVikon 940 spectrophotometer interfaced to an IBM computer. The temperature of the cell holders was regulated by an 80% water/20% ethylene glycol circulating liquid. Sample temperature was decreased from 70 to 0  $^{\circ}$ C and increased back to 80  $^{\circ}$ C at 0.2  $^{\circ}$ C/min with absorption readings at 260 and 440 nm taken every 1–1.2  $^{\circ}$ C. Samples were kept for an additional 30 min at the lowest and highest temperature. Experiments were carried out using a double-stranded DNA target (5'-CCACTTTTAAAGAA-AAGGGGGACTGG-3' / 3'-GGTGAAAAATTTTCTTTTC-CCCCCTGACC-5') (D) in a 10 mM sodium cacodylate buffer (pH 6) containing 10 mM MgCl<sub>2</sub> and 100 mM NaCl. A cacodylate buffer was chosen because of its limited dependence of pH versus temperature. Oligonucleotide

concentrations were 1  $\mu$ M of the duplex target D (with a 1/1.2 ratio of purine/pyrimidine-containing strands) and 1.5  $\mu$ M of the third strand (see sequences in Table 1). For the melting temperature ( $T_m$ ) analysis, the drift of baseline was corrected by subtracting absorptions at 440 nm from those at 260 nm and plotted against temperature ( $^{\circ}$ C). The maximum of the first derivative  $dA/dT$  was taken as a first estimation of the  $T_m$  value. The uncertainty in the  $T_m$  values reported is estimated at  $\pm 1$   $^{\circ}$ C.

## RESULTS AND DISCUSSION

Triple-helix-specific intercalators benzo[e] and benzo[g] pyridoindole [BePI and BgPI] were covalently linked to various positions of a triple-helix-forming 10-mer oligopyrimidine sequence [TFO] 5'-TTTTCTTTTC-3'. Parameters such as the size of the linker chosen to connect the intercalators and the third pyrimidine strand as well as the position of attachment of the linker to the intercalator in the case of BePI derivatives were investigated. We report here the synthesis of the various families of oligonucleotide intercalator conjugates and the results of their binding properties evaluated by absorption spectroscopy.

### A. Synthesis of BePI and BgPI Derivatives 1–20.

**1. Synthesis of the BePI Derivatives 1 and 2 Involving an Amino-Containing Linker Attached to Their Position 11.** The 11-amino-substituted benzo[e]pyridoindole deriva-

**Figure 6.** Oligo-2'-deoxyribonucleotide–BePI conjugates with linkage of the intercalators at an internucleotidic phosphate position via phosphothiotriester **XV–XX** or phosphoramidate **XXI** bonds.

tives **1** and **2** (Figure 1) were obtained as described in the literature (32, 33).

**II. Syntheses of the BePI and BgPI Derivatives Involving a Carboxylated Linker 3–6 and of Activated Esters 15–18.** New benzo[*e*]pyridoindoles substituted at the 3-position (**3** and **4**) (Figure 1, Scheme 1) were synthesized starting from the known 11-chloro-3-methoxy-8-methyl-7H-benzo[*e*]pyrido[4,3-*b*]indole **7** (36). Demethylation of this methoxy derivative in standard conditions under reflux of concentrated HBr or using cetyltrimethylammonium bromide by phase transfer catalysis under reflux of concentrated HCl described in ref 37 was unsuccessful, and the unaltered starting material was recovered, even after a prolonged heating time. To overcome this disappointing result, we examined new conditions for this transformation. It was found that under reflux of concentrated HCl and in the presence of benzyltriethylammonium chloride, compound **7** led to the 3-hydroxybenzo[*e*]pyridoindole **8** in good yield. Treatment of this phenolic derivative **8** with ethyl 4-bromobutyrate

or ethyl 5-bromovalerate, followed by catalytic (Pd/C) hydrogenation, gave the corresponding O-substituted ester derivatives **9** and **10**, and their saponification led to the expected compounds **3** and **4** (Scheme 1).

For compounds **5** and **6** belonging to the benzo[*g*]pyridoindole series, the same transformations were performed under similar conditions starting from the known 7-chloro-3-methoxy-10-methyl-11H-benzo[*g*]pyrido[4,3-*b*]indole **11** (36) via **12**, **13**, and **14** (Scheme 2).

The corresponding activated esters **15–18** of BePI and BgPI derivatives **3–6** were obtained by reaction of pentafluorophenyltrifluoroacetate with the amino-containing linker derivatives **3–6** and directly used after purification on a silica gel column. The iodoacetamide derivatives **19** and **20** were obtained from the BePI derivatives **1** and **2** using a previously reported procedure (34).

**B. Synthesis of the Oligo-2'-deoxyribonucleotide-BePI and Oligo-2'-deoxyribonucleotide–BgPI Conjugates.** BePI derivatives **1** and **2** with different linker sizes attached

to their 11-position were covalently linked to the 5-position of a 2'-deoxyuridine located in place of either the first or the eighth nucleotide of the sequence. These positions were chosen to allow intercalation of the BePI derivatives between the TxA.T base triplets since studies carried out with free BePI derivatives and various triple helices have shown a preferential binding for sequences involving runs of TxA.T triplets (29). The preparation of these conjugates **II–VI** was performed by postsynthetic coupling of the BePI derivatives with modified oligonucleotides involving a modified 2'-deoxyuridine at the site preselected for the linkage of intercalators.

The modified 2'-deoxyuridine-linker derivative was obtained as reported in Scheme 3. First, the 5-bromo-2'-deoxyuridine **21** was reacted with 1,3-dichloro-1,1,3,3-tetraisopropylidisiloxane (**38**) in order to protect the 5'- and 3'-functions (compound **22**). The latter was then reacted with 10-fold excess of 3-amino-1,2-propanediol to

**Scheme 2. Synthesis of the BgPI Derivatives 5 and 6<sup>a</sup>**

<sup>a</sup> (i) Conc HCl/BnEt<sub>3</sub>NCl. (ii) Br(CH<sub>2</sub>)<sub>n</sub>COOEt. (iii) H<sub>2</sub>, Pd/C. (iv) NaOH. v: HCl.

give the 2'-deoxyuridine-linker derivative **23** in 76% yield. The hydroxyl function of the amino-1,2-propanediol linker was protected with benzoyl groups to give compound **24**. The protective group of the 5'- and 3'-hydroxyl functions was then removed by tetrabutylammonium fluoride treatment to give compound **25**, which was dimethoxytritylated at the 5'-position (compound **26**) and transformed into its phosphoramidite derivative **27** following a standard procedure. The modified 2'-deoxyuridine-linker derivative was then incorporated during the oligonucleotide chain elongation, via phosphoramidite chemistry, in replacement of the thymidines at the positions chosen for the linkage of the BePI derivatives. After a standard deprotection step, purification was carried out by reversed-phase HPLC or PAGE to give oligonucleotides **28–30**. The linkage between the BePI-linker derivatives **1** and **2**, ending with an amino group, and the oligonucleotides **28–30** containing the modified 2'-deoxyuridine bearing a diol-containing linker at their 5-position was performed via an amino reductive coupling step (Figure 2). This included periodate treatment to generate the aldehydic derivative, reaction of the latter with amino containing BePI derivatives **1** or **2** and finally a reduction step by sodium cyanoborohydride. Purification of the conjugates was performed by reversed-phase chromatography. The retention times for the conjugates involving one BePI derivative **II** to **V** were higher than those of oligonucleotides **28** and **29** ( $\Delta t_R \approx 6$  min); in the case of compound **30** with two BePI derivatives (compound **VI**), the retention time was even more increased ( $\Delta t_R \approx 10$  min) (Figure 2, Table 1). These results indicate the formation of more lipophilic compounds. UV spectra recorded between 230 and 420 nm indicate the presence of a band corresponding to the BePI derivatives (Table 1 and Figure 3A).

BePI derivative **4** involving a linker attached to its 3-position instead of the 11-position for the above-described conjugates and BgPI derivative **6** with a linker attached to its 3-position (Figure 1) were also covalently linked to the 5-position of another modified 2'-deoxyuridine inserted at the same positions as those reported above. In this case the modified 2'-deoxyuridine involved a more rigid linker ending with an amino function. Oligonucleotides involving these modified 2'-deoxyuridines **31** and **32** were reacted with the carboxyl function (as pentafluorophenyl esters **16** and **18**) of the BePI and BgPI-linker derivatives (including four methylenes) **4** and **6** to give the oligonucleotide-BePI and BgPI conjugates

**Scheme 3. Synthesis of the Modified 2'-Deoxyuridine 26 and Its Incorporation into Oligo-2'-Deoxyribonucleotides<sup>a</sup>**

<sup>a</sup> 5BrdU = 5-bromo-2'-deoxyuridine, DMTr = dimethoxytrityl, Bz = benzoyl. (i) 1, 3-dichloro-1, 2, 3, 3-tetraisopropylidisiloxane, pyridine. (ii) 3-Amino-1, 2-propanediol, EtOH, 80 °C, 17 h. (iii) Benzoylchloride, pyridine. (iv) Tetrabutylammonium fluoride, THF. (v) DMTrCl, pyridine. (vi) 2-Cyanoethoxy-*N,N*-diisopropylaminophosphine, DIEA, CH<sub>2</sub>Cl<sub>2</sub>.

**VII** to **X** (Figure 4). Purification was performed by reversed-phase chromatography. In all cases the retention time for conjugates **VII–X** was a few minutes ( $\Delta t_R \approx 7$  min) higher than that of the starting oligonucleotides **31** or **32** (Table 1). The oligonucleotide–BePI conjugates were characterized by UV–visible spectroscopy.  $\lambda_{max}$  values are given in Table 1. Absorption spectra recorded between 230 and 420 nm of the oligonucleotide–BePI conjugate **VIII** and the oligonucleotide–BgPI conjugate **IX** are shown in Figure 3B.

The BePI with a linker attached to its 3-position and BgPI derivatives described above were then covalently linked to an internal position of the TFO pyrimidine sequence via an additional 2'-deoxyribose moiety bearing a propylamino linker at its 1'-position in the  $\beta$ -anomeric configuration. The 2'-deoxyribose residue was added between the second and third thymidines of the sequence. This strategy was chosen in order to favor intercalation between the two neighboring T.AxT base triplets.

The 2'-deoxyribose-linker derivative was obtained following Scheme 4. The amino function of aminopropanol was protected with the fmoc group to give compound **33**. The latter was reacted with  $\beta$ -D-ribofuranose 1,2,3,5 tetraacetate **34** to give the 2'-deoxyribose-linker derivative **35**. The 5', 3', and 2'-hydroxyl functions were released by KCN treatment (**39**) to give compound **36** protected on the amino function with a fluorenylmethyl group in 30% yield. The 5'- and 3'-functions were then protected using Markiewicz reagent to give compound **37**. The 2'-hydroxyl function was then removed following a

two-step procedure involving its activation with the phenoxythiocarbonyl group (compound **38**) followed by radical deoxygenation in the presence of tributyltin hydride and AIBN (compound **39**). After release of its 5'- and 3'-hydroxyl functions by treatment with tetrabutylammonium fluoride, the modified 2'-deoxyribose **40** was tritylated at its 5'-position (compound **41**) and transformed into its phosphoramidite derivative **42**. The 2'-deoxyribose-linker derivative was incorporated into the sequence by manual coupling and increased time reaction between the second and third thymidines. The modified trityl-on oligonucleotide was then deprotected by concentrated ammonia treatment overnight at room temperature. Purification was performed by ion-exchange chromatography and, after detritylation, analyzed and purified by reversed-phase chromatography. Oligonucleotide **43** was then reacted with the carboxyl function (as pentafluorophenyl ester **15–18**) of the BePI and BgPI-linker derivatives **3–6** (including three or four methylenes) to give the oligonucleotide–BePI and BgPI conjugates **XI** to **XIV** (Figure 5). Purifications were performed by reversed-phase chromatography. In all cases the retention times for the conjugates were a few minutes longer than that for the starting oligonucleotide **43** ( $\Delta t_R \approx 8–11$  min) (Table 2). The oligonucleotide–BePI conjugates were characterized by UV–visible spectroscopy.  $\lambda_{max}$  values are given in Table 2. Absorption spectra recorded between 230 and 420 nm of the oligonucleotide–BePI conjugate **XII** and oligonucleotide–BgPI conjugate **XIII** are shown in Figure 3C.

**Scheme 4. Synthesis of the Modified 2'-Deoxyribose Linker Derivative 41 and Its Incorporation into an Oligo-2'-deoxyribonucleotide<sup>a</sup>**

<sup>a</sup> R = fluorenylmethyl; DMTr = dimethoxytrityl. (i) Trimethylsilyltrifluoromethane sulfonate, 1,2-dichloroethane. (ii) KCN, MeOH. (iii) 1,3-Dichloro-1,1,3,3-tetraisopropylidisiloxane, imidazole, 1,1-dichloromethane. (iv) Phenylchlorothionochloroformate, pyridine. (v) AIBN, toluene. (vi) Tetrabutylammonium fluoride, THF. (vii) DMTrCl, pyridine. (viii) 2-Cyanoethoxy-*N,N*-diisopropylaminochlorophosphine, DIEA, CH<sub>2</sub>Cl<sub>2</sub>.

BePI derivatives **1** and **2**, involving a linker attached to their 11-position were then covalently linked at an internal position of the TFO pyrimidine sequence via internucleotidic thiophosphate and amidophosphate bonds. Purification was performed by reversed-phase chromatography. Iodoacetamide derivatives of BePI derivatives **1** (compound **19**) and **2** (compound **20**) were reacted with oligonucleotides containing either one thiophosphate group **44** or two thiophosphate groups **45** (Figure 6) at preselected positions chosen for the attachment of the BePI derivatives. Compounds **XV–XX** were obtained (Figure 6, Table 2). Purification and analysis steps were performed both by reversed-phase chromatography and 20% PAGE in denaturing conditions. Retention times for the conjugates were higher than for the starting oligo-2'-deoxyribonucleotides:  $\Delta t_R \approx 6$  min in the case of the coupling of one BePI derivative and  $\Delta t_R \approx 10$  min in the case of the coupling of two BePI derivatives (Table 2). Compounds **XV** and **XVI** correspond to each pure diastereoisomer of the oligonucleotide–BePI conjugate. They were separated by reversed-phase chromatography using a weak gradient. PAGE analysis revealed that the con-

jugates **XI** and **XII** possess the same mobilities in denaturing gels (Figure 7). However, their mobilities are lower than that of the starting oligonucleotide involving a thiophosphate group **24**. In the case of conjugate **XIX** involving two BePI residues, the mixture of stereoisomers (four isomers) was not separated. PAGE analysis showed only one band for compound **XIX** with a retarded mobility as compared to the conjugates involving only one BePI derivative **XV** and **XVI**. On the contrary, reversed-phase analysis revealed three peaks (with a higher intensity for the central one) with increased retention times as compared to those of the conjugates involving one BePI residue **1**. UV analysis indicated the presence of BePI in the products corresponding to all three peaks (Table 2). Similar results were obtained with the conjugates **XVII**, **XVIII**, and **XX** involving either one or two BePI derivatives **2**. Absorption spectra recorded between 230 and 420 nm of the oligonucleotide–BePI conjugates **XV** and **XIX** are shown in Figure 3D.

Oligonucleotide–BePI **1** conjugate **XXI** (Table 2) (Figure 6) involving a phosphoramidate linkage was obtained by performing an H-phosphonate coupling step (**40**) at

**Figure 8.** First derivative  $d\text{Absorbance}/dT$  of the UV melting profiles recorded at 260 nm of the duplex in the presence of oligonucleotide **I** (●), oligonucleotide **II** (■), and oligonucleotide **III** (◇).

the selected site for the attachment of the intercalator followed by an oxidation step in the presence of the BePI derivative **1**. Coupling of the BePI derivative resulted in an increase in retention time for conjugate **XXI**.

**C. Stabilities of the Triplexes Formed between Conjugates II–XVII and the Double-Stranded DNA Target (Tables 1 and 2).** The results obtained for the described conjugates, listed in Tables 1 and 2, indicate that the binding of the third strand to the target duplex was stabilized only with BePI-oligo-2'-deoxyribonucleotide conjugates **II** and **III** (Figure 8). In these conjugates, the BePI derivative is attached by its 11-position, via a flexible linker, to the 5-position of a modified 2'-deoxyuridine located at the 5'-end of the sequence. In these cases, BePI probably intercalates at the duplex–triplex junction as previously reported for acridine–oligonucleotide conjugates. Stabilization was more efficient with a shorter linker (conjugate **II**) between the BePI and the third strand compared to that with a longer linker (conjugate **III**). In the case of the shorter linker (conjugate **II**), the  $T_m$  increase is 6 °C superior to that observed with an acridine–oligonucleotide conjugate used as a reference [ $\text{Acr}(\text{CH}_2)_6\text{-P}^5' \text{TTTTCTTTT}^3$ ] (**41**). In this oligonucleotide–acridine conjugate, the cytosine was replaced with 5-methylcytosine. When BePI derivatives, with any position of the linker attachment on the intercalator residue and any linker size, were attached to other positions of the oligonucleotide chain: 5-position of a modified 2'-deoxyuridine (conjugates **IV–VIII**),  $\beta$ -anomeric position of an internal 2'-deoxyribose residue (conjugates **XI** and **XII**), or internucleotidic position (conjugates **XV–XXI**)—only very weak or no stabilization of the triplex was observed. This was also true with BgPI derivatives fixed at internal positions of the sequence either on a modified 2'-deoxyuridine (conjugates **IX** and **X**) or on the  $\beta$ -anomeric position of a 2'-deoxyribose residue (conjugates **XIII** and **XIV**).

We have reported the synthesis and binding properties of a series of oligopyrimidine sequences covalently linked to triple-helix-specific intercalators (BePI and BgPI) derivatives. The influence of the linker attachment position on both the intercalating agent and the oligonucleotide chain as well as the linker size were studied. The syntheses of new BePI and BgPI derivatives (**3–6**) were reported. The preparation of the oligonucleotide–BePI and oligonucleotide–BgPI conjugates (compounds **II–XXI**) was performed by specific coupling reactions between suitable functional groups present on both the intercalating agents and the deprotected oligonucleotides (**28–32**, **43–45**). The incorporation of the functional groups into the modified oligonucleotide at the site preselected

for the coupling of the intercalating agents was performed by using either well-known procedures including phosphorothioate or H-phosphonate chemistry or new modifications such as a modified 2'-deoxyuridine containing a linker ending with a cis-diol or a 2'-deoxyribose residue involving an amino-containing linker at its  $\beta$ -anomeric position. The binding properties of the conjugates synthesized with the double-stranded DNA target were studied by absorption spectroscopy (Tables 1 and 2). The results indicated that a significant stabilization was observed only when BePI derivatives with the linker attached to their 11-position are covalently linked, via a flexible linker, to the 5-position of a modified 2'-deoxyuridine located at the 5'-end of the oligopyrimidine sequence (conjugates **II** and **III**). The strongest stabilization ( $\Delta T_m = 30$  °C) was observed with the shorter linker (conjugate **II**).

#### ACKNOWLEDGMENT

This work is supported by funds from the Agence Nationale de Recherches sur le SIDA (ANRS). We thank M. Novello for the preparation of oligonucleotides **31** and **32**, H. Labbé for recording NMR spectra, and C. Buré for running the electrospray mass spectrometer.

Received July 16, 2002; Revised Manuscript Received November 13, 2002

A novel type of mixed-ligand Tc(III) complexes, [Tc(SCH<sub>2</sub>CH<sub>2</sub>-E-CH<sub>2</sub>CH<sub>2</sub>S)(PR<sub>2</sub>S)] (E = S, N(CH<sub>3</sub>); PR<sub>2</sub>S = phosphinothiolate with R = aryl, alkyl) is described. These “3+2”-coordinated complexes can be prepared in a two-step reduction/substitution procedure via the appropriate chloro-containing oxotechnetium(V) complex [TcO(SES)Cl] {E = S, N(CH<sub>3</sub>)}. Tc(III) compounds have been fully characterized both in solid and solution states and found to adopt the trigonal-bipyramidal coordination geometry. The equatorial trigonal plane is formed by three thiolate sulfur atoms, whereas the phosphorus of the bidentate P,S ligand and the neutral donor of the tridentate chelator occupy the apical positions. The <sup>99m</sup>Tc(III) complexes have been proven to be identical with the <sup>99m</sup>Tc agents prepared at the no-carrier-added level by comparison of the corresponding UV/vis and radiometric HPLC profiles. Challenge experiments with glutathione clearly indicate that this tripeptide has no effect on the stability of the <sup>99m</sup>Tc complexes in solutions. Biodistribution studies have been carried out in rats at 5 and 120 min postinjection. The substituents at the bidentate P,S ligand significantly influence the biodistribution pattern. Remarkable differences are observed especially in brain, blood, lungs, and liver. All the complexes are able to penetrate the blood–brain barrier of rats and showed a relatively fast washout from the brain.

## INTRODUCTION

This paper reports on the synthesis and biological characterization of a novel class of technetium(III) mixed-ligand complexes with tridentate S,E,S and bidentate P,S coordination (E = S, N(R), O). The syntheses of these mixed-ligand species represent an alternative approach for the development of radiotracers because they offer manifold possibilities to combine the metal with a biologically active fragment and to vary bio-relevant molecular properties.

Mixed-ligand complexes of technetium and rhenium contain the metal ion stabilized in an appropriate oxidation state by a suitable ligand framework, which only partially fills the coordination sphere. Examples for such arrangements are described, beside the technetium(I) and rhenium(I) tricarbonyl moiety [M(CO)<sub>3</sub>]<sup>+</sup> (1), mainly for Tc(V). These include the “super-nitrido” fragment [Tc(N)(PNP)]<sup>2+</sup> (PNP = tridentate aminediphosphine ligand) (2), the substitution-inert [Re(O)(L)]<sup>2+</sup> moiety (L = bidentate functionalized phosphine) (3), and the [M(O)-(SES)]<sup>+</sup> group (SES = tridentate dithiol ligand; E = S, NR, O) forming the well-known “3+1” Tc and Re complexes (4, 5). In all cases the coordination sphere of the metal ion is completed by additional mono-, bi-, or

tridentate co-ligands. Among these species, the so-called “3+1” complexes suffer in vitro and in vivo substitution reaction with thiol-containing molecules such as cysteine or glutathione (6–9). To overcome this problem, labile oxo-Tc(V) compounds have been replaced by electron-rich Tc(III) ones in the search for neutral and stable mixed-ligand complexes. So, “4+1” Re and Tc complexes containing 2,2',2''-nitritoltris-(ethanethiol) as a tripodal ligand and tertiary phosphines or isocyanides as co-ligands have shown superior properties compared to the “3+1” complexes in terms of stability (10–12).

Another type of neutral Tc(III) complexes derived from the reaction of oxo-Tc(V) “3+1” precursors with tertiary phosphines, namely, the “3+1+1” complexes of general formula [M(PR<sub>3</sub>)(SES)(SR)] (SES = tridentate dithiol ligand; E = S, NR, O), are still unstable against cysteine and GSH and, sometimes, re-oxidize to the original starting material (13, 14). Stability of this class of compounds can be enhanced by combining the monodentate ligands, i.e., tertiary phosphine and thiol, into a bidentate P,S phosphinothiol to produce “3+2” Tc(III) mixed-ligand complexes of the type [Tc(SES)(R<sub>2</sub>PS)]. Previous investigations have demonstrated that P,S functionalized phosphines allow the synthesis of Tc(III) species of different geometry by varying either the nature of the carbon chain between the phosphorus and the sulfur atoms and/or the substituents at the phosphorus atom (15, 16). Furthermore bis- and monosubstituted nitrido-Tc(V) complexes with phosphinothiolate ligands have been described (17).

The aim of the work presented here was to prepare neutral and stable "3+2" Tc(III) complexes both at macroscopic and at nca level, to confirm their identity by using chromatographic techniques coupled with UV/vis and radiometric detection, to study their reactivity in various media and to check the biodistribution properties in rats of a number of model complexes.

## EXPERIMENTAL PROCEDURES

**General.** All solvents and commercially available substances were of reagent grade and used without further purification. The P,S ligands were prepared by ARGUS Chemicals according to the method reported by Chatt et al. (18). The tridentate ligands 3-thiapentane-1,5-dithiol and 3-oxapentane-1,5-dithiol were obtained from Aldrich. 3-(*N*-Methyl)azapentane-1,5-dithiol was prepared according to standard procedures starting from *N*-methyl-2,2'-iminodiethanol (MERCK-Schuchart) (19).

$^{99}\text{Tc}$  as  $\text{NH}_4\text{TcO}_4$  was obtained from Amersham as 0.3 M aqueous solution.  $^{99\text{m}}\text{TcO}_4^-$  was eluted from a commercial  $^{99}\text{Mo}/^{99\text{m}}\text{Tc}$  generator (Mallinckrodt).

**Instrumentation.** Elemental analyses were performed on a LECO Elemental Analyzer CHNS-932. Melting points were obtained on a Boëtius-Mikroheitzisch and are uncorrected. IR spectra were measured as KBr pellets on a Perkin-Elmer FTIR-spectrometer SPECTRUM 2000. UV/vis spectra were recorded on a SPECORD S10 spectrometer from Carl Zeiss Jena. Proton,  $^{13}\text{C}$ , and  $^{31}\text{P}$  NMR spectra were collected on a Bruker 300 instrument, using  $\text{SiMe}_4$  as internal reference ( $^1\text{H}$  and  $^{13}\text{C}$ ) and 85% aqueous  $\text{H}_3\text{PO}_4$  as external reference ( $^{31}\text{P}$ ). Samples were dissolved in deuterated chloroform at a concentration of ca. 2%. Chemical shifts are reported as  $\delta$  in ppm. Cyclic voltammetry of complexes 1–5 was carried out in dichloromethane solutions ( $3.5 \times 10^{-3} \text{ mol dm}^{-3}$ ), with  $[n\text{-Bu}_4\text{N}][\text{ClO}_4]$  ( $0.1 \text{ mol dm}^{-3}$ ) as supporting electrolyte, at a stationary platinum-disk electrode (area ca.  $1.28 \text{ mm}^2$ ), which was cleaned after each run, with scan rate  $0.2 \text{ V s}^{-1}$  at  $T = 293 \text{ K}$ . Potentials were measured relative to an Ag-wire pseudo-electrode using the  $\text{Fc}/\text{Fc}^+$  couple as internal reference. Controlled potential coulometries of dichloromethane solutions of 1 were performed using an Amel model 721 integrator, in a H-shaped cell containing, in arm 1, a platinum-gauze working electrode and an  $\text{Ag}/\text{Ag}^+$  reference isolated inside a salt bridge by a medium glass frit and, in arm 2, an auxiliary platinum-foil electrode. Thin-layer chromatography (TLC) and high-performance liquid chromatography (HPLC) analyses were performed for controlling the identity, the radiochemical purity, and the stability of the preparations. For TLC studies silica gel plates (Merck 60F $_{254}$ ) and mobile phases of  $\text{MeOH}/0.1 \text{ N HCl}$  (95/5), acetone, or  $\text{BuOH}/\text{water}/\text{MeOH}/25\%$  ammonia (60/20/20/1) were used. The plates were scanned with a Raytest Rita radioanalyzer. HPLC analyses were performed on a Perkin-Elmer device consisting of a Turbo LC System with a quaternary pump (Series 200 LC Pump), a Programmable Absorbance Detector Model 785A, and a homemade  $\gamma$ -ray detector (Bohrloch, NaI-(Ti) crystal). HPLC analyses were carried out with a Hypersil ODS column ( $250 \times 4 \text{ mm}$ ) using a gradient eluent of acetonitrile/ $0.05 \text{ M NH}_4\text{Ac}$  pH 4, and a flow rate of  $1.0 \text{ mL/min}$ . The effluent from the column was monitored by UV absorbance at  $254 \text{ nm}$  for  $^{99}\text{Tc}$  reference complexes or  $\gamma$ -ray detection for the  $^{99\text{m}}\text{Tc}$  complexes.

**X-Ray Data Collection and Processing.** The X-ray data were collected at room temperature ( $293 \text{ K}$ ) on a SMART-CCD diffractometer (SIEMENS), using graphite

monochromatized Mo- $\text{K}_\alpha$  radiation ( $\lambda = 0.71073 \text{ Å}$ ). A summary of the crystallographic data is given in Table 1. The positions of the non-hydrogen atoms were determined by the heavy atom technique. After anisotropic refinement of these positions, the hydrogen positions were calculated according to ideal geometries. Empirical absorption corrections were made using psi scans. Most of the calculations were carried out in the SHELXTL system with some local modifications.

Relevant bond lengths and angles are contained in Table 3. Atomic positional and thermal parameters, full lists of bond lengths and angles, and  $F_o/F_c$  values have been deposited (20).

**Synthesis of  $[\text{TcO}(\text{SCH}_2\text{CH}_2\text{SCH}_2\text{CH}_2\text{S})\text{Cl}]$  (I) and  $[\text{TcO}(\text{SCH}_2\text{CH}_2\text{N}(\text{CH}_3)\text{CH}_2\text{CH}_2\text{S})\text{Cl}]$  (II).** These precursor complexes were prepared by ligand-exchange reaction of  $[\text{N}(\text{C}_4\text{H}_9)]_3[\text{TcOCl}_4]$  with the appropriate tridentate ligand as described elsewhere (21, 22).

**Synthesis Procedure for the Tc(III) Complexes  $[\text{Tc}(\text{SCH}_2\text{CH}_2\text{SCH}_2\text{CH}_2\text{S})(\text{PR}_2\text{S})]$ – $^{99}\text{Tc}$ 1– $^{99}\text{Tc}$ 3.** A  $100 \mu\text{mol}$  sample of the oxotechnetium(V) complex I and  $400 \mu\text{mol}$  of the appropriate phosphinethiol were dissolved in 3 mL of acetonitrile. After addition of  $0.5 \text{ mL}$  of acetic acid, the mixture was stirred at room temperature under argon for 60 min. The color of the solution turned from yellowish-brown to violet. The reaction mixture was reduced in volume to  $1 \text{ mL}$ , and methanol was added until the solution became turbid. The mixture was then allowed to stand overnight in the refrigerator. Recrystallization of the raw precipitates from chloroform/methanol at  $-20 \text{ °C}$  gave  $^{99}\text{Tc}$ 1,  $^{99}\text{Tc}$ 2, and  $^{99}\text{Tc}$ 3 as dark-violet crystals.

**General Synthesis Procedure for the No-Carrier-Added Preparation of the Compounds  $^{99}\text{mTc}(\text{SES})-(\text{PR}_2\text{S})]-^{99}\text{mTc}$ 1,  $^{99}\text{mTc}$ 2,  $^{99}\text{mTc}$ 4,  $^{99}\text{mTc}$ 6– $^{99}\text{mTc}$ 11.** No-carrier-added preparations of "3+2"  $\text{Tc(III)}$  compounds were studied with the tridentate SES ligands 3-thiapentane-1,5-dithiol, 3-(*N*-methyl)azapentane-1,5-dithiol and 3-oxapentane-1,5-dithiol and bidentate P,S ligands illustrated in Figure 4.

A 0.10 mg (for preparing  $[\text{Tc}(\text{SSS}/\text{PR}_2\text{S})]$ ) or 0.05 mg (for preparing  $[\text{Tc}(\text{SNMeS}/\text{PR}_2\text{S})]$  and  $[\text{Tc}(\text{SOS}/\text{PR}_2\text{S})]$ ) sample of the bidentate P,S ligand, dissolved in 0.10 mL of ethanol, and 0.05 mg of the appropriate tridentate SES ligand, dissolved in 0.10 mL of ethanol, were added to a mixture of 0.50–1.0 mL pertechnetate, 0.25 mL propylene glycol, and 0.75 mL of acetonitrile. After addition of 40  $\mu\text{L}$  0.1 N NaOH, the complexes were formed by reduction of pertechnetate with 40  $\mu\text{L}$   $\text{SnCl}_2$  solution (2.0 mg  $\text{SnCl}_2$  dissolved in 5.0 mL 0.1 N HCl). The reaction was completed by heating at 50 °C within 15 min (yields between 60 and 90%).

The preparations were purified for stability and bio-distribution studies by HPLC using a semipreparative Hypersil column (250  $\times$  8 mm, 10  $\mu\text{m}$ ).

**Determination of Partition Coefficients.** Partition coefficients of the  $^{99}\text{mTc}$  complexes were determined by shake-flask method by mixing 0.5 mL of the complex solution (0.9% NaCl solution and 20% propylene glycol) and 0.5 mL *n*-octanol and shaking for 5 min. After centrifugation aliquots of both phases were counted and the partition coefficient calculated.

**Ligand Exchange (Challenge) Experiments with Glutathione (GSH).**  $^{99}\text{mTc}$  complexes, dissolved in a mixture of propylene glycol/MeOH (2:1 v/v), were diluted with an equivalent volume of an aqueous solution of 20 mM GSH containing 25% of propylene glycol immediately

**Scheme 1. Reaction Routes to Tc(III) Complexes with "3+2" Coordination (E = N(CH<sub>3</sub>), S)**

after HPLC separation, resulting in a final glutathione concentration of 10 mM. The analyses were performed by HPLC as described above.

**Stability Studies in Plasma.** A 50  $\mu$ L sample of the appropriate <sup>99m</sup>Tc complex solution (0.9% NaCl, 12% propylene glycol) was incubated in 200  $\mu$ L of rat plasma at 37 °C. After an incubation time of 30 min, the samples were analyzed by HPLC with a Supelguard column (20  $\times$  4.6 mm, 10  $\mu$ m, flow rate 1.0 mL/min) using a linear gradient 95% to 40% A in 15 min [A, 2-propanol/0.1% trifluoroacetic acid (TFA) (10/90); B, 2-propanol/0.1% TFA (90/10)].

**Biodistribution Studies.** The animal studies in male Wistar rats (5–6 weeks old) were carried out according to the relevant national regulations. A 500  $\mu$ L sample of <sup>99m</sup>Tc complex solution (saline, propylene glycol 25%) was injected into the tail vein of rats. After the injection the rats were sacrificed by heart puncture under ether anaesthesia at 5 and 120 min p.i.. Selected organs were isolated for weighing and counting. The accumulated radioactivity in the organs tissue were calculated in terms of percentage of injected dose per organ as well as percent injected dose per gram of blood.

## RESULTS AND DISCUSSION

**Technetium-99 Chemistry. Synthesis.** As shown in Scheme 1, the Tc(III) mixed-ligand complexes can be prepared in a two-step substitution-reduction procedure starting from the prereduced precursor [TcOCl<sub>4</sub>]<sup>−</sup> via the appropriate chloro-containing oxotechnetium(V) complex **I** or **II**. In this case, sequential addition of the relevant dithiol followed by the bidentate phosphinothiol is required. An alternative one-pot reaction with the simultaneous addition of the ligands to the labile [TcOCl<sub>4</sub>]<sup>−</sup> precursor is possible, but the yield of the Tc(III) species is lower. In these reactions the phosphinethiols work as reducing agent as well as coordinating ligand. Both procedures are characterized by a typical change in color from orange to deep-violet indicating the transfer from Tc(V) to Tc(III). There is no evidence for the formation of other oxo-Tc(V) species.

**Characterization.** The Tc(III) complexes have been characterized by (i) elemental analyses, which are in

agreement with the proposed formulations, (ii) cyclic voltammetry, (iii) spectroscopic measurements, including IR, UV/vis, NMR, and (iv) X-ray structure analyses of two prototypic representatives.

The IR spectra of all compounds show characteristic absorptions of the Tc–P stretching vibrations. No bands assignable to the Tc=O core are observed in the range 900–1000 cm<sup>−1</sup> indicating the absence of oxotechnetium species.

The UV/vis spectra of the Tc(III) complexes exhibit very similar and characteristic intense bands at 345–353 nm and less intense absorptions in the visible region (509–552 nm).

The diamagnetism exhibited by this class of Tc(III) complexes is in agreement with low-spin d<sup>4</sup> trigonal bipyramidal configuration (vide infra). Consequently, NMR spectra show sharp proton and carbon signals and allow to distinguish both coordinated dithiolate and phosphinothiolate fragments. On the contrary, room-temperature <sup>31</sup>P{<sup>1</sup>H} spectra exhibit rather broad signals due to the quadrupolar relaxation induced by the <sup>99</sup>Tc nucleus (*I* = 9/2) at the neighbor P atom (23). The <sup>31</sup>P signal moves significantly downfield by ca. 100 ppm upon phosphine coordination (see Table 2) compared to the values exhibited by uncoordinated PMe<sub>2</sub>S = −51.2, PPh<sub>2</sub>S = −17.5, and PCy<sub>2</sub>S = −4.2 ppm. Despite the more shielded values exhibited by those complexes containing the more basic phosphine of the series (i.e., PMe<sub>2</sub>S), this ligand induces the highest chemical shift variation (+114 and +107.8 ppm for [<sup>99</sup>Tc]5 and [<sup>99</sup>Tc]3, respectively), indicating a strong contribution of the phosphine lone pair to the metal-phosphorus bond. Less pronounced is the chemical shift variation induced by the less basic PCy<sub>2</sub>S and PPh<sub>2</sub>S ligands (see Table 2). The nature of the *trans*-axial heteroatom of the tridentate ligand (S or N) affects the <sup>31</sup>P signal and the Tc–P bond as well. In fact, by increasing the  $\pi$ -accepting combination in the series (thioether/phosphine in [<sup>99</sup>Tc]1 vs amine/phosphine in [<sup>99</sup>Tc]4), the Tc–P bond distance elongates from 2.298 to 2.320 Å, whereas the <sup>31</sup>P signal is less downfield shifted. These "3+2" species do not rearrange back to the original oxo-Tc(V) precursors, as it was observed in the case of some isostructural Tc(III) "3+1+1" complexes containing a monodentate phosphine and a monodentate thiolate (13).

Cyclic voltammetric (CV) data support the observations pointed out above. CV oxidation (*E*<sub>p</sub><sup>a</sup>) and reduction (*E*<sup>o</sup>) potentials are reported in Table 2 and a representative voltammogram is depicted in Figure 1. The redox stability window for this class of Tc(III) "3+2" complexes is about 700–800 mV. This range is ca. 100–200 mV larger when compared to the redox windows found in similar T(III) "3+1+1" complexes, indicating an increased stability of the more chelated "3+2" compounds.

Complexes [<sup>99</sup>Tc]1 and [<sup>99</sup>Tc]4, as prototypic representatives of this novel class of neutral Tc(III) compounds, were studied by X-ray structure analysis. A summary of the crystallographic data is given in Table 1. Selected bond lengths and angles are cumulated in Table 3.

As illustrated in Figures 2 and 3, the complexes adopt the trigonal-bipyramidal geometry comprised by three sulfur atoms, the neutral heteroatom of the tridentate ligand, and the tertiary phosphorus atom. The trigonal plane is formed by the three thiolate sulfurs of the tridentate ligand and the bidentate P,S chelator. The phosphorus and the neutral heteroatom of the tridentate chelate ligand occupy the apical positions. This arrange-

**Figure 1.** Cyclic voltammogram of complex  $[^{99m}\text{Tc}]\mathbf{5}$  in 1 mM  $\text{CH}_2\text{Cl}_2$  solution. Potentials are vs  $\text{Ag}/\text{Ag}^+$ . The scan rate is  $200 \text{ mV s}^{-1}$ .

**Figure 2.** Molecular structure of complex  $[^{99m}\text{Tc}]\mathbf{1}$ .

ment is quite common for transition-metal complexes containing two  $\pi$ -acceptor groups (12, 13, 15, 24–26).

The  $\text{Tc}-\text{S}_{\text{thiolato}}$  distances are restricted in a narrow range (2.21–2.24 Å) and compares well with those previously reported for similar trigonal-bipyramidal complexes (12, 13, 26). The unique axial metal thioether-sulfur bond in  $[^{99m}\text{Tc}]\mathbf{1}$  elongates to 2.427 Å. The  $\text{P}-\text{Tc}-\text{E}$  axis shows only slight deviation from linearity. Other angles of the inner coordination sphere are consistent with the *tbp* arrangement. A special order/disorder phenomenon was detected in the crystal packing of  $[^{99m}\text{Tc}]\mathbf{4}$ . As frequently observed in this type of complexes, the “SNS” chelator can change its conformation by a flip-flop mechanism giving rise to a statistical distribution of two equal isomers within the crystal (27).

**Technetium-99m Chemistry and Biodistribution Studies.** *No-Carrier-Added Preparation of the  $^{99m}\text{Tc}$  Complexes.* The “3+2” coordinated  $^{99m}\text{Tc}$  complexes  $[^{99m}\text{Tc}]\mathbf{1}$ ,  $[^{99m}\text{Tc}]\mathbf{2}$ ,  $[^{99m}\text{Tc}]\mathbf{4}$ , and  $[^{99m}\text{Tc}]\mathbf{6}$ – $[^{99m}\text{Tc}]\mathbf{11}$  were prepared by a one-step procedure starting from  $^{99m}\text{TcO}_4^-$  with stannous chloride as reducing agent in nearly neutral solutions using optimized amounts of the bidentate P,S ligands as well as of the tridentate S,E,S

**Figure 3.** Molecular structure of complex  $[^{99m}\text{Tc}]\mathbf{4}$ .

ligands (Scheme 2). While 0.05 mg of the P,S chelators are sufficient for the preparation of the complexes with S,N,S/P,S and S,O,S/P,S coordination, the formation of the S,S,S/P,S complexes needs 1.0 mg of the P,S ligand. For all products the amount of the tridentate ligand was determined to be 0.05 mg.

To establish the structure of the  $^{99m}\text{Tc}$  complexes, comparison by HPLC with the well-characterized  $^{99m}\text{Tc}$  analogues was pursued applying parallel radiometric and photometric detection. Thus, after co-injection of appropriate  $^{99m}\text{Tc}/^{99}\text{Tc}$  complex couples, practically identical retention times were observed, while the recovery through the column was quantitative.

Examination of the octanol/water partition coefficients suggests high lipophilicity for the resulting “3+2”  $^{99m}\text{Tc}$  species (Table 4).

**Glutathione Challenge Experiments.** Glutathione (GSH), the most abundant thiol-containing compound in tissues, is present in almost all animal cells in relatively high concentrations (0.5–12 mM) (28, 29). Therefore, it has to be considered as a potential agent for transchelation reactions in vivo. In fact, GSH is responsible for the in vivo reactivity of “3+1” mixed-ligand  $^{99m}\text{Tc(V)}$  complexes which consist of a monodentate thiol ligand and a tridentate dithiol (9–11). Here a ligand exchange in terms of the replacement of the monodentate ligand by GSH occurs both in vitro and in vivo (6–9). For this reason, we investigated the behavior of  $^{99m}\text{Tc(III)}$  “3+2” complexes against GSH.

Saline-containing preparations of the  $^{99m}\text{Tc}$  compounds were diluted 1:1 (v/v) with a 20 mM GSH solution immediately after HPLC purification. For the complexes formed by the S,S,S and S,N,S tridentate ligand, no additional peaks of hydrophilic Tc-GSH mixed ligand species are observed in HPLC studies. These results clearly indicate that glutathione has no negative effect on the stability of  $^{99m}\text{Tc}$  complexes in solutions. This property exhibited by  $^{99m}\text{Tc(III)}$  “3+2” complexes constitutes an important improvement over oxo- $^{99m}\text{Tc(V)}$  “3+1” and similar Tc(III) “3+1+1” complexes (14).

On the contrary, incubation of  $^{99m}\text{Tc(III)}$  “3+2” compounds containing the S,O,S ligand with GSH leads to the formation of hydrophilic species which are not glutathione related. The reason of such instability is not clear yet. However, this behavior parallels the difficulty encountered in the isolation of the corresponding [ $^{99}\text{Tc}(\text{SOS})(\text{PR}_2\text{S})$ ] compounds. Reoxidation processes may play a role in the reduced stability of these solutions.

**Stability in Aqueous Solution.**  $^{99m}\text{Tc}$  preparations containing the S,S,S/P,S and S,N(CH<sub>3</sub>),S/P,S combinations are stable for hours after HPLC purification. However, species with S,O,S/P,S coordination are slowly transformed into more hydrophilic compounds after dilution with saline or phosphate buffer solution. When the appropriate complex solution is diluted about 1:200 (v/v), as it is normally done for the determination of the partition coefficient in octanol/water, the radiochemical purity of the diluted sample decreases to about 80% after 1 h. Due to the formation of hydrophilic impurities the calculated partition coefficients are too low. For this reason we diluted the original complex solution only 1:1 (v/v) with phosphate buffer solution, added octanol immediately, shaken the solution for 5 min, separated the phases, and measured the partition the following day in a Bohrloch scintillation counter (Table 4).

**Stability in Rat Plasma.** Slight differences in stability between the complexes are confirmed by their incubation in rat plasma. While the S,S,S/P,S and S,N,S/P,S coordinated complexes are stable, the analogous S,O,S/P,S species are bound to plasma proteins, especially to albumin (Figure 4). It remains unclear whether the complex itself or decomposition products are bound to albumin.

**Biodistribution Studies in Rats.** The uptake and clearance behavior of the  $^{99m}\text{Tc}$  complexes was determined by distribution studies in Wistar rats at 5 and 120 min postinjection (Table 5). The results indicate that the substituents at the bidentate P,S chelator significantly influence the distribution pattern. Remarkable differences were observed, especially in brain, blood, lungs, and

liver of rats. All of the complexes are able to penetrate the blood-brain-barrier and show a relatively fast wash-out from the brain. However, no correlation was found between brain uptake and lipophilicity of the complexes. The phenyl derivatives ( $[^{99m}\text{Tc}]\mathbf{1}$ ,  $[^{99m}\text{Tc}]\mathbf{4}$ ,  $[^{99m}\text{Tc}]\mathbf{7}$ ,  $[^{99m}\text{Tc}]\mathbf{9}$ – $[^{99m}\text{Tc}]\mathbf{11}$ ) exhibit the highest initial uptake (0.4–1.0% ID/g at 5 min p.i.), whereas the cyclohexyl-bearing species ( $[^{99m}\text{Tc}]\mathbf{2}$ ,  $[^{99m}\text{Tc}]\mathbf{6}$ ,  $[^{99m}\text{Tc}]\mathbf{8}$ ) show only a moderate uptake up to 0.2% ID/g at 5 min postinjection.

The elimination behavior of the complexes differs significantly. In contrast to the S,S,S and S,N,S donor atom sequence ligands, the S,O,S moiety leads to a high blood activity and to a persistent high activity in lungs and liver. The cyclohexyl derivative  $[^{99m}\text{Tc}]\mathbf{8}$  shows increased activity in the kidneys up to 6.2% ID/g (120 min p.i.).

The liver uptake of the phenyl-bearing complexes  $[^{99m}\text{Tc}]\mathbf{9}$  and  $[^{99m}\text{Tc}]\mathbf{11}$  was found to be extremely high (13.2% ID/g, 5 min p.i. for the S,S,S ligand and 9.5% ID/g, 5 min p.i. for the S,O,S moiety) and is connected with a slow elimination of 9.0% and 8.1% ID/g, respectively, up to 120 min postinjection. The S,N,S derivative  $[^{99m}\text{Tc}]\mathbf{10}$  shows an increasing liver uptake up to 6.4% ID/g, 120 min p.i. (47.5% ID). This uptake and elimination pattern does not correlate with the lipophilicity of the complexes. Corresponding to the observed unstability and plasma protein binding of complexes with S,O,S/P,S coordination (see Table 4), the different in vivo behavior, dependent on the tridentate ligand, can be explained as an unspecific binding on proteins of plasma and tissue in vivo.

## CONCLUSION

The association of a tridentate HS–E–SH ligand ( $E = \text{N}(\text{CH}_3)_3$ , S) with a bidentate  $\text{PR}_2$ –SH chelator leads to the formation of nonpolar, lipophilic technetium complexes,  $[\text{Tc}(\text{SCH}_2\text{CH}_2\text{–E–CH}_2\text{CH}_2\text{S})(\text{PR}_2\text{S})]$ , which contain sterically shielded oxo-free Tc(III) ions. This combination enables easy functionalization in order to fine-tune physicochemical properties of the complexes as well as linking of the chelate unit to biomolecules.

$^{99m}\text{Tc}$  analogues can be prepared at no-carrier-added level in high radiochemical yields. With the exception of complexes containing the S,O,S moiety all other complexes are stable toward ligand exchange in challenge experiments with glutathione. This behavior is considered to be an important advantage over oxo- $^{99m}\text{Tc}(\text{V})$  “3+1” complexes. Furthermore, there are no indications for reoxidation of Tc(III) to Tc(V) species or pertechnetate. There is no tendency of these complexes to bind on plasma components. The substituents at the bidentate P,S chelator significantly influence the biodistribution pattern in rats.

Therefore, we propose this new type of Tc(III) complexes as a useful tool in designing of lipophilic, tunable  $^{99m}\text{Tc}$  radiopharmaceuticals.

# Synthetic Approaches to Multivalent Lipopeptide Dendrimers Containing Cyclic Disulfide Epitopes of Foot-and-Mouth Disease Virus

Eliandre de Oliveira,<sup>†</sup> Judit Villén,<sup>†</sup> Ernest Giralt, and David Andreu<sup>\*,†</sup>

Department of Organic Chemistry, University of Barcelona, Barcelona, Spain Received July 17, 2002;  
Revised Manuscript Received November 5, 2002

The synthesis of a multiantigenic peptide dendrimer incorporating four copies of a cyclic disulfide epitope has been undertaken. Since standard chemoselective ligation procedures involving thioether formation are inadvisable in the presence of a preformed disulfide, conjugation through a peptide bond between the lipidated branched lysine scaffold and a suitably protected version of the cyclic disulfide has been used instead. Several synthetic approaches to the partially protected cyclic disulfide peptide have been explored. The most effective involves building a minimally protected version of the peptide by Boc solid phase synthesis, using fluorenyl-based anchorings and cysteine protecting groups. Peptide–resin cleavage and cysteine deprotection/oxidation are performed simultaneously by base-promoted elimination. The cyclic disulfide epitope is readily obtained in sufficient amounts by this procedure and subsequently incorporated to the lipidated lysine core by peptide bond formation in solution. A final acid deprotection step in anhydrous HF yields a peptide construction containing a maximum of three copies of the cyclic disulfide epitope, the lower substitution being attributable to steric constraints. This immunogen has been successfully used in an experimental vaccination trial against foot-and-mouth disease virus.

## INTRODUCTION

Interest in peptide-based vaccines remains high despite the limited number of practical applications reported to date (1–4). A particular concern in the design and production of peptide vaccines is defining an appropriate carrier/adjuvant system that enhances the generally reduced immunogenicity of free peptides (5). Conjugation of the peptide to a carrier protein (6) is an effective solution but suffers from drawbacks such as poor chemical definition, unwanted peptide or carrier modification during the coupling steps, or undesired response to the carrier (7). Other alternatives, such as encapsulation of the peptide antigen into liposomes (8) or conjugation to poly-lysine-based synthetic carriers (9), have been proposed. A particularly fruitful strategy has been the multiple antigenic peptide (MAP)<sup>1</sup> system (10), a dendrimeric construction that displays four or eight copies of peptide on a branched lysine scaffold. The MAP concept has been further expanded by combining in a single molecular entity the antigen multiplicity provided by the MAP with the adjuvant effect of lipid moieties (11–13). This type of constructs are regarded as promising candidates for a new generation of fully synthetic, peptide-based vaccines.

MAP immunogens have been prepared by either stepwise or convergent synthetic approaches. In the original procedure (10), the construct was synthesized entirely in the solid phase: the four (or eight) amino groups of a tri- (or hepta-) lysine core were used as starting points

for assembly of the immunogenic peptide sequence. The potential advantages of this approach, namely, simplicity and expediency, are usually offset by the difficulties of achieving quantitative couplings within a sterically crowded dendrimer network (14), which result in heterogeneous products. More recently, chemoselective ligation (15) strategies have been shown as convenient alternatives to this procedure. A typical approach involves suitable functionalization (e.g., haloacetylation) of the lysine core followed by conjugation in solution, e.g., S<sub>N</sub>2 reaction with the Cys thiol group of an independently synthesized, well characterized peptide (16–18), to give four (eight) copies of immunogen conjugated to the lysine core through thioether bonds.

The serious economical impact of foot-and-mouth disease (19) has been acutely highlighted by the 2001 outbreak in the U.K. (20). Disadvantages of the use of conventional vaccines against foot-and-mouth disease virus (FMDV), as well as considerable hurdles for new vaccine design, have been described (21). As a result, new

efforts to develop FMDV vaccines requiring no handling or administration of virus particles are under way. Use of synthetic peptides reproducing relevant antigenic sites (22) is particularly attractive in the case of FMDV, given the relevance of the humoral response in the control of the disease (23). We have recently shown (24) that cyclic disulfide versions of the main antigenic site of FMDV (site A) provide excellent mimicry of the bioactive conformation, with a substantial (10–100-fold) improvement in antigenic recognition over the consensus sequence (YTASARGDLAHLTTT, residues 136–150 of viral protein 1 (VP1), isolate C-S8c1). We are seeking to develop these cyclic peptide antigens into practical vaccine candidates by combining them with the known immunogenic properties of lipo-MAP systems. Our target, a lipidated lysine core displaying four copies of the cyclic disulfide peptide (Figure 1), is substantially more complex from the synthetic point of view than any of the MAP constructs reported so far. In this case, the thioether-based ligation strategy described above is not advisable due to the incompatibility of a free thiol and an internal disulfide within the same molecule. In view of these difficulties, we have opted for a more elaborate approach, involving the conjugation, through a peptide bond, of the lipo-MAP core to a protected version of the cyclic disulfide peptide epitope. In this paper we analyze several approaches to this challenging synthetic goal and propose a feasible solution to the problem.

## EXPERIMENTAL SECTION

**General.** 2'-Chlorotrityl chloride resin and *p*-methylbenzhydrylamine resin were from Novabiochem. Poly(ethylene glycol)-polystyrene resin (0.31 mmol/g) was from Perseptive Biosystems (Framingham, MA). Protected (Boc and Fmoc) amino acids were from Bachem (Bubendorf, Switzerland), Neosystem (Strasbourg, France), or Novabiochem (Läufelfingen, Switzerland). In the

Fmoc-based synthesis, the side chain protections were Arg(Pmc), Asn(Trt), Asp(OtBu), Cys(Trt), Cys(Acm), Gln(Trt), Lys(Boc), and Ser(tBu). The Boc-based synthetic runs used Asp(OcHex), Cys(Fm), Lys(ClZ), and Ser(Bn). Peptide-synthesis grade DCM and DMF, and HPLC-grade acetonitrile were from Scharlau (Barcelona, Spain). 2-Aminodecanoic acid (Ada) was a gift from Prof. William Gibbons (School of Pharmacy, University of London). All other chemicals for peptide synthesis were of the highest quality available from Sigma-Aldrich (Madrid, Spain).

Analytical HPLC was performed on Nucleosil C<sub>18</sub> or C<sub>4</sub> reverse-phase columns (4.6 × 250 mm, 5 μm particle size) on a Shimadzu system. Preparative HPLC runs were done on Vydac C<sub>8</sub> column (20 × 250 mm, 10 μm particle size) columns in a Waters Delta Prep 4000 system. Semipreparative HPLC runs were performed on Vydac C<sub>4</sub> (25 × 300 mm, 15–20 μm particle size). Amino acid analyses (AAA) of peptide hydrolysates (6 N HCl, 150 °C, 3 h) were run in a Beckmann 6300 autoanalyzer. MALDI-TOF and ES mass spectra were recorded in Voyager DE-RP (Applied Biosystems, Foster City, CA) and VG-Quattro (Micromass, U.K.) instruments, respectively.

**Lipitated Lysine Core.** The branched Lys<sub>2</sub>-(Lys)-Ada<sub>2</sub>-NH<sub>2</sub> scaffold was synthesized manually by standard Boc chemistry protocols (25) on 0.2 mmol (286 mg) of MBHA resin. The two residues of Boc-Ada (0.4 mmol, 115 mg for each coupling, 2× molar excess) were followed by one, then (after deprotection of both α and ε amino groups) two residues of Boc-Lys(Boc) [0.6 mmol (208 mg) per residue, 3× molar excess], to give the tetravalent dendrimer core. Couplings were mediated by TBTU (equimolar to amino acid) and DIEA (2× molar excess relative to TBTU) in DMF for 1.5 h. The peptide-resin was deprotected at the N-termini with 40% TFA in DCM and then treated with HF/anisole (9:1 v/v, 0 °C, 1 h) to release the lipidated Lys core, which was eluted in 10% HOAc and lyophilized. Purification by preparative HPLC using a linear gradient of 10–50% MeCN in water (+0.05% TFA) over 180 min at a flow rate of 3 mL/min afforded 32.3 mg (22% yield) of the branched lipopeptide. Since two residues of racemic Ada had been used, four clustered peaks were observed by analytical HPLC, corresponding to the possible diastereomers of the product, each of them with the correct mass by MALDI-TOF MS (theoretical: 740.27 Da, found: 740.67 Da).

**Partially Protected Cyclic Disulfide Version of Site A Epitope Peptide.** Four different synthetic approaches (Scheme 1) were attempted, as follows:

**Route A.** The initial substitution (1–1.5 mmol/g) of 300 mg of commercial 2'-chlorotrityl chloride resin was lowered by coupling of a substoichiometrical amount of Fmoc-Ala (0.18 mmol, 56 mg, 0.5 equiv) in the presence of DIEA (1.8 mmol, 308.3 μL) in DCM for 1 h, followed by capping with MeOH (400 μL, 10 min). A new substitution of 0.38 mmol/g was determined by AAA. The remaining amino acids in the target sequence were incorporated by standard Fmoc protocols (26) in a Milligen 9050 synthesizer. Deprotections were done with 20% (v/v) piperidine in DMF (6 min, continuous flow), and couplings with 5 equiv (1.9 mmol) of Fmoc-amino acid and TBTU and 10 equiv of DIEA (3.8 mmol) in DMF for 60 min. After the target sequence was assembled, formation of the internal disulfide was attempted by two different procedures: (i) peptide-resin cleavage and selective deprotection of the two Cys(Trt) residues with simultaneous oxidation and (ii) cleavage and Cys(Trt) deprotection followed by oxidative treatment. In procedure i, 20 mg peptide-resin (ca. 2.5 μmol) were treated

**Scheme 1. Synthetic Approaches to Protected Cyclic Disulfide Epitope Peptides<sup>a</sup>**

Route A

Routes B, C

Route D

<sup>a</sup> (i) I<sub>2</sub> (10 eq) in DCM/TFE/HOAc (7:2:1); (ii) DCM/TFE/HOAc (7:2:1); (iii) I<sub>2</sub> (10 eq); (iv) 0.1 M Hg(OAc)<sub>2</sub> in DMF; (v) β-mercaptoethanol/DMF (1:9); (vi) DCM/TFA (98:2); (vii) 0.1 M NH<sub>4</sub>HCO<sub>3</sub>, pH 8/DMSO (1:1); (viii) DMSO/NMP (2:8) or 20 mM TEA/20 mM CCl<sub>4</sub> in NMP; (ix) piperidine/DMF (1:1).

with 500 μL of a DCM/TFE/HOAc (7:2:1) solution containing 25 μmol iodine (27) for 10 min at 25 °C. The resin was filtered and washed twice with 500 μL DCM/TFE/HOAc (7:2:1), and the combined filtrates were stirred into 1.5 mL of a 0.1% solution of Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>·5H<sub>2</sub>O in water until complete disappearance of the brownish color. The aqueous phase was washed with DCM, and the combined organic phases were briefly dried with anhydrous MgSO<sub>4</sub> and evaporated to dryness under vacuum. In procedure ii, the same amount of peptide-resin was stirred with 500 μL of DCM/TFE/HOAc (7:2:1) for 15 min at 25 °C, filtered, and washed with 500 μL of the same reagent. The combined filtrates were then added dropwise to a solution of 25 μmol I<sub>2</sub> in 1 mL DCM/TFE/HOAc (7:2:1), stirred for 10 min, and worked up as in procedure i.

**Route B.** Fmoc-Ala (0.75 mmol, 5 equivalent) was manually coupled (3 × 30 min) in the presence of DMAP (0.075 mmol, 0.5 equiv) and TBTU (0.75 mmol, 5 equiv) to a PEG-PS resin (0.22 mmol/g) functionalized with the HMPB (28) handle. A substitution of 0.13 mmol/g was determined by AAA. The remaining residues in the target sequence were incorporated by standard Fmoc protocols in a Milligen 9050 synthesizer as in approach A, except that Cys(Acm) (29) instead of Cys(Trt) was used. Recouplings of Arg<sup>138,145</sup>, Asn<sup>139,143</sup>, and Leu<sup>144</sup> were performed. After chain assembly was completed, the Cys(Acm) residues were selectively deprotected by treatment with a 0.1 M solution of Hg(OAc)<sub>2</sub> in DMF for 3 h in the dark (30). The resin was then washed with DMF (6 × 1 min) and treated with β-mercaptoethanol/DMF (1:9 v/v, 6 × 1

**Figure 2.** MALDI-TOF mass spectrum (A) and analytical HPLC (B) of the lipidated lysine core. The peak at 740.61 Da, which fits with the theoretical mass of Lys<sub>2</sub>-Lys-Ada<sub>2</sub>-NH<sub>2</sub> (740.27 Da), is accompanied by its sodium (762.6 Da) and potassium (778.56 Da) adducts. The unusually broad HPLC peak is due to the diastereomeric mixture resulting from use of racemic Ada (see text). HPLC was performed on a C<sub>4</sub> column eluted with a linear gradient of 10–60% B in 30 min, flow rate 1.0 mL/min.

**Figure 3.** Analytical HPLC of a fully deprotected version of the 21-residue peptide epitope prepared by route A. HPLC was performed on a C<sub>18</sub> column eluted with a linear gradient of 10 to 60% B in 30 min, flow rate 1.0 mL/min.

min and overnight) to remove the mercuric salts from the peptide-resin and release the free thiols, which gave a positive (orange) Ellman (31) test. The protected peptide (in free dithiol form) was then cleaved from the resin by treatment with TFA/DCM (1:99 v/v, 4 × 10 mL, 30 s). The filtrates from each treatment were poured over 40 mL H<sub>2</sub>O, combined, concentrated on a rotary evaporator and lyophilized. The residue was dissolved in a 1:1 (v/v) solution of DMSO in 0.1 M NH<sub>4</sub>HCO<sub>3</sub> (1:1), pH 8, to 49 μM peptide concentration, and the progress of the oxidation reaction was monitored by both HPLC and a qualitative Ellman test. For HPLC analysis, 100 μL aliquots of the oxidation solution were neutralized with HOAc, injected into a C<sub>4</sub> column, and eluted with a linear 60–100% gradient of MeCN (+0.036% TFA) into water (+0.045% TFA) over 30 min at 1 mL/min flow rate. Oxidation was judged to be complete after 128 h.

**Route C.** Peptide synthesis and Cys deprotection were performed as in approach B. After the removal of the mercuric salts, the oxidation step was carried out in the solid phase by treating the peptide-resin with either DMSO/NMP (2:8 v/v) or 20 mM carbon tetrachloride-triethylamine (CCl<sub>4</sub>/TEA) in NMP. In both cases, the peptide-resin gave a negative (faint yellow) qualitative

Ellman test after 24 h. The protected peptide was cleaved from the resin by treatment with TFA/DCM (2:98 v/v, 4 × 1 min) and analyzed by HPLC. The identity of the cyclic peptide was further confirmed by AAA and by ES-MS after complete deprotection in TFA/H<sub>2</sub>O/TIS (95:2.5:2.5; v/v/v) (theoretical, 2255.16 Da; found, 2253.35 Da).

**Route D.** The substitution of 1 g of commercial MBHA resin (0.7 mmol/g) was reduced to 0.25 mmol/g by coupling of Boc-Gly (0.3 mmol, 52 mg) with DIC for 2 h in DCM. Next, the HMFS handle (32) (0.375 mmol, 79 mg) was coupled with DIC/HOBt (1:1:1 molar ratio) in DMF (overnight + 2 h recoupling). The first amino acid in the target sequence (Ala) was esterified to the polymer using two 60 min couplings with 5 eq each of Boc-Ala (1.25 mmol, 237 mg) in the presence of DIC (1.25 mmol) and DMAP (0.125 mmol) in DCM. The remaining residues in the target sequence were incorporated by a manual protocol that included (i) Boc deprotection (neat TFA, 1 + 10 min), (ii) washes (DCM, 6 × 1 min), (iii) neutralization (5% DIEA/DCM, 3 × 1 min), washes (DCM, 6 × 1 min), and (iv) single couplings with 5 equiv of both Boc-amino acid and DIC in DCM; for Asn, Arg, and Gln residues that were incorporated without side chain protection, HOBt (5 equiv) was added to the coupling mixture and DCM/DMF (1:1 v/v) was used as solvent. Coupling reactions were run for 30–40 min, until a negative Kaiser ninhydrin test was obtained. Upon completion of chain assembly, the peptide resin was treated with 500 mL piperidine/DMF (1:1) to selectively deprotect/oxidize (33) the Cys(Fm) residues at positions 136 and 155 and simultaneously cleave the peptide from the resin. The oxidation/cyclization reaction was monitored by analytical HPLC of the filtrates and judged to be complete after 3 h. The filtrate was then cooled in an ice bath, acidified to pH 4 by dropwise glacial HOAc addition, and concentrated in a rotary evaporator to induce precipitation of salts, which were removed by filtration. The resulting solution was loaded onto a Vydac preparative C<sub>8</sub> HPLC column (20 × 250 mm) equilibrated with 0.1% TFA in water (solvent A) in a Waters Delta Prep 4000 system. Purification was done by a linear gradient of 0–20% solvent B (0.1% TFA in MeCN) into A over 5 min followed by another linear gradient of 20–70% B into A over 100 min, at a 25 mL/min flow rate.

**Figure 4.** HPLC analysis of epitope peptide prepared according to route B, (A) with protected side chains but Cys in free dithiol form and (B) after oxidative treatment with DMSO in pH 8 buffer. HPLC was performed on a  $C_4$  column eluted with a linear gradient of 60–100% B in 30 min, flow rate 1.0 mL/min.

**Figure 5.** HPLC analysis of epitope peptide prepared according to route C, with protected side chains and free Cys (dithiol form) (A), and after solid-phase oxidation with either DMSO/NMP (2:8) (B) or 20 mM  $CCl_4$ /TEA in NMP (C). HPLC was performed on a  $C_4$  column eluted with a linear gradient of 60–100% B in 30 min, flow rate 1.0 mL/min.

Fractions judged to be homogeneous by analytical HPLC were pooled and lyophilized. The purified partially protected peptide was satisfactorily characterized by MALDI-TOF (theoretical, 2650.19 Da; found, 2644.42 Da) and AAA.

**Synthesis of the Branched Multiple Antigenic Peptide.** The lipidated lysine core (0.05  $\mu$ mol), the partially protected cyclic disulfide site A peptide (prepared by route D, 0.6  $\mu$ mol, 12 equ), WSC, and HOOBt (0.6  $\mu$ mol each) were dissolved in 100  $\mu$ L of DMF and allowed to react for 48 h at 25  $^{\circ}$ C. The reaction mixture was diluted with water (10 mL) and lyophilized and the lipopeptide fully deprotected with HF/anisole (90:10,

0  $^{\circ}$ C, 1 h). After evaporation, the residue was dissolved in 1 M HOAc and lyophilized, and then filtered through a Sephadex G 25 column (300  $\times$  10 mm) eluted with 0.1 M HOAc at 20 mL/h. Fractions shown by MALDI-TOF MS to contain the conjugation product were pooled and lyophilized. The resulting product was characterized by HPLC, AAA, and MALDI-TOF.

## RESULTS AND DISCUSSION

The goal of this work was to develop an efficient synthetic approach to a multivalent format of the previously described, antigenically optimized cyclic disulfide version of site A peptide from FMDV (24). For serotype O<sub>1</sub>BFS, the specific epitope was a 21-residue cyclic

disulfide (CSRNAVPNLRGDLQVLAQKCA) displayed 4-fold on a lipidated branched lysine core (Figure 1). Although this type of structure is conceptually identical to other MAP constructions, the need to incorporate several copies of a large cyclic disulfide (predictably bulkier and less flexible than a linear peptide chain of similar length) substantially increases its synthetic difficulty.

To synthesize MAP type structures, the most reliable approaches involve ligation strategies, i.e., the lysine core and the epitope peptide, are synthesized independently and, after adequate purification and characterization, conjugated in solution. Such an approach has been shown to provide much better products fully stepwise solid phase schemes, where sterical crowding in the dendrimeric structure increases the risk of incomplete couplings and consequently heterogeneous products (34, 35). Thioether-based ligation, a widely used approach for this type of constructs, is clearly unadvisable in the present case, since the integrity of any disulfide (four in our target structure) cannot be guaranteed in the presence of the free thiol required for thioether formation. This drawback forced us to consider as an alternative approach the ligation of the cyclic disulfide epitope to the lipidated MAP core by means of a peptide bond, i.e., linking a suitably protected version of the cyclic disulfide peptide through its C-terminus to the lipo-MAP scaffold. This relatively elaborated approach to disulfide-containing MAP constructions has, to our knowledge, not been previously attempted. In the present work, we have explored several potentially useful synthetic routes and settled for one which in our hands has turned out to be most efficient.

**A. Lipidated Lysine Core.** The carrier structure chosen for our conjugate was a branched lysine scaffold bearing two residues of 2-aminodecanoic acid (Ada) (36) at its C-terminus. The synthesis of this lipo-MAP core was straightforward by standard Boc solid-phase methods. Since the lipoamino acid was used in racemic form, the final product obtained after HF cleavage was an almost equimolar mixture of the four possible diastereomers. We found it expedient to work with this mixture, after ensuring that each of the four peaks observed by HPLC (Figure 2) had a MALDI-TOF spectrum consistent with the desired structure. The amphipathic character of the MAP facilitated its purification by reverse phase HPLC using a simple  $H_2O$ /MeCN gradient.

**B. Partially Protected Cyclic Disulfide Version of Site A Epitope Peptide.** Several synthetic approaches (routes A–D, see Experimental Section) were explored to access the cyclic disulfide version of 21-residue FMDV site A peptide (O<sub>1</sub>BFS serotype) ( $C^{136}$ SRNAVPNLRGDLQVLAQKCA $^{156}$ ) in protected form;

**Figure 6.** HPLC analysis of epitope peptide prepared according to route D, after (A) 20 min and (B) 180 min cleavage and oxidation with piperidine/DMF (1:1). Peaks 1–3 are, respectively, a non-peptide byproduct, the dithiol form of the peptide, and the expected cyclic disulfide, which after preparative HPLC was obtained in highly homogeneous form (C). HPLC was performed on a  $C_4$  column eluted with a linear gradient of 5–95% B in 35 min (A and B) or 35–65% B in 30 min (C), flow rate 1.0 mL/min.

**Figure 7.** MALDI-TOF mass spectrum of the lipidated lysine core conjugated with the cyclic disulfide epitope peptide. The peak at 7558 Da is consistent with a conjugate consisting of three copies of the epitope bound to the  $\text{Lys}_2\text{--Lys--Ada}_2\text{--NH}_2$  core (theoretical mass 7570 Da).

three approaches were based on Fmoc chemistry (Scheme 1, routes A–C) and one on Boc chemistry (route D).

**Route A.** In our first attempt to synthesize the site A cyclic disulfide in protected form, we opted for a maximal protection scheme relying on the 2'-chlorotrytyl chloride resin and trityl-type protection groups, which allowed (i) selective (iodine-mediated) Cys(Trt) deprotection, (ii) disulfide formation, and (iii) peptide–resin cleavage in a single operation (27). An initial synthesis was planned for a 20- (not 21-) residue target, namely, the above sequence lacking the  $\text{Ala}^{156}$  residue. In this case, the first amino acid coupled to the 2'-chlorotrytyl chloride resin was Fmoc–Cys(Trt). A very low incorporation of this amino acid occurred (detectable by the weak absorbance of the Fm–piperidine adduct solution obtained upon deprotection), probably due to steric conflict between the Trt groups of both solid support and Cys side chain. Once chain assembly was complete, treatment with DCM/TFE/HOAc (7:2:1) containing iodine (10 equivalent) was expected to achieve peptide–resin cleavage, Cys deprotection, and disulfide formation in a single step. However, MALDI-TOF or ES MS analysis of the resulting product showed no peaks assignable to the target sequence or related species. Since low solubility might be expected for the protected peptide and eventually complicate its detection, a small amount of peptide resin was cleaved and fully deprotected by means of reagent R (TFA/thioanisole/EDT/anisole; 90:5:3:2) (37). Again, no peaks consistent with the expected structure could be detected in the cleavage mixture.

A new synthetic attempt was done with a one-residue longer peptide as target, i.e., the sterically nonconflicting, native  $\text{Ala}^{156}$  anchored (0.38 mmol/g) to 2'-chlorotrytyl

chloride resin instead of Cys<sup>155</sup>. Again, analysis of the fully deprotected (reagent R) crude by HPLC and MALDI-TOF (Figure 3) showed unsatisfactory results: only traces of the expected peptide, plus a number of peaks attributable to single deletions (Arg, Leu, or Asn) were detected. Thus, despite its well-documented usefulness for the preparation of protected peptides, 2'-chlorotrytyl chloride resin was in our hands inadequate to synthesize this particular peptide.

**Route B.** Our next attempt to synthesize the 21-mer used PEG-PS as solid support, functionalized with the HMPB (28) handle. Since this handle is less acid-labile than 2'-chlorotrytyl chloride resin, we opted for the Acn group as Cys side chain protection. In view of past difficulties, double couplings were done for Arg<sup>138,145</sup>, Asn<sup>139,143</sup>, and Leu<sup>144</sup>. To evaluate the quality of the synthetic product, a small aliquot was fully deprotected and cleaved, showing a rather homogeneous HPLC profile with the expected molecular weight by MALDI-TOF MS (expected 2255.2; found 2256.2). Once the presence of the correct sequence on the resin was assured, we performed selective solid-phase deprotection of the thiol group with 0.1 M  $\text{Hg}(\text{OAc})_2$  in DMF. Mercury salts were removed from the polymer by extensive treatment with  $\beta$ -mercaptoethanol/DMF (1:9), and then the peptide–resin bond was cleaved with TFA/DCM (1:99) to give the partially protected peptide in reasonably pure dithiol form (Figure 4A), ready for oxidation in solution. Unfortunately, this protected precursor was totally insoluble in aqueous solution, even at the high dilution (49  $\mu\text{M}$ ) required to avoid aggregation and intermolecular disulfide bond formation. To improve its solubility we resorted to DMSO, a denaturing cosolvent known for its

added advantage of promoting thiol-disulfide oxidation (38, 39). In our case, the protected peptide could be dissolved in an oxidation buffer containing ca. 40% DMSO, but HPLC monitoring of the reaction showed a complex oxidation mixture (Figure 4B). In addition, and as described by other authors (40), we experienced severe difficulties in removing DMSO, either by reverse-phase HPLC or by selective adsorption of the peptide (carrying several aromatic side chain protections) on an aromatic-binding Diaion column (41). Since our efforts to devise efficient, preparative scale purification conditions were unsuccessful, this synthetic approach was finally abandoned.

**Route C.** Oxidation of free bis-thiol precursors in the solid phase, i.e., while the partially protected peptide remains anchored to the polymeric support, is a well-known strategy for disulfide formation (42–47). Use of a low-substitution resin creates pseudo-dilution conditions that favor intramolecular cyclization (48). Other obvious additional advantages are the facile removal of oxidizing agents by washing and filtration, and the fact that the solubility behavior of the peptide is not an issue. On the down side, the efficiency of solid phase cyclizations tends to depend strongly on the distance between the thiol groups. Though no systematic studies have been performed, not many cycles larger than 18 amino acids have been described (49). A number of Cys protecting groups, oxidizing agents, and conditions have been described for this type of strategy, both for Fmoc [e.g., Trt/iodine (50), AcM/iodine (51), AcM/thallium trifluoroacetate (52), etc.] and for Boc-based [Fm/piperidine (33)] synthetic chemistries.

Our attempt of on-resin oxidation/cyclization used the same anchoring and protection scheme as those in route B. The Cys(AcM) residues were also deprotected with Hg(OAc)<sub>2</sub>, and after removal of Hg(II) salts, the resin-bound bis-thiol was treated with a mild oxidation mixture [NMP/DMSO (8:2)] (to our knowledge not previously reported) or, for comparison, with a well-known solid-phase oxidation reagent, 20 mM CCl<sub>4</sub>/TEA in NMP (53). The reactions were monitored by qualitative Ellman test (31), which after 24 h gave only a very faint yellow coloration (vs strong orange color for the non-oxidized peptide resin). As shown in Figure 5, analytical HPLC profiles of small aliquots of both peptide–resins after full deprotection and cleavage (reagent R) show much cleaner materials than those obtained in solution (approach B). Difficulties, however, appeared when cleavage of the peptide in protected form from the solid support was attempted. Standard cleavage conditions (TFA/DCM (2:98, v/v) were ineffectual. Higher percentages of TFA (5:95 and 10:90, v/v) improved only slightly the cleavage yield but were associated to complex HPLC profiles indicative of undesired partial deprotection of side chains. Due to these difficulties, this initially promising scheme had also to be abandoned.

**Route D.** In view of the shortcomings of the previous Fmoc-based synthetic schemes, a rather different approach was explored, on the basis of (i) Boc chemistry for chain elongation, (ii) minimalist protection scheme (Asn, Arg, and Gln side chains unblocked) to favor solubility of the partially protected cyclic disulfide epitope during coupling to the lipo-MAP core, and (iii) base-labile, fluorenyl-based chemistries for both Cys protection (Fm) and peptide anchoring to the solid support (HMFS handle, 54), which allow deprotection/oxidation and peptide–resin cleavage in a simultaneous step, under conditions orthogonal with other (acid-labile) protecting groups. A potential further advantage of Boc chemistry, vis-à-

vis the difficulties experienced in building up the epitope sequence using Fmoc chemistry in routes A–C, would be a reduced risk of aggregation (and thus of ensuing incomplete couplings) by the use of TFA, an excellent disaggregating agent, at the repetitive N<sup>α</sup>-deprotection steps.

In practice, this last approach turned out to be quite satisfactory. Thus, a single treatment of the peptide–resin with piperidine readily produced the peptide epitope in (partially protected) cyclic disulfide form. An unusually large solvent-to-resin ratio was used at this step, to achieve high dilution conditions favoring the formation of the internal disulfide over other undesirable Cys pairings. Neutralization of the large amount of piperidine in the cleavage/oxidation mixture slightly complicated the work up: after filtering off the initially formed piperidine acetate, recurrent precipitation of this salt upon concentrating the solution in the rotary evaporator made several additional filtration steps necessary. This inconvenience aside, the procedure furnished in adequate purity and yield a correctly oxidized, minimally protected cyclic disulfide peptide epitope, which was further purified to satisfactory specifications by preparative HPLC (Figure 6).

**C. Conjugation of the Cyclic Disulfide Epitope to the Lipidated MAP Core.** The purified, partially protected cyclic disulfide version of antigenic site A of FMDV prepared by route D above was incorporated to the tetravalent lipo-MAP by peptide bond formation between the C-terminal carboxyl of the epitope peptide and the amino groups of the lipidated lysine core. A 3-fold excess of peptide over each amino group (12 equiv in total) was used, with activation by carbodiimide (water-soluble) and HOObt in DMF over 48 h. When HPLC monitoring of this conjugation reaction showed no significant progress (48 h at 25 °C), the reaction mixture was evaporated and submitted to acidolysis with anhydrous HF to remove the protecting groups remaining on the Ser, Asp, and Lys side chains of the disulfide epitope (see Figure 6). The resulting lipopeptide was shown by MALDI-TOF MS (Figure 7) to be predominantly the trivalent version of the conjugate (theoretical, 7565.1 Da; found, 7570.4 Da). The fact that no peak corresponding to the tetravalent conjugate could be detected in the mass spectra, together with the aforementioned lack of progress of the conjugation reaction after 48 h, led us to the temporary conclusion that the tetravalent version of the conjugate was not readily accessible, perhaps due to the predictably substantial steric crowding caused by the cyclic disulfide. This point is currently under investigation. Despite the less-than-optimal result in this particular case, the synthetic approach based on route D is in our opinion the most straightforward and reliable procedure for preparing dendrimeric conjugates of cyclic disulfide epitopes.

The dendrimeric, lipidated, cyclic disulfide version of antigenic site A of FMDV which has been the object of the present study has been preliminarily evaluated as a vaccine candidate with very promising results (De Oliveira et al., manuscript in preparation). Thus, guinea pigs immunized with 500 µg of the trivalent conjugate and boosted with another 500 µg after 27 days elicited antibodies with neutralization titers comparable to control animals immunized with conventional (guinea pig-adapted) FMDV vaccine. When challenged (experimentally infected) with live virus, two out of three animals turned out to be protected (vs three out of three for the conventional vaccine). We look forward to using this type

of conjugate, in combination with other replicas of FMDV antigenic sites, in future synthetic vaccine trials.

## ACKNOWLEDGMENT

Support from Generalitat de Catalunya (CERBA) and the Ministry of Education and Science (DGICYT Grants PB97-0873 and BIO99-0484), Spain, and from the European Union (Grant FAIR5-CT97-3577) is gratefully acknowledged. J.V. is a predoctoral fellow from DURSI (Generalitat de Catalunya, Spain).

# Signal Peptide Mimics Conjugated to Peptide Nucleic Acid: A Promising Solution for Improving Cell Membrane Permeability

Xiaoxu Li,<sup>†</sup> Liangren Zhang,<sup>†</sup> Jingfen Lu,<sup>†</sup> Yaozu Chen,<sup>‡</sup> Jimei Min,<sup>†</sup> and Lihe Zhang<sup>\*,†</sup>

National Laboratory of Natural and Biomimetic Drugs, Peking University, Beijing 100083, P. R. China and Department of Chemistry, Lanzhou University, Lanzhou 730000, P. R. China. Received July 24, 2002; Revised Manuscript Received October 8, 2002

The specific binding ability and biostability of PNA (peptide nucleic acid) with DNA or RNA make PNA not only a good tool for the studies of molecular biology but also the candidate for gene-targeting drugs. However, the main obstacle for its potential usage as a therapeutic is the low cell uptake caused by the poor cell membrane permeability. In this paper the hydrophobic pentadecapeptide and two signal peptide mimics, hexa- and decapeptides ending with a positively charged amino acid, were proposed as the linked carrier for the transportation of PNA T10 through the cell membrane; stable spin label was coupled to the peptide–PNA conjugate so that the ESR measurements can be used for the assessment of their transmembrane movements. The syntheses of spin-labeled peptide–PNA conjugates were carried out on MBHA resin with Boc strategy. The cell membrane permeability of the spin-labeled conjugates of peptides and PNA can be determined with ESR, during the incubation of erythrocyte with the samples. According to ESR measurements, the three conjugates exhibit enhanced uptake into erythrocytes. The hexa- and decapeptide-modified PNA showed suitable water solubility. The peptide–PNA conjugates retained their binding ability to complementary DNA. The results suggest that peptide modification of PNA might be a promising solution for improving cell membrane permeability toward PNA.

## INTRODUCTION

Peptide nucleic acid (PNA) is a structural DNA mimic in which the entire backbone has been replaced by a polyamide backbone composed of *N*-(2-aminoethyl)glycine units (1, 2). PNA can hybridize to the complementary DNA and RNA or dsDNA strand with higher affinity than their oligonucleotide counterparts, obeying either Watson–Crick or Hoogsteen base pairing rules (2–5). Upon binding to DNA or mRNA, PNA exerts biological effects including in vitro transcription and translation modulation (6, 7), and PNA is stable toward both nuclease and protease (8). This character of PNA not only makes it a new tool for the studies of molecular biology but also the potential candidate for gene-targeting drugs (9, 10). However, the main obstacle for its potential usage as a therapeutic is the low cell uptake caused by the poor cell membrane permeability (11). Many physical delivery methods such as microinjection and cell treatment by detergent were reported for the studies of antisense or antigene PNA (6, 12). The efforts via chemical modification have also been made to improve cell uptake of PNA. Receptor-mediated cell or tissue internalization mechanism has been proposed for the specific delivery of PNA; for example, lactose (13), dihydrotestosterone (14), and D-peptide analogue of insulin-like growth factor 1 (IGF1) (15) modified PNAs were designed and exhibited rapid and specific entry into the corresponding cells. The transferrin receptor-mediated endocytosis system (16, 17) was also used to transport PNA through the blood–brain barrier in vivo, and gelatin or protein nanoparticles were

also explored as carriers for PNA (18, 19). On the other hand, PNAs attached with lipophilic groups such as adamantyl (20, 21), phosphonium cation (22), and hydrophobic peptides (23) showed significantly improved membrane penetration in either liposome models or biomembrane systems. Different types of peptides with membrane permeability could be used as a carrier for the membrane transportation of PNA by chemical conjugation. PNA coupled to a retro-inverso delivery peptide was rapidly taken up by cultured cerebral cortex neurons (24); PNA coupled with the cellular transporter peptide, Antennapedia, was efficiently taken up into Bowes cells (25); the cationic peptide (26) linked at the N-end of a PNA pentamer directed at the RNA template of telomerase resulted in enhanced inhibition of telomerase activity; Antennapedia peptide also showed both cell uptake and inhibition of telomerase activity in human melanoma cells (27, 28); SV40 nuclear localization signal (NLS) demonstrated its efficiency for the transportation of PNA as well as the hybridized DNA (29, 30). The accumulated results suggest that peptide conjugation is an attractive strategy for the intracellular delivery of PNA.

Signal peptide is an N-terminal extension of premature secretory protein and directs the translocation of protein through the membrane of endoplasmic reticulum of eukaryotes or the inner membrane of prokaryotes. The sequences of most signal peptides have a hydrophobic core consisting of a stretch of hydrophobic amino acids, basic residues near the N-terminal, and small neutral residues (31, 32). The studies strongly support that the hydrophobic interaction between the hydrophobic region (h-region) of the signal peptide and the lipid bilayer of cell membrane is the main cause of transmembrane movement (33–37). Some signal peptides have been used

as a carrier of certain protein domains to bring the whole polypeptide through the cell membrane (38–41).

In this paper, the peptide corresponding to the h-region of signal sequences from Kaposi FGF (38, 39) (Figure 1a) and two signal peptide mimics hexa- and decapeptides (Figure 1b,c) were designed as the carriers to conjugate with the model PNA T10 at the N-end. To evaluate the transmembrane behavior of the conceived adducts of peptide and PNA, the stable nitroxyl free radical 3-carboxyl-2,2,5,5-tetramethyl-pyrroline-1-oxyl as reporter group (42) was coupled at the N-end of the PNA moiety (Figure 1). Cell membrane penetration can be exhibited by the changes of the ESR signal during the incubation of erythrocyte with the samples (43, 44).

#### EXPERIMENTAL PROCEDURES

**General.** The PNA monomer *N*-(2-Boc-aminoethyl)-*N*-(thymine-1-ylacetyl)glycine<sup>1</sup> (45) and the stable free radical 3-carboxyl-2,2,5,5-tetramethyl-3-pyrroline-1-oxyl (42) are synthesized as described. Boc-protected amino acids MBHA resin are from Pennisular, and DCC is from Aldrich. DCC and DMF are dried with K<sub>2</sub>CO<sub>3</sub> and molecular sieves, respectively, before use; other chemicals are reagent grade from local commercial sources. Solid-phase synthesis is conducted with manual apparatus. Standard Ninhydrin test (46) is used for monitoring the coupling reaction. HPLC purification is performed with a Waters system on C-18 reverse phase column (0.8 × 20 mm); mobile phase gradient is B: 20–80% or 0–50% in A within 50 min (A: H<sub>2</sub>O containing 0.1% TFA; B: acetonitrile containing 0.1% TFA/H<sub>2</sub>O). UV spectra and *T<sub>m</sub>* are recorded with a Pharmacia LKB Biochrom 4060 spectrophotometer. MALDI-TOF mass spectra are recorded with ZAB-HS, and ESR measurements are conducted with a Bruker ESP 300 ESR spectrometer.

**Synthesis.** *Spin-Labeled Pentadecapeptide PNAT10 Conjugate (R15T10).* Oligomerization of spin-labeled peptide conjugated PNAT10 was conducted by manual solid-phase peptide synthesis on MBHA resin (213 mg, substitution 0.35 mmol/g) with Boc strategy in the order of peptide synthesis, PNA monomer condensation (45, 47), and in situ spin labeling. The cycle procedure for the solid-phase peptide synthesis was as follows: Boc-deprotection was completed with TFA/DCM (1:2, v/v), 3 mL, 1 × 2 min and 1 × 30 min, and then neutralization by using TEA/DCM (1:10, v/v), 3 mL, 2 × 2 min. Condensation was carried out with DCC (2 equiv) as coupling

agent. Two equivalents of Boc-protected amino acid or PNA monomer was dissolved in DCC/DMF (1:1, v/v), giving the final concentration of 0.1 M of Boc amino acid or PNA monomer; after the coupling reaction, the unreacted amino groups were blocked by acetylation with a mixture of 2.5 mL of Ac<sub>2</sub>O/DCM (1:1, v/v) and 2.5 mL of TEA/DCM (1:1, v/v) for 20 min. The coupling reaction was allowed to proceed for 2 h with stirring at rt. The Kaiser test (46) was used to monitor the completion of Boc-deprotection and coupling reaction, respectively. For the peptide synthesis, the first Boc-Ala (0.1 mmol) was loaded on MBHA resin, and the coupling was done sequentially with Boc-protected Leu, Leu, Ala, Leu, Leu, Val, Ala, Pro, Leu, Leu, Ala, Val, Ala, and Ala. The PNA monomer condensation was conducted continuously after the completion of amino acid coupling cycles. Following the 10th PNA monomer coupling cycle, 2.5 equiv of 3-carboxy-2,2,5,5-tetramethyl-3-pyrroline-1-oxyl (final concentration was 0.1 M in DCM) was added to the reaction vessel and stirred with PNAT10-peptide-resin in the presence of DCC (2.5 equiv, 0.1 M). The coupling reaction was completed within 2 h according to the Kaiser test. After capping and wash procedures, the product-resin was dried and treated with anhydrous HF (at 0 °C, 1 h) for cleavage of the oligomer from the resin, and the crude product was purified on C-18 RP-HPLC (20–80% B containing 0.1% TFA in A within 50 min, detected at 260 nm). The final product revealed the standard nitroxyl free radical signals under ESR spectrum measurement (three peaks, *g* = 2.0029, *a<sub>N</sub>* = 15.8 G,  $\Delta H_0$  = 2.5 G). MALDI-TOF MS result: 4245, calculated: 4244.

*Spin-Labeled Decapeptide PNAT10 Conjugate (R10T10).* The procedure of oligomerization, cleavage, and purification is the same as spin-labeled pentadecapeptide PNAT10 conjugate, except the coupling order of amino acids is K, A, L, L, A, L, P, L, L, A; MALDI-TOF MS found: 3848, calculated: 3848; ESR measurement gives the standard three-peak signal as above.

*Spin-Labeled Hexapeptide PNAT10 Conjugate (R6T10).* The procedure of oligomerization, cleavage, and purification is the same as spin-labeled pentadecapeptide-conjugated PNA, except the coupling order of amino acids is K, A, L, L, A, L; MALDI-TOF MS found: 3454, calculated: 3453; ESR measurement gives the standard three-peak signal as above.

*Spin-Labeled PNAT10 (RT10).* The procedure of oligomerization and cleavage is the same as the described in spin-labeled pentadecapeptide-conjugated PNAT10, but only K is coupled on the resin before condensation of the PNA monomers. HPLC purification is carried out with B: 0–50% in A within 50 min. MALDI-TOF MS found: 2972, calculated: 2973; ESR measurement gives the standard three-peak signal as above.

*PNA T10 (T10).* The procedure for synthesis of PNA T10 is the same as described above without the spin labeling. MALDI-TOF MS found: 2808, calculated: 2806.

VLLAL	49.49	LALLA	40.20
AVALL	59.92	AAVAL	71.60

**Computer Simulation.** The molecular total energy was calculated on an SGI indy workstation using the Biopolymer module in INSIGHT II 95.0 (Biosym).

**Observation of Membrane Permeability by ESR Measurement.** Healthy adult's erythrocytes were washed three times with isoosmotic phosphate buffer solution (PBS, pH 7.0) by centrifugation (10 min  $\times$  2000 rpm) (43, 44). The erythrocytes were suspended with PBS, and the density of cell in the suspension was adjusted to 50 million/mL and was incubated at 37 °C for 15 min prior to use. The spin-labeled peptide-conjugated PNA or spin-labeled PNA (2 mM) in 200  $\mu$ L PBS (containing 2% DMSO) was mixed with 200  $\mu$ L erythrocyte suspension. The mixture was incubated at 37 °C. The same volume of sample was picked out from the mixture at beginning of incubation, and thereafter periodically, and submitted to ESR measurement on a Bruker ESP 300 ESR spectrometer, respectively, and the spectra as well as signal strength at the same field was recorded. The percentage of ESR signal strength was calculated from the changes of ESR measurements before and after the incubation of erythrocyte with samples (Figure 2).

## RESULTS AND DISCUSSION

The mechanism of signal peptide in transmembrane movement is complex, but in most cases, the hydrophobic region composed of 5–15 amino acid residues is critical to the hydrophobic interaction with the phospholipids on the membrane. Studies also showed that the polarity and the conformation adopted by the signal sequence played an important role to facilitate the crossing membrane behavior: with the basic residue near the N-end, and most of the h-region in the signal sequence, it more readily formed an  $\alpha$ -helix (31, 32). To design the peptide sequences used for PNA modification, computer-aided modeling was used to search the ideal sequence with the lowest systemic energy in simulation of the  $\alpha$ -helix. According to the data of the simulation, two new sequences LALLAK and ALLPLALLAK with the system energy of 40.20 kcal/mol and 90.65 kcal/mol respectively (Table 2, 3) were proposed as the signal peptide mimics for the modification of PNA. A positively charged lysine was selected as a polarity enhancer which can be appended at the end of peptide, and the lysine would also

contribute to its solubility, as well as the possible role of directing the adduct to access the partial polar cell membrane surface (49, 50). To assess the membrane permeability of the conceived peptide-linked PNA, we designed nitroxyl free radical as a report group so that the permeability of the spin-labeled adduct of peptide and PNA could be detected by the measurement of the ESR signal changes. Therefore, three spin-labeled peptide PNA conjugates (R15T10, R10T10, and R6T10) and the control sample, spin-labeled PNA (RT10), were designed and synthesized by standard solid-phase peptide chemistry. After cleavage with HF treatment, the products show the correct molecular weights by MALDI-TOF MS and the ESR signal with standard nitroxyl free radical parameters: three peaks,  $g = 2.0029$ ,  $a_N = 15.8$  G,  $\Delta H_0 = 2.5$  G. The results also demonstrate that the selected spin label molecule cannot be chemically influenced through a series of peptide synthesis conditions including HF treatment (Table 1).  $T_m$  values of R15T10, R10T10, R6T10, and RT10 measured with the complementary sequence dA<sub>10</sub>, respectively, show that such modification has only little influence on its hybridizing behavior (Table 1).

Stable nitroxyl free radical can be readily reduced to hydroxylamine by reductive agent. In erythrocyte the concentration of the reductive agent is 2–3 mM which can reduce the free radical and dramatically quench the ESR signals inside the cell (43, 44). In our experiments, the erythrocyte suspension in isoosmic buffer was free of plasma via a washing procedure so that the changes of ESR signal were only due to the intracellular chemical conditions. The results (Figure 2, curve 1) showed that the ESR signal strength decreased significantly after 3 h incubation of the pentadecapeptide-conjugated PNA (R15T10) with erythrocyte suspension, and no change was observed in the case of control sample (RT10) at the same condition (Figure 2, curve 4). It indicated that the free radical of R15T10 was reduced by the reductive agents inside the cells. The signal changes after 1.5 h incubation was also observed and showed the same as that determined after 3 h. It may infer that peptide-PNA conjugate R15T10 can penetrate the cell membrane rapidly and reach an equilibrium within 1.5 h. The same ESR measurements were used to assess the cell membrane permeability of hexapeptide- and decapeptide-conjugated PNAs, respectively. R10T10 and R6T10 showed almost the same decrease of the ESR signal strength after the incubation with erythrocyte for over 4 h (Figure 2, curve 2 and 3). After 4 h of incubation, no more decrease of ESR signal was exhibited. It means that the two peptide-PNA conjugates bear a similar extent of cell uptake.

Although pentadecapeptide-PNA conjugate R15T10 appears to have a faster penetrating rate than that of the hexa- and decapeptide modifiers, the pentadecapeptide modification makes the whole PNA T10 adduct difficult to dissolve in water. Lower water solubility may constitute another disadvantage for the feasibility of

therapeutics. However, the hexa- and decapeptide modification both improve the cell membrane permeability and in the meantime bear acceptable water solubility (Table 1). To support the ESR results, an antisense oligonucleotide-peptide conjugate containing LALLAK was synthesized, and the antisense activities targeting GLUT-1 in HepG-2 and MCF-7 cells were investigated (51). It was found that the synthetic antisense oligonucleotide-peptide conjugate showed up to 50% inhibition of cell proliferation in HepG-2 and MCF-7 cells. Compared to the previous paper, the same antisense oligonucleotide without peptide conjugated only showed a transient inhibition of HL-60 proliferation of about 25% and the expressed antisense RNA produced over 50% inhibition (52). Therefore, it seems that the efficiency of the synthetic antisense oligonucleotide peptide conjugate is the same as the expressed antisense RNA in the intact cells.

In conclusion, the hydrophobic pentadecapeptide and two signal peptide mimics, hexa and decapeptides ended with a positively charged amino acid, were proposed as the linked carrier for the transportation of PNA T10 through the cell membrane. Stable spin label was coupled to the peptide-PNA conjugate so that the ESR measurements can be used for the assessment of their transmembrane movements. The syntheses of spin-labeled peptide-PNA conjugates were carried out on MBHA resin with Boc strategy. According to the measurement of ESR, the three conjugates, R15T10, R10T10, R6T10, exhibit an enhanced rate of uptake across the erythrocyte membrane. The hexa- and decapeptide modified PNAs, R10T10 and R6T10, show suitable water solubility. The peptide-PNA conjugates retain their binding ability to the complementary DNA. The results suggest that peptide modification of PNA might be a promising solution for improving cell membrane permeability toward PNA.

Successful treatment of cancer by boron neutron capture therapy (BNCT) requires the selective delivery of  $^{10}\text{B}$  to constituent cells within a tumor. The expression of the folate receptor is amplified in a variety of human tumors and potentially might serve as a molecular target for BNCT. In the present study we have investigated the possibility of targeting the folate receptor on cancer cells using folic acid conjugates of boronated poly(ethylene glycol) (PEG) containing 3rd generation polyamidoamine dendrimers to obtain  $^{10}\text{B}$  concentrations necessary for BNCT by reducing the uptake of these conjugates by the reticuloendothelial system. First we covalently attached 12–15 decaborate clusters to 3rd generation polyamidoamine dendrimers. Varying quantities of PEG units with varying chain lengths were then linked to these boronated dendrimers to reduce hepatic uptake. Among all prepared combinations, boronated dendrimers with 1–1.5 PEG<sub>2000</sub> units exhibited the lowest hepatic uptake in C57BL/6 mice (7.2–7.7% injected dose (ID)/g liver). Thus, two folate receptor-targeted boronated 3rd generation polyamidoamine dendrimers were prepared, one containing ~15 decaborate clusters and ~1 PEG<sub>2000</sub> unit with folic acid attached to the distal end, the other containing ~13 decaborate clusters, ~1 PEG<sub>2000</sub> unit, and ~1 PEG<sub>800</sub> unit with folic acid attached to the distal end. In vitro studies using folate receptor (+) KB cells demonstrated receptor-dependent uptake of the latter conjugate. Biodistribution studies with this conjugate in C57BL/6 mice bearing folate receptor (+) murine 24JK-FBP sarcomas resulted in selective tumor uptake (6.0% ID/g tumor), but also high hepatic (38.8% ID/g) and renal (62.8% ID/g) uptake, indicating that attachment of a second PEG unit and/or folic acid may adversely affect the pharmacodynamics of this conjugate.

## INTRODUCTION

BNCT,<sup>1</sup> which has been the subject of recent reviews (1, 2), is a binary approach to cancer therapy based on the nuclear reaction that occurs when  $^{10}\text{B}$  is irradiated with low energy neutrons to yield high LET  $\alpha$ -particles and lithium nuclei. These particles have a short range (<10  $\mu\text{m}$ ) and essentially deposit their energy within single cells. The efficacy of BNCT depends on the selective delivery of a relatively high amount of  $^{10}\text{B}$  to tumor cells while sparing adjacent normal cells. It has been estimated that ~15  $\mu\text{g}$  of  $^{10}\text{B}$  must be delivered to each gram of tumor in order to sustain lethal tumor cell damage (3). Numerous tumor selective low and high MW  $^{10}\text{B}$  carrier systems for BNCT are under investigation (1). High MW  $^{10}\text{B}$  carrier systems include, e.g., monoclonal and bispecific antibodies (4–6); EGF (7–9) as well as receptor-, antigen-, and nontargeted liposomes (10–16).

FR expression is amplified in a variety of human cancers and concomitantly is restricted in most normal

tissues (17, 18). FR-overexpressing tumors that may be suitable for treatment by NCT include those of the brain, lung, and some sarcomas (18). The vitamin FA (MW: 441 Da) [Figure 1 (3)] is transported into cells via FR mediated endocytosis (17, 18) and it has been established that the attachment of FA via its  $\gamma$ -carboxylic function to almost any type of molecule produces conjugates that

**Figure 1.** Schematic presentation of an EDA core 3rd generation PAMAM dendrimer [G3-DE] (1), Na(CH<sub>3</sub>)<sub>3</sub>NB<sub>10</sub>H<sub>8</sub>NCO (2), and folic acid [FA](3).

can be endocytosed by FR-expressing cells in a fashion similar to that which occurs with FA (17, 18). FA-containing conjugates of a variety of diagnostic and therapeutic agents can selectively target FR-expressing cancer cells both in vitro and in vivo (17, 18). In BNCT-related studies, significant quantities of boron were delivered to FR(+) KB cells in vitro by receptor-mediated endocytosis using FA conjugated liposomes (13, 14).

PAMAM DEs [Figure 1 (1)] are spherical precision macromolecules with defined MWs and, depending upon the generation of the DE, an exponentially increasing number of terminal amino groups (19). Biomedical applications of PAMAM and other types of DEs have been reviewed recently (20, 21). These include the delivery of low MW drugs (22), oligonucleotides (23), transgenes (24), MRI contrast agents (25–29), radionuclides (30), as well as boron (4, 8, 9, 31, 32) and gadolinium (33) for NCT. FA-conjugated DEs, in particular, have been prepared as model drug carriers (34) and for MRI (27, 28).

Barth et al. have reported biodistribution studies with an ammonia core G4-BDE-monoconal antibody conjugate using B16 melanoma bearing C57BL/6 mice (4). G4-DE boronation was carried out using a negatively charged decaborate cluster, Na(CH<sub>3</sub>)<sub>3</sub>NB<sub>10</sub>H<sub>8</sub>NCO (35) [Figure 1 (2)]. Following ip injection, 0.4% ID/g of the G4-BDE-monoconal antibody conjugate localized in the tumor and concomitantly there was a high hepatic uptake (20% ID/g). Interestingly, the G4-BDE per se, which contained ~25 decaborate clusters (250 boron atoms), as well as non-boronated ammonia core G2-, G3-, and G4-DEs used in this study had similar hepatic uptake as the G4-BDE-antibody conjugate (4). Another biodistribution study with an ammonia core G4-BDE-EGF conjugate carried out in rats bearing intracerebral implants of the C6 glioma that had been transfected with the gene encoding EGFR resulted in 0.01% ID/g tumor and 12% ID/g liver for the bioconjugate following iv injection (8). The high hepatic uptake observed in this study may in part have been due to the expression of EGFR in the liver (36).

Numerous reports have described PEG modification of a wide variety of molecules, including low MW drugs, proteins, liposomes, and viruses (37–40). Benefits of the PEGylation of these molecules include, for example, improved aqueous solubility, prolonged blood circulation due to reduced renal, and RES clearance as well as reduced enzymatic degradation and toxicity (37). Indeed, during the past decade the FDA has approved several PEGylated agents including the antiviral drug PEGinter-

feron Alfa-2B (PEG-Intron) and the anticancer drug PEGasparaginase (Oncaspar). PEG units, ranging in MW from 5000 Da to 40000 Da, frequently have been used to improve the biological properties of proteins such as enzymes, interferons, and antibodies (37, 38, 40). In the case of liposomes maximum prolongation of blood circulation times has been attained with formulations containing 5–10 mol % PEG<sub>2000</sub> (41–43) although other liposomal formulations, containing both longer and shorter PEG units, also have proven to be effective in prolonging blood circulation times (40, 44). PEGylation also has been applied with some success to improve the biodistribution profiles of therapeutic and diagnostic DEs (22, 24, 26, 29, 32).

On the basis of the studies described above, we report here the synthesis of FA conjugated and nonconjugated PEGylated G3-BDEs as well as their in vitro evaluation using FR(+) cells and in vivo evaluation using a murine tumor model. PEG units were attached to the G3-BDEs in an attempt to reduce hepatic uptake previously observed with non-PEGylated BDEs (4). The in vivo biodistribution profiles of nonconjugated/PEGylated G3-BDEs were determined in nontumor bearing mice. In this pilot study, we have focused on G3-BDEs because of the experience previously obtained in our laboratories with medium sized BDEs (4, 8, 9). If necessary, G5- or even G6-BDEs, suitable for containing up to 250 decaborate clusters (2500 boron atoms), could be used for the preparation of FA conjugated PEGylated BDEs in order to obtain sufficient boron concentrations in FR-overexpressing tumors.

## EXPERIMENTAL PROCEDURES

**General Synthetic/Analytical Methods and Materials.** <sup>1</sup>H NMR and <sup>13</sup>C NMR spectra were obtained on Bruker FT-NMRs (250 or 400 MHz) at The Ohio State University College of Pharmacy. Chemical shifts (δ) are reported in ppm from an internal tetramethylsilane standard and coupling constants are reported in hertz. High-resolution MALDI-TOFMS were obtained by The Ohio State University Campus Chemical Instrumentation Center—Mass Spectrometry Facility (CCIC-MS) group members including Dr. Kari Green-Church, Dr. Johnnie Brown, Nan Kleinholz, Ben Jones, and Rhonda Pitsch on a Bruker Reflex III (Bruker, Bremen, Germany) mass spectrometer. Bond lengths were calculated by MM2 energy minimization calculations using CS Chem

3D Pro Version 4.0 (Cambridge Soft). Precoated glass-backed TLC plates with silica gel 60 F<sub>254</sub> (0.25 mm layer thickness) and silica gel 60 (70–230 mesh) from Merck were used for TLC and column chromatography, respectively. For compound visualization on TLC plates, UV light as well as KMnO<sub>4</sub> and molybdenum phosphate reagent sprays were used. DEAE-Trisacryl Sepharose (Sigma-Aldrich, St. Louis, MO) was used for ion exchange chromatography; Sephadex G-25, Sephadex G-50, and Superdex G-75 (Pharmacia, Piscataway, NJ) were used for size exclusion chromatography.

G3-DE was purchased from Dendritech Inc, Midland MI. Na(CH<sub>3</sub>)<sub>3</sub>NB<sub>10</sub>H<sub>8</sub>NCO was prepared as previously described (35) from (CH<sub>3</sub>)<sub>3</sub>NB<sub>10</sub>H<sub>8</sub>CO, which was purchased from Katchem Ltd., Prague, Czech Republic. Other reagents were purchased from commercial sources as indicated: MBS and SPDP from Pierce, Rockford, IL; MePEG<sub>3000</sub> and MePEG<sub>5000</sub> from Shearwater Polymers Inc., Huntsville, AL; FA, DCC, DMAP, 4-fluoro-3-nitrobenzoic acid, MePEG<sub>550</sub> and MePEG<sub>750</sub> from Sigma-Aldrich Corp., St. Louis, MO; *O,O*-bis(2-aminopropyl)-poly(ethylene glycol)<sub>800</sub> and MePEG<sub>2000</sub> from Fluka, Milwaukee, WI; *O,O*-bis(2-aminoethyl)poly(ethylene glycol)<sub>2000</sub> was gift from Shearwater Polymers Inc., Huntsville, AL; anhydrous DMSO and CH<sub>2</sub>Cl<sub>2</sub> were purchased from EM Science, Gibbstown, NJ. Other chemicals were of reagent grades and obtained from major suppliers.

**Synthesis of Compounds 5a–e.** Compounds **5a–e** were prepared from 4-fluoro-3-nitrobenzoic acid and **4a–e** as described previously (45). Briefing at the example of **5c**: Compound **4c** (4 g, 2 mmol) and 4-fluoro-3-nitrobenzoic acid (0.37 g, 2 mmol) in dichloromethane were treated with DCC (0.453 g, 2.2 mmol) and DMAP (25 mg, 0.2 mmol). The reaction mixture was stirred under an atmosphere of argon at RT overnight and subsequently filtered. The filtrate was washed with water, dried over MgSO<sub>4</sub>, and concentrated in a vacuum. The crude product (**5c**) was purified by silica gel column chromatography using 10% MeOH in CH<sub>2</sub>Cl<sub>2</sub>. The same solvent system was used for compounds **5d** and **5e** while 7.5% MeOH in CH<sub>2</sub>Cl<sub>2</sub> was used for **5a** and **5b**.

**5c.** Yield: 79%; NMR: <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ: 8.8–8.6 (m, 1H, ArH), 8.4–8.1 (m, 1H, ArH), 7.5 (t, 1H, ArH), 4.6 (s, 2H, OCOCH<sub>2</sub>), 3.9–3.4 (m, ~176H, CH<sub>2</sub>CH<sub>2</sub>O), 3.35 (s, 3H, OMe). <sup>13</sup>C NMR (CDCl<sub>3</sub>) δ: 58.8 (OMe), 61.5 (MeO–CH<sub>2</sub>), 69.8, 70.4 (CH<sub>2</sub>O), 159.0 (NO<sub>2</sub>C), 165.0 (C=O). MALDI-TOFMS produced a characteristic bell shaped distribution of spectral lines spaced equally at 44 ± 1 Da apart, corresponding to the MW of one ethylene oxide repeat unit and centered at ~2200 Da (theoretical value: 2167 Da, based on the approximate MW of the PEG<sub>2000</sub> unit indicated by the supplier to be 2000 Da). The *M<sub>n</sub>* (number-average MW) is 2186.3283 and the *M<sub>w</sub>* (weight-average MW) is 2202.8476 with a polydispersity, *D* (*D* = *M<sub>w</sub>*/*M<sub>n</sub>*), of 1.0076. This method of analyzing mass spectroscopic data of PEG containing molecules has been previously described (46–49).

The yields for **5a**, **5b**, **5d**, and **5e** were in the same range as for **5c**. <sup>1</sup>H NMR and <sup>13</sup>C NMR spectra of **5a**, **5b**, **5d**, and **5e** were identical to those of **5c** except for differing signal intensities of the PEG protons around δ 3.9–3.4 [**5a** (~44 H), **5b** (~64H), **5d** (~264H), and **5e** (~448H)] as well as the PEG carbons around δ 71–70 ppm. MALDI-TOFMS produced similar characteristic bell shaped distribution of spectral lines spaced equally at 44 ± 1 Da apart, and centered around ~675 Da, ~1000 Da, ~3100 Da, ~5100 Da with *D*s of 1.0044, 1.0130, 1.0118, and 1.0079 for **5a**, **5b**, **5d** and **5e**, respectively.

**Synthesis of Compounds 6 and 7.** A solution of FA (441 mg, 1 mmol) in anhydrous DMSO (10 mL) and triethylamine (2.5 mL) was reacted with NHS (230 mg, 2 mmol) in the presence of DCC (248 mg, 1.2 mmol) at RT. The reaction was stirred for 4 h followed by the addition of *O,O*-bis(2-aminopropyl)poly(ethylene glycol)<sub>800</sub> (800 mg, 1 mmol) or *O,O*-bis(2-aminoethyl)poly(ethylene glycol)<sub>2000</sub> (2 g, 1 mmol). The resulting mixture was stirred overnight at RT. Dicyclohexylurea was removed by filtration, and the crude product was precipitated with excess acetone, filtered, washed three times with acetone, and dried in a vacuum. The crude product was applied to a DEAE-Trisacryl Sepharose column. Compounds **6** and **7** were eluted with 10 mM NH<sub>4</sub>HCO<sub>3</sub> (pH 8.0). Fractions containing either **6** or **7** were pooled and lyophilized.

**6:** Yield: 52%; <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>) δ: 8.58 (s, 1H, C<sub>7</sub>-H); 7.75 (d, *J* = 8.4 Hz, 2H, Ar-H); 6.95 (br s, 1H, NH); 6.60 (d, *J* = 8.4 Hz, 2H, Ar-H); 5.09 (br s, 1H, NH); 4.55 (d, *J* = 5.1 Hz, 2H, C<sub>9</sub>-H); 3.60–3.30 (br m, PEG protons, ~56H); 1.11 (m, 6H, 2-CH<sub>3</sub>). MALDI-TOFMS produced a slightly deformed bell shaped distribution of spectral lines spaced equally at 44 ± 1 Da apart, corresponding to the MW of one ethylene oxide repeat unit and centered around ~1175 Da (calculated 1223 Da, taking the approximate MW of the PEG<sub>800</sub> unit indicated by the supplier to be 800 Da). *M<sub>n</sub>*: 1093.7049; *M<sub>w</sub>*: 1107.7550; *D*: 1.0128.

**7:** Yield 58%; <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>) δ: 8.63 (s, 1H, C<sub>7</sub>-H); 7.87 (d, *J* = 8.4 Hz, 2H, Ar-H); 6.92 (br s, 1H, NH); 6.62 (d, *J* = 8.4 Hz, 2H, Ar-H); 4.46 (d, *J* = 5.1 Hz, 2H, C<sub>9</sub>-H); 3.60–3.30 (br m, PEG protons, ~176H). MALDI-TOFMS produced a characteristic bell shaped distribution of spectral lines spaced equally at 44 ± 1 Da apart, corresponding to the MW of one ethylene oxide repeat unit and centered at ~2425 Da (calculated 2423 Da, taking the approximate MW of the PEG<sub>2000</sub> unit indicated by the supplier to be 2000 Da). *M<sub>n</sub>*: 1938.3420; *M<sub>w</sub>*: 1938.3420; *D*: 1.0000.

**Synthesis of Compounds 10 and 11a–e.** The introduction of Na(CH<sub>3</sub>)<sub>3</sub>NB<sub>10</sub>H<sub>8</sub>NCO (**2**, Figure 1) to G3-DE (**1**, Figure 1) was carried out as described previously (4). Briefly, compound **1** (53.3 mg, 25.9% w/w in 10% aqueous MeOH, 2 mmol) and **2** (10.29 mg, 44 mmol) were reacted in 1.0 mL of 0.1 M carbonate/bicarbonate buffer, pH 9.0, at RT for 24 h to yield **10** and **5a–e** (4.0 or 24 mmol) were added, and the reaction mixture was incubated in the dark at RT for 4 h. The reaction mixture was then applied to a Sephadex G-50 column in case of **11a** and **11b** and to a Superdex G-75 column in case of **11c–e** and eluted with carbonate/bicarbonate buffer, pH 9.0. The fractions containing both boron and MePEG were pooled and concentrated by ultrafiltration (Amicon, Bedford, MA). The number of PEG units attached to G3-BDE was determined spectrophotometrically by measuring the absorbance at 428 nm (nitroaniline chromophore, ε = 5.45 × 10<sup>3</sup> M<sup>−1</sup>cm<sup>−1</sup>) using a Beckman DU-6 spectrophotometer (Beckman Instruments, Inc., Irvine CA) [Figure 2]. Boron was quantified by means of DCP-AES as previously described (50) [Figure 2] using a Spectraspan VB spectrometer (Applied Research Laboratories, La Brea, CA). Briefly, 10 μL of boron compound solution was diluted to 1 mL with 0.1 M phosphate buffer, pH 8.5, and determined by DCP-AES at 249 nm. The instrument was calibrated by standard boron solution (VHG labs, Manchester, NH). The number of the PEG units and boron clusters in **10**, **11a–e** obtained by using varying molar ratios of **5a–e** are given in Table 1.

**Figure 2.** Sephadex G-50 column chromatographic profile of **11c**. Fractions of 1 mL were collected and analyzed by DCP-AES (A) and spectrophotometrically at 428 nm (B).

<sup>a</sup> C57BL/6 mice were injected ip with **10**, **11a–e**. The % ID/g were determined 6 h postinjection by DCP-AES. Mean ± SDs are based on four animals per group. Compounds **11a–e** were prepared using 2-fold (\*) and 12-fold (\*\*) molar excesses of MePEGs **5a–e** to compound **1**.

**Synthesis of Compounds 15 and 16.** Compound **1** (53.3 mg, 25.9% w/w in 10% aqueous MeOH, 2 mmol) and SPDP (3.12 mg, 10 mmol) were incubated in 1.0 mL of 0.1 M phosphate buffer (pH 7.5) at RT for 30 min and then applied to a Sephadex G-25 column and intermediate **12** was eluted with 0.1 M carbonate buffer (pH 9.0). Subsequently, **5c** (8.8 mg, 4 mmol) and then **2** (10.29 mg, 44 mmol) were reacted with **12** as described for the synthesis of compounds **11a–e** from compound **1**. The disulfide bond was subsequently cleaved using DTT (7.7 mg, 50 mmol) in 0.1 M phosphate buffer (10% DMSO, pH 7.5) for 30 min at RT. The reaction mixture was applied to a Sephadex G-25 column and the intermediate **14** was eluted with 0.1 M phosphate buffer (10% DMSO, pH 7.5). For the synthesis of **13**, compounds **12** and **2** (10.29 mg, 44 mmol) were reacted as described for the synthesis of compound **10** from compound **1**. The disulfide bond subsequently was cleaved using DTT (7.7 mg, 50 mmol) in 0.1 M phosphate buffer (10% DMSO, pH 7.5) for 30 min at RT. The reaction mixture was then applied to a Sephadex G-25 column and intermediate **13** was eluted with 0.1 M phosphate buffer (10% DMSO, pH 7.5). As determined spectrophotometrically by measuring the absorption of released pyridine-2-thione at 343 nm, ~2 free SH-groups were introduced to **13** and **14**. Compound **6** (4.9 mg, 4 mmol) and **7** (9.8 mg, 4 mmol) were reacted with sulfo-MBS (8.32 mg, 20 mmol) in 1.0 mL of 0.1 M

phosphate buffer (pH 7.5) at RT for 30 min to yield compounds **8** and **9**, respectively. After elution from a Sephadex G-25 column, fractions containing **8** and **9** were added directly to solution of **14** and **13**, respectively, resulting in a total reaction volume of 5 mL (0.1 M phosphate buffer and 10% DMSO, pH 7.5). The reaction was terminated after 30 min at RT to yield **15** and **16**, respectively. Both compounds were purified by column chromatography using a Superdex G-75 column and were eluted with 0.1 M phosphate buffer (pH 8.5). The number of MePEG<sub>2000</sub> and FA-PEG<sub>800/2000</sub> units were determined spectrophotometrically by measuring absorbance at 428 nm (nitroaniline chromophore,  $\epsilon = 5.45 \times 10^3 \text{ M}^{-1}\text{cm}^{-1}$ ) and 363 nm (folate,  $\epsilon = 7.5 \times 10^3 \text{ M}^{-1}\text{cm}^{-1}$ ). Boron was quantified by means of DCP-AES. According to these measurements, compound **15** was composed of ~15 boron clusters and ~1 FA-PEG<sub>2000</sub> while compound **16** was composed of ~13 boron clusters, ~1 MePEG<sub>2000</sub> unit, and ~1 FA-PEG<sub>800</sub> unit.

**Cell Culture.** Human FR(+) KB cancer cells (American Type Culture Collection # CCL 17), derived from an epidermal carcinoma of the oral cavity, were obtained as a gift from Dr. Philip S. Low at Purdue University (West Lafayette, IN). The cells were maintained in FA-free RPMI 1640 (Invitrogen, Grand Island, NY) medium supplemented with 100 units/mL penicillin, 100  $\mu\text{M}$ /mL streptomycin, and 5% fetal bovine serum, which provided the only source of FA. The cells were cultured as a monolayer at 37 °C in a humidified atmosphere containing 5% CO<sub>2</sub>. 24JK-FBP, a mouse sarcoma cell line transfected with the gene for human FR (5I), was maintained under the same culture conditions as those used to propagate KB cells.

**In Vitro Uptake of Compounds 15 and 16 in KB Cells.** KB cells were seeded into T-150 flasks and cultured (RPMI 1640, FA free) for 3 days to establish a complete monolayer. Cells were washed with 2 × PBS and harvested with 5 mM EDTA and then briefly exposed to 0.1 M acetate buffer, pH 3.5. Following removal of the acetate buffer, the cells were incubated with RPMI 1640 media (FA free) containing 2% BSA for 20 min at room temperature. Three tubes each containing  $13.3 \times 10^6$  cells were used for each uptake study, which was carried out by adding amounts of **15** and **16** corresponding to 40  $\mu\text{g}$  boron to each tube. The cells then were incubated for 20 min at RT, sedimented, and washed 3 × with PBS. The number of cells was determined by counting in a hemocytometer, and the boron concentration was determined by DCP-AES. For FR blocking studies, the cells were incubated with **15** or **16** in the presence of 1.0 mM FA.

**Hepatic Uptake of Compounds 10, 11a–e in C57BL/6 Mice.** C57BL/6 male mice were purchased from the Animal Production Unit of the National Cancer Institute, Frederick, MD. For hepatic uptake studies, groups of four animals were injected ip with 500  $\mu\text{g}$  of conjugates **10**, **11a–e** in 0.2 mL of 0.1 M phosphate buffer, pH 8.5. The animals were euthanized by cervical dislocation 6 h postinjection and liver samples were obtained. The boron contents in the liver samples were determined by DCP-AES.

**Biodistribution of Compounds 10, 11c, and 16 in C57BL/6 Mice Bearing 24JK-FBP.** For biodistribution studies of **10**, **11c**, and **16**, C57BL/6 male mice were injected subcutaneously with  $2 \times 10^6$  24JK-FBP cell in the back after 10 days on a FA free diet (Dyets, Inc, Bethlehem, PA). Within 10–14 d after implantation, by which time the tumors had attained a size of 100–500 mg, groups of four animals were injected ip with amounts of **10**, **11c**, and **16** corresponding to 120  $\mu\text{g}$  boron in 0.2

mL of 0.1 phosphate buffer, pH 8.5. Blood, liver, spleen, kidneys, tumor, and skeletal muscle samples were obtained after euthanizing the animals 6 h postinjections, and the boron contents in the tissue samples were determined by DCP-AES.

**RESULTS**

**Synthesis of PEG Units, PEGylated G3-BDEs, and FA Conjugated/PEGylated G3-BDEs.** Compounds **5a–e** were prepared and purified as previously reported (45) by reacting 4-fluoro-3-nitrobenzoic acid with MePEGs **4a** [MW: 550], **4b** [MW: 750], **4c** [MW: 2000] (45), **4d** [MW: 3000], and **4e** [MW: 5000] (45) (Scheme 1). Aromatic nucleophilic substitution of the fluorine atom in 4 position of the aryl function in **5a–e** with aliphatic amines generates chromophoric *o*-nitroaniline moieties. This chromophore has been used to quantify the MePEG content of Bovine superoxide dismutase, to which **5c** and **5e** were attached via protein amino groups, by measuring its absorbance at 428 nm (45). We decided to use the same procedure to attach PEG units to the terminal amino functions of G3-BDEs, as shown in Schemes 3 and 4, since this permitted the convenient spectrophotometric quantification of the attached PEG units in the presence or absence of FA, which absorbs UV/vis at 363 nm. The maximum absorbance of FA did not interfere with that of the *o*-nitroaniline group, which permitted the spectrophotometric quantification of FA attached to G3-BDEs in the presence or absence of the *o*-nitroaniline group. MePEGs with MWs ranging from 550 to 5000 were chosen for the attachment to G3-BDE (Scheme 3) in order to evaluate the impact on MePEG chain length on hepatic uptake of MePEG-G3-BDE conjugates (Table 1).

Compounds **6** and **7** were synthesized and purified using a combination of two methods described by Lee et al. for the preparation and purification of FA-PEG<sub>3400</sub>-NH<sub>2</sub> (52, 53) (Scheme 2). Isomeric mixtures of both **6** and **7** were generated with  $\sim 20\%$  substitution at the  $\alpha$ - and  $\sim 80\%$  substitution at the  $\gamma$ -carboxylic function of FA. These were purified, but not separated, by DEAE-trisacryl sepharose ion exchange chromatography as reported previously (54). Compounds **6** and **7** were treated with sulfo-MBS to afford the respective succinimidyl derivatives **8** and **9**, which were used directly for the preparation of G3-BDEs **15** and **16** (Scheme 4).

Boronation of a G3-DE [Figure 1 (1)] was carried out, as previously described (4, 8, 9, 55), using the polyhedral decaborate,  $\text{Na}(\text{CH}_3)_3\text{NB}_{10}\text{H}_8\text{NCO}$  (35) [Figure 1 (2)], carrying a single negative charge (Scheme 3). A 22-fold molar excess of **1** relative to **2** was used ensuring a substitution level of 12–15 boron clusters or 120–150 boron atoms per G3-DE. G3-DE (**1**) has 32 terminal

amino groups, a MW of 6909 Da, and a measured diameter of 36 Å (56). As determined by MM calculations, the total length of all bonds, including EDA core, between two terminal nitrogen atoms in G3-DE was 64.5 Å. The terminal amino groups of G3-DE should be partially protonated under physiological conditions in contrast to the interior tertiary amino groups, which are not sufficiently basic (19). This would leave the G3-DE with a maximum of about 32 positively charged ammonium groups under physiological conditions.

Based on MM calculations, the total length of all bonds between two nitrogen atoms of two terminal boron clusters in **10** (Scheme 3), including the EDA core, is  $\sim 78$  Å. The MW of G3-BDE (**10**) substituted with 15 boron clusters is 10164 Da (excluding sodium). We therefore estimate the actual diameter of **10** to be in the range of  $\sim 40$  Å since the effective diameter of G4-DE (MW: 14,215 Da) is 45 Å (56). Both nitrogens of the urea linker between boron clusters and G3-DE should not be sufficiently basic to be protonated under physiological conditions. Thus, G3-BDE (**10**) should be close to neutral or slightly positively charged under these conditions because the negative charges of the 15 boron clusters would almost completely neutralize the positive charges of the unsubstituted protonated terminal amino groups. MePEGs with MWs ranging from 550 to 5000 were chosen for the attachment to G3-BDE (Scheme 3) in order to evaluate the impact on MePEG chain length on the hepatic uptake of MePEG-G3-BDE conjugates (Table 1).

Introduction of the **5a–e** to G3-BDE (**10**) was carried out as previously described for the attachment of **5c** and **5e** to bovine superoxide dismutase (45). The reaction was carried out using 2-fold and 12-fold molar excess of **5a–e** relative to G3-DE (**1**) in an attempt to obtain substitution levels of about 1–2 and  $\sim 10$  PEG chains, respectively, at **10**. Different substitution levels were chosen in order to evaluate their impact on the hepatic uptake of MePEG-G3-BDE conjugates. The results are summarized in Table 1. The actual substitution levels indicated that it became increasingly more difficult to attach the desired number of MePEGs to G3-BDE (**10**) as the length of the MePEG chain increased. This was most striking when **10** was treated with a 12 molar excess of **5d** (MePEG<sub>3000</sub>) and **5e** (MePEG<sub>5000</sub>), which resulted in only four attached MePEGs in case of **11d** and **11e**, respectively. However, the shielding effect of the MePEGs was noticeably evident when a 2 molar excess of shorter MePEGs chain was used. This, in part, may explain the hepatic uptake levels observed for **11a,b**. It should be noted that the amino function in *N*-alkyl-*o*-nitroanilines, which constitute the chromophoric linker between MePEGs and G3-BDE in **11a–e**, is not sufficiently basic to be protonated under physiological conditions (57). Therefore, compounds **11a–e** should be close to neutral or even negatively charged, depending on the degree of MePEG substitution under these conditions. For reasons outlined in detail later, two FA conjugated PEGylated G3-BSDs were prepared adopting procedures previously described by us (4, 8, 9, 55), one containing  $\sim 15$  boron clusters and  $\sim 1$  PEG<sub>2000</sub> unit with FA attached to the distal end (**15**, Scheme 4), the other containing  $\sim 13$  boron clusters,  $\sim 1$  MePEG<sub>2000</sub>, and  $\sim 1$  PEG<sub>800</sub> unit with FA attached to the distal end (**16**, Scheme 4). Approximately two 3-(2-pyridyldithio) propionate groups were introduced to G3-DE (**1**) using a 5-fold excess of SPDP to yield intermediate **12**. The chromophoric MePEG unit (**5c**) and/or the boron clusters (**2**) were then attached to **12** in accordance with the procedure described above for the synthesis of compounds **11a–e** and **10**. The disulfide bonds in the 3-(2-py-

ridyldithio) propionate groups subsequently were reduced to yield compounds **14** and **13**, respectively, each containing about two free sulfhydryl functions. Compounds **13** and **14** then were treated with compounds **9** and **8**, respectively, to afford target compounds **15** and **16**, respectively. In accordance with preceding considerations, both compound **15** and **16** should be neutral or slightly positively charged under physiological conditions.

**Hepatic Uptake of Compounds G3-BDE and PEGylated G3-BDEs.** The hepatic uptake of G3-BDE (**10**) and PEGylated G3-BDEs (**11a-e**) was studied in C57BL/6 mice and the results are summarized in Table 1. The % IDs/g liver of G3-BDEs (**10**) with 13 and 15 attached boron clusters were  $17.0 \pm 1.4$  and  $14.0 \pm 2.1$ , respectively. These values are comparable with those obtained by Barth et al. using an ammonia core G4-BDE with ~25 attached boron clusters (**4**). Among all prepared

combinations, PEGylated G3-BDEs (**11c**) with 1 MePEG<sub>2000</sub> chain and 13 boron clusters and 1.5 MePEG<sub>2000</sub> chains and 15 boron clusters showed the lowest hepatic uptake with  $7.7 \pm 2.2$  and  $7.2 \pm 1.1\%$  ID/g liver, respectively. The highest hepatic uptake was observed for **11a** (11 MePEG<sub>550</sub> chains, 15 boron cluster) with  $29.0 \pm 9.0\%$  ID/g liver and **11b** (7 MePEG<sub>750</sub> chains, 15 boron cluster) with  $34.0 \pm 12.3$ . Both compounds show similarities in as far as that they possess high numbers of short MePEG chains and are probably negatively charged under physiological conditions. All other PEGylated G3-BDEs had hepatic uptake values, which were in the range of G3-BSD (**10**).

On the basis of these results, it appears that PEGylated G3-BSDs must be carefully designed to reduce opsonization and that there may be a very narrow window for optimal reduction demanding a small number (1–1.5) of PEG<sub>2000</sub> chains for a sufficiently large and flexible shielding layer. Thus, we have applied two different design strategies for the synthesis of FA conjugated/PEGylated G3-BDEs. First, attachment of a single PEG<sub>2000</sub> unit with FA linked to the distal end to a G3-BDE for shielding and FR targeting (compound **15**, Scheme 4). Second, attachment of a MePEG<sub>2000</sub> unit for shielding as well as attachment of an additional second PEG<sub>800</sub> unit with FA linked to the distal end for targeting (compound **16**, Scheme 4).

**In Vitro Evaluation of FA Conjugated PEGylated G3-BDEs.** As shown in Figure 3, both **15** and **16** were taken up in large amounts by FR(+) KB cells. Cellular uptake of **15** was 1.84 times higher than that of **16**. Cellular uptake in the presence of free FA, however, was effectively blocked only with **16**, indicating that it was taken up by FR-mediated endocytosis. In the case of conjugate **15**, the FA moiety may have been shielded from FRs by the coating layer generated by the PEG<sub>2000</sub> chain thereby preventing FR dependent cellular uptake. However, we cannot provide any explanation for the high, and obviously nonspecific, uptake of **15** by KB cells. Gabizon et al. have reported a high degree of nonspecific binding of FA conjugated liposomes to extracellular components in vitro, which may have resulted in inaccurate values for the cellular uptake of FA conjugated liposomes (**58**)

**Figure 3.** Uptake of compounds 15 and 16 by KB cells. Cells were incubated with 15 or 16 in the presence and absence of FA at RT for 20 min. Boron uptake was determined by DCP-AES. A: Compound 15; B: Compound 15 + 1 mM FA; C: Compound 16; D: Compound 16 + 1 mM FA. Mean  $\pm$  SDs are based on three experiments.

and similar problems may have affected the cellular uptake of compound 15 in our studies. On the basis of the in vitro uptake data, conjugate 16 was chosen for biodistribution studies in C57BL/6 mice bearing FR(+) 24JK-FBP tumors.

**Biodistribution of G3-BDE (10), PEGylated G3-BDE (11c), and FA Targeted/PEGylated G3-BDE (16).** The biodistribution of conjugates 10 (~15 boron clusters), 11c (~1 MePEG<sub>2000</sub>, 13 boron cluster), and 16 6 h after ip injection into C57BL/6 mice bearing FR(+) 24JK-FBP tumors are summarized in Table 2. High tumor uptake only was observed for the FA conjugated/PEGylated G3-BDE 16 (6.0%  $\pm$  1.6 ID/g). The hepatic uptake values of 10 and 11c were comparable to those observed in nontumor bearing mice (Table 1). However, conjugate 16 showed a markedly increased hepatic uptake (38.8  $\pm$  5.9%ID/g) compared to 11c, indicating that the low RES clearance of 11c was completely abolished by the attachment of an additional FA-PEG<sub>800</sub> unit, either by the presence of the PEG<sub>800</sub> moiety, FA, or both. The very high renal uptake of 10 (104.2  $\pm$  20.7%ID/g) was consistent with renal uptake values previously reported for low and mid generation DEs (25, 26, 28, 59, 60). Modification of 10 with a MePEG<sub>2000</sub> chain increased the MW and, subsequently, decreased renal retention, as observed for 11c (45.0  $\pm$  13.4 ID/g). This also was consistent with previously reported data of Kobayashi et

<sup>a</sup> 24JK-FBP tumor bearing C57BL/6 mice were injected ip with 10, 11c, and 16. The % ID/g were determined 6 h post injection by DCP-AES. Mean  $\pm$  SDs are based on four animals per group. n.m.: not measurable.

al. (25, 26). Additional attachment of FA-PEG<sub>800</sub> again increased the renal uptake ( $62.8 \pm 14.5\%$  ID/g), which was expected because of the high expression of FR in the kidneys (61). In case of **10**, **11c**, and **16** high boron accumulation was also detected in the spleen while blood and muscle values were low. Preliminary studies with **10**, **11c**, and the FA-PEG<sub>350</sub>-G3-BDE derivative of **16** in a small number of FR(+) 24JK-FBP tumor bearing mice at 3 and 24 h after ip injection, indicating that uptake values shown in Table 2 were almost constant over a 21 h period for the indicated tissues (data not shown).

## DISCUSSION

Despite growing interest in the use of PAMAM DEs as macromolecular carriers (20, 21), little is known about their biological behavior following in vivo administration, which ultimately is critical for their use in biomedical applications. In an early study using ammonia core DE-monoclonal antibody conjugates, we observed that <sup>125</sup>I-labeled DE-monoclonal antibodies showed an increasing propensity to localize in the liver and spleen of B16 melanoma bearing mice as the size of the DE increased from 0 to 4th generation (4). Both an ammonia core G3-DE (59) and an EDA core <sup>125</sup>I-labeled iodo-benzoyl-biotinylated G2-DE (60) had high renal uptake in Swiss-Webster rats and athymic nude mice, respectively. In another study carried out with Wistar rats both cationic and anionic DEs showed high hepatic uptake (62). Kobayashi et al. evaluated the biodistribution pattern of EDA core G3-, G4-, G5-, and G6-DEs, that had been heavily substituted with Gd-DTPA chelates, in BALB/c mice and found that hepatic and renal uptake of the DEs was generation dependent. G6-DE had the highest hepatic uptake and lowest renal uptake while G3-DE had the lowest hepatic and highest renal uptake (25). Kobayashi et al. also explored the biodistribution of Gd-DTPA-G4-DEs either mono- or disubstituted with PEG<sub>2000</sub> with that of a non-PEGylated Gd-DTPA-G4-DE in mice (26). Renal uptake was extremely high for the non-PEGylated conjugates and decreased significantly with increasing MW in case of monoPEGylation and even more pronounced in case of diPEGylation. The hepatic uptake of the non-PEGylated conjugate was high and decreased significantly with diPEGylation but not with monoPEGylation. Margerum et al. prepared a G3-DEs substituted with Gd-chelates and noticed moderate hepatic uptake for this conjugate in Sprague-Dawley rats, which appeared to increase when this conjugate was modified with varying quantities of PEG<sub>2000</sub> or PEG<sub>5000</sub> units (29).

Overall, it appears that hepatic uptake depends to a significant degree on the MW and, consequently, the size of a DE. The attachment of PEG units to a DE increases its MW/size. The affinity of PEGylated DEs for the RES system may therefore depend strongly on a finely tuned balance between overall MW/size and shielding effect of the PEG layer. Studies have shown that the level of substitution with PEG units drastically affects the actual size of a PEGylated liposome and that the size, as well as a dense and rigid surface coating, may negatively affect its biodistribution pattern (63–65). In contrast, a relatively small number of hydrophilic and highly flexible liposomal surface polymers may effectively protect a liposome from being opsonized and filtered out of the vascular compartment by the RES (65).

In case of G3-BDEs **11a** and **11b**, a small number of short PEG<sub>550</sub> and PEG<sub>750</sub> chains may not effectively shield the G3-BDE surface while a large number of short PEG<sub>550</sub>

and PEG<sub>750</sub> chains may generate a dense and fairly rigid surface layer, which simply increases the MW/size of the G3-BDE but does not effectively shield the conjugate from opsonization. The latter also may apply to some extent to large numbers of PEG<sub>2000</sub> chains (**11c**) as well as small and large numbers of PEG<sub>3000</sub> (**11d**) and PEG<sub>5000</sub> (**11e**) chains attached to G3-BDE.

Wiener et al. have evaluated the biodistribution of a FA conjugated gadolinium containing G4-DE in athymic nude mice carrying FR(+) SKOV3 tumors and found tumor selective uptake of the conjugate (3.62% ID/g tumor), high hepatic uptake (6.35%/g), and very high renal uptake (70.77% ID/g) (28). The results reported by Wiener et al. are similar to those obtained with **16** in our biodistribution study. In another study, Kobayashi et al. compared the biodistribution of avidine targeted Gd-DTPA-G6-DE with nontargeted Gd-DTPA-G6-DE in SHIN3 tumor bearing BALB/c mice and found highly tumor selective uptake for the former conjugate (103% ID/g) compared with the latter conjugate (~30% ID/g) while the hepatic uptake of both bioconjugates were similarly (~17.5% ID/g) (33). The results obtained by us, Wiener et al. (28), and Kobayashi et al. (33) clearly demonstrate that receptor/antigen targeted DEs may have significant potential in MRI and NCT applications.

In summary, we have developed synthetic methods for the preparation of chromophorically labeled PEGylated BDEs and FA conjugated/PEGylated BDEs. The number of MePEGs and FA units attached to BDE can be easily determined spectrophotometrically by taking advantage of the differences in the absorbance maxima of FA and an attached *o*-nitroaniline moiety. PEGylated G3-BDEs with 1 MePEG chain and 13 boron clusters and 1.5 MePEG chains and 15 boron clusters showed the lowest hepatic uptake of all evaluated conjugates with  $7.7 \pm 2.2$  and  $7.2 \pm 1.1\%$  ID/g liver, respectively. The optimal modification of BDEs, as well as DEs in general, with PEG chains to reduce RES affinity appears to be highly complex endeavor that depends on a variety of factors, which will require extensive evaluation. A FA conjugated/PEGylated G3-BDE was prepared, which was taken up in vitro by FR(+) KB cells apparently by FR mediated endocytosis. The same conjugate showed significantly increased tumor selectivity compared with non-PEGylated BDE-antibody and BDE-EGF conjugates previously evaluated for potential application in BNCT (4, 8). However, the hepatic and renal uptake of this conjugate was very high. The results obtained in this study warrant further effort in the optimization of biodistribution profiles of receptor/antigen targeted PEGylated BDEs.

## Modulation of the T Cell Response to $\beta$ -Lactoglobulin by Conjugation with Carboxymethyl Dextran

Kazuo Kobayashi, Tadashi Yoshida, Koji Takahashi, and Makoto Hattori\*

Department of Applied Biological Science, Faculty of Agriculture, Tokyo University of Agriculture and Technology, Tokyo, Japan. Received July 31, 2002; Revised Manuscript Received October 22, 2002

We have previously prepared  $\beta$ -lactoglobulin ( $\beta$ -LG)–carboxymethyl dextran (CMD) conjugates with water-soluble carbodiimide and achieved reduced immunogenicity of  $\beta$ -LG. In the present study, to elucidate the mechanism for the reduced immunogenicity of  $\beta$ -LG, we investigated changes in the T cell response to  $\beta$ -LG after conjugation with CMDs differing in molecular weight (about 40 and 162 kDa). Lymph node cells from BALB/c, C3H/He, and C57BL/6 mice that had been immunized with  $\beta$ -LG or the conjugates were stimulated with  $\beta$ -LG, and the *in vivo* T cell response was then evaluated by BrdU (5-bromo-2'-deoxyuridine) ELISA as the *ex vivo* proliferative response. T cells from the conjugate-immunized mice showed a lower proliferative response than those from the  $\beta$ -LG-immunized mice. T cell epitope scanning, using synthesized peptides, showed that the T cell epitope profiles of the conjugates were similar to those of  $\beta$ -LG, whereas the proliferative response to each epitope was reduced. These results indicate that the lower *in vivo* T cell response with the conjugates was not due to induction of conjugate-specific T cells, but due to a decrease in the number of  $\beta$ -LG-specific T cells. After the lymph node cells from  $\beta$ -LG-immunized mice had been stimulated with  $\beta$ -LG or the conjugates, the efficiency of the antigen presentation of the conjugate to  $\beta$ -LG-specific T cells was evaluated by BrdU ELISA as the *in vitro* proliferative response. The antigen presentation of  $\beta$ -LG to the T cells was reduced by conjugation with CMD. In addition, conjugation with CMD enhanced the resistance of  $\beta$ -LG to cathepsin B and cathepsin D, which suggest that conjugation with CMD inhibited the degradation of  $\beta$ -LG by proteases in APC and led to suppression of the generation of antigenic peptides including T cell epitopes from  $\beta$ -LG. It is therefore considered that the suppressive effect on the generation of T cell epitopes reduced the antigen presentation of the conjugates and that this reduction led to a decrease in the number of  $\beta$ -LG-specific T cells *in vivo*. As a result, the decreased help to B cells by T cells would have reduced the antibody response to  $\beta$ -LG. We conclude that suppression of the generation of T cell epitopes by conjugation with CMD is important to the mechanism for the reduced immunogenicity of  $\beta$ -LG.

### INTRODUCTION

Allergic reactions to food and dietary components have shown a tendency to increase in advanced countries, and food allergies have become an important human health problem. It has been reported that 12.6% of children in Japan had experienced an allergic reaction within 1 h after ingesting food and that the most common sources of food allergens involved were eggs (52.3% of food allergy cases), milk (31.8%), and seafoods (10.6%) (1). Although the fundamental therapy for food allergy is a food elimination diet, a prolonged period of food elimination affects a child's growth (1). In particular, milk is a basic food component that plays a predominant role in the first

years of life. The major allergen in cow's milk is  $\beta$ -lactoglobulin ( $\beta$ -LG), and about 82% of milk allergy patients are sensitive to this protein (2).  $\beta$ -LG, a major whey protein, is a globular protein of MW 18 400 consisting of 162 amino acids and possesses two disulfide bonds and one free cysteine (3). Although the physiological function of  $\beta$ -LG still remains unclear, it is tentatively considered to be the binding and transportation of small hydrophobic ligands such as retinol and fatty acids, and the protein is categorized as a member of the lipocalin superfamily (4).  $\beta$ -LG has a  $\beta$ -barrel structure (5, 6) which is a common feature among the lipocalins. This kind of molecule has high allergenic potential, and several allergens of animal origin belong to the lipocalin superfamily (7, 8).

In terms of food science,  $\beta$ -LG is considered to be a valuable protein because it has useful functional properties such as emulsifying, foaming and gelling properties (9–11), as well as a high content of essential amino acids (3). It is therefore desirable to develop new methods that would reduce the allergenicity of  $\beta$ -LG. Although attempts to reduce the allergenicity of proteins have been made by enzymatic digestion and denaturation (12–15), these methods destroy the physiological functions of the proteins and bring about problems with their taste. In contrast, protein conjugation is superior to other hypoallergenic methods in that it can simultaneously

achieve improved functions (thermal stability, solubility, emulsifying ability, etc.) and low allergenicity and immunogenicity, while maintaining the physiological functions of proteins (16–20).

Many attempts to reduce the antigenicity and immunogenicity of proteins by conjugation methods have been made. Poly(ethylene glycol) (PEG) conjugates of recombinant IL-2 have been reported to elicit a 100–1000-fold lower level of antigen-specific IgG antibody production than recombinant IL-2 (21). High lipophilization of  $\beta$ -LG has been shown to be effective in reducing the production of anti- $\beta$ -LG IgG and IgE (22). Conjugates of monoclonal and polyclonal antibodies with oxidized dextrans of low molecular weight have been reported to have optimal immunoreactivity, in vivo pharmacokinetics, and tumor localization properties, as well as low immunogenicity in vivo (23). The conjugation of allergens with oligodeoxynucleotides having CpG sequences has been shown to suppress allergic responses (24, 25). However, the mechanism for the reduced antigenicity and immunogenicity of the proteins is still unclear despite such work.

Our objective in this study was to create hypoallergenic neoglycoconjugates of  $\beta$ -LG with high thermal stability and improved functional properties, while maintaining retinol-binding activity, and to elucidate the mechanism involved. We have achieved, in our previous studies (16–18, 26, 27), reduced immunogenicity, high thermal stability, improved emulsifying ability, and retained the retinol-binding activity, while maintaining an almost nativelike conformation, by conjugating  $\beta$ -LG with carboxymethyl dextran (CMD). We have shown that the molecular weight of the polysaccharides used as modifiers and the saccharide content in the conjugates affected the immunogenicity of  $\beta$ -LG and that one mechanism involved in the reduced immunogenicity of  $\beta$ -LG by conjugation with CMD was responsible for masking B cell epitopes by the saccharide chain from the results of B cell epitope scanning of  $\beta$ -LG and the conjugates (26, 27).

We investigated, in the present study, changes in the T cell response to  $\beta$ -LG after conjugation with CMD to further elucidate the mechanism. Antigens delivered from an extracellular source are processed by proteases within APC to create antigenic peptides including T cell epitopes and then presented on the APC surface by major histocompatibility complex (MHC) class II molecules for recognition by T cells (28). The T cells provide help to B cells through direct cell–cell interaction and secretion of cytokines that promote their proliferation and differentiation into antibody-producing cells (29). Thus, modulation of the T cell response by conjugation is considered to affect the immunogenicity of proteins. In particular, we focus on changes in the epitope profiles of  $\beta$ -LG after conjugation in elucidating the mechanism. Although the T cell epitope profiles of proteins, including  $\beta$ -LG (30–32), have been reported, there have been hardly any reports on the changes in epitope profiles of proteins after conjugation with saccharides. Epitope scanning of proteins after conjugation provides useful information such as the elimination of epitopes and generation of neo-epitopes. After preparing covalently bonded  $\beta$ -LG-CMD conjugates with CMDs of different molecular weight ( $M_r$  = about 40 and 162 kDa), we investigate the in vivo T cell response, T cell epitope profiles, antigen presentation to  $\beta$ -LG-specific T cells, and the susceptibility to cathepsin B and cathepsin D. Our data show that suppression of the generation of T cell epitopes by conjugation with CMD was involved in the mechanism for the reduced immunogenicity of  $\beta$ -LG.

## MATERIALS AND METHODS

**Materials.** Dextran T40 ( $M_r$  = about 40 kDa) and Dextran 162 ( $M_r$  = about 162 kDa) were purchased from Amersham Pharmacia Biotech (Buckinghamshire, U.K.) and Sigma Chemical Co. (St. Louis, MO), respectively. 1-Ethyl-3-(3-dimethylaminopropyl)carbodiimide (EDC) hydrochloride was purchased from Dojindo (Kumamoto, Japan).

**Carboxymethylation of Dextran.** Each dextran sample was carboxymethylated with monochloroacetic acid under alkaline conditions as previously described (16–18, 26). The carboxymethyl dextrans prepared from Dextran T40 and Dextran 162 are termed CMD 40 and CMD 162, respectively. The numbers of carboxyl groups attached to one molecule of dextran were determined by  $^1\text{H}$  NMR (400 MHz JEOL AL-400, Japan) to be 39 and 162, respectively, for CMD 40 and CMD 162.

**Preparation and Purification of  $\beta$ -LG.** Crude  $\beta$ -LG (genotype AA) was prepared from fresh milk of a Holstein cow according to the method of Armstrong et al. (33). Crude  $\beta$ -LG was purified with a DEAE-Sepharose Fast Flow column (3.0 ID  $\times$  40 cm; Amersham Pharmacia Biotech, Buckinghamshire, U.K.) by referring to the method described previously (16). The purity of  $\beta$ -LG was confirmed by polyacrylamide gel electrophoresis (PAGE), performed by the method of Davis (34).

**Preparation and Purification of the  $\beta$ -LG-CMD Conjugates.** The  $\beta$ -LG-CMD conjugates were prepared by using EDC as previously described (27). In brief,  $\beta$ -LG (1 g) and each CMD (CMD 40, 8.48 g; CMD 162, 9.375 g) in the molar ratio of amino groups of  $\beta$ -LG:carboxyl groups of CMD = 1:10 were dissolved in distilled water (125 mL), and the pH value of the solution was adjusted to 4.75 with 1 M HCl. An EDC solution (1.67 g/10 mL) in a molar ratio of amino groups of  $\beta$ -LG:EDC = 1:10 was added over a 30 min period, the pH value being maintained at 4.75 by adding 1 M HCl. The reaction mixture was incubated at 25 °C for 3 h before a 2 M acetate buffer at pH 5.5 (10 mL) was gradually added over a period of 10 min to stop the reaction. After dialyzing against distilled water at 4 °C and lyophilizing, the crude  $\beta$ -LG-CMD conjugates were obtained. These crude conjugates were purified by hydrophobic chromatography and anion-exchange chromatography as described previously (27). The conjugates prepared from CMD 40 and CMD 162 are termed Conj. 40 and Conj. 162, respectively. The amount of protein in each conjugate was determined by measuring the absorbance at 280 nm. The amount of CMD bound to  $\beta$ -LG was determined by measuring the absorbance at 490 nm after coloring by the phenol-sulfuric acid method (35).

**Immunization.** Female BALB/c, C3H/He, and C57BL/6 mice (Clea Japan, Tokyo, Japan) at 6 weeks of age (7–8 animals/group) were subcutaneously immunized in the hind footpads and base of the tail with  $\beta$ -LG or the conjugates (100  $\mu\text{g}$  as protein) emulsified in Freund's complete H37 Ra adjuvant (Difco Laboratories, Detroit, MI). After 7 days, the inguinal and popliteal lymph nodes were removed.

**T Cell Proliferation Assay and T Cell Epitope Scanning.** The T cell proliferation assay and T cell epitope scanning were performed in 96-well culture plates (Beckton Dickinson, Franklin Lakes, NJ) in 200  $\mu\text{L}$ /well of an RPMI1640 medium (Nissui Pharmaceutical, Tokyo, Japan) supplemented with 0.03% glutamine, 0.2%  $\text{NaHCO}_3$ , 2-mercaptoethanol (2-ME; 50  $\mu\text{M}$ ), penicillin (100 U/mL), streptomycin (100  $\mu\text{g}/\text{mL}$ ), and 1% autologous normal mouse serum. For T cell epitope scanning,

**Table 1. Immunological Properties of the  $\beta$ -LG-CMD Conjugates<sup>a</sup>**

mice	immunogenicity (%) <sup>b</sup> (anti- $\beta$ -LG antibody response)		novel immunogenicity (anti-conjugate antibody response)		B cell epitope distribution		antibody response to epitopes	
	Conj. 40	Conj. 162	Conj. 40	Conj. 162	Conj. 40	Conj. 162	Conj. 40	Conj. 162
BALB/c	54.2	39.5	not emerged		not changed		reduced (Conj. 40 < Conj. 162)	
C3H/He	54.0	44.0	not emerged		not changed		reduced (Conj. 40 < Conj. 162)	
C57BL/6	59.7	34.5	not emerged		not changed		reduced (Conj. 40 < Conj. 162)	

<sup>a</sup> This table summarized the data reported previously (27). <sup>b</sup>BALB/c, C3H/He, and C57BL/6 mice were immunized i.p. with  $\beta$ -LG, Conj. 40, or Conj. 162 emulsified in Freund's complete adjuvant and boosted 14 days later with the proteins emulsified in Freund's incomplete adjuvant. Seven days after secondary immunization, each antiserum was prepared. Immunogenicity was evaluated by ELISA using the antisera. Anti- $\beta$ -LG antibody response in the antisera prepared from the  $\beta$ -LG-immunized mice was as 100%, and that from conjugate-immunized mice was relatively calculated.

a series of overlapping 15-mer peptides moving one amino acid residue at a time in accordance with the amino acid sequence of  $\beta$ -LG were synthesized with a five-in-one B cell and T cell epitope scanning kit (Chiron Mimotopes, Clayton, Victoria, Australia) as described previously (26). The concentration of the synthesized peptides was approximately 1 nmol/ $\mu$ L from the results of an amino acid analysis. The lymph node cells were suspended at  $5 \times 10^5$  cells/well in the culture plates and then stimulated with protein ( $\beta$ -LG or the conjugates) at various concentrations, a synthesized peptide solution (10  $\mu$ L) or PBS (blank). Cultures were set up in triplicate for stimulation with the proteins, while one well for each peptide was tested for the peptide series. After culturing in a humidified atmosphere of 5% CO<sub>2</sub> in air for 3 days at 37 °C, the T cell proliferative response was measured with a BrdU proliferation kit (Roche Molecular Biochemicals, Basel, Switzerland). In short, the cells in the culture plates were pulsed with a 100  $\mu$ M BrdU solution (20  $\mu$ L/well) for 2 h under the same culture conditions. The culture plates were centrifuged at 1250 rpm for 10 min at 4 °C and the supernatant was removed, before the plates were dried for 1 h at 60 °C. A FixDenat solution (200  $\mu$ L) was added to each well, and the plates were incubated for 1 h at 25 °C. The FixDenat solution was removed, and peroxidase-labeled anti-BrdU mAb (100  $\mu$ L/well) that had been diluted 100-fold with the Antibody dilution solution was added, before the plates were incubated for 2 h at 25 °C. The peroxidase-labeled anti-BrdU mAb solution was removed, and each well was washed three times with PBS (200  $\mu$ L each). A tetramethylbenzidine solution (100  $\mu$ L/well) was added, and the plates were incubated for 5–10 min. After adding 1 M H<sub>2</sub>SO<sub>4</sub> (25  $\mu$ L/well) to stop the enzymatic reaction, the absorbance at 450 nm was measured with an MPR-A4i microplate reader (Tosoh, Tokyo, Japan).

The following criteria were used for the peptides adopted as positive in determining the T cell epitopes: (1) those which showed response greater than the mean value plus three times the standard deviation of the absorbance to the peptide (PLAQGGGGGGGGGG) in the absence of the  $\beta$ -LG sequence (31), (2) those which showed positive response to at least two consecutive overlapping peptides, and (3) those which showed reproducibility in two individual experiments (31). The common amino acid sequences among the peptides that fulfilled these criteria were identified as the epitopes according to the method of Gammon et al. (36).

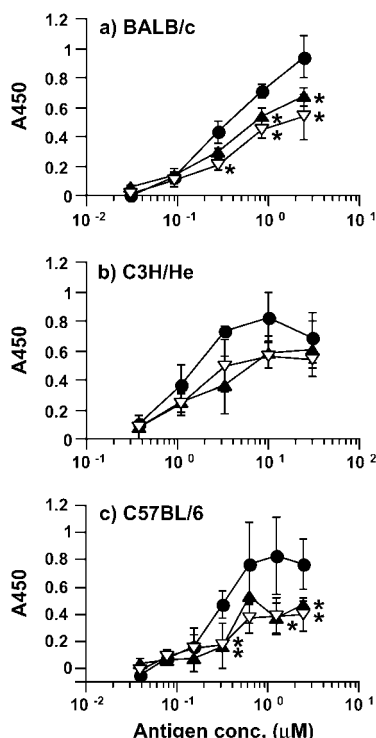

**Digestion of the  $\beta$ -LG-CMD Conjugates with Cathepsin B and Cathepsin D.**  $\beta$ -LG or each conjugate (0.1% (w/v) as the protein concentration) was dissolved in a 0.2 M citric acid/Na<sub>2</sub>HPO<sub>4</sub> buffer (pH 5.0) containing EDTA (1 mM) and 2% (v/v) 2-ME, and the solution was incubated at 37 °C for 12 h. Cathepsin B (EC 3.4.22.1) or cathepsin D (EC 3.4.23.5) from bovine spleen (Sigma

Chemical Co., St. Louis, MO) was added to the solution (enzyme:substrate = 1:10), and the mixture was incubated at 37 °C for various times. Digestion was stopped by adding the loading buffer for sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and by heating at 100 °C for 5 min. The digested sample was applied to SDS-PAGE (37), and the gel was stained with Coomassie Brilliant Blue R-250. After destaining, the digestibility of each sample was evaluated by densitometry.

## RESULTS AND DISCUSSION

To reduce the immunogenicity of  $\beta$ -LG by conjugation with polysaccharides and to elucidate the mechanism involved, we have previously prepared two  $\beta$ -LG-CMD conjugates (Conj. 40 and Conj. 162) by using EDC and investigated the immunological properties of each conjugate in BALB/c, C3H/He and C57BL/6 mice (27). We prepared conjugates having a similar saccharide content with CMDs of different molecular weight to evaluate the influence of the molecular weight of the polysaccharides on the immunological properties of the conjugates. The respective molar ratios of  $\beta$ -LG to CMD in the conjugates were 8:1 and 7:1 for Conj. 40 and Conj. 162. The immunological properties of the conjugates are shown in Table 1. In all the three strains of mice, the immunogenicity of  $\beta$ -LG (production of the  $\beta$ -LG-specific antibody) was reduced without inducing any novel immunogenicity (production of a conjugate-specific antibody) by conjugation with CMD. The reduced immunogenicity was more evident in the case of Conj. 162 than Conj. 40. To elucidate the mechanism for the reduced immunogenicity of  $\beta$ -LG, we investigated changes in the B cell epitope profiles of the conjugates by ELISA, using the overlapping 15-mer peptides synthesized on the basis of the amino acid sequence of  $\beta$ -LG (27). The linear B cell epitope profile of each conjugate was similar to that of  $\beta$ -LG in terms of the epitope distribution, whereas the antibody response to each epitope was reduced. The reducing effect was Conj. 40 < Conj. 162, so we concluded that masking of the B cell epitopes by the saccharide chain was responsible for reducing the immunogenicity of  $\beta$ -LG.

**In Vivo T Cell Response of the  $\beta$ -LG-CMD Conjugates.** Since T cells provide help to B cells through direct cell-cell interaction and secretion of cytokines that promote their proliferation and differentiation into antibody-producing cells (29), T cells are considered to play an important role in antibody response. To elucidate the mechanism for the reduced immunogenicity of  $\beta$ -LG by conjugation with CMD, we investigated the in vivo T cell response of each conjugate. After BALB/c, C3H/He, and C57BL/6 mice had been immunized with  $\beta$ -LG or the conjugates, the lymph node cells from the mice were

**Figure 1.** Proliferative response to  $\beta$ -LG of lymph node cells from mice immunized with  $\beta$ -LG or the  $\beta$ -LG-CMD conjugates. After immunizing BALB/c (a), C3H/He (b), and C57BL/6 (c) mice with  $\beta$ -LG (●), Conj. 40 (▲), or Conj. 162 (▽), the lymph node cells from the mice were removed and stimulated with  $\beta$ -LG at various concentrations. The magnitude of the in vivo T cell response was evaluated as the ex vivo proliferative response by BrdU ELISA. Each value is expressed as the mean absorbance at 450 nm and standard deviation of triplicate cultures after subtracting the background values (stimulated with PBS). Significant differences ( $p < 0.05$ ) between  $\beta$ -LG and each conjugate were determined by Student's  $t$ -test and are indicated by asterisks.

removed and then stimulated with  $\beta$ -LG at various concentrations. The magnitude of the in vivo T cell response was evaluated as the ex vivo proliferative response by BrdU ELISA (Figure 1). In BALB/c mice (Figure 1a), T cells from the groups immunized with the conjugates showed lower response than those from  $\beta$ -LG-immunized mice, this being particularly evident with Conj. 162. In C3H/He (Figure 1b) and C57BL/6 mice (Figure 1c), although the T cell proliferative responses of the Conj. 40- and Conj. 162-immunized groups were similar, the proliferative response of T cells from the conjugate-immunized groups was lower than that from the  $\beta$ -LG-immunized group. This result indicates that the response of the T cells to  $\beta$ -LG in the conjugate-immunized mice was reduced by conjugation with CMD. Two possibilities are considered as the reason for this result. (1) A decrease in the number of  $\beta$ -LG-specific T cells: since the induction of  $\beta$ -LG-specific T cells was suppressed by conjugation with CMD, the number of  $\beta$ -LG-specific T cells might have been reduced. (2) Changed T cell epitopes by conjugation: McCool et al. (38) have found that lymph node cells from mice immunized with a protein-polysaccharide conjugate recognized additional peptides that were not recognized by lymph node cells from mice immunized with the original protein. In our study, T cells in the conjugate-immunized mice might have shown the reduced response to  $\beta$ -LG owing to the induction of conjugate-specific T cells which could not recognize native  $\beta$ -LG by the generation of the

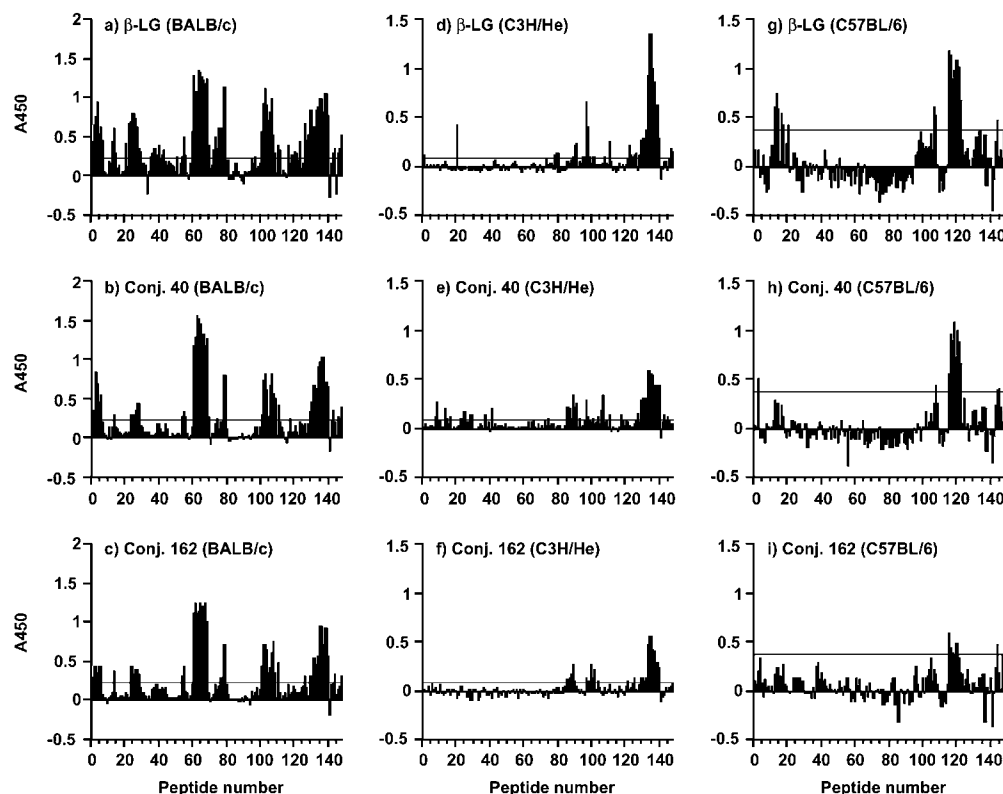

neo-epitopes that are not recognized by  $\beta$ -LG-specific T cells after conjugation with CMD.

**T Cell Epitope Profiles of the  $\beta$ -LG-CMD Conjugates.** Since the proliferative response of T cells to whole proteins is polyclonal, we next investigated in detail the T cell epitope profiles of the conjugates. After the lymph node cells from BALB/c, C3H/He, and C57BL/6 mice immunized with  $\beta$ -LG or the conjugates had been stimulated with the overlapping peptides synthesized on the basis of the sequence of  $\beta$ -LG, the T cell proliferative response to the peptides was measured by BrdU ELISA. Figure 2 shows the T cell epitope profiles of  $\beta$ -LG and the  $\beta$ -LG-CMD conjugates. The horizontal axis indicates the N-terminal amino acid residue number of each 15-mer peptide corresponding to the position in the  $\beta$ -LG sequence, and the vertical axis indicates the T cell proliferative response to each peptide. The T cell epitopes identified according to the method of Gammon et al. (36) are summarized in Figure 3, in which the horizontal axis indicates the sequence number in  $\beta$ -LG and the line thickness indicates the intensity of the response to each epitope.

The T cells from BALB/c mice immunized with  $\beta$ -LG showed proliferative response to peptides 1–7, 14–15, 23–29, 35–40, 42–43, 54–55, 60–70, 73–79, 101–109, 111–112, 119–122, 127–133, 133–140, 143–144, and 147–148 (Figure 2a). The T cell epitopes of  $\beta$ -LG that had been recognized in BALB/c mice were determined to be  $^{15}\text{Met}$ – $^{28}\text{Val}$ ,  $^{15}\text{Val}$ – $^{28}\text{Asp}$ ,  $^{29}\text{Ile}$ – $^{37}\text{Ala}$ ,  $^{40}\text{Arg}$ – $^{49}\text{Thr}$ ,  $^{43}\text{Val}$ – $^{56}\text{Ile}$ ,  $^{55}\text{Glu}$ – $^{68}\text{Gln}$ ,  $^{70}\text{Lys}$ – $^{74}\text{Glu}$ ,  $^{79}\text{Pro}$ – $^{87}\text{Leu}$ ,  $^{109}\text{Asn}$ – $^{115}\text{Gln}$ ,  $^{112}\text{Glu}$ – $^{125}\text{Thr}$ ,  $^{122}\text{Leu}$ – $^{133}\text{Leu}$ ,  $^{133}\text{Leu}$ – $^{141}\text{Lys}$ ,  $^{140}\text{Leu}$ – $^{147}\text{Ile}$ ,  $^{144}\text{Pro}$ – $^{157}\text{Glu}$  and  $^{148}\text{Arg}$ – $^{161}\text{His}$ , the dominant epitopes being  $^{70}\text{Lys}$ – $^{74}\text{Glu}$ ,  $^{109}\text{Asn}$ – $^{115}\text{Gln}$ , and  $^{140}\text{Leu}$ – $^{147}\text{Ile}$  (Figure 3). No changes in the epitope distribution was apparent for T cells from the conjugate-immunized BALB/c mice, but the proliferative response to the epitopes was lower throughout the entire amino acid sequence than that of the  $\beta$ -LG-immunized group (Figure 2a–c). The magnitude of the response to Conj. 162 was lower than that to Conj. 40. The T cell epitopes of the conjugates recognized in BALB/c mice were determined to be  $^{6}\text{Thr}$ – $^{15}\text{Val}$ ,  $^{25}\text{Ala}$ – $^{38}\text{Pro}$ ,  $^{28}\text{Asp}$ – $^{41}\text{Val}$ ,  $^{70}\text{Lys}$ – $^{75}\text{Lys}$ ,  $^{109}\text{Asn}$ – $^{115}\text{Gln}$ ,  $^{140}\text{Leu}$ – $^{144}\text{Pro}$  and  $^{148}\text{Arg}$ – $^{161}\text{His}$  for Conj. 40, and  $^{6}\text{Thr}$ – $^{15}\text{Val}$ ,  $^{28}\text{Asp}$ – $^{38}\text{Pro}$ ,  $^{69}\text{Lys}$ – $^{75}\text{Lys}$ ,  $^{109}\text{Asn}$ – $^{115}\text{Gln}$ , and  $^{140}\text{Leu}$ – $^{146}\text{His}$  for Conj. 162 (Figure 3).

The results obtained with the C3H/He and C57BL/6 mice are shown in Figure 2d–f, and the T cell epitope profiles of  $\beta$ -LG and the conjugates were determined as shown in Figure 3. The T cell epitopes of  $\beta$ -LG recognized in the C3H/He mice were determined to be  $^{91}\text{Lys}$ – $^{103}\text{Leu}$ ,  $^{99}\text{Tyr}$ – $^{111}\text{Ala}$ ,  $^{102}\text{Tyr}$ – $^{115}\text{Gln}$ ,  $^{125}\text{Thr}$ – $^{137}\text{Asp}$ ,  $^{137}\text{Asp}$ – $^{143}\text{Leu}$ , and  $^{148}\text{Arg}$ – $^{161}\text{His}$ , the dominant epitope being  $^{137}\text{Asp}$ – $^{143}\text{Leu}$  (Figure 3). In the C3H/He mice immunized with the conjugates, the epitope distribution of both conjugates was similar to that of  $\beta$ -LG, whereas the proliferative response to the epitopes was lower throughout the entire amino acid sequence than that of the  $\beta$ -LG-immunized group (Figure 2d–f). The signal intensity to the epitopes in the Conj. 162-immunized group was weaker than that in the Conj. 40-immunized group. The T cell epitopes of each conjugate recognized in C3H/He mice were determined to be  $^{91}\text{Lys}$ – $^{101}\text{Lys}$ ,  $^{98}\text{Asp}$ – $^{111}\text{Ala}$ ,  $^{119}\text{Cys}$ – $^{132}\text{Ala}$ ,  $^{137}\text{Asp}$ – $^{144}\text{Pro}$  and  $^{140}\text{Leu}$ – $^{151}\text{Phe}$  for Conj. 40, and  $^{90}\text{Asn}$ – $^{101}\text{Lys}$ ,  $^{101}\text{Lys}$ – $^{114}\text{Glu}$ ,  $^{131}\text{Glu}$ – $^{144}\text{Pro}$ , and  $^{139}\text{Ala}$ – $^{147}\text{Ile}$  for Conj. 162 (Figure 3).

The T cell epitopes of  $\beta$ -LG recognized in C57BL/6 mice were determined to be  $^{15}\text{Val}$ – $^{27}\text{Ser}$ ,  $^{108}\text{Glu}$ – $^{121}\text{Cys}$ , and  $^{123}\text{Val}$ – $^{130}\text{Asp}$ , the dominant epitope being  $^{123}\text{Val}$ –

**Figure 2.** Proliferation of the lymph node cells from mice immunized with  $\beta$ -LG or the  $\beta$ -LG-CMD conjugates to the overlapping 15-mer peptides covering the amino acid sequence of  $\beta$ -LG. After immunizing BALB/c (a–c), C3H/He (d–f), and C57BL/6 mice (g–i) with  $\beta$ -LG (a, d, g), Conj. 40 (b, e, h), or Conj. 162 (c, f, i), the lymph node cells from the mice were removed and stimulated with the overlapping synthesized peptides. The proliferative response of T cells to the peptides was measured by BrdU ELISA. The horizontal lines in the figures indicate cutoff values to judge whether the observed response was positive. Representative epitope profiles from two individual experiments are shown.

<sup>130</sup>Asp (Figure 3). No changes in the epitope distribution were apparent for the T cells from the conjugate-immunized C57BL/6 mice, but the proliferative response to the epitopes was lower throughout the entire amino acid sequence than that of the  $\beta$ -LG-immunized group (Figure 2g–i). The signal intensity to the epitopes in the Conj. 162-immunized group was weaker than that in the Conj. 40-immunized group. The T cell epitopes of the conjugates recognized in C57BL/6 mice were determined to be <sup>123</sup>Val–<sup>130</sup>Asp for Conj. 40 and <sup>118</sup>Val–<sup>30</sup>Asp and <sup>121</sup>Cys–<sup>134</sup>Glu for Conj. 162 (Figure 3).

Totsuka et al. (31) have clarified the T cell epitope profiles of  $\beta$ -LG in BALB/c, C3H/He and C57BL/6 mice by a conventional <sup>3</sup>H-thymidine incorporation assay. Although some differences are apparent between our results and those of Totsuka et al. with respect to the signal intensity, the epitope distribution is similar. We have previously shown that the glycosylation sites in  $\beta$ -LG after conjugation with CMD of 10 kDa were <sup>47</sup>Lys, <sup>60</sup>Lys, <sup>101</sup>Lys, and <sup>138</sup>Lys (26). Other investigators (39–41) have reported that the preferential lactosylation sites of  $\beta$ -LG by the Maillard reaction were <sup>47</sup>Lys and/or <sup>100</sup>Lys. The conjugates prepared in this study tended to reduce the response to the epitope regions around these Lys residues. The human T cell epitopes of  $\beta$ -LG have recently been identified as <sup>1</sup>Leu–<sup>21</sup>Ser, <sup>14</sup>Lys–<sup>29</sup>Ile, <sup>30</sup>Ser–<sup>47</sup>Lys, <sup>47</sup>Lys–<sup>67</sup>Ala, <sup>77</sup>Lys–<sup>97</sup>Thr, <sup>97</sup>Thr–<sup>117</sup>Leu, and <sup>142</sup>Ala–<sup>162</sup>Ile by using synthesized peptides (32). Since most of these T cell epitopes are located in the vicinity of the plausible glycosylation sites just mentioned, the conjugates prepared in this study would modulate the T cell response in humans.

It has been reported that a protein–polysaccharide conjugate showed a different pattern of T cell reactivity

to epitopes derived from original protein (38); however, our results from the epitope scanning of Conj. 40 and Conj. 162 show that the T cell epitope profiles of the conjugates were similar to those of  $\beta$ -LG in all the strains of mice tested, which indicates that the location of epitopes recognized by T cells induced in vivo in the conjugate-immunized mice did not change by conjugation with CMD. In fact, when lymph node cells from the conjugate-immunized mice were stimulated with  $\beta$ -LG or the conjugates, the proliferative response to the conjugate was no higher than that to  $\beta$ -LG (data not shown). The signal intensity to the epitopes in the conjugate-immunized groups was lower than that in the  $\beta$ -LG-immunized group in the three strains of mice, indicating a decrease in the number of  $\beta$ -LG-specific T cells owing to the low induction of  $\beta$ -LG-specific T cells in vivo after conjugation with CMD. Therefore, the low in vivo T cell response in the conjugate-immunized groups, as shown in Figure 1, is considered to have been due to the lower number of  $\beta$ -LG-specific T cells induced in vivo by conjugation with CMD.

**Antigen Presentation of the  $\beta$ -LG-CMD Conjugates to  $\beta$ -LG-Specific T Cells.** To elucidate the mechanism for the decrease in number of  $\beta$ -LG-specific T cells in vivo by conjugation with CMD, we investigated antigen presentation of the conjugates to  $\beta$ -LG-specific T cells. After the three strains of mice had been immunized with  $\beta$ -LG, the lymph node cells were removed and stimulated with  $\beta$ -LG or the conjugates at various concentrations. The efficiency of the antigen presentation was evaluated as the in vitro T cell proliferative response by BrdU ELISA (Figure 4). In the BALB/c (Figure 4a) and C3H/He mice (Figure 4b), the proliferative response of the  $\beta$ -LG-specific T cells to Conj. 40 was similar to that

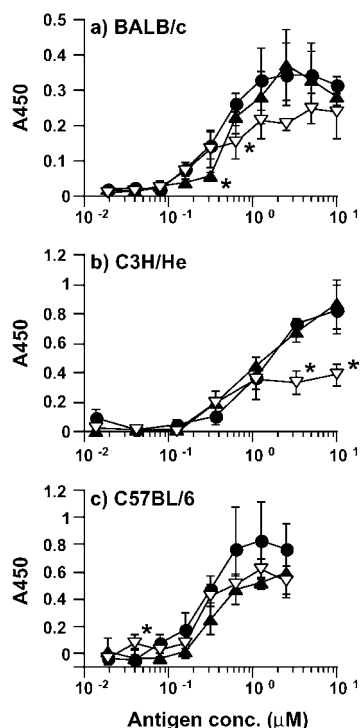

**Figure 3.** T cell epitope profiles of  $\beta$ -LG and the  $\beta$ -LG-CMD conjugates. The common regions of at least two overlapping peptides, which showed a response greater than the mean value plus three times the standard deviation of the absorbance when the lymph node cells were stimulated with the peptide (PLAQGGGGGGGGGG) in the absence of the  $\beta$ -LG sequence and which showed reproducibility in two individual experiments, were identified as epitopes according to the method of Gammon et al. (36).

to  $\beta$ -LG, whereas the response to Conj. 162 was lower than that to  $\beta$ -LG. In C57BL/6 mice (Figure 4c), Conj. 40 and Conj. 162 both showed lower T cell proliferative response than that to  $\beta$ -LG. CMD 40 and CMD 162 had no effect on the T cell proliferative response, even at a concentration of 10  $\mu$ M/well (data not shown). This lower T cell proliferative response indicates that the antigen presentation of  $\beta$ -LG to the  $\beta$ -LG-specific T cells was suppressed by the conjugation with CMD. In particular, the proliferative response of  $\beta$ -LG-specific T cells to Conj. 162 from CMD of the higher molecular weight was lower than that to  $\beta$ -LG in the three strains of mice. Hence, conjugation with CMD of high molecular weight is considered to be effective for suppression of the antigen presentation of  $\beta$ -LG which would lead to a decrease in the number of  $\beta$ -LG specific T cells in vivo.

**Susceptibility of the  $\beta$ -LG-CMD Conjugates to Cathepsin B and Cathepsin D.** Three possible mechanisms are considered plausible for suppressing the antigen presentation of  $\beta$ -LG to T cells by conjugation with CMD: (1) suppression of the generation of T cell epitopes, (2) inhibition of binding between MHC and the antigenic peptide, and (3) inhibition of MHC-peptide complex recognition by the T cell receptor. To examine the first possibility, we investigated the susceptibility of

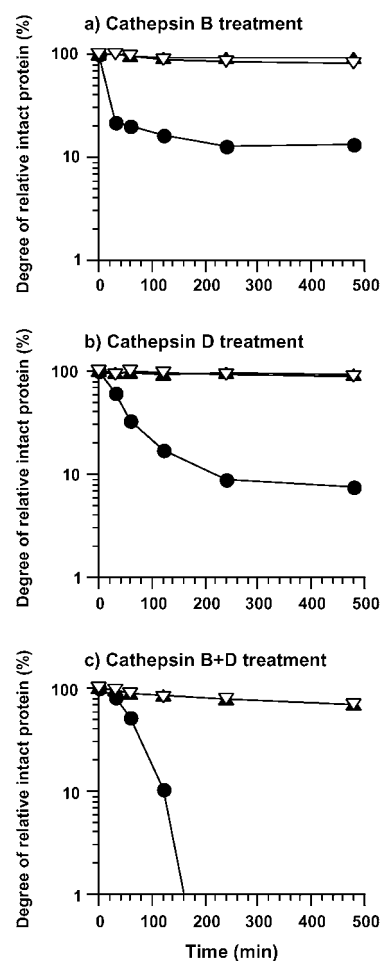

the conjugates to cathepsin B and cathepsin D, which are regarded as representative enzymes involved in the generation of antigenic epitopes (28). The processing of many antigens requires reduction of the disulfide bonds (28, 42) as well as proteolysis in APC, so the conjugates were digested with the cathepsins in the presence of 2-ME (Figure 5). About 90% of  $\beta$ -LG was digested with cathepsin B (Figure 5a) and cathepsin D (Figure 5b) after 8 h, whereas no more than 10% of the conjugates was digested. In respect of the endosomal protease involved in antigen processing, it has been suggested that the processing of most antigens occurs through the sequential action of more than one enzyme, that endoproteases including cathepsin D may be important in revealing and releasing antigens, and that exopeptidases including cathepsin B may trim epitopes to their final size (28, 43). Hence, the conjugates were digested with a mixture (1:1) of cathepsin B and cathepsin D (Figure 5c).  $\beta$ -LG was completely digested after about 2 h, whereas about 70% of each conjugate remained intact even after 8 h of digestion.  $\beta$ -LG was not digested when incubated for 8 h in the absence of the cathepsins (data not shown). In all experiments, both conjugates showed much higher resistance to the cathepsins than  $\beta$ -LG. These results indicate that conjugation with CMD inhibited the deg-

**Figure 4.** Proliferative response to  $\beta$ -LG and the  $\beta$ -LG-CMD conjugates of the lymph node cells from the mice immunized with  $\beta$ -LG. After immunizing BALB/c (a), C3H/He (b), and C57BL/6 (c) mice with  $\beta$ -LG, the lymph node cells from the mice were removed and stimulated with  $\beta$ -LG (●), Conj. 40 (▲), or Conj. 162 (▽) at various concentrations. The T cell proliferative response to the proteins was measured by BrdU ELISA. Each value is expressed as the mean absorbance at 450 nm and standard deviation of triplicate cultures after subtracting the background values (stimulated with PBS). Significant differences ( $p < 0.05$ ) between  $\beta$ -LG and each conjugate were determined by Student's  $t$ -test and are indicated by asterisks.

radiation of  $\beta$ -LG by proteases in APC and would have led to suppression of the generation of T cell epitopes from  $\beta$ -LG. It is considered that this suppressive effect on the generation of T cell epitopes by conjugation with CMD reduced the antigen presentation of the conjugates. This proposal is supported by the findings that the lysozyme stabilized by intramolecular cross-linking depressed T cell epitope generation by increasing the resistance to proteolysis (44) and that proteophosphoglycan, a major product secreted from *Leishmania mexicana* amastigotes, did not elicit a specific CD4<sup>+</sup> T cell response due to no degradation occurring in macrophages (45). The reduced antigen presentation of the conjugates would bring about a decrease in the number of  $\beta$ -LG-specific T cells in vivo and, as a result, the decreased help to B cells by T cells would reduce the antibody response to  $\beta$ -LG. Consequently, we conclude that suppression of the generation of T cell epitopes by conjugation with CMD played an important role in the mechanism for reducing the immunogenicity of  $\beta$ -LG. As for the other possibilities, the inhibition of binding between MHC and the antigenic peptide must be taken into consideration, because the plausible glycosylation sites already mentioned are located within some of the T cell epitopes identified in this study. In fact, T cell epitopes with internal but not external glycosylation did not bind MHC class II molecules and had less T cell proliferative response (46).

**Concluding Remarks.** We have shown in this study that the suppressive effect on the generation of T cell epitopes by conjugation with CMD played an important role in the mechanism for the reduced immunogenicity

**Figure 5.** Susceptibility of  $\beta$ -LG and the  $\beta$ -LG-CMD conjugates to cathepsin B and cathepsin D.  $\beta$ -LG (●), Conj. 40 (▲), and Conj. 162 (▽) were digested with cathepsin B (a), cathepsin D (b), and a mixture (1:1) of cathepsin B and cathepsin D (c) for various times in the presence of 2-ME. The digested samples were applied to SDS-PAGE, and the digestibility of the samples was evaluated by densitometry. The intensity of the bands of each sample at 0 min is taken as 100%, and that of the samples at subsequent times is relative to the value at 0 min. All results are expressed relative to the intact protein (%).

of  $\beta$ -LG. Our work is valuable in that we could clarify the change in the T cell epitope profile of a protein after conjugation with polysaccharides differing in molecular weight to elucidate the mechanism for the reduced immunogenicity. Taken together with our previous results (26, 27), both masking of the B cell epitopes by the saccharide chain and suppression of the generation of T cell epitopes in APC are considered to be important for the reduced immunogenicity of protein by conjugation with a polysaccharide. Both factors would be involved in the induction of a low IgE response by conjugation methods, and further studies focusing on these aspects should be carried out. We have particular interest in the change in qualitative T cell response to proteins after conjugation or modification (47–51). With regard to the difference in the molecular weight of CMD used as a modifier, although not all experiments showed a distinct difference between Conj. 40 and Conj. 162, the effect of Conj. 40 did not exceed that of Conj. 162. Conjugation with a polysaccharide of high molecular weight is therefore considered to be effective for modulating the T cell response to proteins. The results of the present study are essential to develop the design of novel hypoallergenic foods.

# Lactose-Installed Poly(ethylene glycol)–Poly(D,L-lactide) Block Copolymer Micelles Exhibit Fast-Rate Binding and High Affinity toward a Protein Bed Simulating a Cell Surface. A Surface Plasmon Resonance Study

Eduardo Jule,<sup>†,§</sup> Yukio Nagasaki,<sup>‡</sup> and Kazunori Kataoka<sup>\*,†</sup>

Department of Materials Science and Engineering, Graduate School of Engineering, The University of Tokyo, 7–3–1 Hongo, Bunkyo-ku, Tokyo 113-8656, Japan, and Department of Materials Science, Science University of Tokyo, 2641 Yamazaki, Noda, Chiba 278-8510, Japan. Received August 26, 2002; Revised Manuscript Received October 15, 2002

Lactose molecules were installed on the surface of poly(ethylene glycol)–poly(D,L-lactide) (PEG–PLA) block copolymer micelles in the scope of seeking specific recognition by cell surface receptors at hepatic sites. This, in turn, is expected to result in the formation of a complex displaying prolonged retention times and thus enhanced cellular internalization by receptor-mediated endocytosis. The so-obtained particles based on a block copolymer of molecular weight 9400 g/mol (4900/4500 g/mol for the PEG and PLA blocks, respectively) were found to have an average hydrodynamic diameter of 31.8 nm, as measured by dynamic light scattering. Further, the particle size distribution ( $\mu_2/\bar{\Gamma}^2$ ) was found to be lower than 0.08. Lactose–PEG–PLA micelles (Lac-micelles) were then injected over a gold surface containing *Ricinus communis* agglutinin lectins simulating the aforementioned glycoreceptors, and their interaction was studied by surface plasmon resonance. Then, a kinetic evaluation was carried out, by fitting the observed data mathematically. It appears that Lac-micelles bind in a multivalent manner to the lectin protein bed, which logically results in low dissociation constants. Micelles bearing a ligand density of 80% (Lac-micelles 80%: 80 lactose molecules per 100 copolymer chains) exhibit fast association phases ( $k_{a1} = 3.2 \times 10^4 \text{ M}^{-1} \text{ s}^{-1}$ ), but also extremely slow dissociation phases ( $k_{d1} = 1.3 \times 10^{-4} \text{ s}^{-1}$ ). Recorded sensorgrams were fitted with a trivalent model, conveying a calculated equilibrium dissociation constant ( $K_{D1} = k_{d1}/k_{a1}$ ) of about 4 nM. The importance of cooperative binding was also assessed, by preparing Lac-micelles bearing different ligand densities, and by discussing the influence of the latter on kinetic constants. Interestingly enough, whereas Lac-micelles 80% bind in a trivalent manner to the protein bed, Lac-micelles 20% are still capable of forming bivalent complexes with the same protein bed ( $K_{D1} = 1360 \text{ nM}$ ). Therefore, despite enhanced kinetic values brought about by a supplementary bond, lower ligand densities appear to be more effective on a molecular basis.

## 1. INTRODUCTION

Combining the properties of colloidal particles such as liposomes or polymeric micelles with those of certain biomolecules such as antibodies, peptides, or carbohydrates can bring about a new array of properties to the bioconjugates. This, in turn, can be exploited in fields not applicable to each of the separate species. For quite some time now, it has been acknowledged that carbohydrates and proteins play a fundamental role in cellular processes such as growth, recognition, and inflammation (1), so that extensive research has focused on the design of carbohydrate analogues, for example to target receptors such as the asialoglycoprotein receptor at hepatic sites (2). Yet, these efforts are undermined by the intrinsic low affinity of carbohydrates toward proteins such as lectins, which of course presents only limited interest for the design of drug delivery systems. Multivalency is known to greatly

enhance kinetic values, and starlike particles greatly enhance binding constants (3). Much in the same manner, colloidal particles bearing an important ligand density on their surface could be expected to enhance such parameters and demonstrate interesting properties from the standpoint of cellular uptake by receptor-mediated endocytosis (RME).

Macromolecular assemblies such as polymeric micelles are promising systems, as they can ensure the actual transport and delivery of a wide variety of compounds (4–6). Indeed, block copolymers bearing blocks of dissimilar natures, i.e., a hydrophilic and a hydrophobic block, are known to spontaneously associate into colloidal particles. Micelles have thus a hydrophobic inner core surrounded by an external hydrophilic corona, a unique feature that permits the entrapment of compounds otherwise poorly soluble in body fluids such as the bloodstream. Micelles based on acetal-poly(ethylene glycol)–poly(D,L-lactide) (Ac-PEG–PLA) block copolymers meet these stipulations, forming particles in the tens-of-nanometers scale, a good compromise for avoiding urinary excretion while escaping recognition by reticuloendothelial systems (6). Aside from this, cellular surface receptors could be targeted by bioconjugates such as Ac-

PEG-PLA micelles bearing a specific ligand on their surface. Indeed, the acetal end of the PEG block can be deprotected into an aldehyde reactive group through which surface formulation of micelles can be achieved, as previously reported (7, 8). Whereas charged peptides have been shown to regulate the uptake of particles in the liver and spleen (9), carbohydrates are expected to form a complex with the receptor protein in a highly specific manner, displaying selective accumulation at target cells. The affinity of complex formation shall be well characterized, then, if one is to optimize the uptake by RME (10). Another factor that appears to be critical in the design of multivalent devices is the ligand density, or the amount of ligands to be displayed to targeted receptors. As shall be explained herein, lactose-bearing PEG-PLA micelles (Lac-micelles) appear to be an interesting model for a detailed study on this matter, since what will be referred to as the lactose functionality or density can be controlled in a facile way.

*Ricinus communis* agglutinin (RCA) lectins were thus immobilized on a gold surface plasmon resonance (SPR) surface, to simulate asialoglycoprotein receptors on the surface of hepatocytes whereas Lac-micelles were injected in order to evaluate their interaction. A kinetic evaluation was carried out, to further characterize in a more qualitative manner what has previously been reported (11). The interaction was found to be highly specific and of many orders superior to that of micelles bearing no such ligand, rendering the former of obvious therapeutic interest. As shall be exposed herein, Lac-micelles exhibit fast-rate binding kinetics to the protein bed, whereas the ligand density on their surface results in multivalent binding to the protein bed, which in turn yields diminished kinetic dissociation and thus lowered equilibrium dissociation constants. Furthermore, micelles bearing different ligand densities were analyzed so that the influence of multivalency on kinetic values is also discussed. An innovative technique, SPR, demonstrates the perspective of recording responses in real time, so that kinetic assays can readily be conducted, if one is to set aside the inherent difficulty of controlling mass transport phenomena which heavily compromise such evaluations.

## 2. EXPERIMENTAL SECTION

**2.1. Materials and Methods.** Commercial tetrahydrofuran (THF), 3,3'-diethoxypropanol (DEP), and ethylene oxide (EO) were purified by conventional distillations under argon atmosphere. Commercial D,L-lactide (LA) was recrystallized from ethyl acetate twice, under argon atmosphere, and sublimated under vacuum at 110 °C. Potassium naphthalene was used in a THF solution, the concentration of which was determined by an appropriate titration. *Ricinus communis* agglutinin (RCA-I) lectins (Funakoshi Corporation, Japan) were used as received. Water was purified with a Milli-Q instrument (Millipore, Bedford, MA).

Gel permeation chromatography (GPC) measurements of the prepared polymers were conducted using a JASCO liquid chromatograph equipped with TSK gel columns (G4000H<sub>HR</sub> and G3000H<sub>HR</sub>) and an internal refractive index (RI) detector (930-R1, JASCO, Japan). Dimethyl formamide (DMF) containing 10 mM LiBr was used as eluent at a flow rate of 0.8 mL/min. Molecular weight calibrations were done using a series of standard PEGs (Polymer Laboratories, UK). Samples dissolved in the eluent at a concentration of 2 mg/mL were injected into the GPC circuit through a 100  $\mu$ L loop. The <sup>1</sup>H NMR spectra of polymer samples were established at 80 °C in

DMSO-*d*<sub>6</sub> or at 25 °C in CDCl<sub>3</sub>-*d* with a JEOL GSX-270 spectrometer at 270 MHz.

**2.2. Preparation and Characterization of Block Copolymers.** The Ac-PEG-PLA block copolymer was synthesized via an anionic ring-opening polymerization at room temperature under argon atmosphere. The typical procedure is described hereafter: 0.16 mL (1 mmol) of DEP and 3.2 mL (1 mmol) of a 0.31 M naphthalene potassium solution in THF were introduced in a flask containing 20 mL of dry THF and stirred for 10 min. A 5.7 mL (114 mmol) volume of EO was then added and polymerized for 2.5 days. After sampling a small volume of the solution for GPC analysis, 46 mL (40 mmol) of a LA solution in THF (0.88 mol/L) was introduced in the medium, and the polymerization was allowed to proceed for 4 h. The polymer was then precipitated into a 50-fold excess of ice-cooled isopropyl alcohol (IPA) and then centrifuged at 8000g for 30 min. The polymer was then freeze-dried from benzene, affording white flakes in a yield of 90%. The sample was stored at -20 °C until use.

The molecular weight of the PEG segment was determined by GPC using the fraction sampled at the end of the first stage of the copolymerization. Given that interference of the block copolymers with the GPC separating columns, often yielding apparent lower molecular weights, has been observed, the size of the PLA block was calculated based on the molecular weight of the PEG block as obtained by GPC and the NMR spectrum of the block copolymer. Therefore, it is possible to correlate the number average molecular weight (*M<sub>n</sub>*) of the PEG block and the intensity ratio of methine protons on the PLA block (COCH(CH<sub>3</sub>)O:  $\delta$  = 5.2 ppm) and methylene protons on the PEG block (OCH<sub>2</sub>CH<sub>2</sub>:  $\delta$  = 3.6 ppm).

**2.3. Preparation and Characterization of Micelles.** The Ac-PEG-PLA copolymer was dissolved in *N,N*-dimethylacetamide (DMAc), a good solvent of both the hydrophilic and hydrophobic blocks, in a 5 mg/mL solution. The solution was then filtered through a 0.2  $\mu$ m PTFE filter (Ekicrodisk, Japan) into a preswollen semi-permeable membrane (Spectra/Por, Spectrum, Rancho Dominguez, CA, molecular weight cutoff 3500) and dialyzed for 24 h against a 100-fold excess of distilled water. The dialysate was exchanged at times 2, 5, and 8 h. The micelles were eventually filtered through a 0.45  $\mu$ m PTFE filter (Millipore).

The hydrodynamic radius and the size distribution of micelles were determined by dynamic light scattering (DLS). The gyration radius and the apparent molecular weight of micelles were established by static light scattering (SLS). All measurements were carried out at 25 °C on a light scattering spectrophotometer (DLS-7000, Photol, Otsuka Electronics, Japan), and the scattering was carried out with a vertically polarized incident beam at 488 nm supplied by an argon ion laser. A scattering angle of 90° was used for the DLS evaluations, and the particle size distribution was estimated from the correlation function profile using the cumulant method (12).

SLS measurements of a colloidal dispersion yield values for *K<sub>c</sub>/R<sub>90</sub>* that can be used to determine the apparent molecular weight of the particles (13). A plot of this value against the particle concentration is known as a Debye plot and can be analyzed with the equation:

$$Kc/R_{90} = 1/M_w + A_2c + \dots$$

where *K* is a constant, given for vertically polarized light by the expression  $7\pi n_0^2(N_A^2\lambda^4)^{-1}(dn/dc)^2$ , for which *n*<sub>0</sub> is

the solvent refractive index;  $N_a$ , Avogadro's number,  $\lambda$  the wavelength of the scattered light, and  $dn/dc$  the gradient in the refractive index against the sample concentration  $c$ .  $R_\theta$  is the experimentally measured excess Rayleigh ratio,  $\theta$  is the scattering angle,  $M_w$  is the apparent molecular weight of the particle, and  $A_2$  is the second virial coefficient. A series of polymer solutions, ranging from 0.5 mg/mL to 4 mg/mL (0.5, 1, 2, 3, and 4) were thus scattered at angles spanning from 30° to 135° (30, 45, 60, 75, 90, 105, 120, and 135). Deionized water and benzene were used as references for the scattering and refractive index gradient evaluations, respectively.

The increment of the refractive index ( $dn/dc$ ) of the polymer solutions was evaluated using a DRM-120 double-beam differential refractometer (Otsuka Electronics Co., Ltd., Osaka, Japan).

**2.4. Sugar Installation on the Surface of the Micelles.** Deprotection of the acetal functions at the PEG block end was conducted by mild acidification of the corresponding Ac-PEG-PLA micellar solution to pH 2, using a 0.1 M HCl solution. The solution was stirred for 2 h before being brought back to the initial pH of micelles (pH 5) with a 0.1 M NaOH solution. At this stage, a small volume was sampled in order to evaluate the aldehyde functionality. The system was then concentrated to 4 mg/mL and placed in a phosphate buffer saline (PBS, pH 7.4;  $I = 0.1$  M) before introducing a 10-fold molar excess of *p*-aminophenyl- $\beta$ -D-lactopyranoside, the amine terminal group of which forms a Schiff base with the aldehyde groups previously obtained by deprotection of the acetal groups. After another hour of stirring, the Schiff base was reduced to a secondary amine using a 10-fold molar excess of  $\text{NaH}_3\text{BCN}$ , and the system was stirred for another 96 h. Unreacted species were removed by dialysis on a preswollen membrane (Spectra/Por, Spectrum, molecular weight cutoff 1000). Micelles were eventually filtered through a 0.45  $\mu\text{m}$  PTFE filter (Millipore). The polymer was once more freeze-dried and stored at  $-20^\circ\text{C}$  until use.

The sugar functionality, defined as the number of sugar ends bound at the end of the PEG block per 100 polymer chains, was determined by NMR measurements of the freeze-dried polymer in  $\text{DMSO}-d_6$  at  $80^\circ\text{C}$ . The intensity of the methine peaks on the phenyl groups of the lactopyranoside at 6.4 and 6.8 ppm was then related to the intensity of the methine peak on the PLA block ( $\delta = 5.2$  ppm).

**2.5. Surface Plasmon Resonance Measurements.** Surface plasmon resonance (SPR) evaluations were carried out on a BIACORE 3000 device (Biacore AB, Uppsala, Sweden). Proteins were bound to the carboxymethyl dextran gel on the surface of a CM5 chip by amine coupling. Both the ends of the gel matrix and the protein to be bound on the gel were electrostatically activated by flowing a buffer at a pH lower than the pI of the protein (acetate buffer pH 5,  $I = 0.01$  M) as a preparation for the chemical binding of the proteins. Then, 70  $\mu\text{L}$  of a freshly prepared 1:1 mixture of 0.2 M *N*-ethyl-*N*-(3-dimethylaminopropyl)carbodiimide hydrochloride (EDC) and 0.05 M *N*-hydroxysuccinimide (NHS) was injected, chemically activating the surface of the gel. This was followed by the injection of a 50  $\mu\text{g/mL}$  RCA-I solution, the volume of which depended on the amount of bound proteins desired. Finally, the injection of 70  $\mu\text{L}$  of 1 M ethanolamine/HCl pH 8.5 ensured the deactivation of nonreacted carboxyl ends on the surface of the gel. A similar procedure was carried out over a reference channel, for which the ligand injection was a blank injection of buffer. Internal reference subtraction was

then used to establish all data in the report. The buffer was subsequently changed to a PBS (pH 7.4, 0.1 M) and flowed until reaching a stable baseline. All buffers were degassed and filtered through a 0.45  $\mu\text{m}$  PTFE filter (Millipore).

**2.6. Fitting Models.** Aside from the Langmuir and bivalent models included within the BIAevaluation Software provided with the SPR apparatus, a trivalent model was introduced to fit the obtained data. In the trivalent model, the binding process is described as follows:

where  $a$  would be a lactose molecule on the surface of a micelle,  $b$  a lectin on the protein bed,  $ab$  the complex subsequently formed, and  $ab_2$  the complex formed between two lactose molecules on the same micelle and two lectins on the protein bed, etc. These equations can be transcribed into the following equations:

$$\begin{aligned} d[ab]/dt = & (k_{a1}[a][b] - k_{d1}[ab]) - \\ & (k_{a2}[ab][b] - k_{d2}[ab_2]) - (k_{a3}[ab_2][b] - k_{d3}[ab_3]) \end{aligned}$$

$$\begin{aligned} d[ab_2]/dt = & (k_{a2}[ab][b] - k_{d2}[ab_2]) - \\ & (k_{a3}[ab_2][b] - k_{d3}[ab_3]) \end{aligned}$$

$$d[ab_3]/dt = (k_{a3}[ab_2][b] - k_{d3}[ab_3])$$

where  $[a]$  is the concentration of Lac-micelles and  $[b]$  the concentration of lectins.  $[a]$  is equal to 0 at time  $t = 0$  or to the Lac-micelles concentration at time  $t$ .  $[b]$  can then be expressed as  $[b] = \text{lectin concentration at time } t - ([ab] + [ab_2] + [ab_3])$ , if steric hindrance or the binding of more than one lactose molecule to the same protein is neglected. These issues are to be discussed in a later section.

### 3. RESULTS AND DISCUSSION

**3.1. Preparation of the Block Copolymer.** As thoroughly described in our previous reports, ring-opening anionic polymerizations result in block copolymers, the final block molecular weights being dependent on initial monomer/initiator ratios. Furthermore, these polymers display low size distributions, a feature particularly desirable for drug delivery, as micelles prepared from these polymers also to display low size distributions (14). After polymerization of the poly(ethylene glycol) (PEG) block, a small amount of mixture was sampled and analyzed by GPC, exhibiting an average  $M_n$  and  $M_w$  of 4876 g/mol and 5099 g/mol, respectively, as compared to the 5016 g/mol theoretically calculated from initial ratios. The polydispersity index,  $I_p = M_w/M_n$  was found to be 1.046. After subsequent copolymerization of the lactide and purification of the resulting Ac-PEG-PLA block copolymer (Figure 1 presents the synthetic route to the block copolymer), the molecular weight of the latter was analyzed by GPC and by combined GPC/NMR measurements. GPC conveys an average  $M_n$  and  $M_w$  of 8125 g/mol and 8872 g/mol, respectively, with an  $I_p = 1.092$ . Combined GPC and NMR evaluations convey an average molecular weight of 4500 g/mol for the lactide block, and of 9400 g/mol for the copolymer, for a theoretical value of 10000 g/mol. Noteworthy is the fact that the size

**Figure 1.** Synthetic route to an acetal-poly(ethylene glycol)-poly(D,L-lactide). The one-pot, ring-opening polymerization was carried out at room temperature under argon atmosphere in tetrahydrofuran (THF).

distribution of the polymer remains low even after copolymerization of the second block.

**3.2. Preparation and Characterization of Sugar-Installed Micelles.** Micelles were found to have a particle size of  $30 \pm 0.2$  nm. The cumulant method also provides the value  $\mu_2/\bar{\Gamma}^2$ , a measure of the particle size distribution, found to be in average lower than 0.09.

Deprotection of acetal ends is carried out more efficiently in micellar solution, because, first of all, aldehyde groups located at the distal end of the PEG block are presented at the surface of micelles. Thus, they are more accessible than those in random-coiled PEG strands are. Second, aldol groups are prone to undergo an aldol condensation in solution, thus reducing the yield of the subsequent coupling reaction. This phenomenon is remarkably quenched in micellar solution, most probably due to the restricted motion of polymer chains that prevents the condensation of aldehyde groups, which would be moreover entropically unfavorable (15).

What will be defined hereupon as the aldehyde functionality, that is, the number of aldehyde groups per 100 copolymer chains, was calculated using NMR measurements. Certainly, by relating the intensity of the aldehyde proton peak ( $\delta = 9.8$  ppm) to that of the methine peak of the PLA block ( $\delta = 5.2$  ppm), it is possible to assess to what extent acetal groups can be converted to aldehyde groups. As the former peak is not always readily detectable by such spectroscopy, a second calculation based on the ratio of the intensity of the  $\alpha$ -methine proton peak ( $\delta = 1.6$  ppm) to that of the aforementioned methine peak is carried out. For both evaluations, the aldehyde functionality was found to be of 80%. A similar evaluation, carried out with the final lactose-poly(ethylene glycol)-poly(D,L-lactide) (Lac-PEG-PLA) block copolymer and based on the correlation of intensities of the aromatic protons on the phenyl group of the *p*-aminophenyl- $\beta$ -D-lactopyranoside ( $\delta = 6.4$  and 6.8 ppm) and the methine peak on the PLA block demonstrated similar results. The coupling reaction would then proceed in a quantitative way. Of deeper relevance is the fact that the size of the particle was not greatly modified, despite the chemical nature of the process, as, indeed, lactose-micelles (Lac-micelles) were found to have a hydrodynamic diameter of  $31.8 \pm 0.2$  nm and a size distribution of 0.12. The slight increase in the former value might be explained by the creation of a thin lactose layer around micelles.

**3.3. Kinetic Evaluations.** As thoroughly described elsewhere, not only has surface plasmon resonance (SPR) analysis provided evidence of the specific recognition and retention of Lac-micelles by a lectin bed, it has also provided a quite original tool for dealing with fundamen-

tal parameters that would severely affect the efficiency of any ligand-installed micelles. Such parameters, the ligand density or, more fundamentally, the critical association concentration (cac), are most crucial in that they would have direct consequences on the biodistribution of Lac-micelles after intravenous administration. Therefore, multivalency in the binding has been shown to greatly enhance complex formation in a clear example of cooperativity. Moreover, recorded sensorgrams have allowed the observation of complex formation between micelles and lectins due to the specific interaction between lactose molecules on the surface of micelles and binding sites on the protein bed. Beyond this specificity, the intensity of complex formation has indicated a link between binding ability and self-assembling structure of the polymer in aqueous solution and thus to calculating the cac of Lac-micelles. More interestingly, the SPR evaluation has resulted in values in good accordance with those obtained using the environment-dependent fluorescence of pyrene (11).

Yet, all of the data discussed in our previous report was recorded at equilibrium, which is somehow the completion of the binding between Lac-micelles and a protein bed. It shall, however, be recalled that of a nonetheless fundamental relevance is the rate of complex formation since it is to have a direct repercussion on the binding of Lac-micelles to target sites. In this regard, further information can be obtained by a closer and more careful analysis of the recorded sensorgrams. Indeed, recording the change of the angle at which the total reflection effect takes place, the fundamental principle of SPR, is carried out in real time under a constant buffer flow over the ligand-installed surface. Therefore, as the response of the adsorption and desorption processes can be recorded and plotted on a sensorgram, a function of time, information about the speed at which these processes take place can be obtained. The subsequent use of simulation software demonstrates the possibility of fitting the observed data with kinetic models, allowing the calculation of kinetic binding rates as the apparent association and dissociation rate constants ( $k_a$  and  $k_d$ , respectively), or the equilibrium constants  $K_A$  or  $K_D$ . In such regard, the evaluation itself is not especially difficult, if one takes precautions such as to diminish mass transport phenomena, nonspecific adsorption, and avidity, which heavily compromise SPR analysis (16). What certainly poses a far more delicate problem is to fit the experimental data with a model that fully accounts of all the involved parameters. In this evaluation, the multivalency of micelles (17) and the bivalency of the protein and its density on the surface of the gel are all

to be taken into account to reach a proper understanding of the system. It is quite apparent that several assumptions have to be accepted if a valid and accurate evaluation is to be undertaken.

**3.4. Preliminary Considerations.** For the sake of simplicity, the amount of bound lectins on the surface of the chip is to be kept as low as accuracy in the measurements will allow (18). Previous evaluations showed that no coherence in the binding of micelles was observed for lectin densities lower than 2000 resonance units (RU), as recorded values varied randomly and were not reproducible. Thus, this value was set as a standard for all kinetic evaluations. Because the equivalence  $1 \text{ RU} = 1 \text{ pg/mm}^2$  (provided by BIAcore), it is possible to convert resonance units into molecular concentrations and further into intermolecular distances; 2000 RU are thus equivalent to  $2000 \text{ pg/mm}^2$ . Given that the molecular weight of RCA-I lectins is  $\sim 120\,000 \text{ g/mol}$ , it follows that  $2000 \text{ pg/mm}^2 = 1.67 \times 10^{-14} \text{ mol/mm}^2 = 1.00 \times 10^{10} \text{ proteins/mm}^2 = 1.00 \times 10^{-2} \text{ proteins/nm}^2$ . Thus, 2000 RU are equivalent to 1 protein/99.6  $\text{nm}^2$ . The distance between two protein molecules at the very surface of the protein bed can then be approximated to  $D_{\text{prot-prot}} \sim 10 \text{ nm}$  (8.9–9.0 nm for a protein density of 2500 RU, the maximum protein density used for these experiments), that is, if all the proteins are considered to be at the surface of the gel as a first approximation.

Another consideration, the distance between two lactose molecules on the surface of a single micelle, was assessed. In this view, the association numbers of Ac-micelles and that of Lac-micelles were evaluated by static light scattering (SLS) measurements. The so-obtained Debye plots (data not shown) convey increments of the refractive index ( $dn/dc$ ) of 0.1070 and 0.1148, as well as micelle apparent molecular weights of 1100000 g/mol and 1050000 g/mol for acetal-poly(ethylene glycol)-poly(D,L-lactide) micelles (Ac-micelles) and Lac-micelles, respectively. Considering that the molecular weight of one copolymer chain is 9400 g/mol, it can be readily established that the association number accounts for  $\sim 112$  chains of copolymer per Lac-micelle. Taking into account the lactose functionality calculated by NMR, it can be presumed there are about 89 lactose molecules on the surface of a single Lac-micelle 80%, and that a single lactose molecule centers in an area of  $(4\pi r^2)/89 = 31 \text{ nm}^2$  ( $r$  was calculated by either DLS measurement). In the simplest case of molecules distributed in a grid, this is equivalent to an interlactose distance of 5.6 nm. Given the distance between two lactose molecules on the surface of a micelle, it is then possible to simplify lectin bivalency to monovalency, as it is not likely that two sugar molecules bind to the same protein unless the micelle structure is heavily distorted.

**3.5. Specificity of the Binding.** Injection of Lac-micelles led to a considerable increase in the signal of the lectin-installed flow cell due to the specific interaction between lectins and lactose molecules on the surface of micelles. Conversely, only feeble responses (less than 8 RU) were recorded for injections of Lac-micelles on the reference flow cell bearing no such receptors. Ac-micelles, used as a control of the specificity in the recognition by lectins, exhibited low responses on both flow cells (data not shown). Therefore, a double specificity can be claimed, as both types of micelles bind to the dextran gel in negligible levels (i.e., nonspecific binding) and as Lac-micelles bind to the protein bed due to the molecular recognition between lactose molecules on the surface of micelles and lectins (i.e., specific binding).

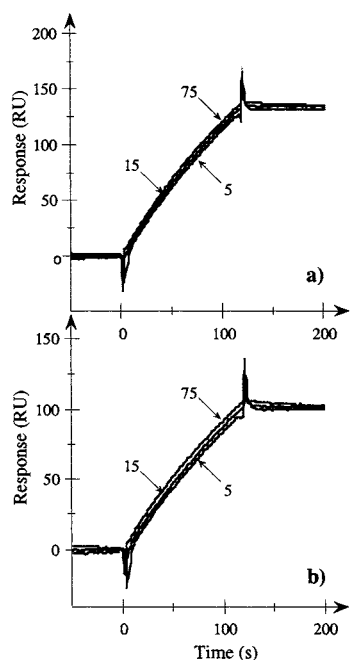

**Figure 2.** Recorded sensorgrams for Lac-micelles 80% at different micelle concentrations. Values next to sensorgrams express the micelle concentration, in  $\mu\text{g/mL}$ .

**3.6. Kinetic Evaluations.** Prior to fitting the data comes the evaluation itself. A series of concentrations: 0 (blank injection), 25, 50, 75, 100, and 200  $\mu\text{g/mL}$  (23.8, 47.6, 71.4, 95.2, and 190.5 nM, as established from the apparent molecular weight obtained by SLS measurements) was randomly injected over both a protein bed and a blank cell. The latter cell serves as reference for subsequent internal signal subtraction in order to discard nonspecific binding. Special care was taken in choosing the lowest, readily detectable polymer concentration, as this concentration should be above the  $\text{cac}$  of 7.5  $\mu\text{g/mL}$ . Every sample was then injected for 3 min at a flow rate of 30  $\mu\text{L/min}$ , followed by a 10-min dissociation time. Since only low dissociation from the protein bed has been observed even after several hours of buffer flow (data not shown), regeneration of the surface was ensured by a 15  $\mu\text{L}$  injection of free galactose. Each measurement was carried out twice.

As seen in Figure 2, after subtraction of the reference cell signal, the slopes of all association phases are quite steep, reaching complex formation rates close to 30 RU/s. But far more remarkable is the fact that dissociation phases are characterized by poor slopes. Lac-micelles 80% exhibit fast association and slow dissociation rates at any given concentration. This behavior has been previously observed and proven to be due to the multivalent interaction between micelles and the protein bed (11). Yet another point that is worth mentioning is the reproducible character of the measurements, as responses varied from 0.54% to 3.25% from the average value.

The obtained data was subsequently fitted with BIAcore software models. Yet, most of the equations used in the software illustrate, of course, the behavior of an ideal system. Several factors complicate the kinetic evaluation, the most important being the presence of several binding sites available to the several molecules of lactose on the surface of micelles which makes it difficult to attain a 1:1 interaction with lectins on the protein bed. Second, one might cite cooperative effects between neighboring lactose molecules that are to enhance association rates, especially at the beginning of the adsorption phase, again probably conveying a deviation from the simplest Langmuir model. Third, if the association rate is considerably high, diffusion or mass transport can occur, compromising the validity of the equations discussed beforehand, complicating the proper fitting of the experimental data or the creation of a new kinetic model, should this be required. Of the three considerations, it is mass transport control experiments which are to be assessed first, as these are independent of the fitting model used and therefore of a far more critical importance.

**Figure 3.** (a) Response generated by the injection of Lac-micelle 80% solution at 25  $\mu\text{g/mL}$ , as a function of time. The values above the arrows correspond to the flow rate expressed in  $\mu\text{L/min}$ . (b) Injection of Lac-micelle 60% solution under the same conditions.

**3.7. Mass Transport Control Experiments.** Mass transport occurs when the binding rate of the analyte to the ligand is faster than the diffusion of the analyte to the ligand. This phenomenon results in the existence of concentration gradients of the analyte over the ligand bed and heavily complicates the use of kinetic models. Furthermore, and due to the same reasons, the analyte concentration does not instantly drops to zero at the end of the sample injection, favoring rebinding phenomena. In which case, as the dissociation phase proceeds, binding sites become available so that the analyte can rebind to the surface (19). This generally results in apparently lower dissociation constants.

Kinetic processes are independent of the flow rate. Should association rates considerably vary with it, mass transport phenomena have a non-negligible repercussion on the reaction, and far more complicated models have to be used in order to fit the data. Bearing this in mind, micelles at the lowest, yet readily detectable, concentration (25  $\mu\text{g/mL}$ ) were injected over a fixed period of time at different flow rates (5, 15, and 75  $\mu\text{L/min}$ ). The sensorgrams are plotted in Figure 3. It is obvious that the slopes of the association phases do not greatly differ from one curve to the other. Combined with the above-described evaluation, safe ground can be laid as to state that this evaluation is mainly kinetically driven, most probably due to the colloidal nature of polymeric micelles, which ensures fast diffusion over the SPR surface and thus prevents the generation of a concentration gradient.

**3.8. Fitting of the Data.** *3.8.1. The Langmuir and Bivalent Models.* As one has to start from the beginning, the basic Langmuir model was assessed and shown to demonstrate a poor fitting of the data (fitting not shown). Whether the variables are fitted globally or locally,  $\chi^2$ , a measure of the accuracy of the fitting, was found to be disparate and superior to 100. Since fitting with a Langmuir-based model conveyed results lacking any coherence, a bivalent model was used. Within this model, binding would be ensured by the sequential complex

**Figure 4.** (a) Fitting of the sensorgrams recorded for Lac-micelles 80%, using the trivalent model. (b) Relative deviation to the trivalent model, or relative residuals, expressed in RU. Values next to sensorgrams express the micelle concentration, in  $\mu\text{g/mL}$ .

formation between two lactose molecules on the surface of a micelle and two receptor sites on the lectin bed. This model correlates well the sensorgrams obtained for micelles bearing lower lactose densities, as will be explained in the following section, but not sensorgrams obtained for Lac-micelles 80%. A more complex model has to be used in order to fit these data, as association with lectins seems to be ensured by more than two lactose molecules. Indeed, applying the bivalent model conveys both a visual appearance and thus a  $\chi^2$  that are far from being ascertained (data not shown). Be that as it may, it seems appropriate at this point to reflect upon what is the most likely situation to evolve for the studied system. Clearly, Lac-micelles 80% bind in a multivalent manner, with a valency  $\geq 3$ . This can be approached by using a simple theoretical calculation, that a 30 nm particle approaching the protein bed will "shadow" an area of  $A = \pi R^2 = \pi(15^2) \sim 707 \text{ nm}^2$ . If this value is to be related to the interprotein distance calculated in section 3.4 (10 nm), one single micelle will cover an area occupied by about seven binding sites, of which not all are attainable for lactose molecules on the surface of a micelle, given the spherical shape of the latter. Roughly, it can be thus stated that the valency of the binding is likely to be somewhere between 3 and 7 and most probably less than 7, as far as the beginning of the adsorption phase is concerned. Subsequent relaxation of the micelle structure, or further interaction with lectins not at the very surface of the protein bed, might result in an increased multivalent effect. These two cases will not be taken into account in this first approximation, since none of them can be experimentally assessed.

*3.8.2. The Trivalent Model.* The recorded sensorgrams were then fitted using the trivalent model described in section 2.5. In Figure 4, not only is a relatively satisfactory visual appearance observed, but also a narrow scatter of relative residuals (that is, residuals divided by recorded responses) around 0, except for the very beginning of the desorption phase, for which a small trend can be discerned. Still, this deviation is feeble, representing

**Table 1. Kinetic Binding Constants Obtained for the Kinetic Assay of Lac-micelles 80%, Using the Trivalent Model<sup>a</sup>**

sample name	$k_{a1}$ ( $M^{-1} s^{-1}$ )	$k_{d1}$ ( $s^{-1}$ )	$k_{a2}$ ( $RU^{-1} s^{-1}$ )	$k_{d2}$ ( $s^{-1}$ )	$k_{a3}$ ( $RU^{-1} s^{-1}$ )	$k_{d3}$ ( $s^{-1}$ )	$K_{D1}$ (nM)	$\chi^2$

<sup>a</sup>  $k_{a1}$  was fitted locally, while the rest of the parameters were done so globally. The statistical value  $\chi^2$  assesses the goodness of the fitting.

at most a 3.5% deviation from recorded values. Yet, this trend might be due to a detail of the dissociation process, a feature that shall be studied in detail in the future.  $\chi^2$ , a statistical measure of the goodness of the numerical fitting, was found to be 6.3. Kinetic constants are presented in Table 1, and  $K_{D1}$ , calculated as  $k_{d1}/k_{a1}$ , was thus found to be 3.4 nM. Equilibrium constants are expressed as  $K_{D1}$ , as the first binding appears to be the critical step in the binding to the protein bed. As estimated in the previous section, the valency of the binding is restrained here by the amount of protein sites available to one micelle and somewhere between 3 and 7. To discard a higher cooperative effect, a tetravalent model was also devised, and the data recorded for Lac-micelles 80% fitted accordingly. Yet, no enhancement in the fitting was observed; quite the contrary, a stronger deviation was found (data not shown). These observations point in the direction that the binding between Lac-micelles 80% and the protein bed would occur through the driving force of the binding of one lactose molecule. A similar study conducted by Lortat-Jacob et al. dealt with an adenovirus fiber binding in a trivalent manner to its receptor immobilized on a SPR chip (20). Their analysis indicated that the leading event in the fiber attachment to the receptor bed was the binding of the first fiber head molecule to one receptor, with a  $K_{D1}$  of 23 nM.

**3.9. Kinetic Constants and Multivalency.** Another point that is worth discussing is the influence of multivalency on kinetic constants. It is known that the transition between monovalency and multivalency induces a nonlinear increase of kinetic rates. Certainly, the ligand density influences parameters such as the stoichiometry of the binding, the rate of complex formation, and the inter-receptor distance (21).

Lac-micelles bearing different ligand functionalities were prepared by mixing the Lac-PEG-PLA with its Ac-PEG-PLA counterpart in different ratios, in DMAc solution. After that, the mixtures were dialyzed against water following the conventional procedure to prepare micelles. Predictably enough, the size of the particles was not altered but rather in a negligible manner (data not shown). Thus, Lac-micelles 60%, Lac-micelles 40%, Lac-micelles 20%, and Lac-micelles 10% were chosen to be analyzed to assess the influence of multivalency on kinetic values, following a similar procedure as that described in section 3.6.

No coherent data was recorded for micelles bearing a lactose functionality of 10% (data not shown). Indeed, response values varied randomly and in a nonreproducible manner, so any kinetic values obtained would have been anyway of a quite dubious nature. Although we cannot explain this behavior, it might be suggested that low ligand densities generate important areas where no single lactose molecule is present. That is, 11 lactose molecules would be present in an area of more than 2800 nm<sup>2</sup>, conveying an average interligand distance of about 16 nm, generating highly heterogeneous ligand surfaces and thus nonreproducible responses.

The recorded sensorgrams for all other batches, on the other hand, appeared to be more reliable. The first

**Figure 5.** Recorded response at equilibrium for micelles bearing different ligand densities, at different concentrations. The numbers next to the symbols correspond to the ligand density. Dotted fragments indicate the transition phase between unimers and micelles.

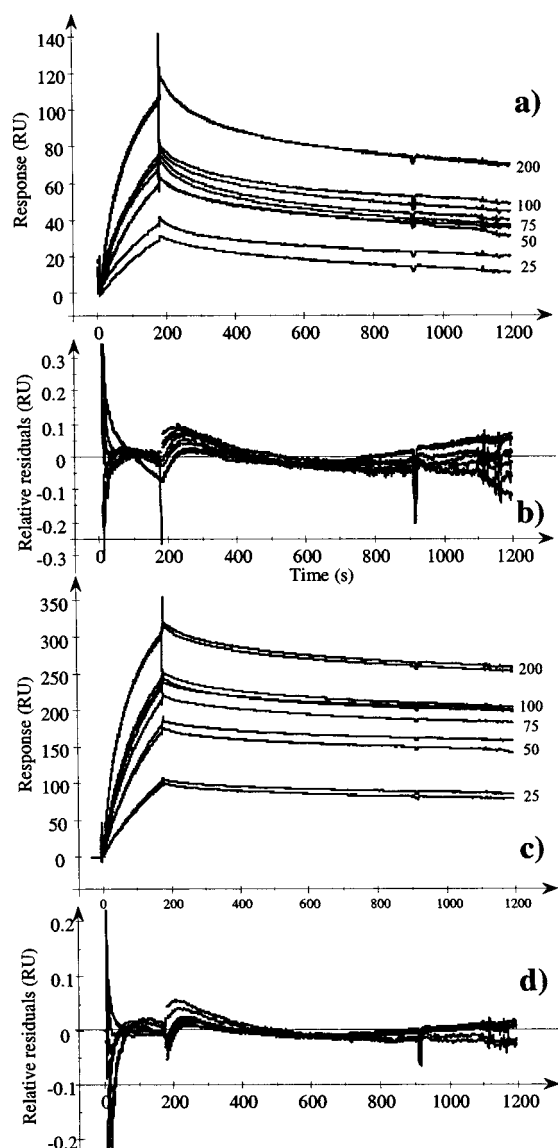

observation originating from the recorded sensorgrams is that the intensity of the binding to the protein bed increases with, quite logically, an increasing concentration. Second, at any given concentration, the amount of complex formation increases with an increasing ligand density, conferring a equilibrium binding of about 110 RU for Lac-micelles 20% and of 460 RU for Lac-micelles 80% (Figure 5).

Sensorgrams recorded for Lac-micelles 20% and 40% were successfully fitted using the bivalent model provided within the original BIAevaluation Software.  $\chi^2$  was found to be 3.4 in the case of the former and 4.0 in the case of the latter. Small tendencies also appear on the relative residues, but remain small scatters, representing less than 3% of the recorded values. The trivalent model described in section 3.8.3 was also used to fit the data, but no enhancement in the fitting was observed, even though certain comments should be made regarding Lac-micelles 40%. Certainly, using the trivalent model did not improve the accuracy of the fitting of the sensorgrams, but still a low enough  $\chi^2$  was recorded (6.0), making this fit also acceptable by BIAcore standards ( $\chi^2 < 10$ ). This led to the difficult choice of which model is most adequate for the ongoing discussion. This is not an isolated remark, but is based on the following consideration. As can be seen in Figure 5, and as it was reported in detail in a previous paper (11), there is a nonlinear increase in complex formation between micelles and the lectin bed when the lactose functionality exceeds what seems to be a critical value of 40%. Similar experiments carried out by measuring the turbidity of the system had conveyed comparable results but a lower value (20%), an observation that can be understood through the differing conditions and spatial geometry of the measurement systems, as discussed by the Kiessling group (22). In any way, a ligand density of 40% seems to set a transition in the valence of the binding and is most probably to be set somewhere between 2 and 3.

**Table 2. Kinetic Binding Constants Obtained for the Kinetic Assay of Lac-micelles 20% and 40%, Using the Bivalent Model<sup>a</sup>**

sample name	$k_{a1}$ ( $M^{-1} s^{-1}$ )	$k_{d1}$ ( $s^{-1}$ )	$k_{a2}$ ( $RU^{-1} s^{-1}$ )	$k_{d2}$ ( $s^{-1}$ )	$K_{D1}$ (nM)	$\chi^2$

Lac-micelles 40%	$2.48 \times 10^4 \pm 0.27$	0.0225	$3.84 \times 10^{-5}$	$1.23 \times 10^{-4}$	907	3.96

<sup>a</sup>  $k_{a1}$  was fitted locally, while the rest of the parameters were done so globally.

**Figure 6.** (a, c) Recorded sensorgrams for Lac-micelles 20% and Lac-micelles 40%, using the bivalent model. (b, d) Relative deviation to the bivalent model, or relative residuals, expressed in RU. Values next to sensorgrams express the micelle concentration, in  $\mu g/mL$ .

Be that as it may, it appears that the main driving force of the kinetic process is the initial binding, characterized by  $k_{a1}$  and  $k_{d1}$ , as their values are of far more consequence than those of the other two steps.  $K_{D1}$ , calculated as  $k_{d1}/k_{a1}$ , was thus found to be 1360 nM for Lac-micelles 20% and 907 nM (28 nM when fitted with the trivalent model) for Lac-micelles 40% (Table 2). Figure 6 presents both recorded sensorgrams and the relative residuals from the fitted data (fittings are not shown) for both micelle batches.

Sensorgrams recorded for Lac-micelles 60% were accurately fitted using the trivalent model, even if the fitting was of lower quality ( $\chi^2 = 8.69$ , data not shown) (Table 3).  $K_{D1}$ , in this case, was calculated to be 8.4 nM.

Another interesting observation to be made is that the  $K_{D1}$  of Lac-micelles 60% is more than double that of Lac-micelles 80%. Even still, the stoichiometry of the binding was not altered.

As mentioned earlier in this section, equilibrium complex formation is of about 110 RU for Lac-micelles 20%, whereas it reaches 460 RU for Lac-micelles 80%. The former exhibited a  $k_{d1}$ , the main driving constant in the dissociation process, of  $1.85 \times 10^{-2} s^{-1}$ . When fitted with the trivalent model, Lac-micelles 80% yielded a  $k_{d1}$  of  $1.28 \times 10^{-4} s^{-1}$ , which represents a 145-fold decrease in the main dissociation constant. Much in the opposite way, the  $k_{a1}$  of both micelles are in the same range of values ( $1.36 \times 10^4 M^{-1} s^{-1}$  for Lac-micelles 20%;  $3.18 \times 10^4 M^{-1} s^{-1}$  for Lac-micelles 80%, or a 2.3-fold difference), an observation in good accordance to what was discussed earlier. An increase in the ligand density seems to bring about a tremendous decrease in kinetic dissociation constants, not an increase in kinetic association constants (Figure 7). If one is to next analyze the behavior of the second binding step,  $k_{a2}$  varies from  $8.36 \times 10^{-6} RU^{-1} s^{-1}$  for Lac-micelles 60% to  $4.68 \times 10^{-5} RU^{-1} s^{-1}$  for Lac-micelles 80%, which represents a 5.6-fold difference between these two maximums. Albeit an inverse tendency is observed for Lac-micelles 60%, it can be said that the second kinetic association constant tends to increase as the lactose functionality increases. The second binding between lactose molecules and lectins occurs at a faster rate with increasing lactose functionality. This observation is not unreasonable, as at higher ligand functionalities, a higher number of lactose molecules are available to bind locally to the protein bed, thus favoring the second binding to the protein bed. Conversely,  $k_{d2}$  shifts from a minimum of  $1.23 \times 10^{-4} s^{-1}$  for Lac-micelles 40% to  $0.019 s^{-1}$  for Lac-micelles 80%, accounting for a 154-fold difference between the two values. Quite surprisingly, the second kinetic dissociation constant increases with an increase in the ligand functionality (Figure 8), yielding an overall increase of the second equilibrium constant  $K_{D2}$ . To this tendency, it can be hypothesized that the second binding is ensured by the equilibrium of more than one complex formed between one or more lactose molecule(s) and several binding sites on the protein bed. This observation should become more pronounced at higher ligand densities as, logically enough, more lactose molecules are available. As for the third step, no firm conclusions can be drawn, as only two sets of values are available. Briefly, it can be said that the system as a whole appears to be further stabilized at higher ligand densities, as the third equilibrium constant  $K_{D3}$  decreases.

Yet another curious observation about the ligand density is its influence on the binding ability of the system. Lac-micelles 80% would have an interligand distance half that of Lac-micelles 20% (5.6 and 11.2 nm, respectively), if one is to trust the calculations presented earlier in this paper (see section 3.4). And remarkably enough, the former would bind to the protein bed in a trivalent way whereas the latter in a bivalent way. In other words, despite a higher ligand density, Lac-micelles 80% are only able to bind in a trivalent manner to the

**Table 3. Kinetic Binding Constants Obtained for the Kinetic Assay of Lac-micelles 60% and 80%, Using the Trivalent Model<sup>a</sup>**

sample name	$k_{a1}$ ( $M^{-1} s^{-1}$ )	$k_{d1}$ ( $s^{-1}$ )	$k_{a2}$ ( $RU^{-1} s^{-1}$ )	$k_{d2}$ ( $s^{-1}$ )	$k_{a3}$ ( $RU^{-1} s^{-1}$ )	$k_{d3}$ ( $s^{-1}$ )	$K_{D1}$ (nM)	$\chi^2$
Lac-micelles 40%	$1.94 \times 10^4 \pm 0.34$	$3.68 \times 10^{-4}$	$5.41 \times 10^{-6}$	0.000128	$3.01 \times 10^{-4}$	$2.07 \times 10^{-3}$	18.9	6.07

Slanting squares represent kinetic constants for Lac-micelles 40% fitted with the trivalent model.

lectin bed. To put it in yet another way, a 2-fold decrease in the interligand distance only brings about one extra ligand binding to the protein bed. Therefore, whereas Lac-micelles 80% present an enhanced binding in terms of kinetic and equilibrium constants, Lac-micelles 20% seem to be more effective if understood through the amount of available lactose molecules, as reported by Cairo et al. (23). Their data clearly shows how, on a molecular basis, the most efficient compounds are those bearing the lowest ligand densities whereas higher ligand densities convey the largest ligand–receptor clusters.

Perhaps the flexible structure of PEG and micelles in general is to be accounted for this trend. Certainly, the mobility of micelles is to be restricted as the first binding takes place. This will of course draw the micelle into closer contact with the protein bed, and yet, lactose molecules at the distal end of the hydrophilic block are to remain mobile due to the extreme high mobility and elongation of PEG chains (24) so that further bindings are rather facilitated. Therefore, independently of the ligand density, Lac-micelles will tend to form multivalent bindings to the protein bed, a property of certain interest in the design of drug delivery systems devised to achieve specific accumulation at defined sites.

#### 4. CONCLUSION

Lac-micelles form highly specific complexes when interacting with a lectin bed. These complexes are furthermore stable, since little dissociation is observed even after hours of buffer flow. Lac-micelles also exhibit colloidal properties such as fast diffusion over a surface, remarkably quenching mass transport limitations, a quite common handicap in kinetic studies carried out by SPR. They exhibit fast-rate binding as well as decreased dissociation rates. Such properties are expected to facilitate binding and subsequent complex formation with specific asialoglycoprotein receptors present in high levels at hepatic sites. Due to the strength of the association, prolonged retention at these sites is expected, which should certainly favor uptake by receptor-mediated endocytosis. Data otherwise obtained in cellular assays point in this direction and are to be published soon.

Multivalency once more has been shown to considerably alter kinetic values toward slower dissociation processes and thus enhanced equilibrium constants. An increase in the ligand functionality on the surface of micelles will lead to higher levels of complex formation, as well as to stronger affinities essentially brought about by decreased kinetic dissociation constants. Although the stoichiometry of the systems does not dramatically increase, there is a remarkable decrease in equilibrium dissociation constants.

#### ACKNOWLEDGMENT

The authors wish to express their gratitude to Biacore Japan, for invaluable discussions on the use of Biaevaluation software. Much in the same manner, they wish to express their thankfulness to Professor Yukihiro Shimogaki, Faculty of Engineering at the University of Tokyo, for enriching discussions. This work was supported by the Core Research Program for Evolutional Science and Technology (CREST), the Japan Science and Technology Corporation (JST), and by the Special Coordination Fund for Promoting Science and Technology of the Ministry of Education, Science, Sports and Culture of Japan (MEXT).

Virtanen-Institute, P.O. Box 1627, FIN-70211 Kuopio, Finland. Received August 29, 2002; Revised Manuscript Received October 10, 2002

A novel, stable, biotin aldehyde derivative is reported in which the biotin moiety is *N*1,*N*3-protected by the allyloxycarbonyl group. The derivative is stable to sodium cyanoborohydride mediated reductive alkylation and is cleaved under mild Pd [0] catalysis. This novel biotin aldehyde should have wide application in avidin- and streptavidin-based detection systems and bioassays. The derivative is utilized in the synthesis of a biotinylated doxorubicin analogue that retains topoisomerase activity.

## INTRODUCTION

The avidin–biotin interaction is one of the strongest between a small molecule and a protein, with a  $K_d$  measured at  $10^{-15}$ . This pseudo-irreversible interaction has found many applications in biology, mostly in visualization or detection systems. In most cases biotin **1** (Chart 1) is attached to proteins, peptides, and small molecules via an amide bond or by conjugate addition of a protein or peptide thiol to a biotin–enone. We report here a novel stable biotin-aldehyde derivative **2** suitable for attachment of biotin by reductive alkylation. The method is compatible with highly functionalized molecules and is illustrated here, by the preparation of a biotinylated doxorubicin derivative. This molecule can be used as a probe for cancer therapy systems, employing avidin (*1*) or streptavidin targeting.

Such systems include three step radioimmunotherapy and the Scavidin gene therapy system (*2*). Three step immunotherapy (*3*) relies on predelivery of a tumor targeting antibody, followed by the streptavidin protein and finally delivery of a biotinylated radionuclide. The Scavidin gene therapy system induces expression of a synthetic hybrid receptor at the cell surface. This receptor comprises the avidin protein linked to the macrophage scavenger class A receptor (*4*), the avidin portion of the receptor binds biotin tightly and enables cellular internalization of biotinylated molecules.

One could imagine that molecular probes for such systems could come in many forms; however, a doxorubicin **3** probe was attractive in that extracellular and intracellular localization could be monitored by confocal fluorescence microscopy (*5*). It was desirable to maintain the topoisomerase activity of doxorubicin in order to have an additional functional readout of activity. A metaboli-

## Chart 1. Structures

cally stable linker had the advantage of allowing us to observe the fate of the molecule without the complication of ongoing cleavage. In the design of our linker, we needed to retain the basic nitrogen on the glycoside of doxorubicin **3**, as this is a prerequisite for topoisomerase II activity of anthracycline cytotoxics. This is also an attractive position for attachment via reductive alkylation, as the basicity of the nitrogen is maintained and several potent analogues of doxorubicin, substituted at this position, are known (*6*). Furthermore, the reductive alkylation reaction conditions do not affect the sensitive functionality of doxorubicin (*7*).

These initial experiments directed us toward employing a reductive alkylation approach. There are few reports, however, on the successful preparation of biotin aldehyde derivatives. These are limited to the low-temperature generation of biotin-4-aldehyde by DIBALH (*8*). *N*1,*N*3-Dibenzylated aldehydes were prepared during a total synthesis of biotin (*9*). Intramolecular formation of hemiaminal derivatives such as **4** is indicated (*10*) for

<sup>§</sup> University of Kuopio.

**Chart 2. Numbering Convention**

biotin aldehydes. The literature evidence and our preliminary work demonstrated the need for a stable *N*-3-blocked biotin aldehyde derivative, which would avoid formation of intra and intermolecular hemiaminal derivatives and would allow single step reaction with highly functionalized cytotoxic agents followed by mild deprotection.

A survey of protecting groups identified allyloxycarbonyl (alloc) as a likely candidate. This group would be stable to reductive amination ( $\text{NaCNBH}_3$ ) and be removed utilizing palladium [0] catalysis. We envisaged that these conditions would be compatible with attachment to doxorubicin or other antineoplastic agents such as mitomycin C, bleomycin, or methotrexate. The direct introduction of ureido protecting groups on urea is rare. Some photolabile urethanes (*11*) represent the only example reported for biotin derivatives. We also included a long linker chain to maintain tight binding interaction with the avidin protein (*12*).

**EXPERIMENTAL DETAILS**

**General. Chemicals.** Biotin and tetrakis(palladium) (0) triphenylphosphine were purchased from Avocado. Doxorubicin was purchased from LKT laboratories (USA). *N,N*-Dimethylformamide di-*tert*-butyl acetal was obtained from Lancaster and was used without further purification. Avidin was purchased from Pierce. Other common reagents were purchased from Sigma or Lancaster. Anhydrous organic solvents were used as the highest quality grade packaged under nitrogen and were not distilled prior to use, unless otherwise indicated.

**Equipment.** NMR spectra were recorded on a Bruker AMX-300 (or an Avance-500) spectrometer, operating at 300 (or 500) MHz for  $^1\text{H}$  NMR and 75.41 (or 125.65) MHz for  $^{13}\text{C}$  NMR. NMR spectra of compounds **2** and **5–10** were recorded in  $\text{CDCl}_3$ , using TMS as external reference ( $\delta$  0.0 ppm) for  $^1\text{H}$  NMR and using  $\text{CDCl}_3$  ( $\delta$  77.0 ppm) for  $^{13}\text{C}$  NMR. For  $^1\text{H}$  and  $^{13}\text{C}$  NMR spectra of compounds **3**, **12**, and **11**, chemical shifts were reported in the scale relative to the solvent used as an internal reference. FAB and HRMS mass spectra were recorded on a VG ZO-SE spectrometer. Electrospray mass and LC/MS data were recorded either on a Micromass Quattro LC-mass spectrometer or a Finnigan AQA LC-mass spectrometer. IR spectra were recorded from KBr pellets or  $\text{CHCl}_3$  solutions using NaCl plates, on a Perkin-Elmer Spectrum One FT-IR spectrophotometer. UV spectra were recorded on a Unicam Helios  $\alpha$  spectrometer. Melting points were determined on a Gallenkamp melting point apparatus and are uncorrected. Microanalyses were performed by the Analytical Services Section, Department of Chemistry, University College London.

**Chromatography.** Column chromatography was performed either with bulk silica gel Merck (40–63  $\mu\text{m}$ ) or

on Isolute Flash-Si prepacked columns (FlashMaster automated chromatographic system, Jones chromatography). Reverse-phase Isolute Flash-C18 support (40–70  $\mu\text{m}$ , Jones chromatography) was used for the purification of compound **11** (see procedure below). HPLC and LC/MS analyses of compounds **5–12** were conducted on a Gilson gradient pumping system with a variable wavelength UV/visible detector. Reverse phase HPLC chromatography was carried out using a Hypersil BDS C18 column (5  $\mu\text{m}$ , 100  $\times$  4.6 mm) with a gradient solvent system at a flow rate of 1 mL/min, the solvents A (water) and B (acetonitrile) composing the gradient mixture contained 0.1%  $\text{CF}_3\text{COOH}$  as additive. Size exclusion HPLC analyses used in the avidin binding assay were conducted on a Shimadzu HPLC equipped with a gradient solvent pumping system and a diode array detector (Shimadzu, SPD-M10A), using a Spherogel TSK G5000PW column (10  $\mu\text{m}$ , 7.5 mm  $\times$  300 mm, stainless steel, Tosoh Biosep). HPLC analyses were run at a flow rate of 1.0 mL/min using a 50 mM potassium phosphate buffer (300 mM NaCl, 1 mM EDTA, 1 mM  $\text{NaN}_3$ , pH 6.8) as the mobile phase.

**Numbering Conventions and NMR Data.** *Numbering Conventions.* The numbering system adopted below uses the trivial systems commonly adopted for numbering biotin and anthracyclines (Chart 2).

For simplicity, numbers for atoms of the biotin moiety are preceded by B (to avoid confusion with the atoms of the anthracyclic moiety), whereas the numbers referring to atoms from the spacer moiety are preceded by an S.

*NMR data.* All the NMR spectra summarized below were assigned on the basis of 2D  $^1\text{H}$ – $^1\text{H}$  (COSY) and  $^1\text{H}$ – $^{13}\text{C}$  (HMQC) correlation experiments performed at 500 MHz. As an illustration, the 2D  $^1\text{H}$ – $^1\text{H}$  and  $^1\text{H}$ – $^{13}\text{C}$  spectra for compound **10** are represented in Figures S1 and S2 see Supporting Information. The assignment of compounds **5–9** and compound **12** is unambiguous. The assignment proposed for the conjugates **10** and **11** is in agreement with NMR data published in the literature for biotin (*13*) and Doxorubicin (*14*). The methylenic protons on the carbon 6 of the biotin pattern ( $\text{C}^{\text{B}6}$ ) are labeled  $\text{H}^{\text{B}6}_{\text{syn}}$  and  $\text{H}^{\text{B}6}_{\text{anti}}$  (where “syn” and “anti” refer to the relative configuration vs the proton  $\text{H}^{\text{B}6a}$ ), when the difference in their respective vicinal coupling constant with  $\text{H}^{\text{B}6a}$  is sufficient to allow an unambiguous assignment (see compounds **5** and **11**). In intermediates **7**, **9**, **2**, and **10**, the presence of the sterically demanding alloc protecting groups on the urea moiety of the biotin pattern induces a conformational change (strain), which results in vicinal coupling constants  $^3J(\text{H}^{\text{B}6a}, \text{H}^{\text{B}6}_{\text{syn}})$  and  $^3J(\text{H}^{\text{B}6a}, \text{H}^{\text{B}6}_{\text{anti}})$  being within the same range. In addition, the respective signals for protons  $\text{H}^{\text{B}3a}$  and  $\text{H}^{\text{B}6a}$  (at the junction of the bicyclic biotin pattern) overlap with the resonance of the allylic protons from the two alloc groups. As a consequence, NOE experiments could not be envisaged to resolve the assignment of the two protons  $\text{H}^{\text{B}6}$ . Therefore, NMR data reported for intermediates **7**, **2**, and **10** refer to protons  $\text{H}^{\text{B}6}$  as  $\text{H}^{\text{B}6}_{\text{I}}$  and  $\text{H}^{\text{B}6}_{\text{II}}$ , when a particular chemical shift could not be assigned to a particular configuration (syn/anti). For the same reason as mentioned above, in the case of intermediates **7**, **2**, and **10**, the three vicinal coupling constants ( $^3J$ ) observed for the resonance of the proton  $\text{H}^{\text{B}4}$  cannot be assigned unambiguously to the respective couplings of  $\text{H}^{\text{B}3a}$ ,  $\text{H}^{\text{B}7}_{\text{I}}$ , and  $\text{H}^{\text{B}7}_{\text{II}}$  with  $\text{H}^{\text{B}4}$ .

**Synthesis and Characterization of Conjugate 11 (B-Dox).** Biotin *tert*-Butyl Ester **5**. Biotin (10.03 g, 41.07 mmol) was suspended in 38 mL (158.48 mmol, 3.85 equiv) of *N,N*-dimethylformamide di-*tert*-butyl acetal.

The suspension was stirred vigorously under a nitrogen pressure and heated progressively to 80 °C in order to get a homogeneous brown solution after 20 min. The mixture was then gently stirred at 80 °C for 48 h. The reaction mixture was then cooled to ambient temperature, affording massive precipitation of the remaining starting material. The precipitate was washed several times with cold CH<sub>2</sub>Cl<sub>2</sub> and discarded in order to be recycled. The CH<sub>2</sub>Cl<sub>2</sub> washings were combined to the filtrate, and after evaporation, the residue was suspended in CH<sub>2</sub>Cl<sub>2</sub> (1 L) and water (300 mL). The organic layer was washed successively with saturated NaHCO<sub>3</sub> (3 × 300 mL) and brine (3 × 300 mL). After drying (MgSO<sub>4</sub>), the crude product was purified by silica gel chromatography, using CHCl<sub>3</sub>–MeOH (100:0 to 24:1) as eluent, to afford 5.075 g of Biotin *tert*-butyl acetal (16.89 mmol, 41% yield) as a white powder. <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>, 27 °C, TMS) δ 5.73 (br s, 1H; NH), 5.46 (br s, 1H; NH), 4.48 (dd, <sup>3</sup>J(H-<sup>B</sup>3a, H-<sup>B</sup>6a) = 7.36 Hz, <sup>3</sup>J(H-<sup>B</sup>6<sub>anti</sub>, H-<sup>B</sup>6a) = 4.96 Hz, 1H; H-<sup>B</sup>6a), 4.29 (dd, <sup>3</sup>J(H-<sup>B</sup>3a, H-<sup>B</sup>6a) = 7.36 Hz, <sup>3</sup>J(H-<sup>B</sup>3a, H-<sup>B</sup>4) = 4.95 Hz, 1H; H-<sup>B</sup>3a), 3.15 (1H, m, H-<sup>B</sup>4), 2.90 (dd, <sup>2</sup>J = 12.75 Hz, <sup>3</sup>J(H-<sup>B</sup>6<sub>anti</sub>, H-<sup>B</sup>6a) = 4.96 Hz, 1H; H-<sup>B</sup>6<sub>anti</sub>), 2.73 (d, <sup>2</sup>J = 12.75 Hz, 1H; H-<sup>B</sup>6<sub>syn</sub>), 2.23 (t, <sup>3</sup>J(H-<sup>B</sup>9, H-<sup>B</sup>10) = 7.43 Hz, 2H; CH<sub>2</sub>-<sup>B</sup>10), 1.52–1.70 (m, 4H; CH<sub>2</sub>-<sup>B</sup>7, CH<sub>2</sub>-<sup>B</sup>8 or CH<sub>2</sub>-<sup>B</sup>9), 1.43 (s, 9H; 3 CH<sub>3</sub>), 1.43 (m, 2H; CH<sub>2</sub>-<sup>B</sup>9 or CH<sub>2</sub>-<sup>B</sup>8). <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>, 27 °C) δ = 173.01 (COO-), 163.54 (C-<sup>B</sup>2), 80.13 (C(CH<sub>3</sub>)<sub>3</sub>), 61.97 and 60.15 (C-<sup>B</sup>6a, C-<sup>B</sup>3a), 55.39 (C-<sup>B</sup>4), 40.51 (C-<sup>B</sup>6), 35.19 (C-<sup>B</sup>10), 28.12 (3 CH<sub>3</sub>), 28.39, 28.27 and 24.92 (C-<sup>B</sup>7, C-<sup>B</sup>8 and C-<sup>B</sup>9). mp 124 °C. **Allyl *para*-Nitrophenyl Carbonate 6.** Allyl alcohol (9.40 mL, 135.60 mmol) was added to a vigorously stirred solution of bis(*para*-nitrophenyl) carbonate (50 g, 162.72 mmol, 1.2 equiv) in 420 mL of CH<sub>2</sub>Cl<sub>2</sub>. After 10 min, *N,N*-diisopropylethylamine (72 mL, 406.80 mmol, 3 equiv) was added dropwise, affording a bright yellow coloration of the reaction mixture. The experiment was run overnight at ambient temperature. The reaction mixture was then diluted with 1 L of CH<sub>2</sub>Cl<sub>2</sub> and extracted successively with 15% citric acid (3 × 300 mL), water (2 × 250 mL), and brine (2 × 250 mL). After drying (MgSO<sub>4</sub>) and evaporation of the solvent, the crude product was adsorbed on silica and purified by silica gel chromatography using EtOAc–cyclohexane (1:9 to 1:1) as the eluent. Concentration of the corresponding fractions afforded precipitation of the allyl *para*-nitrophenyl carbonate (28.41 g, 127.29 mmol, 94% yield) as pale yellow needles, the purity of which was sufficient for the following step. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>, 27 °C, TMS) δ = 8.29 (dt, <sup>3</sup>J(Ar H-o, Ar H-m) = 9.21 Hz, <sup>4</sup>J(Ar H-m, Ar H-m') ~ <sup>5</sup>J(Ar H-m, Ar H-o') ~ 2.70 Hz, 2H; 2 Ar H-m/m'), 7.39 (d, <sup>3</sup>J(Ar H-o, Ar H-m) = 9.21 Hz, <sup>4</sup>J(Ar H-o, Ar H-o') ~ <sup>5</sup>J(Ar H-o, Ar H-m') ~ 2.70 Hz, 2H; 2 Ar H-o/o'), 6.01 (ddt, <sup>3</sup>J(vinyl H, cis vinyl H) ~ 17.0 Hz, <sup>3</sup>J(vinyl H, trans vinyl H) ~ 11.8 Hz, <sup>3</sup>J(vinyl H, allyl H) = 5.56 Hz, 1H; vinyl CH), 5.46 (ddd, <sup>3</sup>J = 17.18 Hz, <sup>2</sup>J = 2.45 Hz, <sup>4</sup>J = 1.38 Hz, 1H; terminal cis vinyl CH), 5.38 (dd, <sup>3</sup>J = 9.34 Hz, <sup>2</sup>J = 2.45 Hz, <sup>4</sup>J = 1.07 Hz, 1H; terminal trans vinyl CH), 4.78 (dt, <sup>4</sup>J(allyl H, cis vinyl H) ~ 1.27 Hz, <sup>3</sup>J(allyl H, vinyl H) = 5.56 Hz, 2H; allyl CH<sub>2</sub>O). <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>, 27 °C) δ = 155.56 and 152.30 (Ar CNO<sub>2</sub> and Ar CO(CO)), 145.48 (O(CO)O), 130.63 (CH=CH<sub>2</sub>), 125.28 and 121.75 (4 Ar CH), 120.11 (CH=CH<sub>2</sub>), 69.72 (CH<sub>2</sub>–allyl). mp 45 °C. **[N1,N3-bis(alloc)]Biotin *tert*-Butyl Ester 7.** Sodium hydride, 90% in mineral oil (755 mg, 28.23 mmol, 1.0 equiv), was added progressively at ambient temperature to a solution of Biotin *tert*-butyl ester (8.48 g, 28.23 mmol) in DMF (110 mL) stirred under a nitrogen atmosphere. After 1 h, allyl *p*-nitrophenyl carbonate (6.3 g, 28.23 mmol, 1.0 equiv) was added to the solution, which instantly became bright yellow. The reaction mixture was stirred further for 1 h before the introduction of an additional equivalent of sodium hydride (755 mg). After another hour, a second sample of allyl *p*-nitrophenyl carbonate (7.56 g, 33.88 mmol, 1.2 equiv) was added to the mixture in order to get the bis(carbamate) protection of the urea function. The reaction mixture became progressively orange. Since the free position of the mono(alloc) protected intermediate is less reactive than the starting material, the mixture was heated progressively to 80 °C, but due to the instability of the bis(alloc) protected urea compound at high temperature, the experiment was stopped after 15 h, even if TLC analysis (using CHCl<sub>3</sub>–MeOH 49:1 as eluent) indicated incomplete bis-protection. After evaporation of the solvent at 40 °C under a high vacuum, the resulting oil was suspended into CH<sub>2</sub>Cl<sub>2</sub> (2 L) and extracted with 5% NaHCO<sub>3</sub> (at least 15 × 650 mL, until the aqueous layer was not bright yellow anymore) and then with brine (5 × 500 mL). The organic phase was dried (MgSO<sub>4</sub>) and evaporated. The brown oily residue was purified by flash chromatography on silica gel using CHCl<sub>3</sub>–MeOH 100:0 to 49:1 as eluent. The [N1,N3-bis(alloc)]biotin *tert*-butyl ester **7** (6.085 g, 12.99 mmol, 46% yield) was eluted first, followed by the residual *p*-nitrophenol and the mono(alloc)biotin *tert*-butyl ester (**8a/8b** in mixture, 3.256 g, 8.47 mmol, 30% yield). The mixture of **8a** and **8b** was then recycled in a similar experiment using 1.0 equiv of sodium hydride and 1.2 equiv of allyl *p*-nitrophenyl carbonate, to afford after workup and chromatography 2.73 g of additional [N1,N3-bis(alloc)]biotin *tert*-butyl ester **7** (7.11 mmol). The colorless oil was stored at 4 °C in the absence of light. <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>, 27 °C, TMS) δ = 5.94 (m, 2H; 2 vinyl CH), 5.44 (dt, <sup>3</sup>J = 18.50 Hz, <sup>2</sup>J = <sup>4</sup>J = 1.31 Hz, 2H; 2 terminal cis vinyl CH), 5.30 (dt, <sup>3</sup>J ~ 8.36 Hz, <sup>2</sup>J = <sup>4</sup>J = 1.20 Hz, 2H; 2 terminal trans vinyl CH), 4.67–4.79 (m, 6H; 2 allyl CH<sub>2</sub>–O, H-<sup>B</sup>3a, H-<sup>B</sup>6a), 3.50 (m, 1H; H-<sup>B</sup>4), 3.29 (dd, 1H; <sup>2</sup>J = 13.10 Hz, <sup>3</sup>J(H-<sup>B</sup>6a, H-<sup>B</sup>6<sub>I</sub>) = 6.07 Hz, H-<sup>B</sup>6<sub>I</sub>), 2.92 (dd, <sup>2</sup>J = 13.10 Hz, <sup>3</sup>J(H-<sup>B</sup>6a, H-<sup>B</sup>6<sub>II</sub>) = 5.11 Hz, 1H; H-<sup>B</sup>6<sub>II</sub>), 2.04 (t, <sup>3</sup>J(H-<sup>B</sup>9, H-<sup>B</sup>10) ~ 6.78 Hz, 2H; CH<sub>2</sub>-<sup>B</sup>10), 1.45–1.85 (m, 4H; CH<sub>2</sub>-<sup>B</sup>7, CH<sub>2</sub>-<sup>B</sup>8 or CH<sub>2</sub>-<sup>B</sup>9), 1.44 (s, 4H; 3 CH<sub>3</sub>), 1.18–1.45 (m, 2H; CH<sub>2</sub>-<sup>B</sup>9 or CH<sub>2</sub>-<sup>B</sup>8). <sup>13</sup>C NMR (75 MHz, CDCl<sub>3</sub>, 27 °C) δ = 172.76 (COO-), 151.53 and 151.33 (2 NC(O)O–allyl), 148.18 (C-<sup>B</sup>2), 130.98 and 130.94 (2 CH=CH<sub>2</sub>), 119.58 and 119.40 (2 CH=CH<sub>2</sub>), 80.12 (C(CH<sub>3</sub>)<sub>3</sub>), 67.72 and 67.66 (2 CH<sub>2</sub>–allyl), 60.41 and 58.60 (C-<sup>B</sup>6a, C-<sup>B</sup>3a), 52.43 (C-<sup>B</sup>4), 36.20 (C-<sup>B</sup>6), 35.34 (C-<sup>B</sup>10), 28.11 (3 CH<sub>3</sub>), 27.71, 27.30, and 24.57 (C-<sup>B</sup>7, C-<sup>B</sup>8, and C-<sup>B</sup>9). **[N1,N3-bis(alloc)]Biotinyl-6-aminoalcohol 2.** A 70  $\mu$ L sample of water (3.85 mmol) was solvated in 70 mL of CH<sub>2</sub>Cl<sub>2</sub> by drawing the solvent mixture into and expelling it from a disposable pipet several times. The wet CH<sub>2</sub>Cl<sub>2</sub> was added slowly via a dropping funnel to a vigorously stirring solution of [N1,N3-bis(alloc)]biotinyl-6-aminoalcohol (1.77 g, 3.46 mmol) and Dess–Martin periodinane (2.231 g, 5.19 mmol, 1.5 equiv) in 21 mL of dry CH<sub>2</sub>Cl<sub>2</sub> at ambient temperature under a nitrogen atmosphere. The clear solution grew cloudy toward the end of wet CH<sub>2</sub>Cl<sub>2</sub> addition, which required 1 h. After 3 h, the reaction mixture was diluted with EtOAc and then concentrated into a few mL of solvent by rotary evapora-

tor. The residue was taken up in 500 mL of EtOAc and then washed (2 × 150 mL) with a (1:1) mixture of 10% Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> and 5% NaHCO<sub>3</sub>, followed by water (2 × 200 mL) and brine (2 × 150 mL). The aqueous washings were back-extracted with EtOAc (5 × 75 mL), and this organic layer was washed with water and brine. The combined organic layers were dried with MgSO<sub>4</sub> and concentrated. Flash chromatography (50:1 to 20:1 of CHCl<sub>3</sub>-MeOH) afforded [N1,N3-bis(alloc)]biotinyl-6-aminoalcohol (1.57 g, 3.08 mmol, 89% yield) as a colorless oil. The compound was stored under nitrogen, in the absence of light at -20 °C. <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>, 27 °C, TMS)  $\delta$  = 9.76 (t,  $^3J$ (H-<sup>S</sup>1, H-<sup>S</sup>2) = 1.60 Hz, 1H; CHO), 5.95 (m, 2H; 2 vinyl CH), 5.62 (br t, 1H; C(O)-NH), 5.45 (ddt,  $^3J$  = 17.16 Hz,  $^2J$  =  $^4J$  ~ 1.49 Hz, 2H; 2 terminal cis vinyl CH), 5.31 (ddd,  $^3J$  = 10.46 Hz,  $^4J$  = 4.03 Hz,  $^2J$  ~ 1.20 Hz, 2H; 2 terminal trans vinyl CH), 4.64–4.82 (m, 6H; 2 allyl CH<sub>2</sub>-O, H-<sup>B</sup>3a, H-<sup>B</sup>6a), 3.51 (ddd,  $^3J$  = 11.96 Hz,  $^3J$  = 5.70 Hz,  $^3J$  = 3.20 Hz, 1H; H-<sup>B</sup>4), 3.29 (dd,  $^2J$  = 13.06 Hz,  $^3J$ (H-<sup>B</sup>6a, H-<sup>B</sup>6<sub>l</sub>) = 6.32 Hz, 1H; H-<sup>B</sup>6<sub>l</sub>), 3.26 (t,  $^3J$ (H-<sup>S</sup>5, H-<sup>S</sup>6) ~ 6.09 Hz, 1H; H-<sup>S</sup>6<sub>l</sub>), 3.24 (t,  $^3J$ (H-<sup>S</sup>5, H-<sup>S</sup>6) ~ 6.09 Hz, 1H; H-<sup>S</sup>6<sub>l</sub>), 2.95 (dd,  $^2J$  = 13.06 Hz,  $^3J$ (H-<sup>B</sup>6a, H-<sup>B</sup>6<sub>l</sub>) = 5.26 Hz, 1H; H-<sup>B</sup>6<sub>l</sub>), 2.45 (td,  $^3J$ (H-<sup>S</sup>2, H-<sup>S</sup>3) = 7.22 Hz,  $^3J$ (H-<sup>S</sup>1, H-<sup>S</sup>2) = 1.57 Hz, 2H; CH<sub>2</sub>-<sup>S</sup>2), 2.15 (m, 2H; CH<sub>2</sub>-<sup>B</sup>10), 1.47–1.73 (m, 8H; CH<sub>2</sub>-<sup>B</sup>8, CH<sub>2</sub>-<sup>B</sup>9, CH<sub>2</sub>-<sup>S</sup>3, CH<sub>2</sub>-<sup>S</sup>5), 1.31–1.42 (m, 2H; CH<sub>2</sub>-<sup>S</sup>4), 1.20–1.30 (m, 2H; CH<sub>2</sub>-<sup>B</sup>7). <sup>13</sup>C NMR (125 MHz, CDCl<sub>3</sub>)  $\delta$  = 202.36 (C-<sup>S</sup>1), 172.46 (CH<sub>2</sub>C(O)NH), 151.34 and 151.08 (2 NC(O)O-allyl), 148.06 (C-<sup>B</sup>2), 130.77 and 130.73 (2 CH=CH<sub>2</sub>), 119.42 and 119.29 (2 CH=CH<sub>2</sub>), 67.58 and 67.51 (2 CH<sub>2</sub>-allyl), 60.19 (C-<sup>B</sup>3a), 58.41 (C-<sup>B</sup>6a), 52.25 (C-<sup>B</sup>4), 43.53 (C-<sup>S</sup>2), 38.94 (C-<sup>S</sup>6), 36.29 and 36.06 (C-<sup>B</sup>6, C-<sup>B</sup>10), 29.23, 27.73, 27.15, 26.16 and 21.39 (C-<sup>B</sup>7, C-<sup>B</sup>8, C-<sup>B</sup>9, C-<sup>S</sup>3, C-<sup>S</sup>4, C-<sup>S</sup>5), 25.00 (C-<sup>S</sup>4). **N3'-[N1,N3-bis(alloc)]Biotinyl-6-aminohexanyl]-doxorubicin 10.** A 1 M solution of NaCNBH<sub>3</sub> in tetrahydrofuran (200  $\mu$ L, 0.200 mmol, 0.255 equiv) was added to a stirred solution of doxorubicin hydrochloride (457.5 mg, 0.7888 mmol), [N1,N3-bis(alloc)]biotinyl-6-aminohexanal (982 mg, 1.9269 mmol, 2.44 equiv) and glacial AcOH (100  $\mu$ L, 2.13 equiv) in degassed CH<sub>3</sub>CN–H<sub>2</sub>O (2:1) (50 mL). The mixture was maintained under a nitrogen atmosphere at ambient temperature in the absence of light. The progress of the reaction was monitored by TLC in CHCl<sub>3</sub>/MeOH (4:1). When reaction was complete (after 5h30), the solution was concentrated under vacuum, then diluted with CH<sub>2</sub>Cl<sub>2</sub> (250 mL), and extracted repeatedly (5  $\times$  80 mL) with CH<sub>2</sub>Cl<sub>2</sub>–MeOH (9:1). The product was purified by column chromatography on silica gel using CHCl<sub>3</sub>–MeOH (from 95:5 to 50:50) as the eluent to yield 268 mg (0.2584 mmol, 33% yield) of N3'-[N1,N3-bis(alloc)]biotinyl-6-aminohexanyl]-doxorubicin ( $R_f = 0.5$  in CHCl<sub>3</sub>–MeOH 4:1) as a red amorphous film. A 76 mg (0.07314 mmol, 9%) sample of the reduced form of the conjugate (both rings B and C in hydroquinone form) ( $R_f = 0.27$  in CHCl<sub>3</sub>–MeOH 4:1) was additionally isolated from the chromatography.

**N3'-[Biotinyl-6-aminohexan]-yl]-doxorubicin Hydrochloride 11.** A solution of N3'-[N1,N3-bis(alloc)]-biotinyl-6-aminohexanyl]-doxorubicin (206 mg, 0.1986 mmol) in degassed CH<sub>2</sub>Cl<sub>2</sub>–MeOH (2:1) (6 mL) was treated with *N,N*-dimethylbarbituric acid (24 mg, 0.1537 mmol, 0.77 equiv) and tetrakis(palladium) (0) triphenylphosphine (46 mg, 0.03972 mmol, 0.2 equiv). The reaction mixture was stirred in the absence of light under a nitrogen atmosphere at ambient temperature for 3 h. The solvents were evaporated (30 °C), and the dark red film was suspended in 2 mL of MeOH. The suspension was filtered, and the material soluble in MeOH was treated at 0 °C with diethyl ether (10 mL) and a 1 M solution of HCl in diethyl ether (1.55 mL). After 10 min, the mixture was cooled to –40 °C to afford more efficient precipitation of the N3'-[biotinyl-6-aminohexan]-yl]-doxorubicin hydrochloride. The filtrate was decanted, and the precipitate was repeatedly suspended in cold diethyl ether (10 mL), triturated, and sonicated until the pH of the filtrate was approximately 3–4. Then the precipitate was suspended in degassed water (10 mL) and worked up with diethyl ether (5  $\times$  3 mL). The crude material insoluble in MeOH was suspended in water (20 mL) and the insoluble residue discarded. The aqueous solution was treated at 0 °C with a few drops of a 0.1M HCl in order to adjust the pH to  $\sim$ 3. The solution was then diluted with water (50 mL) and worked up with diethyl ether. Aqueous layers were combined and filtered through a small layer of reverse-phase C18 support in order to discard the palladium salts. The support was washed with degassed water (2  $\times$  10 mL) and the product eluted selectively with degassed water–acetonitrile mixture (1:1) (6  $\times$  10 mL). The fractions were analyzed by TLC and by (ES<sup>+</sup>)MS. The fractions containing the conjugate **11** ( $R_f = 0.15$  in CHCl<sub>3</sub>–MeOH 4:1) were evaporated, and the combined residue was lyophilised to afford N3'-[Biotinyl-6-aminohexan]-yl]-doxorubicin hydrochloride (136 mg, 0.1504 mmol, 76% yield) as an orange solid. <sup>1</sup>H NMR (500 MHz, CD<sub>3</sub>OD, 27 °C)  $\delta = 7.79$  (m, 2H; H-1, H-3), 7.52 (app t,  $^3J(\text{H-1,H-2}) \sim ^3J(\text{H-2,H-3}) \sim 4.81$  Hz, 1H; H-2), 5.47 (app s, 1H; H-1'), 4.99 (app d,  $^3J(\text{H-7,H-8}) = 2.33$  Hz, 1H; H-7), 4.77 (d,  $^2J = 4.55$  Hz, 2H; CH<sub>2</sub>-14), 4.51 (m, 1H; H-B<sub>6a</sub>), 4.30 (m, 2H; H-B<sub>3a</sub>, H-5'), 4.02 (s, 3H; OCH<sub>3</sub>), 3.88 (app s, 1H; H-4'), 3.59 (app t,  $^3J(\text{H-2'},\text{H-3'}) \sim 8.68$  Hz, 1H; H-3'), 3.19 (m, 2H; H-B<sub>4</sub>, H-S<sub>6i</sub>), 3.10 (app t,  $J = 6.87$  Hz, 1H; H-S<sub>6ii</sub>), 2.92–3.06 (m, 3H; H-10<sub>eq</sub>, CH<sub>2</sub>-S<sub>1</sub>), 2.92 (dd,  $^2J = 12.84$  Hz,  $^3J(\text{H-B}_{6a},\text{H-B}_{6anti}) = 8.15$  Hz, 1H; H-B<sub>6anti</sub>), 2.81 (d,  $^2J = 18.34$  Hz, 1H; H-10<sub>ax</sub>), 2.71 (d,  $^2J = 12.84$  Hz, 1H; H-B<sub>6syn</sub>), 2.36 (app dd,  $^2J \sim 15.56$  Hz,  $^3J(\text{H-7,H-8}_{eq}) \sim 1.72$  Hz, 1H; H-8<sub>eq</sub>), 2.12–2.31 (m, 3H; H-8<sub>ax</sub>, CH<sub>2</sub>-B<sub>10</sub>), 2.09 (app d,  $^3J(\text{H-2'},\text{H-3'}) = 8.21$  Hz, 2H; CH<sub>2</sub>-2'), 1.24–1.81 (m, 14H; CH<sub>2</sub>-B<sub>7</sub>, CH<sub>2</sub>-B<sub>8</sub>, CH<sub>2</sub>-B<sub>9</sub>, CH<sub>2</sub>-S<sub>2</sub>, CH<sub>2</sub>-S<sub>3</sub>, CH<sub>2</sub>-S<sub>4</sub>, CH<sub>2</sub>-S<sub>5</sub>), 1.33 (d,  $^3J(\text{H-5'},\text{CH}_3) = 6.87$  Hz, 3H; CH<sub>3</sub>). <sup>13</sup>C NMR (125 MHz, CD<sub>3</sub>OD, 27 °C)  $\delta = 215.59$  (C-13), 188.58 and 188.35 (C-5, C-12), 176.79 (CH<sub>2</sub>C(O)NH), 166.76 (C-B<sub>2</sub>), 163.20 (C-4), 158.09 (C-6), 156.81 (C-11), 138.09 (C-2), 136.91 (C-6a), 136.35 and 135.98 (C-10a, C-12a), 122.09 (C-4a), 121.29 and 121.22 (C-1, C-3), 113.12 and 112.87 (C-5a, C-11a), 101.88 (C-1'), 77.79 (C-9), 72.20 (C-7), 68.69 (C-5'), 67.04 (C-4'), 66.49 (C-14), 64.29 (C-B<sub>3a</sub>), 62.56 (C-B<sub>6a</sub>),

**Avidin Binding Assay.** The conjugate **11** (B-Dox) was assayed for avidin binding using the size exclusion HPLC methodology developed by Wilbur et al. (15, 16), where the Doxorubicin moiety of the conjugate is the dye, and with a few modifications described below: (1) Duplicate samples containing avidin (4.4 nmol) in phosphate buffer and compound **11** (18 nmol) in 10% aq. DMSO were incubated at 25 °C for 1 h before an aliquot of 100  $\mu$ L was removed for HPLC analysis. Then, 233 nmol (76 equiv.) of biotin was added to the samples, and the very low displacement of avidin-bound **11** by biotin was monitored by size exclusion HPLC for at least 48 h (using triplicate samples). (2) Since the free conjugate **11** (MW 869) was not eluted from the TSK G5000 PW column after 2 h, the HPLC analysis was performed in a slightly different way to that reported in refs 15 and 16: only the avidin-bound **11** was detected at the maximum wavelength corresponding to the biotinylated dye ( $\lambda_{\text{max}}$  = 487 nm). Integration of this peak compared to the integration of the peak corresponding to the "total" quantity of avidin in the sample (HPLC trace at 280 nm) allows monitoring the percentage of displacement by biotin of the avidin-bound **11** over the time, using the "total avidin" as an internal standard. Due to the very small relative increase in molecular weight generated by binding of **11** to avidin (MW ~ 68 kDa) free avidin and avidin-bound **11** coelute in the conditions of the HPLC assay (retention time  $t_R$  = 8.95 min). Diode array detection (Shimadzu, SPD-M10A) affords a straightforward dual-wavelength readout. B-Dox (**11**) binds tightly to avidin, since the incubation of **11** with 76 mol equiv of biotin affords only 27% of displacement after 24 h. HPLC analysis of a blank (avidin incubated in absence of conjugate **11**) affords a complete flat chromatogram at 487 nm, whereas the analysis of a sample containing avidin (4.4 nmol) and Doxorubicin (18 nmol) in place of **11** after a 12 h incubation as described above allowed to ensure that if some nonspecific avidin binding occurs (due to possible hydrophobic interactions with the drug), it is not detectable in the conditions of the assay.

**Topoisomerase II Relaxation Assay.** Each reaction contained 250ng supercoiled plasmid pBR322 (New England Biolabs). Reactions in a final volume of 20  $\mu$ L were carried out in 10mM Tris-HCl, pH 7.9, containing 50 mM NaCl, 50 mM KCl, 5 mM MgCl<sub>2</sub>, 100  $\mu$ M EDTA, 15  $\mu$ g/mL BSA, 1mM ATP. Test compound and 5 units Topoisomerase II (Amersham Pharmacia Biotech) were added on ice, and the mixture was incubated at 30 °C for 15 min. Reactions were stopped by the addition of 2  $\mu$ L 7mM EDTA/0.77% SDS. A 2  $\mu$ L gel loading buffer was added, and samples electrophoresed on a 1% agarose gel for approximately 2.5 h at 100V. DNA was stained with ethidium bromide (0.5  $\mu$ g/mL) and visualized under UV. Data are shown in Figure 1.

## RESULTS AND DISCUSSION

The bis-alloc-protected biotin aldehyde derivative was synthesized as shown in Scheme 1. Biotin *tert*-butyl ester **5** was treated with allyl *para*-nitrophenyl carbonate, in

**Figure 1.** Topoisomerase II activity of biotinylated doxorubicin (B-dox) **11** compared to free doxorubicin and etoposide.

## Scheme 1. Synthesis of the Biotin Aldehyde

## Scheme 2. Reductive Alkylation of Doxorubicin

a two step procedure to give the *N1,N3*-bis-alloc compound **7** together with the mono alloc regioisomers **8a**/**8b** in 46% and 30% yield. Difficulty in realizing clean bis-protection of *N1* and *N3* positions of biotin has been noted by others (17, 18). Cleavage to the acid **9** was followed by coupling with 6-aminohexanol using HATU. Dess–Martin periodinane oxidation gave bis-(*N1,N3*)-alloc protected biotinyl-6-aminohexanal **2**.

The reductive alkylation of doxorubicin HCl **3** by **2** using NaCNBH<sub>3</sub> is shown in Scheme 2. This procedure gave the alloc protected conjugate **10** in 33% yield. The

**Chart 3. Doxorubicin Derivative Utilized as a Model Compound**

structure of **10** was confirmed with the aid of 2D COSY and HMQC spectra. Deprotection of **10** using Pd[0] in the presence of *N,N*-dimethylbarbituric acid (NMDBA) as scavenger gave biotin-doxorubicin conjugate **11** (B-Dox) in 76% yield.

B-Dox **11** showed strong binding to avidin protein and was not displaced by a large excess of free biotin (data not shown). Electrophoretic analysis of DNA topoisomerase activity is shown in Figure 1. Each lane contains 250 ng of supercoiled plasmid DNA (pBR322). Addition of topoisomerase II cuts the DNA and the fragments appear as separate bands. This activity is inhibited by doxorubicin (1–10  $\mu$ M) and etoposide (100  $\mu$ M). The B-Dox **11** has activity in the range of 10–30-fold less than doxorubicin (10–100  $\mu$ M). Some loss in activity for attachment of a reporter molecule is observed in other systems (3).

The reductive alkylation of Doxorubicin hydrochloride was conducted first on a 50 mg scale using phenyl propionaldehyde as the substrate. The "test" conjugate **12** (Chart 3) obtained in this way proved very useful for the complete assignment of NMR data of the bis(alloc)-biotin-doxorubicin conjugate **10** and its deprotected derivative **11**.

**CONCLUSIONS**

Reductive alkylation is a process carried out under weakly acidic (NaCNBH<sub>3</sub>) or neutral (pyridine–BH<sub>3</sub>) conditions and is compatible with sensitive and complex functionality. It is also compatible with attachment to proteins (19), via their lysine side chains, without altering the charge state on the amine functionality. Alloc removal using Pd[0] may be effected under aqueous conditions (20, 21), in addition biocompatible Pd[0] Sonogashira couplings are reported (22). Our novel derivative may find therefore find use as an alternative biotinylation reagent for proteins. Experiments to validate the use of **2** and similar reagents for biotinylation of proteins are in progress.

# Spectroscopic Study and Evaluation of Red-Absorbing Fluorescent Dyes

Volker Buschmann,<sup>†</sup> Kenneth D. Weston,<sup>‡</sup> and Markus Sauer<sup>\*,†</sup>

Physikalisch-Chemisches Institut, Universität Heidelberg, Im Neuenheimer Feld 253, 69120 Heidelberg, Germany and Department of Chemistry and Biochemistry, Florida State University, Tallahassee, Florida 32306. Received September 4, 2002; Revised Manuscript Received October 21, 2002

The spectroscopic characteristics (absorption, emission, and fluorescence lifetime) of 13 commercially available red-absorbing fluorescent dyes were studied under a variety of conditions. The dyes included in this study are Alexa647, ATTO655, ATTO680, Bodipy630/650, Cy5, Cy5.5, DiD, DY-630, DY-635, DY-640, DY-650, DY-655, and EVOblue30. The thorough characterization of this class of dyes will facilitate selection of the appropriate red-absorbing fluorescent labels for applications in fluorescence assays. The influences of polarity, viscosity, and the addition of detergent (Tween20) on the spectroscopic properties were investigated, and fluorescence correlation spectroscopy (FCS) was utilized to assess the photophysical properties of the dyes under high excitation conditions. The dyes can be classified into groups based on the results presented. For example, while the fluorescence quantum yield of ATTO655, ATTO680, and EVOblue30 is primarily controlled by the polarity of the surrounding medium, more hydrophobic and structurally flexible dyes of the DY-family are strongly influenced by the viscosity of the medium and the addition of detergents. Covalent binding of the dyes to biotin and subsequent addition of streptavidin results in reversible fluorescence quenching or changes in the relaxation time of other photophysical processes of some dyes, most likely due to interactions with tryptophan residues in the streptavidin binding site.

## INTRODUCTION

The interest in fluorescent dyes for qualitative and quantitative assays has increased considerably during the last 20 years (1–4). The sensitivity, simplicity, and selectivity of fluorescence-based techniques make them particularly attractive for *in vitro* and *in vivo* cellular and molecular biology studies (5). There are several major advantages of using fluorescent dyes that absorb in the red over those that absorb at shorter blue and green wavelengths. The most important of these advantages is the reduction in background that ultimately improves the sensitivity achievable. There are three major sources of background: (i) elastic scattering, i.e., Rayleigh scattering, (ii) inelastic scattering, i.e., Raman scattering, and (iii) fluorescence from impurities. The efficiencies of both Rayleigh and Raman scattering are dramatically reduced by shifting to longer wavelength excitation. (scales with the  $1/\lambda^4$ ). Likewise, the number of fluorescent impurities is significantly reduced with longer excitation and detection wavelengths (6–8). Besides reduced background, a further advantage is that low-cost, energy efficient, rugged diode lasers can be used in place of the more expensive and shorter lived gas lasers. A variety of highly sensitive detectors in the visible-near-IR region are now available. A recent report demonstrated that the use of red-absorbing fluorescent labels and diode laser excitation at 635 nm provides sufficiently low autofluorescence of biological samples so that individual antigen and antibody molecules can be detected in human serum samples (21, 22).

The advantages of red-absorbing fluorophores has prompted current efforts to develop new fluorescent dyes which absorb and emit above 620 nm but still exhibit a sufficient fluorescence quantum yield, especially in an aqueous surrounding (9–11). Among these new red-absorbing dyes are rhodamine (10, 12), bora-diaza-indacene (4, 13), oxazine (10, 14), squaraine (15, 16), and indocarbocyanine dyes (17–20). Excitation in the red spectral region is also advantageous when working with live cells because of reduced cell damage (23).

Several applications benefit from efficient red-absorbing fluorescent dyes when used in combination with shorter wavelength dyes to increase the spectral range over which detection is possible. In multicolor imaging, the number of simultaneously imaged species can be increased by including red and near-IR absorbing dyes (24). Red-absorbing fluorescent dyes are also needed as acceptors in fluorescence resonance energy transfer (FRET) measurements (25–27). Red-absorbing dyes are also useful in dual-laser fluorescence cross-correlation experiments (28, 29).

The absorption and emission spectra, fluorescence quantum yield, and fluorescence lifetime of dyes often vary with environmental conditions. Thus, many fluorescent dyes can be used as sensors to probe their local environments in biological and analytical applications. For example, coumarin (30), rhodamine (10, 31, 32), oxazine (33), and bora-diaza-indacene (34) dyes are known to be efficiently quenched by the nucleobase guanosine (dG) and the amino acid tryptophan (Trp). It has been proposed that the mechanism of fluorescence quenching is a photoinduced electron transfer reaction from the guanosine or tryptophan ground-state to the excited singlet state of the dye. The difference between dG or Trp and the other DNA bases and amino acids can

\* To whom correspondence should be addressed. Phone: +49-6221-548460, Fax: +49-6221-544255, E-mail: sauer@urz.uni-heidelberg.de.

<sup>†</sup> Universität Heidelberg.

<sup>‡</sup> Florida State University.

be attributed to their low oxidation potential (30, 35). Although this quenching effect is not always desirable, it can be used to develop new, highly sensitive probes for the detection of specific DNA sequences (36) or proteins (22). Others examples of the sensitivity of fluorescent dyes to their local surroundings is the increase in fluorescence intensity and lifetime of some dyes, such as DY-630 and DY-635, upon binding to bovine serum albumin (BSA) (37) and the dependence of the cis/trans isomerization rate in some indocarbocyanine dyes on the viscosity of the surrounding medium (38, 39).

An understanding of the dependence of the spectroscopic properties of fluorescent dyes on environmental conditions is crucial for the development of new fluorescence-based assays. Fluorescence quenching effects such as those mentioned above are especially important in fluorescence resonance energy transfer (FRET)-applications, where spectral shifts, fluorescence lifetime, quantum yield changes, and changes in the isomerization rates of the donor or acceptor dye influence the measured FRET efficiencies.

Motivated by these considerations, we studied the spectroscopic characteristics of most of the commercially available fluorescent dyes that absorb and emit in the wavelength range of 640–700 nm and can be conjugated to biological molecules. The fluorescence quantum yield and excited state lifetime of dyes are influenced by the rate of internal conversion, which is controlled by the rigidity of the dye structure (40). Since highly viscous solvents impair structural mobility, an increase in fluorescence lifetime and quantum yield is expected with increasing solvent viscosity. The influence of viscosity on the spectroscopic parameters was examined by measuring the spectral properties of the dyes in solvent mixtures of water and glycerin. The influence of solvent polarity on the spectral properties was investigated by comparing measurements in water and ethanol.

To reveal the photophysical properties of the dyes under high excitation conditions, fluorescence correlation spectroscopy (FCS) measurements were performed. FCS permits measurements of a number of photophysical properties of fluorescent dyes such as the triplet lifetime, intersystem crossing yield, photoinduced isomerization, and photobleaching rates (41) and is commonly used in fluorescence assays. An often-neglected effect that dramatically influences the achievable detection sensitivity is the hydrophobicity of the dye structure. Very hydrophobic dyes often aggregate or form dimers in aqueous solvents. Therefore, often in fluorescence assays utilizing hydrophobic fluorophores, a detergent such as Tween20 (a nonionic detergent) is included in the buffer to facilitate solvation and prevent dimerization. Consequently, the photophysical characteristics of all red-absorbing fluorescent dyes were also investigated in aqueous medium containing Tween20.

The strong binding of biotin to the 60 kDa protein streptavidin ( $K_D = 10^{-15}$  M) has become a standard tool in molecular biology (42, 43). Each hydrophobic binding pocket of streptavidin contains four tryptophan residues that are involved in strong biotin binding (46). Because of the importance of the biotin–streptavidin techniques, dyes were covalently attached to biotin and the effect of binding the conjugates to streptavidin was investigated. Quenching or dequenching of the dye's fluorescence upon binding have been observed and were attributed to dye/dye interactions, such as the formation of nonfluorescent dimers or quenching interactions between the dye and the tryptophan-containing binding pocket of streptavidin (44, 45).

## EXPERIMENTAL PROCEDURES

**Fluorescent Dyes and Conjugates.** The dyes used in this study were obtained as *N*-hydroxysuccinimidyl esters. ATTO 655 and ATTO 680 were purchased from ATTO-TEC (Siegen, Germany), Alexa 647, DiD (DiIC<sub>18</sub> (5)), and Bodipy630/650 from Molecular Probes (Göttingen, Germany), Cy5 and Cy5.5 from Amersham Pharmacia Biotech (Freiburg, Germany), and DY-630, DY-635, DY-640, DY-650, DY-655, and EvoBlue30 from Dyomics (Jena, Germany). When dissolved in water, *N*-hydroxysuccinimidyl esters are believed to be deactivated within minutes to hours.

For the biotin–streptavidin studies, the activated dye was coupled with biotin cadaverine (Molecular Probes, Göttingen, Germany) in dimethylformamide with 1% *N*-ethyl-diisopropylamine. The reaction solution was incubated for 90 min at room temperature, and the product was purified by HPLC (Hewlett-Packard, Böblingen, Germany) using a reversed-phase column (Knauer, Berlin, Germany) with octadecylsilan-hypersil C18. Separation was performed in 0.1 M triethylammonium acetate, using a linear gradient from 0% to 75% acetonitril in 20 min. Yields >80% were obtained. For coupling to biotin, the dyes Alexa 647 (elution time: 6.5 min), Bodipy 630/650 (15.0 min), Cy5 (8.9 min), DY-630 (14.5 min), and DY-640 (14.5 min) were used. Biotin conjugates of ATTO 655 (9.3 min) and ATTO 680 (9.5 min) were obtained from ATTO-TEC (Siegen, Germany). All of the dyes, with the exception of DiD, could be linked to biotin–cadaverine in DMF; the HPLC elution time was between the free dye and the activated ester.

**Ensemble Spectroscopy.** Absorption spectra were taken on a Cary 500 UV–vis–NIR spectrometer (Varian, Darmstadt, Germany). Steady-state fluorescence spectra were measured in standard quartz cuvettes with a LS100 spectrometer (Photon Technology International, Wedel, Germany). Corrected fluorescence spectra were obtained using a high-pressure xenon flash lamp as excitation source. To avoid re-absorption and re-emission effects, concentrations were kept strictly below 1  $\mu$ M (typically 0.1  $\mu$ M) in all measurements. Ensemble fluorescence lifetime measurements were performed on a 5000MC spectrometer (IBH, Glasgow, U.K.) using the time-correlated single-photon counting (TCSPC) technique. The excitation source was a pulsed laser diode emitting at 635 nm with a repetition rate of 1 MHz and pulse lengths of  $\sim$ 200 ps (fwhm). With this setup an instrument response function (IRF) of 220 ps (fwhm) was measured. To exclude polarization effects, fluorescence was observed under magic angle (54.7°) conditions. Typically, 5000 photon counts were collected in the maximum channel using 2056 channels (Figure 1). The decay parameters were determined by least-squares deconvolution, and their quality was judged by the reduced  $\chi^2$  values and the randomness of the weighted residuals. In the case that a monoexponential model was not adequate to describe the measured decay, a multiexponential model was used to fit the decay (eq 1),

$$I(t) = I(0) \sum a_i \tau_i \quad (1)$$

where  $a_i$  are the preexponential factors that describe the ratio of the excited species and  $\tau_i$  denote their lifetimes.

**Fluorescence Correlation Spectroscopy (FCS).** The setup for fluorescence correlation spectroscopy (FCS) measurements has been described recently (13). A pulsed diode laser served as excitation source operating at a repetition rate of 64 MHz (PicoQuant, Berlin, Germany).

**Figure 1.** Fluorescence decay of ATTO 680 in EtOH. The instrument response function (IRF), and corresponding fit revealed a monoexponential fluorescence lifetime of 3.04 ns with a reduced  $\chi^2$  of 1.160. The weighted residuals of the fit are also shown.

The laser beam passed an excitation filter (639DF9; Omega Optics, Brattleboro, MA) and entered an inverted microscope (Axiovert 100TV, Zeiss, Jena, Germany) through the back port. It was coupled into an oil immersion objective (100 $\times$ , NA = 1.4, Nikon, Japan) by a dichroic beam splitter (645DLRP, Omega Optics, Brattleboro, MA). The fluorescence signal was collected through the same objective, filtered by two band-pass filters (680HQ60, 675DF50), and imaged onto a 100  $\mu$ m pinhole diameter directly in front of the avalanche diode (SPAD, AQ 141, EG&G Optoelectronics, Canada). The APD output was connected to a correlator card (model 5000/E, ALV, Langen, Germany). For a correlation curve, 6 runs of 30 s were averaged. All fluorescence measurements were done at room temperature (25  $^{\circ}$ C).

**Data Analysis.** Fluorescence intensity autocorrelation functions were calculated by the correlator board and saved as ASCII files. The autocorrelation functions were analyzed with Origin (Microcal Software, Northampton, MA). Fluorescence correlation spectroscopy (FCS) measures the fluorescence fluctuations arising from fluorescent molecules as they pass the detection volume to obtain information about dynamic processes at the molecular level (47). Using FCS, the time dependent fluorescence signal  $F = \delta F + \langle F \rangle$  is described by the fluorescence fluctuations  $\delta F(t)$  about an average value  $\langle F \rangle$ . These fluctuations are analyzed in the form of a normalized autocorrelation function  $G(\tau)$ , where  $\tau$  denotes the correlation time (eq 2).

$$G(\tau) = \frac{\langle F(t)F(t+\tau) \rangle}{\langle F(t) \rangle^2} = 1 + \frac{\langle \delta F(t)\delta F(t+\tau) \rangle}{\langle F(t) \rangle^2} \quad (2)$$

FCS can be used to gain information about all processes influencing the fluorescence intensity in the detection volume, e.g., translational diffusion, triplet states, or equilibrium constants (38, 39, 41, 47).

## RESULTS AND DISCUSSION

**Absorption and Emission Characteristics of Red-Absorbing Fluorescent Dyes.** The molecular structures of some of the investigated dyes are available (Bodipy 630/650, Cy5, Cy5.5, DiD, DY-630, DY-635; see Figure 2), while for other red-absorbing dyes the structures are proprietary (Alexa 647, ATTO 655, ATTO 680, DY-640, DY-650, DY-655, EvoBlue30). Absorption and

**Figure 2.** Molecular structures (the free carboxyl group structure without succinimidyl ester) of some of the red-absorbing fluorescent dyes used in this study.

emission maxima of all red-absorbing dyes in different solvents are listed in Table 1. Starting from water, all dyes except DiD show a red-shift in the absorption and emission maximum with increasing glycerol concentration. For most dyes, the absorption and emission maximum is also shifted to the red in ethanol. In contrast, some chromophores, such as ATTO 655, ATTO 680, and DY-640 show distinct shifts to shorter wavelengths in ethanol, especially for the absorption maxima.

Due to long alkyl side chains ( $C_{18}$ ) and the lack of sulfonate groups, the carbocyanine dye DiD shows a strong aggregation tendency in aqueous solvents which promotes the formation of nonfluorescent dimers and aggregates. DiD and related dyes exhibit a strong fluorescence increase when incorporated into membranes (48), organic solvents, or immobilized on dry glass surfaces (49). The addition of 0.05% (v/v) Tween20 reduces the aggregation tendency and increases the fluorescence lifetime and intensity significantly (Table 1). The absorption and emission characteristics of dyes of the DY-family are also strongly influenced by the addition of Tween20. For example, the absorption maximum of DY-635 is 16 nm red-shifted from 635 to 651 nm upon addition of the detergent.

Figure 3 shows the retention times of the red-absorbing dyes measured by HPLC on a reversed-phase column using a water/acetonitrile gradient. The measured retention times suggest the classification of the dyes into two groups: hydrophilic dyes (Alexa 647, ATTO 655, ATTO 680, Cy5, Cy5.5, and EvoBlue30) and hydrophobic dyes (DiD, Bodipy 630/650, and the dyes of the DY-family). In general, the more hydrophobic chromophores are influenced by the addition of Tween20 while more hydrophilic dyes are not. The spectroscopic data of the

<sup>a</sup> The extinction coefficients reported by the manufacturers,  $\epsilon$  (L mol<sup>-1</sup> cm<sup>-1</sup>) are  $2.5 \times 10^5$  for Cy5, Cy5.5, and Alexa 647,  $0.97 \times 10^5$  for Bodipy630/650,  $>1.2 \times 10^5$  for DY-630 and DY-635,  $2.6 \times 10^5$  for DiD, and  $1.0 \times 10^5$  for ATTO 655 and ATTO 680. <sup>b</sup> The quality of the fit was judged by the reduced  $\chi^2$  values and the randomness of the weighted residuals (Figure 1). For all fits,  $\chi^2$  values between 0.900 and 1.200 were obtained. Viscosities of the solvents at 20 °C are 1.00 mPa s (water), 2.025 mPa s (20% glycerol, v/v), 4.95 mPa s (40% glycerol, v/v), and 1.2 mPa s (ethanol). Fluorescent dyes of the DY-family show only weak fluorescence intensity and nonexponential fluorescence kinetics. Therefore average fluorescence lifetimes,  $\tau_{\text{av}} = a_1\tau_1 + a_2\tau_2$ , are given. <sup>c</sup> The carbocyanine dye DiD shows a strong aggregation tendency in aqueous solvents which promotes the formation of nonfluorescent dimers or aggregates.

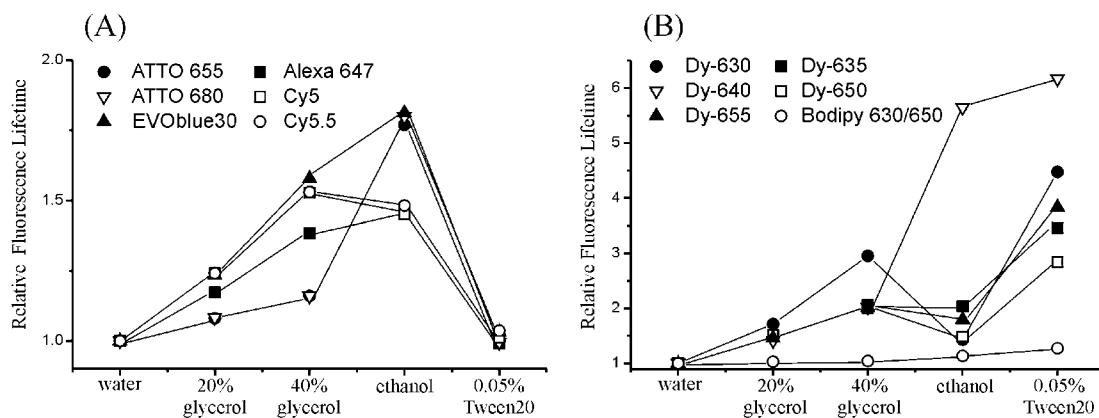

**Figure 3.** Retention times of red-absorbing fluorescent dyes measured by HPLC. The dye DiD did not elute under the applied experimental conditions. Separation was performed in 0.1 M triethylammonium acetate, using a linear gradient from 0% to 75% acetonitril in 20 min.

hydrophobic bora-diaza-indacene dye Bodipy 630/650 are nearly unaffected by the surrounding medium (Table 1).

Neglecting the dielectric constant,  $\epsilon$ , dye-solvent interactions are, in general, described by the refractive index of the solvent,  $n$ , if the interactions are predominated by dispersion forces (50). Generally, an increase of the refractive index is expected to result in a red-shift of the absorption maximum. The refractive indices of the solvents used in our experiment are 1.33 (water), 1.36 (ethanol), 1.36 (20% glycerol in water), and 1.40 (40% glycerol in water). As can be seen from Table 1, the absorption and emission maxima of all dyes investigated show a red-shift with increasing glycerol concentration. Using ethanol as the solvent also increases the refractive index, but the effect on the absorption and emission spectra is less pronounced. This, and the fact that some dyes (ATTO 655, ATTO 680, EVOblue30, and Bodipy 630/650) show a blue-shift in ethanol mixtures means that other effects, such as the polarity and the solvation of the different chromophore structures must also influence the absorption and emission maxima.

**Fluorescence Lifetimes of Red-Absorbing Fluorescent Dyes.** Due to problems associated with adsorption of hydrophobic dyes to the walls of the quartz cuvettes, we have not attempted to report the measured values of the fluorescence quantum yields. However, since the fluorescence quantum yield,  $\Phi_f$ , is defined as  $\Phi_f = \tau/\tau_n$  in the absence of static fluorescence quenching ( $\tau_n$ : native radiative lifetime without any nonradiative processes), an increase or decrease in the measured fluorescence lifetime is always related to an increase or decrease in fluorescence quantum yield.

Figure 4 shows the relative fluorescence lifetimes (relative to pure water value) measured for each dye in each of the various solvent conditions tested. On the basis of the dependence of the fluorescence lifetime on the different solvents, the red-absorbing dyes investigated in this study can be divided into the following groups: (i) fluorescent dyes for which the lifetime is independent of the surrounding medium (Bodipy 630/650), (ii) fluorescent dyes for which the lifetime is much longer in ethanol than water, but does not change significantly in the presence of Tween20 (ATTO 655, ATTO 680, Alexa 647, EVOblue30, Cy5, and Cy5.5; see Figure 4A), and (iii) fluorescent dyes from the DY-family for which the lifetime is much longer with Tween20 than in pure water. Within these groups there are still some differences: For example, the fluorescence lifetimes of ATTO 655, ATTO 680, and EVOblue30 dyes are less sensitive to solvent viscosity, e.g., in 40% glycerol, than they are to solvent polarity (ethanol). These observations, especially the strong increase in fluorescence lifetime of ATTO 655, ATTO 680, and EvoBlue30 in ethanol, indicate a more rigid chromophore structure. It was recently shown that several red-absorbing rhodamine and oxazine dyes (both xanthene dyes with rigid structures) exhibit shorter fluorescence lifetimes in water than in ethanol (3, 10). On the other hand, the viscosity (and temperature) dependence of the fluorescence characteristics is only weak. From these findings, we assume that the three red-absorbing fluorescent dyes ATTO 655, ATTO 680, and EVOblue30 have a rigid planar chromophore structure which do not show cis/trans isomerization processes

**Figure 4.** Relative fluorescence lifetimes measured for the red-absorbing fluorescent dyes in different solvents. Relative fluorescence lifetimes were calculated by dividing the measured values by the value obtained in water.

commonly observed for chromophores with flexible polymethine groups.

The other three dyes of this group (Figure 4A), Alexa 647, Cy5, and Cy5.5 show shorter fluorescence lifetimes but otherwise absolutely identical dependencies. Due to the flexibility of the polymethine backbone of carbocyanine dyes and consequential cis/trans isomerization possibilities, the fluorescence lifetimes and quantum yields are strongly influenced by the viscosity (Figure 4A). This is in good agreement with earlier findings for most cyanine dyes at room temperature in alcoholic or aqueous solutions which demonstrated that viscosity is the dominating solvent property influencing the fluorescence intensity and that the polarity of the solvent plays only a minor role (51). As expected for more hydrophilic dyes (Figure 3), the fluorescence properties of all red-absorbing fluorescent dyes of this group (Figure 4A) are very weakly influenced by the addition of 0.05% Tween20 (v/v) to an aqueous solution.

The fluorescent dyes from the DY-family (Figure 4B) all show a similar increase in fluorescence lifetime upon changing the solvent from water to water/glycerol mixtures or pure ethanol. Only for the dye DY-640, both the viscosity and the polarity strongly influence the fluorescence intensity and lifetime to the same degree (see lifetimes in ethanol and upon addition of Tween20). Nevertheless, the strong increase in fluorescence lifetime and intensity upon addition of 0.05% Tween20 (v/v) to an aqueous solution (up to 6-fold) is unexpected. Certainly, the addition of Tween20 reduces the aggregation tendency and promotes the solubility of these rather hydrophobic dye structures in aqueous solutions (Figure 3), but the degree of this increase in fluorescence intensity indicates that other effects have to be taken into account. For example, as can be seen in Figure 2, at least two dyes of the DY-family are asymmetric carbocyanine dyes (DY-630, DY-635). It may be that those dyes associate with Tween20 molecules or micelles thereby increasing the solubility and decreasing the internal conversion rate by reducing the flexibility of the polymethine backbone.

**Fluorescence Correlation Spectroscopy (FCS) Measurements.** The dyes used in this study, particularly the more hydrophobic dyes, show dynamic adsorption on the cover slides used for FCS measurements. Furthermore, some dyes show strong adsorption to nonfluorescent impurities, e.g., dust particles, in aqueous solutions. These problems render the analysis of the normalized autocorrelation functions more difficult. There-

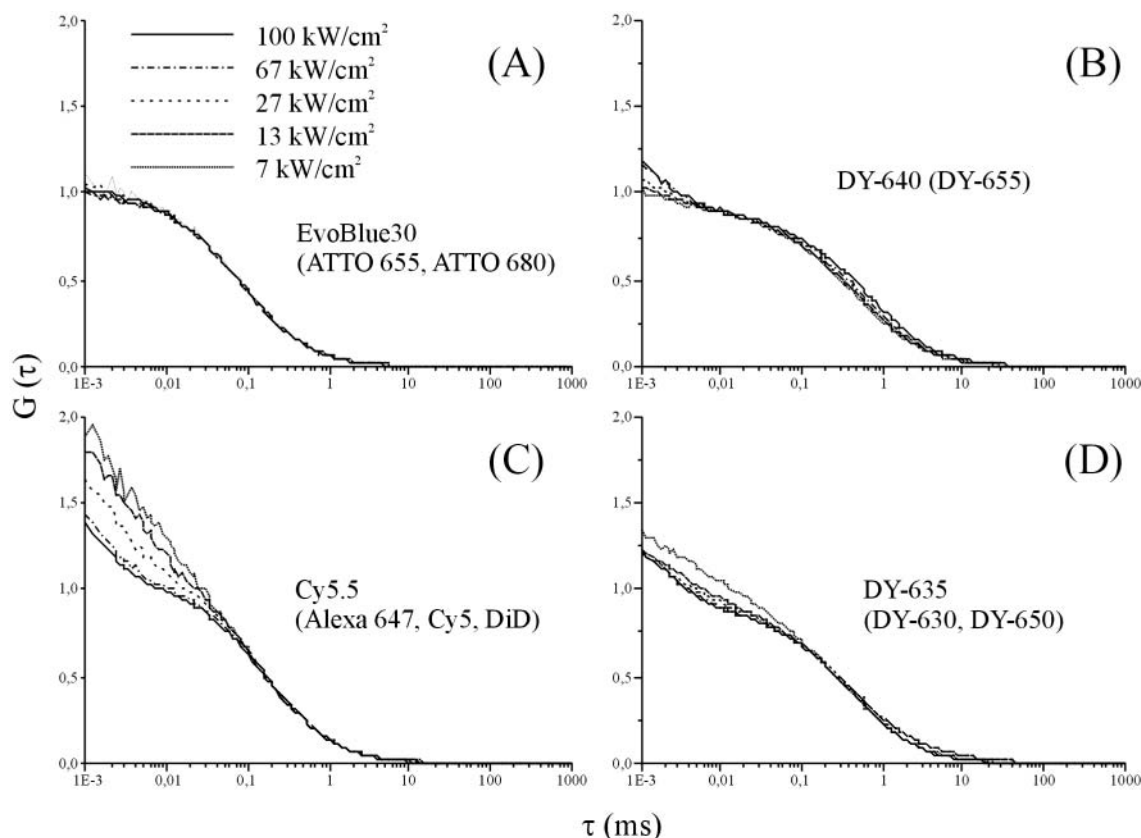

fore, experiments were performed in water containing 0.05% Tween20 (v/v), which effectively eliminates these problems.

In FCS measurements, transient nonfluorescent states such as triplet states or cis-conformations (as in the case of the carbocyanine dye Cy5) (38) give rise to fluorescence fluctuations that are superimposed on those caused by 3D-translational motion (Brownian motion) of the fluorescent molecule in and out of the sample volume element. Since the lifetime of these transient states are usually shorter, i.e., in the range of several microseconds, than the typical diffusion time of a fluorescent dye molecule through the sample volume element, they can be analyzed separately (41). While translational diffusion is, as a first approximation, independent of the laser excitation energy (neglecting photobleaching effects), intersystem crossing and photoinduced cis/trans isomerization is not. Widengren and Schille recently showed that the correlation times for cis/trans isomerization for the carbocyanine dye Cy5 are drastically reduced with higher excitation intensities but that the amplitude of this process (about 50%) is not excitation power dependent (38).

Figure 5 shows representative FCS curves of the red-absorbing fluorescent dyes for a range of excitation intensities in water containing 0.05% Tween20 (v/v). In these experiments, four different types of FCS curves and excitation intensity dependencies were observed. The FCS curves obtained for EVOblue30 under various excitation intensities (Figure 5A) are representative for FCS curves measured for ATTO 655, ATTO 680. They are also representative for Bodipy 630/650, except that Bodipy 630/650 has a slightly longer diffusion time. FCS curves of these fluorescent dyes can be described exclusively by translational diffusion up to an excitation energy of 100 kW/cm<sup>2</sup>. This indicates that the intersystem crossing yield is very low under moderate excitation conditions. Figure 5B shows the FCS curves measured for DY-640 under various excitation intensities. Similar curves were obtained for DY-655. For these dyes, a second exponential process could be observed at excitation intensities of > 27 kW/cm<sup>2</sup> with an amplitude of 30–35% (at 100 kW/cm<sup>2</sup>). This second process can be ascribed to intersystem crossing into the triplet state. In addition, at excitation intensities above 27 kW/cm<sup>2</sup> a distinctly faster decay of the autocorrelation curves due to photobleaching is evident.

The normalized intensity autocorrelation curves presented in Figure 5C are representative for carbocyanine dyes showing photoinduced cis/trans isomerization. These

**Figure 5.** FCS curves of some red-absorbing fluorescent dyes in water containing 0.05% Tween20 (v/v) at excitation intensities of 7, 13, 27, 67, and 100 kW/cm<sup>2</sup>. (A) EVOblue30; similar curves were obtained for ATTO 655, ATTO 680 and, with a longer diffusion time, for Bodipy 630/650. (B) DY-640; similar traces were obtained for DY-655. (C) Cy5.5; similar curves were obtained for Alexa 647, Cy5 and DiD. (D) DY-635; similar curves were obtained for DY-630 and DY-650.

dyes, Cy5, Cy5.5, DiD, and Alexa 647, all show identical excitation intensity dependence in FCS curves. The relaxation times for cis/trans isomerization are drastically reduced with higher excitation intensities. At the highest excitation intensity (100 kW/cm<sup>2</sup>) weak triplet state population is observed. Although the molecular structure of Alexa 647 has not been published, the FCS curves and fluorescence lifetimes strongly indicate that it has a carbocyanine structure. For DiD, significant photobleaching, manifested by faster decays of the FCS curves for excitation intensities above 20 kW/cm<sup>2</sup>, is evident.

The FCS curves recorded for DY-630, DY-635, and DY-650 under various excitation intensities (Figure 5D) exhibit behavior similar to those shown in Figure 5C. The major difference is that a second component (other than translational diffusion) is required to describe the curves even under weak excitation conditions. Besides the apparent photobleaching at higher excitation intensities, the more hydrophobic red-absorbing dyes, especially the dyes of the DY-family shown in Figs. 5B and 5D and Bodipy630/650, show slower translational diffusion. This implies that those dyes tend to adsorb to Tween20 micelles, which increases the observed diffusion time.

To summarize, the best signal-to-noise ratios in the FCS measurements were obtained for all dyes applying an excitation intensity of 67 kW/cm<sup>2</sup>. For our excitation wavelength and filter combination, Alexa 647, Cy5, ATTO 655, DY-640, and Bodipy 630/650 proved to be the brightest red-absorbing fluorescent dyes in aqueous solutions containing 0.05% Tween 20. Since the cis and triplet states of dyes such as Cy5, Cy5.5, or Alexa 647 are also potential nonfluorescent energy transfer acceptors, the use of these dyes as acceptors in FRET mea-

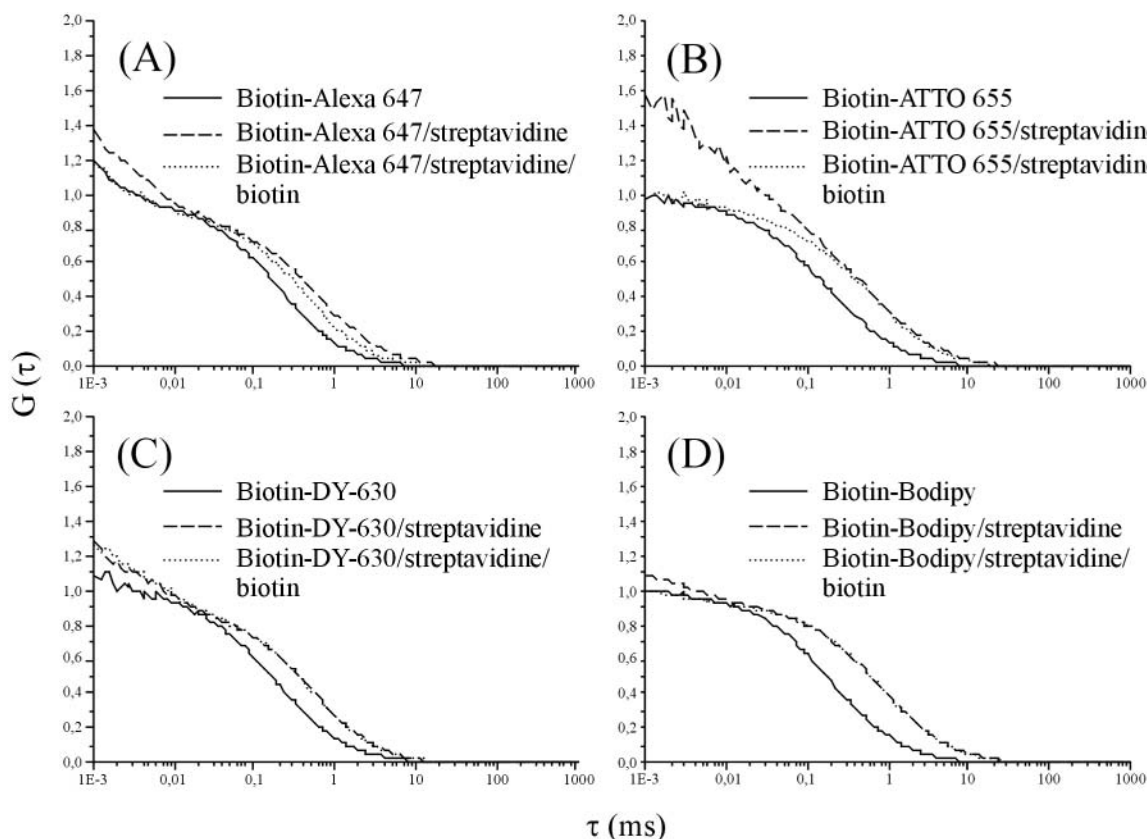

surements is more problematic (39, 52). Due to their low intersystem crossing yields, ATTO 655, ATTO 680, DY-640, and Bodipy 630/650 offer efficient alternatives. Fluorescent dyes of the DY-family require the addition of detergents to compete.

**Biotin Conjugates and Streptavidin Binding.** The steady-state absorption and fluorescence spectra of the biotin conjugates of Alexa 647, ATTO 655, ATTO 680, Cy5, DY-630, and DY-640 are all shifted slightly to the red compared to the free dyes (Table 2). In addition, most biotin conjugated dyes exhibit a slight increase in fluorescence lifetime. However, the absorption and fluorescence excitation spectra of the Bodipy 630/650 biotin conjugate indicate the formation of nonfluorescent dimers. From the data shown in Table 2, it is clear that the addition of streptavidin significantly alters the spectroscopic properties of all conjugates investigated. To prevent dye/dye interactions between biotin conjugated dyes bound to neighboring binding sites of the same streptavidin, an excess of streptavidin was used (44). Carbocyanine dyes such as Cy5 show bathochromic shifts in absorption and emission and a considerable increase in fluorescence lifetime. The fact that Cy5 and Alexa 647 both show this behavior is another indicator that they are similar in structure. The two conjugates from the DY-family (DY-630, DY-640) show a strong increase in fluorescence lifetime and intensity upon addition of streptavidin. The fluorescence decays of the DY-630 and DY-640 biotin conjugates show a second dominant component with a long fluorescence lifetime, similar to the fluorescence lifetimes obtained upon addition of Tween20 to an aqueous solution of the free dyes. Surprisingly, the emission maximum of the DY-640 biotin conjugate showed a 10 nm blue-shift upon addition of streptavidin.

**Table 2. Spectroscopic Characteristics (Absorption Maxima,  $\lambda_{\text{abs}}$  (nm), Emission Maxima,  $\lambda_{\text{em}}$  (nm), Fluorescence Lifetimes,  $\tau$  (ns)) of Dye–Biotin Conjugates in the Absence/Presence of an Excess of Streptavidin in Water<sup>a</sup>**

<sup>a</sup> The quality of the fit was judged by the reduced  $\chi^2$  values and the randomness of the weighted residuals. Most biotin conjugates show a biexponential fluorescence decay upon binding to streptavidin.

**Figure 6.** FCS curves of some biotin conjugates in water measured at an excitation intensity of 67 kW/cm<sup>2</sup>. The solid lines give the FCS curves of the biotin conjugates, the dashed line upon addition of an excess of streptavidin, and the dotted line upon a subsequent addition of an excess of unlabeled biotin. (A) Biotin–Alexa 647, similar curves were obtained for Cy5. (B) Biotin–ATTO 655, similar curves were obtained for ATTO 680. (C) Biotin–DY-630, similar curves were obtained for DY-640. (D) Biotin–Bodipy 630/650.

In contrast, the biotin conjugates of ATTO 655, ATTO 680, and Bodipy 650/680 show fluorescence quenching upon addition of an excess of streptavidin, indicated by the appearance of a shorter component in the fluorescence decay (Table 2). In the case of the Bodipy 630/650 biotin conjugate, the dimers disappear completely upon binding to streptavidin.

Figure 6 shows FCS curves recorded for some biotin conjugates in water with and without the addition of an excess of streptavidin (solid line and dashed line, respectively). The binding of the biotin conjugates to streptavidin can be confirmed and monitored by the shift of the diffusional correlation times. Because we want to observe this shift, these measurements were performed in pure water, i.e., without Tween20.

Upon addition of streptavidin, all the FCS curves showed an increased translational diffusion time, confirming that streptavidin binds each dye conjugate. The FCS curves also showed additional fast correlation times in the presence of an excess of streptavidin for all biotin-conjugated dyes. For example, biotin conjugates of Alexa

647 (Figure 6A) and DY-630 (Figure 6C) that show the expected short correlation times due to cis/trans isomerization and intersystem crossing in the absence of streptavidin show an increase of the short correlation terms after streptavidin binding in the short-time range. In almost the same manner, the FCS curves of the Bodipy 630/650 conjugates show an additional term in the short time range in the presence of streptavidin (Figure 6D). However, the biotin conjugates of ATTO 655 and ATTO 680 show the most pronounced changes upon addition of streptavidin (Figure 6B, FCS curves for ATTO 655). The data shown in Table 2 indicate fluorescence quenching of the dye due to binding of the biotin conjugate to streptavidin. This quenching correlates with the appearance of the additional short-time FCS decay components.

It is likely that the additional short correlation times observed in the FCS curves upon streptavidin binding is caused by reversible quenching of the dye with tryptophan residues of streptavidin. The quenching could be from tryptophan residues at the streptavidin binding site, or from one (or more) of the three neighboring, unoc-

cupied binding sites. To distinguish these two possibilities, an excess of unlabeled biotin was added. The addition of excess free biotin blocks neighboring binding sites and suppresses possible interactions between the dye and those tryptophan residues. Another possible process to consider is that unlabeled and labeled biotins compete for the same streptavidin binding sites, i.e., dye-labeled biotin may be displaced (42–45). The FCS curves of the biotin conjugates of hydrophobic dyes (DY-630, DY-640, Bodipy 630/650; see Figures 6C and 6D) do not change upon addition of excess free biotin, but the conjugates of more hydrophilic dyes such as Alexa 647, Cy5, ATTO 655, and ATTO 680 do show a decrease in the translational diffusion times (Figures 6A and 6B).

Hydrophilic dyes bind in the binding pocket, hence they can be displaced by competing free biotin; hydrophobic dyes bind nonspecifically, i.e., not at the binding sites, therefore they are not displaced by free biotin.

With the exception of DY-630 and DY-640 (Figure 6C), the additional short-time FCS decay component disappears when an excess of biotin is added to the streptavidin–biotin–dye complexes. The disappearance of the additional fast process for Alexa 647, Cy5, ATTO 655, ATTO 680, and Bodipy 630/650 indicates that these dyes interact with neighboring binding sites, likely with the tryptophan residues, that are inhibited upon addition and binding of unlabeled biotin molecules. In the case of ATTO 655, ATTO 680, and Bodipy 630/650, the quenching probably occurs via an electron transfer reaction from the ground state tryptophan residue to the first excited singlet state of the dye (22, 33, 34, 36). Since carbocyanine dyes such as Cy5 exhibit a lower electron accepting tendency, they are not quenched (14). The loss of the additional short-time component for the Alexa 647 and Cy5 streptavidin complexes in excess free biotin are not easily explained. It is likely that the observed changes are related to a change in the cis/trans isomerization rate brought on by a conformational change that occurs when the neighboring binding sites are filled. The reason that the additional short-time FCS decay components do not disappear on addition of free biotin for DY-630 and DY-640 conjugates is that these biotin–dye complexes are in fact bound to streptavidin nonspecifically through hydrophobic interactions of the dye and the protein interior. As a result, the binding to streptavidin is independent of whether free biotin is present at the streptavidin binding sites.

## CONCLUSIONS

The spectroscopic data of 13 commercially fluorescent dyes absorbing in the red-wavelength range (620–700 nm)—a very promising wavelength range for diagnostic applications—are measured and compared using ensemble steady-state and time-resolved fluorescence spectroscopy as well as fluorescence correlation spectroscopy (FCS). The best signal-to-noise ratios in aqueous solutions are obtained for the relatively hydrophilic dyes Cy5, Cy5.5, Alexa 647, ATTO 655, and ATTO 680. The data obtained strongly suggest that besides Cy5 and Cy5.5, Alexa 647 also belongs to the class of symmetric carbocyanine dyes which show excitation intensity dependent cis/trans isomerization and short fluorescence lifetimes of ~1 ns in aqueous solutions. Due to their similar spectroscopic behavior, the red-absorbing dyes EVOblue30 and the two ATTO-dyes probably belong to the same class of structurally rigid chromophores such as rhodamines or oxazines. ATTO 655 and ATTO 680 exhibit longer fluorescence lifetimes in aqueous solutions than the

carbocyanine dyes, thus allowing an improved discrimination against autofluorescent impurities which normally have very fast fluorescence decays. On the other hand, both chromophore classes might be used to probe the local environment due to specific quenching processes or changes in the cis/trans isomerization rates. Although the fluorescence intensity and lifetime of Bodipy 630/650 is superior and nearly independent of the surrounding medium, the strong dimerization and nonspecific adsorption tendency renders its application more difficult in aqueous solutions. The relatively hydrophobic fluorescent dyes of the DY-family proved to be only weakly fluorescent in aqueous solutions. However, upon addition of Tween20 or binding of biotin conjugates to streptavidin, the fluorescence drastically increases.

The results presented demonstrate that knowledge of the spectroscopic behavior of the dyes used under various conditions is crucial for the design of any application. As an example, the binding of labeled biotin conjugates to streptavidin was monitored. Selective fluorescence quenching of dyes by tryptophan residues in proteins has great potential for the development of diagnostic applications (22). Furthermore, the data show that changes in the fluorescence lifetime of the dye or any other photophysical properties such as cis/trans isomerization might be used advantageously in developing fluorescence-based assays. Finally, the data suggest that the fluorescent dye that exhibits the highest signal-to-noise ratio is not necessarily the best dye for any desired application. It is also important to consider experimental details such as the excitation intensity, the optimum solvent conditions, and the protein/peptide or DNA/RNA sequence of the probe or target molecule.

# Capture of Peptides with N-Terminal Serine and Threonine: A Sequence-Specific Chemical Method for Peptide Mixture Simplification

Dirk Chelius\* and Thomas A. Shaler

Thermo Finnigan, 355 River Oaks Parkway, San Jose, California. Received September 13, 2002;  
Revised Manuscript Received October 24, 2002

The objective of this study was to evaluate a sequence-specific chemistry for the ability to specifically capture peptides that contain N-terminal serine or threonine residues from mixtures. The first step is the oxidation of the 1,2-amino alcohol structure  $-\text{CH}(\text{NH}_2)\text{CH}(\text{OH})-$  of peptides containing N-terminal serine or threonine with periodate. The newly formed aldehyde reacts with a labeling reagent containing a hydrazide,  $\text{RCONHNH}_2$ , to form a hydrazone-peptide conjugate,  $\text{RCONHN}=\text{CH}-$  peptide. Biotin-labeled conjugates can then be isolated by affinity purification with streptavidin. The method described in this report can be useful in simplifying the complex mixtures of peptides that are generated in typical proteomic analysis, where proteins are digested with trypsin and analyzed using liquid chromatography mass spectrometry data. The sequence-specific peptide selection not only reduces the complexity of digest mixtures, but also provides additional information for peptide identification. The targeted peptides are those that have either serine or threonine adjacent to a protease cleavage site. The sequence information should greatly aid in both database matching for protein identification and for de novo sequence determination.

## INTRODUCTION

Large-scale analysis of a proteome typically includes separation of complex biological mixtures into individual proteins followed by the identification of the fractionated proteins. Typically, two-dimensional gel electrophoresis followed by mass spectrometry analysis is used (1–3). Alternative methods are based on two-dimensional chromatography coupled with mass spectrometry (4). The identification of proteins in both approaches includes tryptic digestion of the protein and identification of the tryptic peptides either directly by mass or by fingerprinting of these peptides during tandem mass spectrometry. Large numbers of peptides are typically generated during such experiments and the separation and identification remains a challenge.

The objective of this study was to develop a method to reduce the large number of peptides that are generated during large-scale protein identification techniques. To evaluate if peptides containing N-terminal serine or threonine are distributed in sufficient amounts in all proteins, a computer program was written to generate and identify all peptides that fit the criteria from the *C. elegans* database.

The sequence-specific chemistry to isolate peptides containing N-terminal serine or threonine residues was optimized for our purpose, including oxidation with periodate, linkage to biocytin hydrazide, and binding and release from streptavidin-coated beads. The oxidation by periodate of N-terminal 1,2-amino alcohols serine ( $\text{R} = \text{CH}_2\text{OH}$ ) or threonine [ $\text{R} = \text{CH}(\text{OH})\text{CH}_3$ ] residues  $\text{NH}_2-\text{CHR}-\text{CO}-$  of a polypeptide to an aldehyde func-

tion  $\text{O}=\text{CH}-\text{CO}-$  has been known for many years (5). This mild oxidation has been exploited for the synthesis of bioconjugates through formation of hydrazone, thiazolidine, or oxime ( $-\text{ON}=\text{CH}-\text{CO}-$ ) bonds (6–11). Reaction of the aldehyde with a hydrazide was reported to be very effective and could be achieved quantitatively (6). The conjugation reaction was used to generate biocytinylated peptides that could be isolated on streptavidin-coated beads. The biocytin is similar to biotin and has a very strong affinity to streptavidin. Elution of the captured peptides could be achieved by incubation in acid conditions.

The results presented in this study described a method to specifically capture peptides containing N-terminal serine or threonine residues. The method can potentially lead to improvements in large-scale protein identification strategies. Additionally the potential for an alternative method for protein quantitation similar to the isotope-coded affinity tags (ICAT) method is demonstrated (12).

## EXPERIMENTAL PROCEDURES

**Theoretical Modeling.** Bioinformatic modeling of theoretical digests and the simplifications resulting for different types of peptide selection for the *C. Elegans* database was performed with software written in-house. The *C. Elegans* protein database was obtained from the National Center for Biotechnology Information (NCBI).

**Chemistry.** Ten microgram pure peptides (Sigma, St. Louis, MO) or peptide mixtures (Table 1) were incubated with 10  $\mu\text{L}$  sodium periodate (40  $\mu\text{mol}$ ) in 20  $\mu\text{L}$  PBS (pH 7.2) at room temperature for 10 min in the dark. Peptides were exchanged into 100 mM sodium acetate (pH 4.5), and 100  $\mu\text{g}$  biocytin hydrazide (EZ-Link, Pierce, Rockford, IL) was added. The mixture was incubated for 1 h at room temperature and then incubated with streptavidin-coated magnetic beads (CPG Inc., Palo Alto, CA). After 1 h at room temperature, the beads were washed five times

<sup>a</sup> Peptides were analyzed by LC/MS as described in the Experimental Procedure section. Although ions were observed in a variety of multiple charge states, observed masses are calculated as molecular masses of neutrals. The masses are identified as average.

**Figure 1.** Bioinformatic modeling of theoretical digests and the simplifications resulting for different types of peptide selection for the *C. Elegans* database (NCBI) was performed with software written in-house. A: Distribution of the numbers of peptides per protein generated by tryptic digestion from *C. Elegans* database. B: Peptides per protein containing cysteine residues from tryptic digestion of the *C. Elegans* database. C: Peptides per protein containing N-terminal serine or threonine residues from tryptic digestion of the *C. Elegans* database.

with the sodium acetate buffer to remove nonbiotinylated peptides. The aldehyde form of the peptides could be eluted from the beads by incubation of the beads at 60 °C for 1 h in 10% formic acid. Each step in the reaction scheme (Figure 2) was monitored by LC/MS/MS on an LCQ DECA ion trap mass spectrometer (Thermo Finnigan, San Jose, CA).

**Sample Analysis.** The peptide samples were analyzed using a fully automated nanoflow LC/MS/MS system (13). Aliquots of the sample digest (250 fmol each peptide) were placed in wells of a 96-well plate (Nalge Nunc International, Rochester, NY). The plate was sealed with plastic film to minimize evaporation and inserted into the auto-sampler of a Surveyor HPLC system (Thermo-Finnigan, San Jose, CA), where it was kept at 4 °C while waiting for analysis. The auto-sampler was equipped with no-waste injection capability, which enables injection volumes as low as 1  $\mu$ L. The injected peptides were first loaded onto a reversed-phase poly(styrene-divinylbenzene) peptide trap (Michrom Bioresources, Auburn, CA) with a flow rate of 10  $\mu$ L/min for 3 min. The peptides were eluted from the trap and separated on a reversed-phase capillary column (PicoFrit; 5  $\mu$ m BioBasic C18, 300 Å pore size; 75  $\mu$ m  $\times$  10 cm; tip 15  $\mu$ m, New Objective, Woburn, MA) with a 30 min linear gradient of 0–60% acetonitrile in 0.1% formic acid/water at a flow rate of

approximately 0.1  $\mu$ L/min after split. The HPLC was directly coupled to a ThermoFinnigan LCQ Deca ion trap mass spectrometer equipped with a nano-spray ionization source. The spray voltage was 2.0 kV, and the capillary temperature was 200 °C. The ion-trap collisional fragmentation spectra were obtained using collision energies of 35%. Each full-scan mass spectrum was followed by one MS/MS spectra of the most intense peak. Full mass spectra and tandem mass spectra were analyzed manually by comparing the data with the predicted data based on the amino acid sequence of the peptides.

## RESULTS

**Computer Modeling.** A computer program was written to generate and identify all peptides from a tryptic digest that contain N-terminal serine or threonine residues from the *C. elegans* database. The results are summarized in Figure 1. Only 1500 proteins from the *C. elegans* database do not contain such peptides (Figure 1C). Therefore, our proposed method of peptide reduction would not be able to identify these proteins. However, the *C. elegans* database contains 63 394 proteins, so that only 2.3% of all proteins would be missed. This result was compared to peptides containing cysteine residues (Figure 1b). Capture of cysteine residue is commonly used for reduction of peptide complexity and for quantitation

**Table 2. Calculated and Observed Molecular Weights (MW) of Peptides after Oxidation with Periodate<sup>a</sup>**

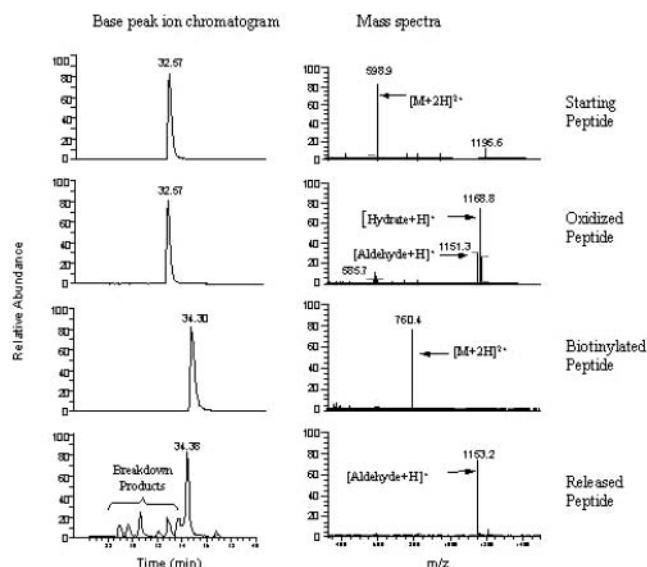

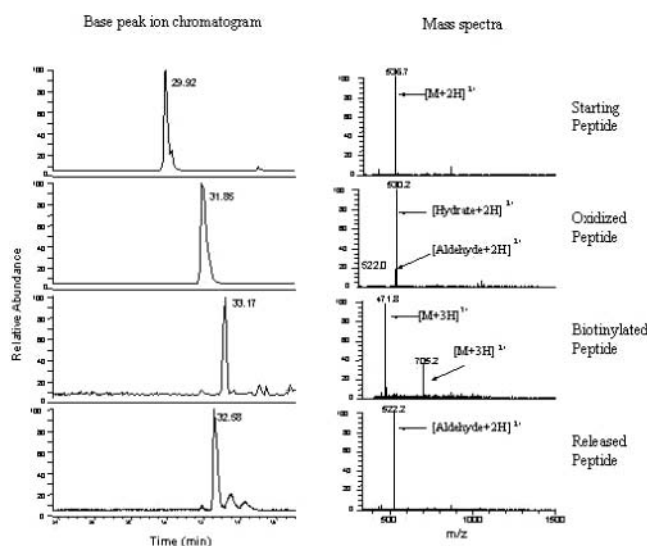

#	<i>m/z</i>	observed MW	calculated MW (hydrate)	calculated MW (aldehyde)
1	1151.3 (1 <sup>+</sup> ); 1168.8 (1 <sup>+</sup> )	1150.3; 1167.8	1168.3	1150.3
2	646.9 (2 <sup>+</sup> );	1291.8	1291.4	1273.4
3	530.2 (2 <sup>+</sup> ); 522.0 (2 <sup>+</sup> )	1058.4; 1042.0	1058.3	1040.3
4	588.0 (2 <sup>+</sup> ); 1173.6 (1 <sup>+</sup> )	1174.0	1173.4 <sup>b</sup>	—

<sup>a</sup> Peptides were oxidized with periodate and the products were analyzed by LC/MS as described in the Experimental Procedures section. Although ions were observed in a variety of multiple charge states, observed masses are calculated as molecular masses of neutrals. The masses are identified as average. <sup>b</sup> The molecular weight of peptide 4 MNLYAFPRM was calculated under the assumption that both methionines were oxidized which correlates to the addition of 32 Da to the molecular weight.

**Figure 2.** Schematically representation of the peptide derivatization chemistry performed in this study.

applications such as the ICAT method. The distribution of cysteine containing tryptic peptides is similar to the distribution of tryptic peptides containing N-terminal serine or threonine residues. The result demonstrates that our proposed method would generate sufficient amounts of peptides to identify more than 97% of all proteins of the *C. elegans* database.

**Chemistry.** The four peptides used in this study, including two peptides with N-terminal serine residue and one peptide with N-terminal threonine residue, were analyzed by LC/MS/MS analysis to ensure the purity and to confirm the molecular weight. The results are summarized in Table 1. The oxidation of N-terminal 1,2 amino alcohols with periodate was optimized using one synthetic peptide containing a N-terminal threonine residue and one peptide containing an N-terminal serine residue. Oxidation of peptide 1 (TFQAYPLREA) resulted in the formation of the aldehyde form and the aldehyde-hydrate form (to be referred to as hydrate). The calculated molecular weight and the measured molecular weight are shown in Table 2. The singly charged ion with an *m/z* value of 1151.3 correlates well with the calculated molecular weight of the aldehyde (1150.3). Additionally the hydrate form could be detected with an *m/z* value of 1168.8 (calculated 1168.3). The corresponding chromato-

See the Experimental Procedures for details.**Figure 4.** LC/MS/MS analysis of reaction products after each step during capture of peptide 3 (SIPSKDALLK). See the Experimental Procedures for details.

grams and mass spectra are shown in Figure 3. The reaction was found to be quantitative. Similar results could be obtained with the oxidation of peptide 3 (SIPSKDALLK). The doubly charged ions with *m/z* values of 522.0 and 530.2 correspond to peptides with apparent molecular weight of 1042.0 and 1058.4 Da, which agrees well with the calculated molecular weight for the aldehyde (1040.4 Da) and the hydrate-form (1058.3). The results are shown in Table 2 and Figure 4. The alde-

hyde-hydrate was the major product in both reactions. Incubation of the oxidation products with biocytin hydrazide yields the biocytinylated peptides. For peptide **1** the bioconjugate was calculated to have a molecular weight of 1518.8 (the molecular weight of the linker 386.5 Da plus the molecular weight of the aldehyde 1150.3 Da minus 18 ( $\text{H}_2\text{O}$ ) = 1518.8). This correlates very well with the major peak found in the chromatogram, where the doubly charge ion of 760.4 corresponds to a molecular weight of 1518.8 Da (Figure 3). The conjugation reaction of peptide **3** shows two major peaks with  $m/z$  values of 471.8 ( $3^+$ ) and 705.2 ( $2^+$ ), corresponding to a molecule with a molecular weight of  $1410.4 \pm 2.0$  Da (Figure 4). This corresponds well with the calculated molecular weight of peptide **3** linked to biocytin hydrazide of 1408.8 Da (same calculation as above). The reaction appears to be quantitative on the basis of the chromatogram. In the final step the biocytinylated peptides were bound to streptavidin-coated beads, washed and eluted with 10% formic acid. LC/MS analysis of the eluted samples showed the aldehyde form of either peptide **1** or peptide **3** as major peaks. Elution of peptide **1** shows one major peak with an  $m/z$  value of 1153.2 corresponding to the aldehyde form of peptide **1** (Figure 3). Several smaller peaks could be detected but not identified. Most likely, these peaks correspond to breakdown products of peptide **1**. Elution of peptide **3** shows one major peak with an  $m/z$  value of 522.2, corresponding to the aldehyde form of peptide **3** (Figure 4). Additionally, several smaller peaks could be also detected but not identified. LC/MS analysis of the products after every step of chemical synthesis confirms that the peptide modifications were performed as planned and complete.

The method was further evaluated to test if this approach could be used to specifically capture peptides, which contain N-terminal serine or threonine residues from a mixture of four synthetic peptides, two containing N-terminal serine (peptide **2** SGQSWRPQGRF and peptide **3** SIPSKDALLK), one containing N-terminal threonine (peptide **1** TFQAYPLREA), and one containing neither N-terminal serine nor threonine but N-terminal methionine (peptide **4** MNYLAFPRM). The peptide mixture was first oxidized with periodate as described in the Experimental Procedure section. The sample mixture was analyzed by LC/MS, and the results are shown in Figure 5. The four major peaks in the chromatogram could be identified as the oxidized isoforms of peptides **1**, **2**, **3**, and **4**. The aldehyde form and the hydrate form of peptide **1** (calculated MW of 1150.3 and 1168.3 Da) can be identified as a singly charged ions with an  $m/z$  value of 1151.4 and 1167.8, respectively. The doubly charge ion with an  $m/z$  value of 646.9 corresponds to the hydrate form of peptide **2**, and the doubly charge ions with an  $m/z$  value of 521.7 and 530.3 corresponds to the aldehyde form and the hydrate form of peptide **3**. Additionally peptide **4** was identified in the oxidized form as a doubly charged ion with an  $m/z$  value of 588.0 and a singly charge ion with an  $m/z$  value of 1173.6. The observed molecular weight of peptide **4** differs by 32 from the calculated molecular weight of peptide **4** (1141.4). The difference can be explained with the oxidation of the two methionines in peptide **4**. The oxidized peptide mixture was incubated with biocytin hydrazide as described in the Experimental Procedures section, and the bioconjugates were bound to the streptavidine-coated beads. After several washing steps to remove all unspecific bound material, the peptides were eluted with 10% formic acid as described in the Experimental Procedures section. The eluate was analyzed by LC/MS/MS, and the ion chromatograms and

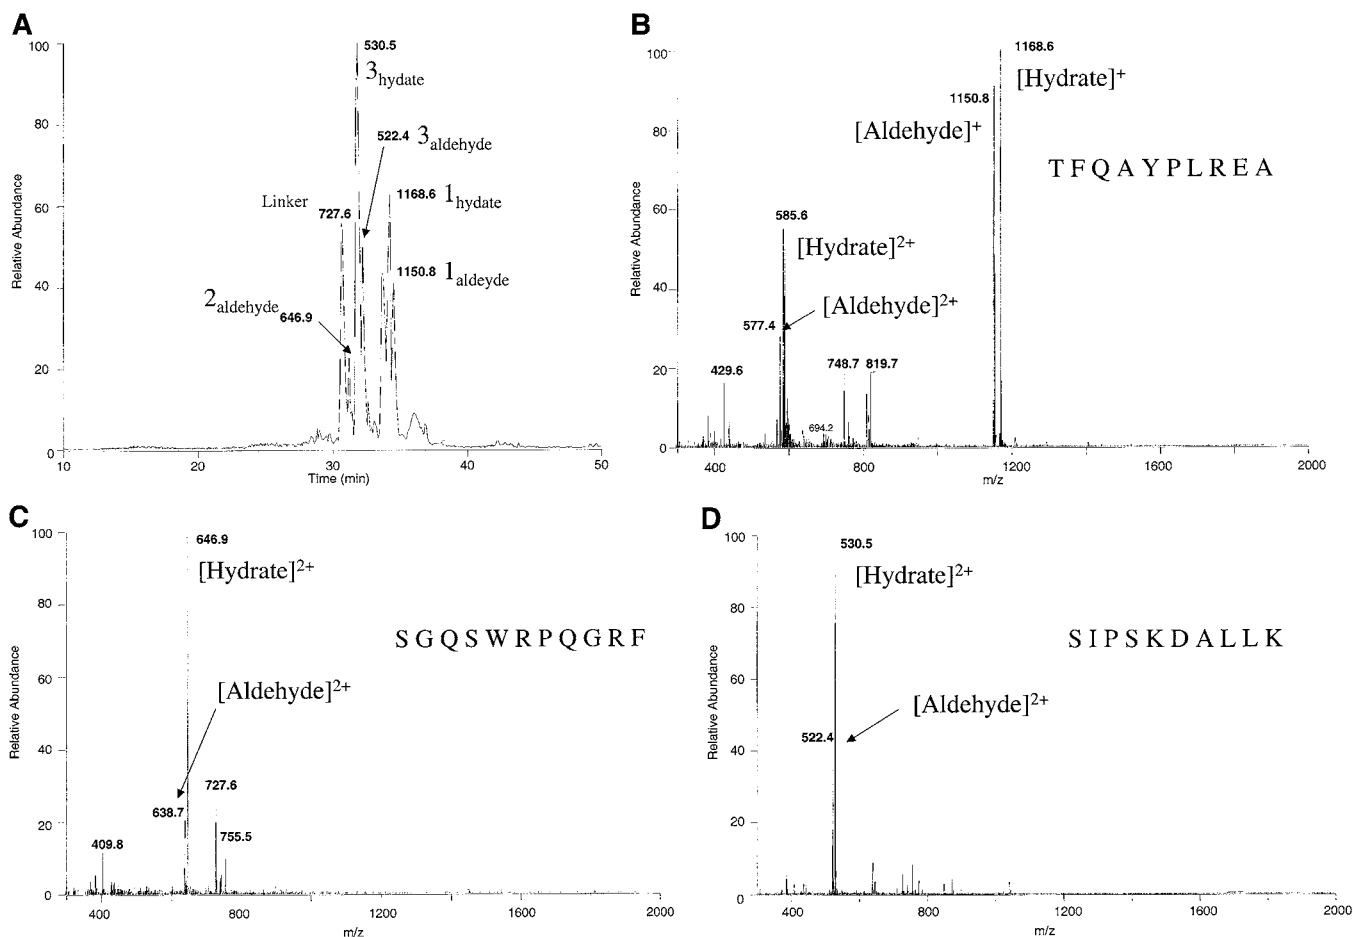

**Figure 5.** LC/MS/MS analysis of the four peptides after oxidation with periodate. See the Experimental Procedures for details. The amino acid sequence of the four peptides is shown in Table 1. The full-scan mass spectrum is the sum of all mass spectra recorded during the elution of the peptides (elution time: 28–35 min).

mass spectra are shown in Figure 6. As predicted peptide **4** could not be identified. However, peptides **1**, **2**, and **3** could be identified as both, the aldehyde form and the hydrate form. Peptide **1** showed ions with  $m/z$  values of 1150.8 ( $1^+$ ) and 577.4 ( $2^+$ ) that correlate well with the predicted molecular weight of the aldehyde form of peptide **1** (see Table 2). Additionally the hydrate form of peptide **1** could be identified as singly charge ion with a  $m/z$  value of 1168.6 (calculated molecular weight of hydrate 1168.3 Da) and as a doubly charged ion with a  $m/z$  value of 585.6. Peptide **2** could be identified as doubly charge ions at  $m/z$  values of 646.9 (hydrate) and 638.7 (aldehyde), and peptide **3** could be identified as doubly charged ions with  $m/z$  values of 530.5 (hydrate) and 522.4 (aldehyde) (see Table 2). Additionally a species with an  $m/z$  value of 727.6 (singly charged ion) could be detected. Fragmentation of the 727.6 ion resulted in a major peak with an  $m/z$  value of 387.4 (data not shown), which correlates with the molecular weight of the linker (386.5) indicating that the unidentified peak at 727.6 might be a linker related adduct. The results demonstrated that the peptide modifications were performed as planned and the specific capture of peptides, containing N-terminal serine or threonine residues was successful.

## DISCUSSION

Analysis of the theoretical tryptic digest of the *C. elegans* database showed that 1500 proteins do not generate tryptic peptides that contain N-terminal serine or threonine residues. These proteins could not be identified if the proposed method for protein identifications would be used. However, the NCBI database contains a

**Figure 6.** A mixture of peptides 1–4 (the amino acid sequences of the peptides are shown in Table 1) was oxidized and biotinylated as described in the Experimental Procedures section. The biotinylated peptides were captured on magnetic beads and released by acid hydrolysis. The eluate was analyzed by LC/MS/MS as described in the Experimental Procedures section. A: Base peak ion chromatogram. B: Full mass spectra at a retention time of 34.2 min (peptide 1 TFQAYPLREA). C: Full mass spectra at a retention time of 31.3 min (peptide 2 SGQSWRPQGRF). D: Full mass spectra at a retention time of 32.0 min (peptide 3 SIPSKDALLK).

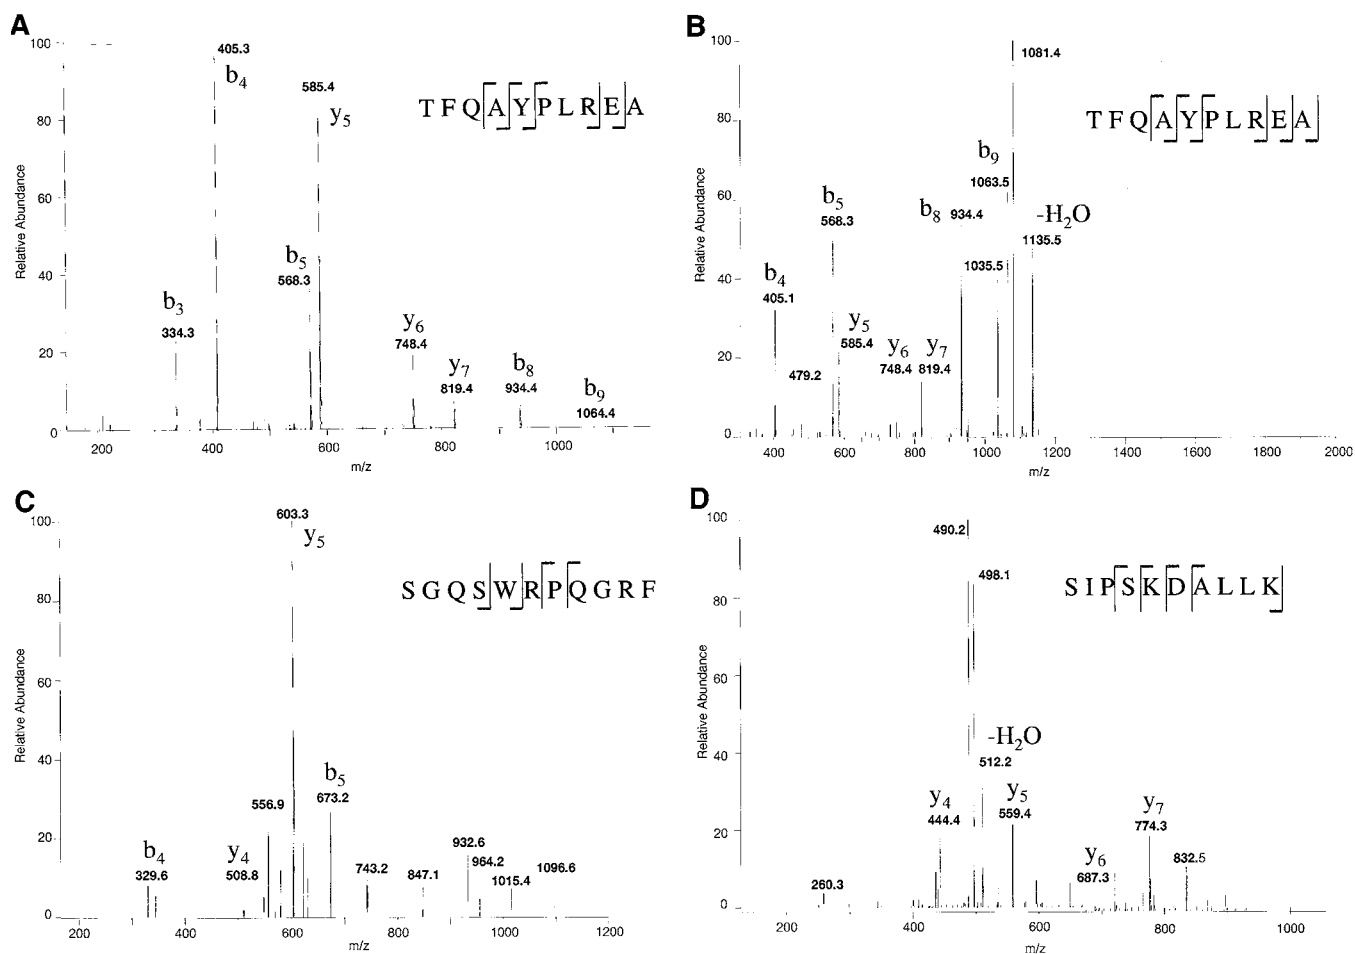

total of 63394 protein entries for *C. elegans* so that only 2.3% of all proteins would be missed. The reduction of total numbers of peptides in a complex mixture should greatly enhance the peptide ionization efficiency during electrospray process and should therefore facilitate the identification of low abundant proteins. The percentage of proteins missed using this technology depends on the database and it is possible that more proteins would be missed for other organisms. The ICAT (isotope-coded affinity tags) method for protein quantitation uses cysteine residues to specifically label and isolate certain peptides (12). The distribution of tryptic peptides containing cysteine residues is very similar to tryptic peptides containing N-terminal serine or threonine residues in the *C. elegans* database. The distribution of tryptic peptides containing cysteine or N-terminal serine or threonine residues might also be different for other databases.

After theoretical proof of the concept, that indeed the capture of peptides containing N-terminal serine or threonine residues could reduce the complexity of a complex mixture of tryptic peptides without losing a significant amount of protein information, a chemistry was developed to capture those peptides. The oxidation of N-terminal 1,2 amino alcohols serine or threonine with periodate was optimized. Alcohols were converted to aldehydes within 10 min reaction time, and the reaction was found to be quantitative. The aldehyde is in equilibrium with the diol form (in the text revert to as aldehyde–hydrate or hydrate), and under the conditions

used in this experiment, the hydrate form is the predominant species. This fact does not affect the next reaction step with hydrazide as shown in results. The reaction was performed under mild conditions however oxidation of methionine was also observed. This unwanted side reaction should not present any problems for our proposed method, since oxidation of methionine to the thiol form seems to be quantitative, too.

The next step was the linkage of the generated aldehydes to the biocytin hydrazide reagent. The reaction was also found to be quantitative demonstrating that our method of specifically labeling peptides containing N-terminal serine or threonine was successful. As expected, peptides that do not contain N-terminal serine or threonine do not react with the biocytin hydrazide.

Finally the labeled peptides could be bound to streptavidin-coated beads, allowing the isolation of the labeled peptides. Elution of the peptides was found to be somewhat tricky. The biocytin–streptavidine interaction is very strong. In fact, initial attempts to remove the peptides with guanidine hydrochloride and incubation at high temperature resulted in very bad yields (data not shown). Fortunately the peptides could be released by incubation in 10% formic acid at 60° for 30 min. The chemistry was not studied in detail, however hydrolysis of hydrazone bonds is well reported in the literature (6). The main product for the three peptides tested was the aldehyde form of those peptides. Several other fragments could be eluted from the beads. These fragments could not be identified but are most likely breakdown product

**Figure 7.** Tandem mass spectra analysis of peptides eluted from the streptavidin-coated magnetic beads (see Experimental Procedures for details). The full scan mass spectra are shown in Figure 6B–D. A: Tandem mass spectrum derived by collision induced dissociation of the  $(M + 2H)^{2+}$  precursor ion,  $m/z = 577.4$  of peptide **1** (retention time 34.2). B: Tandem mass spectrum derived by collision induced dissociation of the  $(M + H)^+$  precursor ion,  $m/z = 1150.8$  of peptide **1** (retention time 34.2). C: Tandem mass spectrum derived by collision induced dissociation of the  $(M + 2H)^{2+}$  precursor ion,  $m/z = 646.9$  of peptide **2** (retention time 31.3). And D: Tandem mass spectrum derived by collision induced dissociation of the  $(M + 2H)^{2+}$  precursor ion,  $m/z = 522.4$  of peptide **3** (retention time 32.0). Fragment ions in all four spectra represent mainly singly event preferential cleavage of the peptide bonds resulting in the sequence information recorded from both N (b-ions) and C (y-ions) termini of the peptides simultaneously.

of the bioconjugates. Either peptide bonds are hydrolyzed under the acid conditions or other parts of the linker are labile to acid hydrolyzation.

Clearly the acid hydrolysis for peptide release is not the optimal solution. Although all three peptides could be identified, the appearance of additional peptide fragments is not desirable and could complicate the peptide identification. However, several linkers are commercially available that contain a cleavable linker attached to a biotin or biocytin label and a hydrazine reactive group. The use of such linkers should greatly enhance the yield of our proposed method and reduce the formation of breakdown products. Additionally one could imagine the construction of linkers, which are different only in certain isotopes that could be used similar to the ICAT method in protein quantitation (12). The idea behind such quantitation method is the labeling of control and experimental sample with tags that are different in mass but chemically identical ( $H/D$  or  $C^{12}/C^{13}$ ). After labeling, the control and experimental samples are combined and differences in the protein profile can be analyzed by comparing the signal intensity of the labeled peptides. The labeling of peptides containing N-terminal serine or threonine residues could complement the ICAT method, which labels peptides containing cysteine residues.

The huge advantage of our proposed method becomes obvious when looking at the tandem mass spectra in

Figure 7. Although all peptides could be identified in the full mass spectra, the tandem mass spectra frequently do not contain sufficient fragmentation information for automatic peptide identification. Our method is sequence-specific, and the targeted peptides are those that have either serine or threonine adjacent to a protease cleavage site. This additional sequence information should greatly aid in both database matching for protein identification and for de novo sequence determination.

## CONCLUSIONS

Peptides that contain serine or threonine at the N-terminus can be specifically modified and captured from mixtures. The initial oxidation step with periodate occurs under mild conditions and is rapid and quantitative, although methionine sulfoxide formation occurs. Treatment of the N-terminal aldehydes with biocytin hydrazide allows the modified peptides to be tagged with affinity selection groups. These bioconjugates can be captured on streptavidin-coated magnetic beads. The release of the peptide aldehydes from the solid support was achieved by acidic hydrolysis of the hydrazone. This release reaction can lead to peptide degradation. However, all peptides containing N-terminal serine or threonine could be isolated from a mixture of peptides with this method. The described approach to simplify complex

peptide mixture could have an impact on large-scale protein identification and quantification.

Received September 16, 2002; Revised Manuscript Received October 9, 2002

A series of vanadium compounds, chelated by ligands containing a thiazolidinedione moiety as an additional insulin-enhancing component, were produced in this study to create potentially synergistic compounds. A set of four bifunctional ligand precursors were synthesized: ( $\pm$ )-5-[4-[(5-hydroxy-4-oxo-4H-pyran-2-ylmethyl)amino]benzyl]thiazolidine-2,4-dione (HL<sup>1</sup>), ( $\pm$ )-5-[4-[(5-hydroxy-1-methyl-4-oxo-1,4-dihydro-pyridin-2-ylmethyl)amino]benzyl]thiazolidine-2,4-dione (HL<sup>2</sup>), 5-[4-(5-hydroxy-4-oxo-4H-pyran-2-ylmethoxy)benzylidene]thiazolidine-2,4-dione (HL<sup>3</sup>), and ( $\pm$ )-5-[4-(5-hydroxy-4-oxo-4H-pyran-2-ylmethoxy)benzyl]thiazolidine-2,4-dione (HL<sup>4</sup>), each containing a metal chelating portion as well as a thiazolidinedione moiety. From this set of ligand precursors, air-stable VO(L<sup>1</sup>)<sub>2</sub>, VO(L<sup>3</sup>)<sub>2</sub>, and VO(L<sup>4</sup>)<sub>2</sub> were prepared. The four ligand precursors and three complexes were tested for insulin-enhancing potential in STZ-diabetic rats and compared to rosiglitazone and BMOV, respectively. Both the ligand precursors HL<sup>1</sup> and HL<sup>3</sup> showed enhanced activity compared with that of rosiglitazone. The complex VO(L<sup>3</sup>)<sub>2</sub> showed the most efficacious hypoglycemic effects in this study; however, neither additive nor synergistic effects were observed using this acute animal model.

## INTRODUCTION

Diabetes mellitus includes a heterogeneous group of diseases which have become an important health concern in our society, affecting 1 in 20 persons in industrialized nations. The disease is characterized by hyperglycemia, alterations in carbohydrate and lipid metabolism, and vascular and neurological complications. It can be roughly divided into two classes: type 1, insulin-dependent diabetes mellitus (IDDM), and type 2, non-insulin-dependent diabetes mellitus (NIDDM). Treatment may involve daily subcutaneous injections of insulin (most common for type 1), diet and exercise, administration of one or more of the currently available hypoglycemic agents (type 2), or combination therapy. Numerous therapies designed to supplement or enhance insulin action have been developed to aid in the treatment of NIDDM. Combined with diet and exercise, these regimens have proven to be fairly effective, but none are ideal. Thus, there is a need to find effective, orally active drugs that mimic or enhance the properties of insulin.

Vanadium was first demonstrated to have insulin-like properties in vitro in 1979 (1), in skeletal muscle and adipose tissue, and in vivo in 1985 (2). Since this time there has been a great deal of interest in determining the biological role of vanadium, including its mechanism of action, and in the development of new vanadium

compounds as alternatives to conventional diabetes therapy. The mechanism of vanadium's in vivo effects has been the subject of much debate (3–8), most probably due to the multiplicity of its effects (5, 9). Current evidence points to a site (or sites) of action downstream from the insulin receptor (10) in the insulin signaling cascade. The therapeutic value of inorganic vanadium, in the form of vanadate ([VO<sub>4</sub>]<sup>3-</sup>) or vanadyl ([VO]<sup>2+</sup>), as an orally active agent against diabetes has been well documented (5, 11). Poor absorption from the gastrointestinal tract (GI) into the bloodstream, as well as a narrowness of the window of optimal effectiveness in vivo, limits the utility of administering vanadium to diabetic patients in this form. However, vanadium complexes such as bis(maltolato)oxovanadium(IV), commonly known by its acronym BMOV (12, 13) (Chart 1), have shown increased efficacy over inorganic vanadium in STZ-diabetic rat studies (14). BEOV (the ethyl analog) has recently completed phase 1 human clinical trials. Complexation of vanadyl ([VO]<sup>2+</sup>) with the approved food additive maltol improved GI (gastrointestinal) absorption, thereby decreasing the vanadium dose required for effective glucose lowering (14, 15). Numerous small ligands have been subsequently used in this manner to increase the potency of the vanadium center (15, 16). In an effort to further increase the efficacy of the drug candidates, the coupling of vanadium with a ligand that contains an insulin-action-enhancing drug has been explored (17). The coupling of vanadyl with a series of biguanides failed to produce additive or synergistic effects; however, this was most likely due to the large dosage differences required for these two classes of drugs (17–19). In an advance on this approach herein, we have chelated the vanadium center to a series of thiazolidinedione-containing ligands; dosage differences be-

**Chart 3**

tween oxovanadium(IV) compounds and representative thiazolidinediones are small (18, 20).

The thiazolidinediones are named for the five-membered heteronuclear ring common to all compounds of this class (Chart 2). Of the thiazolidinedione compounds, ciglitazone, troglitazone, englitazone, pioglitazone, and rosiglitazone have been clinically examined as potential antidiabetic compounds (21). Both pioglitazone and rosiglitazone are available on the market for the treatment of type 2 diabetes. Thiazolidinediones act by indirectly enhancing peripheral insulin sensitivity, thereby lowering the levels of both glucose and insulin (22). Thiazolidinediones are known to activate the peroxisome proliferator-activated receptor gamma ( $PPAR\gamma$ ).  $PPAR\gamma$  regulates numerous metabolic pathways involving lipoprotein lipase, glucose transporters and insulin signaling pathways (23). Nonetheless, binding affinity of the thiazolidinediones for  $PPAR\gamma$  does not always correlate with euglycemic activity (24). A major benefit of the thiazolidinediones is that unlike sulfonylurea derivatives,  $\alpha$ -glucosidase inhibitors, or insulin, they influence insulin resistance. Compounds which improve insulin resistance enable the continued treatment of NIDDM patients without inducing hypoglycemia (21).

To form stable neutral complexes with the vanadyl ion, bifunctional ligands were developed, tethering the active portion of the thiazolidinedione molecule to a suitable chelator. Kojic acid **1** (Chart 3) was chosen for this purpose because, like maltol, it forms water soluble, neutrally charged complexes with appropriate metal ions (25). Simple kojic acid complexes with  $VO^{2+}$  have shown

significant antidiabetic activity (16). The planar ring system of kojic acid was also well suited for interacting with the binding domain of the  $PPAR\gamma$  receptor (26). It was hypothesized that kojic acid would be the most versatile binding moiety, as the planar ring system is also capable of chelating vanadium.

The concept of combining vanadium and a thiazolidinedione-containing ligand to form a compound that exhibits additive or synergistic effects is quite appealing. The preparation and characterization of a series of such bifunctional ligand precursors and their associated oxovanadium(IV) complexes are presented herein. Results from preliminary acute STZ-diabetic rat studies of four ligand precursors and three of the corresponding complexes are also reported and compared to rosiglitazone and BMOV, respectively.

## RESULTS AND DISCUSSION

**Ligand Preparation.** All four ligand precursors **HL**<sup>1</sup>, **HL**<sup>2</sup>, **HL**<sup>3</sup>, and **HL**<sup>4</sup> were prepared by various routes from kojic acid **1**. Kojic acid **1** was first protected at the ring hydroxyl using the method of Thomas and Marxer (27) to afford the benzyl protected compound **2**. This compound was further elaborated to synthesize the four distinct ligand precursors. An effort was made to preserve the active portion of the thiazolidinediones (the 5-(4-substituted-benzyl)thiazolidine-2,4-dione moiety) in these bifunctional ligands (Chart 2).

For the amino-tethered ligand (Scheme 1), 5-benzyloxy-2-hydroxymethyl-pyran-4-one **2** was reacted with methanesulfonyl chloride to afford the mesylate **3**. Compound **3** was then coupled with ( $\pm$ )-5-(4-amino-benzyl)thiazolidine-2,4-dione **6**, which was synthesized by a more direct route than that available in the literature (28), to afford **7**. To synthesize **6**, 4-nitrobenzaldehyde **4** was coupled with thiazolidine-2,4-dione using reported conditions (29) to afford **5**, which was then reduced using  $NaBH_4$  in the presence of a cobalt/dimethylglyoxime catalyst formed in situ (30). Using this method, both the nitro group and the double bond were reduced simultaneously. Benzyl group removal from the coupled product **7** in strong acid afforded the amino-tethered thiazolidinedione ligand **HL**<sup>1</sup>.

Synthesis of the pyridinone-type ligand (Scheme 2) proceeded in much the same manner as with **HL**<sup>1</sup>. A pyridinone-type chelator was examined because N-substitution into a pyrone ring has been shown to increase metal binding affinity (31, 32). Benzyl-protected kojic acid **2** was reacted with methylamine to form the pyridinone **8** in an improved yield over that reported (33). Compound **8** was then converted to the chloride **9** with thionyl chloride in good yield. The coupling step proceeded to give the protected compound **10** from which the benzyl group was removed to afford the pyridinone-type ligand precursor **HL**<sup>2</sup>.

The unsaturated ether-tethered ligand (Scheme 3) **HL**<sup>3</sup> was synthesized using the mesylate **3** as the starting material. Compound **3** was coupled with 4-hydroxybenzaldehyde to afford the aldehyde **11**, which then underwent a Knoevenagel condensation with thiazolidine-2,4-dione to yield compound **12**. The original intent at this point was to reduce the C–C double bond connecting the thiazolidinedione ring. Unfortunately we were not able to effect this transition selectively, despite employing a variety of conditions, because of the many other unsaturation points in the molecule. Because previous work (34, 35) had shown that the activity of certain thiazolidinediones with an unsaturation point in an identical

**Scheme 1. location exhibited equal or more impressive activity than their saturated analogues, we decided to continue by deprotecting **12** to form the unsaturated ether-tethered ligand **HL<sup>3</sup>**.

The ether-tethered ligand (Scheme 4) **HL<sup>4</sup>** was synthesized in a manner similar to that employed for **HL<sup>1</sup>**. In this case 5-benzyloxy-2-chloromethyl-pyran-4-one **13** was used in the coupling step because the mesylate **3** did not afford any coupled product. The slower reactivity of the chloride derivative presumably minimized side-reactions allowing the coupling reaction to take place. Compound **13** was coupled with 5-(4-hydroxy-benzyl)-thiazolidine-2,4-dione (**28**) **16**, which was synthesized by a Knoevenagel condensation of 4-hydroxybenzaldehyde **14** with thiazolidine-2,4-dione to form **15**, and then subsequent reduction. The coupled product **17** was then deprotected to afford the ether-tethered ligand **HL<sup>4</sup>**. The low yield of the coupling step here is most likely because of the similar nucleophilicities of the thiazolidinedione

nitrogen and the ring hydroxyl oxygen of compound **16**. Indeed, both coupling products were isolated, with the O-alkylation product occurring in a higher proportion.

The saturated ligand precursors **HL<sup>1</sup>**, **HL<sup>2</sup>**, and **HL<sup>4</sup>** are presumed to exist as a mixture of enantiomers with the stereogenic center located at C-5 of the thiazolidinedione ring. No attempt was made to synthesize or isolate selectively one enantiomer because this center is prone to rapid racemization at physiological pH (36). Interestingly, it has been reported that the (S)-(−)-enantiomer of rosiglitazone **5** was responsible for the binding affinity to PPAR $\gamma$  with a  $t_{1/2}$  for racemization of 3 h at pH 7.2(36).

**Vanadyl–Thiazolidinedione Complexes.** The neutral oxovanadium(IV)–thiazolidinedione complexes were prepared (Scheme 5) by refluxing vanadyl sulfate and two equivalents of the appropriate ligand precursor in mildly acidic aqueous medium (pH ~5). The precipitated products were isolated and washed with water and

**Scheme 4. The Synthesis of VO(L<sup>1</sup>)<sub>2</sub> (83%), VO(L<sup>3</sup>)<sub>2</sub> (93%), and VO(L<sup>4</sup>)<sub>2</sub> (88%)<sup>a</sup>**<sup>a</sup> VOSO<sub>4</sub>, H<sub>2</sub>O.

diethyl ether to afford, after drying in vacuo light brown, gray, and brown solids, characterized as VO(L<sup>1</sup>)<sub>2</sub>, VO(L<sup>3</sup>)<sub>2</sub>, and VO(L<sup>4</sup>)<sub>2</sub>, respectively. Unfortunately, the extremely low solubility of the pyridinone-type ligand HL<sup>2</sup> precluded complexation to vanadium under a variety of conditions.

Characteristic stretching frequencies of the V=O bond in oxovanadium(IV) complexes generally occur in the region 930–1030 cm<sup>-1</sup> (37). The complexes VO(L<sup>1</sup>)<sub>2</sub>, VO(L<sup>3</sup>)<sub>2</sub>, and VO(L<sup>4</sup>)<sub>2</sub> exhibit V=O stretching frequencies of 982, 985, and 975 cm<sup>-1</sup>, respectively. The corresponding bis(kojato)oxovanadium(IV) (VO(ka)<sub>2</sub>) complex exhibits a similar V=O stretch at 980 cm<sup>-1</sup> (16).

Elemental analyses of the three complexes were consistent with the calculated values. All exhibited one molecule of residual water which could not be eliminated with prolonged drying. The mass spectra (+ ESIMS) support the VO(L)<sub>2</sub> formulation showing parent ion M + 1 peaks ([HVOL<sub>2</sub>]<sup>+</sup>), as well as expected fragmentation patterns.

All complexes prepared were paramagnetic in the solid state. Room-temperature paramagnetic susceptibilities were obtained. By correcting for the diamagnetic susceptibilities of the ligands using Pascal's constants, the effective magnetic moments of the complexes were calculated. With an electronic configuration of [Ar]3d<sup>1</sup>, vanadium(IV) has one unpaired electron for which the spin-only formula predicts a magnetic moment of 1.73 μ<sub>B</sub>. The experimental values are in the range 1.69–1.75 μ<sub>B</sub> for the three vanadyl complexes.

Electron paramagnetic resonance spectroscopic data for the three complexes showed the characteristic eight-line

**Table 1. Spin Hamiltonian Parameters for VO(L)<sub>2</sub>; L = L<sup>1</sup>, L<sup>3</sup>, L<sup>4</sup>, Ma, Ka**

complex	<i>g</i> <sub>iso</sub> <sup>a</sup>	<i>A</i> <sub>iso</sub> <sup>b</sup>

<sup>a</sup> Error, ±0.001. <sup>b</sup> Units for the vanadium hyperfine coupling are ± 0.1 × 10<sup>-4</sup> cm<sup>-1</sup>. <sup>c</sup> Ref 12. <sup>d</sup> Ref 16.

pattern expected for V (IV). The three vanadium–thiazolidinedione complexes exhibited identical *g*-values and very similar isotropic vanadium nuclear hyperfine couplings (Table 1). In addition, the experimental values compare very well with those reported for BMOV (12) and VO(ka)<sub>2</sub> (16) (Table 1). Dissolution of each vanadium–thiazolidinedione complex in MeOH:CH<sub>2</sub>Cl<sub>2</sub> (1:1) most probably results in solvated MeOH species. Possible sites for solvent coordination are trans (T) or cis (C) to the oxo-O, yielding six possible species in solution (38). X-ray crystal-structure analysis would give a much more detailed understanding of the coordination environment; however, many crystallization attempts did not produce the required single crystals.

**In Vivo Results.** Animal studies were completed in four sets of trials the first three of which used, in each trial, a diabetic control, a ligand precursor, the associated vanadyl complex of the ligand precursor, and BMOV as a representative standard. The fourth trial used a diabetic control, a ligand precursor, rosiglitazone, and BMOV. The percent decrease in blood glucose was

**Table 2.** Glucose Lowering of Four Thiazolidinedione Ligand Precursors and Three of Their Corresponding Complexes Compared with BMOV, and Rosiglitazone

<sup>a</sup> Glucose lowering of test compounds in STZ-diabetic rats was calculated as in eq 1 (21). Each value represents the mean ± SEM (*n* = 10). <sup>b</sup> Dose: 0.1 mmol/kg. <sup>c</sup> Combination of four trials (*n* = 26).

**Figure 1.** Hypoglycemic activity (% plasma glucose lowering) of four thiazolidinedione ligand precursors and three of their corresponding complexes compared with BMOV and rosiglitazone.

calculated for each compound utilizing a common method (21, 39), and the results are displayed in Table 2. A visual representation of the data is presented in Figure 1. The BMOV results are a combination of the four trials.

The results for the amine tethered ligand precursor **HL<sup>1</sup>** and the associated complex **VO(L<sup>1</sup>)<sub>2</sub>** suggest that these compounds may be taken up more slowly because there was no observed glucose lowering at 12 h. Positive effects were evident, however, at the 24 and 48 h time points, with both compounds exhibiting half of the *in vivo* activity of BMOV in acute testing. The pyridinone-type ligand precursor **HL<sup>2</sup>** showed minimal glucose lowering at 12 h, but the effect was not sustained. The very low solubility of this compound leading to a lack of absorption *in vivo* was most probably responsible for the observed response. This low solubility precluded complexation with vanadium as well.

The unsaturated ether-tethered ligand precursor **HL<sup>3</sup>** and complex **VO(L<sup>3</sup>)<sub>2</sub>** showed the most efficacious hypoglycemic effects in this study. Both compounds exhibited enhanced glucose lowering compared to BMOV at the 12 h time point. Whereas the glucose lowering effect of the ligand was lessened from 12 to 48 h, the effect of **VO(L<sup>3</sup>)<sub>2</sub>** on blood glucose levels was sustained, similar to BMOV. On the basis of these promising results, we

tested the saturated analogues **HL<sup>4</sup>** and **VO(L<sup>4</sup>)<sub>2</sub>**. The ligand precursor did not show any glucose lowering, while the complex exhibited glucose-lowering at 12 and 24 h but the effect was not sustained to 48 h. The results for **VO(L<sup>4</sup>)<sub>2</sub>** contrast that for **VO(L<sup>1</sup>)<sub>2</sub>** in that the former complex was faster acting but the positive effects were not sustained. These results could be explained by quicker uptake of **VO(L<sup>4</sup>)<sub>2</sub>** followed by faster metabolism and/or excretion.

Both the ligand precursors **HL<sup>1</sup>** and **HL<sup>3</sup>** were more proficient in lowering plasma glucose levels in this testing protocol when compared with rosiglitazone (Avandia), a marketed PPAR $\gamma$  agonist. While these results are preliminary, the increased activity of **HL<sup>1</sup>** and **HL<sup>3</sup>** compared to that of rosiglitazone is very encouraging. **HL<sup>2</sup>** showed minimal hypoglycemic activity at 12 h, but the effect was not sustained. The very low solubility of this compound most probably hampered its activity. **HL<sup>3</sup>** lowered plasma glucose much more effectively than rosiglitazone, a significant finding that warrants further attention. It has been reported that unsaturated thiazolidinediones show lesser fold transactivation of PPAR $\alpha$  and PPAR $\gamma$  than their saturated analogues (29, 40). This suggests that **HL<sup>3</sup>** and other unsaturated thiazolidinediones exhibit their antidiabetic effects through other, yet to be determined, mechanisms. Interestingly the saturated analogue **HL<sup>4</sup>** did not show any activity in this testing protocol. This lack of activity could have been due to poor pharmacokinetics as the solubility of this ligand precursor was satisfactory. Further testing in a more specific animal model of type 2 diabetes, such as db/db mice, is planned to elucidate more clearly the potential of these structurally novel thiazolidinediones, especially **HL<sup>3</sup>** (34, 35).

Studies of the combined effects of treatment with rosiglitazone and BMOV on glucose-lowering in STZ-diabetic rats have shown possible additivity (41). Neither additive nor synergistic effects were observed in this study; however, this could be due to the limited amount of information available from this short-term testing protocol. With these preliminary results in hand, it is clear that **VO(L<sup>3</sup>)<sub>2</sub>** is comparable to BMOV in lowering plasma glucose levels in STZ diabetic rats. Again, further testing would be prudent in a specific model of type 2 diabetes whereby effects on other important parameters such as plasma triglycerides and insulin could be determined (39).

## CONCLUDING REMARKS

To design vanadyl-thiazolidinedione complexes was appealing because of the potential for associative or synergistic effects via complexation of vanadium to thiazolidinedione-containing compounds. There is considerable evidence for the orally effective glucose-lowering properties of V(V) and V(IV), and a number of thiazolidinediones are either in late-stage clinical trials or are available for the treatment of type 2 diabetes. In preliminary animal investigations with this class of compounds the ligand precursors **HL<sup>1</sup>** and **HL<sup>3</sup>** showed enhanced activity in lowering blood glucose compared with that of rosiglitazone. The complex **VO(L<sup>3</sup>)<sub>2</sub>** exhibited comparable activity to BMOV and had a more prolonged treatment effect than the ligand alone.

## EXPERIMENTAL PROCEDURES

**Chemicals and Instrumentation.** All solvents and chemicals (Fisher, Aldrich) were reagent-grade and used without further purification unless otherwise specified.

Rosiglitazone was a gift from Kinetek Pharmaceuticals Inc. Water was deionized (Barnstead D9802 and D9804 cartridges) and distilled (Corning MP-1 Megapure Still) before use. Melting points were measured on a Mel-Temp apparatus and are uncorrected.

The ligands and complexes synthesized were characterized by infrared (IR) spectroscopy, mass spectrometry, elemental analysis, magnetic susceptibility, and  $^1\text{H}$  NMR, where appropriate. Infrared spectra were recorded as KBr disks in the range  $4000\text{--}400\text{ cm}^{-1}$  on a Galaxy Series FTIR spectrometer. Mass spectra (+ ion) were obtained with a Kratos MS 50 (electron-impact ionization, EI), a Kratos MS 80 (desorption chemical ionization, DCI), or a Macromass LCT (electrospray ionization, ESI) instrument. Room-temperature (293 K) magnetic susceptibilities were measured on a Johnson Matthey balance, using  $\text{Hg}[\text{Co}(\text{NCS})_4]$  as the susceptibility standard; diamagnetic corrections were estimated using Pascal's constants (42). C, H, and N analyses were performed either in this department by Mr. Peter Borda (Carlo Erba analytical instrumentation) or by Delta Microanalytical Services.  $^1\text{H}$  NMR spectra of samples were recorded on either a Bruker AM-300 or an AX-400 instrument at 300.13 or 400.13 MHz, respectively. Room-temperature X-band EPR spectra were recorded on a Bruker ECS-106 EPR spectrometer in  $20\text{ }\mu\text{L}$  quartz capillaries. Computer simulations of the isotropic EPR spectra were performed using Bruker's WINEPR/SIMFONIA package.

**Synthesis of Bifunctional Ligands.** *5-Benzyloxy-2-hydroxymethyl-pyran-4-one (2)*. This compound was prepared in a manner similar to that in the literature (27). To a solution of sodium (2.3 g, 100 mmol) in dry MeOH (200 mL) was added kojic acid **1** (14.2 g, 100 mmol) in portions. To this solution was added benzyl chloride (14 mL, 100 mmol) dropwise, and the mixture was heated to reflux for 5 h, cooled to room temperature, and then poured into  $\text{H}_2\text{O}$  (1 L). The precipitate was collected and recrystallized from a minimum of hot EtOH (80 mL) to afford 12.7 g (55%) of the title compound **2** as colorless crystals; mp  $120\text{--}122\text{ }^\circ\text{C}$ .  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 300 MHz):  $\delta$  8.00 (s, 1H), 7.38 (m, 5H), 6.50 (s, 1H), 5.01 (s, 2H), 4.39 (s, 2H). EIMS  $m/z$  (relative intensity) = 232 ( $\text{M}^+$ , 60), 91 (100). Anal. Calcd. (found) for  $\text{C}_{13}\text{H}_{12}\text{O}_4$ : C, 67.23 (67.42); H, 5.21 (5.26).

*Methanesulfonic Acid 5-Benzyloxy-4-oxo-4H-pyran-2-ylmethyl Ester (3)*. To a suspension of 5-benzyloxy-2-hydroxymethyl-pyran-4-one **2** (0.303 g, 1.3 mmol) in dry  $\text{CH}_2\text{Cl}_2$  (10 mL) was added triethylamine (0.36 mL, 2.6 mmol). The suspension was then cooled in an ice bath and methanesulfonyl chloride (0.12 mL, 1.6 mmol) was added dropwise. The mixture was stirred for 0.5 h, quenched with saturated  $\text{NaHCO}_3$  (15 mL), and then extracted with  $\text{CH}_2\text{Cl}_2$  ( $2 \times 15\text{ mL}$ ); the combined organic extracts were dried over anhydrous  $\text{Na}_2\text{SO}_4$ , and then concentrated. The slightly colored oil **3** was used without further purification.  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 300 MHz):  $\delta$  7.57 (s, 1H), 7.38 (m, 5H), 6.55 (s, 1H), 5.08 (s, 2H), 4.95 (s, 2H), 3.08 (s, 3H).

*5-(4-Nitro-benzylidene)thiazolidine-2,4-dione (5)*. To a solution of 4-nitrobenzaldehyde **4** (5.00 g, 33.0 mmol) and thiazolidine-2,4-dione (3.87 g, 33.0 mmol) in toluene (200 mL) was added benzoic acid (0.68 g, 5.5 mmol) and piperidine (0.55 mL, 5.5 mmol). The resulting mixture was refluxed for 2 h with the continuous removal of water using a Dean–Stark water separator. The reaction was then cooled to room temperature and the resulting precipitate was collected and washed with  $\text{CH}_2\text{Cl}_2$  and  $\text{Et}_2\text{O}$  to yield 4.50 g (55%) of compound **5** as a pale yellow solid; mp  $250\text{ }^\circ\text{C}$ .  $^1\text{H}$  NMR ( $\text{DMSO}-d_6$ , 300 MHz):  $\delta$  8.35

(d,  $J = 8.6\text{ Hz}$ , 2H), 7.91 (s, 1H), 7.87 (d,  $J = 8.6\text{ Hz}$ , 2H). EIMS  $m/z$  (relative intensity) = 250 ( $\text{M}^+$ , 35), 179 (100), 89 (70). Anal. Calcd. (found) for  $\text{C}_{10}\text{H}_6\text{N}_2\text{O}_4\text{S}$ : C, 48.00 (48.00); H, 2.42 (2.46); N, 11.20 (10.99).

( $\pm$ )-5-(4-Amino-benzyl)thiazolidine-2,4-dione (**6**). This compound was prepared by a more direct method than that reported in the literature (28).  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$  (0.30 g, 1.3 mmol) and dimethylglyoxime (0.56 g, 4.9 mmol) were added to  $\text{H}_2\text{O}$  (300 mL). After addition of NaOH (3 mL, 1 M), the brown solution was cooled to  $0\text{ }^\circ\text{C}$  in an ice bath and  $\text{NaBH}_4$  (7.90 g, 209 mmol) was added in portions. 5-(4-Nitro-benzylidene)thiazolidine-2,4-dione **5** (5.22 g, 20.9 mmol) was then added slowly as a slurry in THF (50 mL). The reaction mixture was stirred at room-temperature overnight. The pH was then adjusted to 9 with  $\text{CH}_3\text{COOH}$ , and the mixture was extracted with THF ( $3 \times 200\text{ mL}$ ). The combined organic extracts were dried over  $\text{Na}_2\text{SO}_4$  and concentrated. The residue was chromatographed over silica gel using a mixture of MeOH and  $\text{CH}_2\text{Cl}_2$  (5:95) as the eluent to afford 3.31 g (71%) of the title compound **6** as a pale yellow solid; mp  $152\text{--}153\text{ }^\circ\text{C}$ .  $^1\text{H}$  NMR ( $\text{DMSO}-d_6$ , 300 MHz):  $\delta$  6.89 (d,  $J = 8.3\text{ Hz}$ , 2H), 6.49 (d,  $J = 8.3\text{ Hz}$ , 2H), 4.65 (dd,  $J = 9.3, 4.4\text{ Hz}$ , 1H), 3.20 (dd,  $J = 14.4, 4.4\text{ Hz}$ ), 2.91 (dd,  $J = 14.4, 9.3\text{ Hz}$ ). EIMS  $m/z$  (relative intensity) = 222 ( $\text{M}^+$ , 60), 106 (100). Anal. Calcd. (found) for  $\text{C}_{10}\text{H}_{10}\text{N}_2\text{O}_2\text{S}$ : C, 54.04 (54.26); H, 4.53 (4.53); N, 12.60 (12.45); S, 14.42 (14.26).

( $\pm$ )-5-[4-[(5-Benzyloxy-4-oxo-4H-pyran-2-ylmethyl)amino]benzyl]thiazolidine-2,4-dione (**7**). Methanesulfonic acid 5-benzyloxy-4-oxo-4H-pyran-2-ylmethyl ester **3** (2.67 g, 9.05 mmol) and ( $\pm$ )-5-(4-amino-benzyl)thiazolidine-2,4-dione **6** (2.00 g, 9.0 mmol) were dissolved in dry  $\text{CH}_3\text{CN}$  (50 mL).  $\text{K}_2\text{CO}_3$  (2.50 g, 18 mmol) was then added as a solid, and the resulting mixture was heated at  $50\text{ }^\circ\text{C}$  for 24 h with stirring. The solvent was then removed and the residue partitioned between  $\text{CH}_2\text{Cl}_2$  (50 mL) and saturated  $\text{NaHCO}_3$  (30 mL). The mixture was extracted with  $\text{CH}_2\text{Cl}_2$  ( $2 \times 50\text{ mL}$ ); the organic extracts were dried over  $\text{Na}_2\text{SO}_4$  and concentrated. The crude product was chromatographed on silica gel using a mixture of MeOH and  $\text{CH}_2\text{Cl}_2$  (3:97) as the eluent to afford 2.73 g (69%) of the title compound **7** as a pale yellow solid; mp  $57\text{--}59\text{ }^\circ\text{C}$ .  $^1\text{H}$  NMR (acetone- $d_6$ , 300 MHz):  $\delta$  7.86 (s, 1H), 7.37 (m, 5H), 6.95 (d,  $J = 8.3\text{ Hz}$ , 2H), 6.59 (d,  $J = 8.3\text{ Hz}$ , 2H), 6.21 (s, 1H), 5.02 (s, 2H), 4.82 (dd,  $J = 8.4, 4.1\text{ Hz}$ , 1H), 4.57 (s, 1H), 3.33 (dd,  $J = 14.1, 4.1\text{ Hz}$ , 1H), 3.09 (dd,  $J = 14.1, 8.4\text{ Hz}$ , 1H). EIMS  $m/z$  (relative intensity) = 436 ( $\text{M}^+$ , 10), 196 (20), 106 (100), 91 (55). Anal. Calcd. (found) for  $\text{C}_{23}\text{H}_{20}\text{N}_2\text{O}_5\text{S}$ : C, 63.29 (63.39); H, 4.62 (4.59); N, 6.42 (6.43).

( $\pm$ )-5-[4-[(5-Hydroxy-4-oxo-4H-pyran-2-ylmethyl)amino]benzyl]thiazolidine-2,4-dione (**HL<sup>1</sup>**). 5-[4-[(5-Benzyloxy-4-oxo-4H-pyran-2-ylmethyl)amino]benzyl]thiazolidine-2,4-dione **7** (3.75 g, 8.6 mmol) was dissolved in a mixture of concentrated HCl (20 mL) and  $\text{CH}_3\text{COOH}$  (40 mL) and heated at  $70\text{ }^\circ\text{C}$  with stirring for 48 h. The yellow solution was rotary evaporated to dryness and then  $\text{H}_2\text{O}$  (3 mL) was added and the pH adjusted to 5. The precipitate was isolated and washed with a minimum of cold  $\text{H}_2\text{O}$  to afford, after drying, 2.71 g (70%) of the title compound as a pale yellow solid; mp  $146\text{ }^\circ\text{C}$ .  $^1\text{H}$  NMR ( $\text{D}_2\text{O}$ , 300 MHz):  $\delta$  7.85 (s, 1H), 7.29 (d,  $J = 8.5\text{ Hz}$ , 2H), 7.22 (d,  $J = 8.5\text{ Hz}$ , 2H), 5.76 (s, 1H), 4.58 (dd,  $J = 6.4, 4.8\text{ Hz}$ , 1H), 4.5 (s, 2H), 3.76 (dd,  $J = 15.5, 6.4\text{ Hz}$ , 1H), 3.63 (dd,  $J = 15.5, 4.8\text{ Hz}$ , 1H). EIMS  $m/z$  (relative intensity) = 346 ( $\text{M}^+$ , 4), 106 (100). Anal. Calcd. (found) for  $\text{C}_{16}\text{H}_{14}\text{N}_2\text{O}_5\text{S} \cdot 0.5\text{H}_2\text{O}$ : C, 54.08 (54.21); H, 4.25 (4.06); N, 7.88 (7.74).

5-Benzyloxy-2-hydroxymethyl-1-methyl-1H-pyridin-4-one (**33**) (**8**). This compound was synthesized in a higher yield than that reported in the literature (**33**). 5-Benzyloxy-2-hydroxymethyl-pyran-4-one **2** (0.99 g, 4.27 mmol) was suspended in a mixture of EtOH and H<sub>2</sub>O (10 mL/10 mL), and methylamine (0.56 mL, 40% w/w, 6.42 mmol) was added. The mixture was heated to reflux for 6 h and then cooled to r.t., at which time the product crystallized from the solution. The solid was washed with Et<sub>2</sub>O and dried in vacuo to afford 0.81 g (77%) of the title compound **8** as an off-white solid; mp 218–220 °C. <sup>1</sup>H NMR (CD<sub>3</sub>OD, 300 MHz): δ 7.60 (s, 1H), 7.48 (d, *J* = 7.2 Hz, 2H), 7.37 (m, 3H), 6.61 (s, 1H), 5.10 (s, 2H), 4.55 (s, 2H), 3.77 (s, 3H). DCIMS *m/z* = 245 (M<sup>+</sup>, 100), 168 (15), 139 (85), 91 (74). Anal. Calcd. (found) for C<sub>14</sub>H<sub>15</sub>N O<sub>3</sub>: C, 68.56 (68.42); H, 6.16 (6.22); N, 5.71 (5.81).

5-Benzyloxy-2-chloromethyl-1-methyl-1H-pyridin-4-one Hydrochloride Salt (**9**). 5-Benzyloxy-2-hydroxymethyl-1-methyl-1H-pyridin-4-one **8** (2.10 g, 8.57 mmol) was added with stirring to form a suspension in dry CH<sub>2</sub>Cl<sub>2</sub> (20 mL). Thionyl chloride (5.0 mL, 68.9 mmol) was then added dropwise. The resulting light yellow solution was stirred overnight under Ar, and then the solvent was removed under reduced pressure. Ethyl acetate (15 mL) was added, and the triturated solid was collected and washed with hexanes to afford 2.45 g (96%) of the title compound **9** as a white solid; mp 170–172 °C. <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>, 300 MHz): δ 8.62 (s, 1H), 7.40 (m, 6H), 5.17 (s, 2H), 5.04 (s, 2H). DCIMS *m/z* = 263 (M<sup>+</sup>, 16), 228 (20), 157 (30), 91 (100). Anal. Calcd. (found) for C<sub>14</sub>H<sub>14</sub>ClNO<sub>2</sub>: C, 56.00 (56.00); H, 5.00 (5.04); N, 4.67 (4.72).

(±)-5-{4-[(5-Benzyloxy-1-methyl-4-oxo-1,4-dihydro-pyridin-2-ylmethyl)amino]benzyl}thiazolidine-2,4-dione (**10**). (±)-5-(4-Amino-benzyl)thiazolidine-2,4-dione **6** (1.55 g, 6.98 mmol) and 5-benzyloxy-2-chloromethyl-1-methyl-1H-pyridin-4-one hydrochloride salt **9** (2.08 g, 6.98 mmol) were dissolved in DMF (50 mL). Triethylamine (3 mL, 21 mmol) was added dropwise, and the resulting mixture was stirred for 22 h. Water (60 mL) was added and the resulting mixture extracted with CH<sub>2</sub>Cl<sub>2</sub> (2 × 70 mL). The combined organic extracts were dried over Na<sub>2</sub>SO<sub>4</sub>, filtered, and then evacuated. The crude product was chromatographed on silica gel eluting with MeOH:CH<sub>2</sub>Cl<sub>2</sub> (5:95) to afford 2.65 g (88%) of the title compound **10** as a pale yellow solid; mp 85–87 °C. <sup>1</sup>H NMR (CDCl<sub>3</sub>, 300 MHz): δ 7.32 (m, 5H), 6.85 (s, 1H), 6.84 (d, *J* = 8.3 Hz, 2H), 6.43 (d, *J* = 8.3 Hz, 2H), 6.12 (s, 1H), 5.08 (s, 2H), 4.44 (dd, *J* = 8.0, 3.9 Hz, 1H), 4.42 (s, 2H), 3.35 (s, 3H), 3.20 (dd, *J* = 14.2, 3.9 Hz, 1H), 3.06 (dd, *J* = 14.2, 8.0 Hz, 1H); EIMS *m/z* = 449 (M<sup>+</sup>, 45), 344(10), 238(35), 106(80), 91(100). Anal. Calcd. (found) for C<sub>24</sub>H<sub>23</sub>N<sub>3</sub>O<sub>4</sub>S·HCl: C, 59.32 (59.52); H, 4.98 (4.90); N, 8.65 (8.49).

(±)-5-{4-[(5-Hydroxy-1-methyl-4-oxo-1,4-dihydro-pyridin-2-ylmethyl)amino]benzyl}thiazolidine-2,4-dione (**HL**<sup>2</sup>). The title compound **HL**<sup>2</sup> (1.50 g, 73%) was prepared as a light yellow solid from (±)-5-{4-[(5-benzyloxy-1-methyl-4-oxo-1,4-dihydro-pyridin-2-ylmethyl)amino]benzyl}thiazolidine-2,4-dione **10** (2.60 g, 5.80 mmol) by a procedure analogous to that described for **HL**<sup>1</sup>; mp 108–110 °C. <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>, 300 MHz): δ 7.58 (s, 1H), 6.94 (d, *J* = 8.1 Hz, 2H), 6.58 (d, *J* = 8.1 Hz, 2H), 5.99 (s, 1H), 5.06 (dd, *J* = 8.9, 4.2 Hz, 1H), 4.69 (s, 2H), 3.69 (s, 3H), 3.34 (dd, *J* = 14.1, 4.2 Hz, 1H), 3.04 (dd, *J* = 14.1, 8.9 Hz, 1H). EIMS *m/z* = 359 (M<sup>+</sup>, 30), 254 (60), 181 (30), 106 (100). Anal. Calcd. (found) for C<sub>17</sub>H<sub>17</sub>N<sub>3</sub>O<sub>4</sub>S·0.5H<sub>2</sub>O: C, 55.42 (55.19); H, 4.92 (4.75); N, 11.41 (11.28).

4-(5-Benzyloxy-4-oxo-4H-pyran-2-ylmethoxy)benzaldehyde (**11**). Methanesulfonic acid 5-benzyloxy-4-oxo-4H-pyran-2-ylmethyl ester **3** (5.37 g, 17.3 mmol) was dis-

solved in DMF (150 mL) and 4-hydroxybenzaldehyde **14** (2.11 g, 17.3 mmol) was added. To this stirred solution K<sub>2</sub>CO<sub>3</sub> (7.18 g, 52 mmol) was added and the mixture was heated at 60 °C overnight. Water (250 mL) was then added and the mixture extracted with CH<sub>2</sub>Cl<sub>2</sub> (3 × 200 mL). The combined organic extracts were washed with brine (50 mL), dried over Na<sub>2</sub>SO<sub>4</sub>, and concentrated. The crude material was washed with acetone to afford 3.72 g (64%) of **11** as a white solid; mp 155 °C. <sup>1</sup>H NMR (acetone-*d*<sub>6</sub>, 300 MHz): δ 9.93 (s, 1H), 8.04 (s, 1H), 7.92 (d, *J* = 8.5 Hz, 2H), 7.40 (m, 5H), 7.25 (d, *J* = 8.5 Hz, 2H), 6.54 (s, 1H), 5.15 (s, 2H), 5.07 (s, 2H). EIMS *m/z* (relative intensity) = 336 (M<sup>+</sup>, 4), 214 (10), 91 (100). Anal. Calcd. (found) for C<sub>20</sub>H<sub>16</sub>O<sub>5</sub>: C, 71.42 (71.59); H, 4.79 (4.72).

5-[4-(5-Benzyloxy-4-oxo-4H-pyran-2-ylmethoxy)benzylidene]thiazolidine-2,4-dione (**12**). The title compound **12** (1.50 g, 57%) was prepared as a light orange solid from 4-(5-benzyloxy-4-oxo-4H-pyran-2-ylmethoxy)benzaldehyde (2.11 g, 6.28 mmol), thiazolidine-2,4-dione (0.74 g, 6.28 mmol), benzoic acid (0.15 g, 1.25 mmol), and piperidine (0.12 mL, 1.25 mmol) by a procedure analogous to that described for **5**; mp 253–254 °C. <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>, 300 MHz): δ 12.52 (s, 1H), 8.27 (s, 1H), 7.75 (s, 1H), 7.58 (d, *J* = 8.6 Hz, 2H), 7.39 (m, 5H), 7.20 (d, *J* = 8.6 Hz, 2H), 6.56 (s, 1H), 5.10 (s, 2H), 4.94 (s, 2H). EIMS *m/z* (relative intensity) = 435 (M<sup>+</sup>, 7), 91 (100). Anal. Calcd. (found) for C<sub>23</sub>H<sub>17</sub>NO<sub>6</sub>S: C, 63.44 (63.16); H, 3.93 (4.06); N, 3.22 (3.21).

5-[4-(5-Hydroxy-4-oxo-4H-pyran-2-ylmethoxy)benzylidene]thiazolidine-2,4-dione (**HL**<sup>3</sup>). The title compound **HL**<sup>3</sup> (1.60 g, 67%) was prepared as a light beige solid from 5-[4-(5-benzyloxy-4-oxo-4H-pyran-2-ylmethoxy)benzylidene]thiazolidine-2,4-dione **12** (3.00 g, 6.90 mmol) by a procedure analogous to that described for **HL**<sup>1</sup>; mp 275–276 °C. <sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>, 300 MHz): δ 12.54 (s, 1H), 9.26 (s, 1H), 8.12 (s, 1H), 7.76 (s, 1H), 7.59 (d, *J* = 8.8 Hz, 2H), 7.20 (d, *J* = 8.8 Hz, 2H), 6.57 (s, 1H), 5.10 (s, 2H). DCIMS *m/z* (relative intensity) = 346 (M<sup>+</sup>, 100), 221 (40), 203 (35), 150 (60), 125 (100). Anal. Calcd. (found) for C<sub>16</sub>H<sub>11</sub>NO<sub>6</sub>S: C, 55.65 (55.23); H, 3.21 (3.19); N, 4.06 (4.03).

5-Benzyloxy-2-chloromethyl-pyran-4-one (**13**). The title compound **13** (2.01 g, 62%) was prepared as a white solid from 5-benzyloxy-2-hydroxymethyl-pyran-4-one (3.00 g, 12.9 mmol) by a procedure analogous to that described for **9**; mp 109–110 °C. <sup>1</sup>H NMR (CDCl<sub>3</sub>, 300 MHz): δ 7.58 (s, 1H), 7.38 (m, 5H), 6.56 (s, 1H), 5.09 (s, 2H), 4.29 (s, 2H). EIMS *m/z* (relative intensity) = 250 (M<sup>+</sup>, 7), 126 (10), 108 (28), 91 (100). Anal. Calcd. (found) for C<sub>13</sub>H<sub>11</sub>ClO<sub>3</sub>: C, 62.29 (62.41); H, 4.42 (4.41).

5-(4-Hydroxy-benzylidene)thiazolidine-2,4-dione (**15**). The title compound (17.69 g, 98%) was prepared as a bright yellow solid from 4-hydroxybenzaldehyde **14** (10.00 g, 81.9 mmol), thiazolidine-2,4-dione (9.58 g, 81.9 mmol), benzoic acid (1.51 g, 12.3 mmol), and piperidine (1.2 mL, 12.1 mmol) by a procedure analogous to that described for **5**; mp 291–292 °C. <sup>1</sup>H NMR (CD<sub>3</sub>OD, 300 MHz): δ 7.72 (s, 1H), 7.43 (d, *J* = 8.6 Hz, 2H), 6.90 (d, *J* = 8.6 Hz, 2H). EIMS *m/z* (relative intensity) = 221 (M<sup>+</sup>, 40), 151 (10), 150 (100), 121 (17), 75 (11). Anal. Calcd. (found) for C<sub>10</sub>H<sub>7</sub>NO<sub>3</sub>S: C, 54.29 (54.69); H, 3.19 (3.30); N, 6.33 (6.44).

(±)-5-(4-Hydroxy-benzyl)thiazolidine-2,4-dione(**28**) (**16**). CoCl<sub>2</sub>·6H<sub>2</sub>O (0.02 g, 0.08 mmol) and dimethylglyoxime (0.04 g, 0.3 mmol) were added to H<sub>2</sub>O (80 mL). After the addition of NaOH (1 M, 1 mL), the brown solution was cooled to 0 °C in an ice bath and NaBH<sub>4</sub> (1.20 g, 31.7 mmol) was added in portions. 5-(4-Hydroxy-benzylidene)-

thiazolidine-2,4-dione **15** (1.00 g, 4.5 mmol) was then added slowly as a solid over 15 min, and then the reaction mixture was stirred at room-temperature overnight. The pH was adjusted to 6 with  $\text{CH}_3\text{COOH}$ , and then the mixture was extracted with  $\text{CHCl}_3$  ( $3 \times 60$  mL). The combined organic extracts were dried over  $\text{Na}_2\text{SO}_4$ , filtered, and decolorized with charcoal (refluxed for 5 min and filtered). Evaporation of the solvents afforded 0.64 g (64%) of the title compound **16** as a white solid; mp 156–157 °C.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 300 MHz):  $\delta$  7.06 (d,  $J = 8.6$  Hz, 2H), 6.71 (d,  $J = 8.6$  Hz, 2H), 4.65 (dd,  $J = 9.2$ , 3.9 Hz, 1H), 3.34 (dd,  $J = 14.2$ , 3.9 Hz, 1H), 3.03 (dd,  $J = 14.2$ , 9.2 Hz, 1H). EIMS  $m/z$  (relative intensity) = 223 ( $\text{M}^+$ , 35), 107 (100), 91 (4), 77, (13). Anal. Calcd. (found) for  $\text{C}_{10}\text{H}_9\text{O}_3\text{S}$ : C, 53.80 (53.76); H, 4.06 (3.95); N, 6.27 (6.15).

( $\pm$ )-5-[4-(5-Benzyloxy-4-oxo-4H-pyran-2-ylmethoxy)benzyl]thiazolidine-2,4-dione (**17**). Sodium hydride (0.40 g, 16.7 mmol) was added to DMF (45 mL) cooled in an ice bath. To this stirring mixture ( $\pm$ )-5-(4-hydroxy-benzyl)-thiazolidine-2,4-dione **16** (1.70 g, 7.6 mmol) was added as a solid in portions causing considerable gas evolution. After 0.5 h 5-benzyloxy-2-chloromethyl-pyran-4-one **13** (2.00 g, 8.0 mmol) was added dropwise as a solution in DMF (30 mL). The resulting mixture was warmed to room temperature and stirred for 18 h. Saturated  $\text{NaHCO}_3$  (125 mL) was then added and the mixture was extracted with  $\text{CH}_2\text{Cl}_2$  ( $3 \times 125$  mL). The combined organic portions were washed with brine (100 mL), dried over  $\text{Na}_2\text{SO}_4$ , and then the solvent was evaporated. The crude product was chromatographed on silica gel eluting with  $\text{MeOH}:\text{CH}_2\text{Cl}_2$  (1:99) to afford 1.20 g (35%) of **17** as a pale yellow solid; mp 165–166 °C.  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 400 MHz):  $\delta$  8.71 (s, 1H), 7.57 (s, 1H), 7.40 (m, 5H), 7.16 (d,  $J = 8.6$  Hz, 2H), 6.86 (d,  $J = 8.6$  Hz, 2H), 5.07 (s, 2H), 4.80 (s, 2H), 4.47 (dd,  $J = 9.2$ , 3.9 Hz, 1H), 3.42 (dd,  $J = 14.2$ , 3.9 Hz, 1H), 3.11 (dd,  $J = 14.2$ , 9.2 Hz, 1H). EIMS  $m/z$  (relative intensity) = 437 ( $\text{M}^+$ , 3), 214 (10), 107 (53), 91 (100). Anal. Calcd. (found) for  $\text{C}_{23}\text{H}_{19}\text{NO}_6\text{S}$ : C, 63.15 (63.09); H, 4.38 (4.40); N, 3.20 (3.32).

( $\pm$ )-5-[4-(5-Hydroxy-4-oxo-4H-pyran-2-ylmethoxy)benzyl]thiazolidine-2,4-dione (**HL<sup>4</sup>**). The title compound **HL<sup>4</sup>** (0.50 g, 93%) was prepared as a white solid from ( $\pm$ )-5-[4-(5-benzyloxy-4-oxo-4H-pyran-2-ylmethoxy)benzyl]thiazolidine-2,4-dione **17** (0.68 g, 1.6 mmol) by a procedure analogous to that described for **HL<sup>1</sup>**; mp 174 °C.  $^1\text{H}$  NMR ( $\text{CD}_3\text{OD}$ , 300 MHz):  $\delta$  8.04 (s, 1H), 7.24 (d,  $J = 8.6$  Hz, 2H), 6.98 (d,  $J = 8.6$  Hz, 2H), 6.60 (s, 1H), 4.99 (s, 2H), 4.73 (dd,  $J = 8.9$ , 4.2 Hz, 1H), 3.42 (dd,  $J = 14.2$ , 4.2 Hz, 1H), 3.11 (dd,  $J = 14.2$ , 8.9 Hz, 1H); EIMS  $m/z$  (relative intensity) = 347 ( $\text{M}^+$ , 10), 231 (70), 125 (100), 107 (63). Anal. Calcd. (found) for  $\text{C}_{16}\text{H}_{13}\text{NO}_6\text{S}$ : C, 55.33 (54.87); H, 3.77 (3.75); N, 4.03 (4.03).

**Synthesis of Vanadyl–Thiazolidinedione Complexes.** *Bis*( $\pm$ )-5-[4-(5-alkoxy-4-oxo-4H-pyran-2-ylmethyl)-amino]benzylthiazolidine-2,4-dionato)oxovanadium(IV) Hydrate (**VO(L<sup>1</sup>)<sub>2</sub>·H<sub>2</sub>O**). **HL<sup>1</sup>** (0.91 g, 2.64 mmol) was dissolved in  $\text{H}_2\text{O}$  (15 mL) and  $\text{VOSO}_4 \cdot 5\text{H}_2\text{O}$  (0.28 g, 1.12 mmol) was added. The pH was adjusted to 5 with 1 M  $\text{NaOH}$  and the mixture was refluxed under Ar for 22 h. The reaction mixture was filtered hot and the precipitate was washed with  $\text{H}_2\text{O}$  to afford, after drying in vacuo, 0.71 g (83% based on V) of the title compound as a brown solid; mp 175–176 °C. IR ( $\text{cm}^{-1}$ , KBr disk): 3500–3000 ( $\nu_{\text{N-H}}$ ,  $\nu_{\text{C-H}}$ ); 1752, 1681 ( $\nu_{\text{C=O}}$  thiazolidinedione); 1610, 1563, 1516, 1475 (pyrone  $\nu_{\text{C=O}}$ , ring  $\nu_{\text{C=C}}$ ); 982 ( $\nu_{\text{V=O}}$ ). ESIMS  $m/z$  (relative intensity) = 758 ( $[\text{HVO}(\text{L}^1)_2]^+$ , ( $\text{M}+1$ )<sup>+</sup>, 6), 740 (16), 444 (15), 412 (60), 347 (100). The room-temperature solid-state magnetic moment was 1.75

$\mu_{\text{B}}$ . Anal. Calcd. (found) for  $\text{C}_{32}\text{H}_{26}\text{N}_4\text{O}_{11}\text{S}_2\text{V} \cdot \text{H}_2\text{O}$ : C, 49.55 (49.25); H, 3.64 (3.54); N, 7.22 (6.94).

*Bis*( $\pm$ )-5-[4-(5-alkoxy-4-oxo-4H-pyran-2-ylmethoxy)benzyl]thiazolidine-2,4-dionato)oxovanadium(IV) Hydrate (**VO(L<sup>3</sup>)<sub>2</sub>·H<sub>2</sub>O**). The title compound **VO(L<sup>3</sup>)<sub>2</sub>·H<sub>2</sub>O** (1.00 g, 88%) was prepared as a gray solid from **HL<sup>3</sup>** (1.03 g, 2.98 mmol) and  $\text{VOSO}_4 \cdot 5\text{H}_2\text{O}$  (0.38 g, 1.60 mmol) by a procedure analogous to that described for **VO(L<sup>1</sup>)<sub>2</sub>**; mp 189–192 °C. IR ( $\text{cm}^{-1}$ , KBr disk): 3500–3000 ( $\nu_{\text{N-H}}$ ,  $\nu_{\text{C-H}}$ ); 1745, 1679 ( $\nu_{\text{C=O}}$  thiazolidinedione); 1596, 1562, 1510, 1472 (pyrone  $\nu_{\text{C=O}}$ , ring  $\nu_{\text{C=C}}$ ); 985 ( $\nu_{\text{V=O}}$ ). *Bis*( $\pm$ )-5-[4-(5-alkoxy-4-oxo-4H-pyran-2-ylmethoxy)benzyl]thiazolidine-2,4-dionato)oxovanadium(IV) Hydrate (**VO(L<sup>4</sup>)<sub>2</sub>·H<sub>2</sub>O**). The title compound **VO(L<sup>4</sup>)<sub>2</sub>·H<sub>2</sub>O** (0.51 g, 93%) was prepared as a brown solid from **HL<sup>4</sup>** (0.71 g, 2.05 mmol) and  $\text{VOSO}_4 \cdot 5\text{H}_2\text{O}$  (0.29 g, 1.21 mmol) by a procedure analogous to that described for **VO(L<sup>1</sup>)<sub>2</sub>**; mp 174 °C. IR ( $\text{cm}^{-1}$ , KBr disk): 3500–3000 ( $\nu_{\text{N-H}}$ ,  $\nu_{\text{C-H}}$ ); 1750, 1692 ( $\nu_{\text{C=O}}$  thiazolidinedione); 1610, 1563, 1510, 1476 (pyrone  $\nu_{\text{C=O}}$ , ring  $\nu_{\text{C=C}}$ ); 975 ( $\nu_{\text{V=O}}$ ). ESIMS  $m/z$  = 760 ( $[\text{HVO}(\text{L}^4)_2]^+$ , ( $\text{M}+1$ )<sup>+</sup>, 50), 445 (100), 413 (49), 370 (10). The room-temperature solid-state magnetic moment was 1.69  $\mu_{\text{B}}$ . Anal. Calcd. (found) for  $\text{C}_{32}\text{H}_{24}\text{N}_2\text{O}_{13}\text{S}_2\text{V} \cdot \text{H}_2\text{O}$ : C, 49.43 (48.98); H, 3.37 (3.25); N, 3.60 (3.52).

**Glucose-Lowering Studies.** Male Wistar rats weighing 190–210 g (Animal Care Unit, UBC) were housed two per cage (polycarbonate) on a 12 h light:dark cycle. Animals were allowed ad libitum access to food (Purina Rat Chow #5001) and water, and were cared for in accordance with the principles and guidelines of the Canadian Council for Animal Care. Animals were allowed to acclimatize for a period of 7 days, and then diabetes was induced by a single tail vein injection of streptozotocin (STZ) (60 mg  $\text{kg}^{-1}$  in 0.9%  $\text{NaCl}$ ) under light halothane anesthesia. Diabetes was confirmed 3 days after STZ-injection by tail-vein blood glucose determination (Ames Glucometer II and Glucostix), with blood levels over 13 mM being accepted as diabetic. One week after STZ-injection, animals were divided into treatment groups: carboxymethylcellulose (CMC) alone, thiazolidinedione compound, congeneric vanadium complex, or BMOV. All drugs were administered as suspensions in 1% CMC. Animals were not fasted prior to drug administration. Blood, 50  $\mu\text{L}$ , was collected for glucose analysis immediately prior to drug administration and at selected times up to 72 h after drug administration. Blood was collected from the tail vein into heparinized capillary tubes and centrifuged (10 000g  $\times$  15 min), and plasma was collected for immediate determination of glucose using Boehringer Mannheim kits (glucose oxidase method). The hypoglycemic activity of the test compounds was calculated as shown in eq 1 (21, 39):

$$\text{Hypoglycemic activity (\%)} = \left( \frac{\text{PG}_c - \text{PGT}}{\text{PG}_c} \right) \times 100\% \quad (1)$$

$\text{PG}_c$  is plasma glucose in control mice, and  $\text{PG}_T$  is plasma glucose in the mice treated with test compounds. Values are presented as means  $\pm$  SEM at 12, 24, and 48 h. At all time points, the animals were observed for signs of toxicity (e.g. diarrhea).

**Intraperitoneal (i.p.) Administration in STZ-Diabetic Rats.** Studies were done on 4 separate occa-

sions, in each study four groups were examined CMC, BMOV, ligand, and vanadyl complex. For  $\text{VO}(\text{L}^1)_2$ , the animals were divided into CMC ( $n = 5$ ), BMOV ( $n = 5$ ),  $\text{HL}^1$  ( $n = 10$ ),  $\text{VO}(\text{L}^1)_2$  ( $n = 10$ ); for  $\text{HL}^2$ , CMC ( $n = 5$ ), BMOV ( $n = 6$ ),  $\text{HL}^2$  ( $n = 10$ ), rosiglitazone ( $n = 10$ ); for  $\text{VO}(\text{L}^3)_2$ , CMC ( $n = 6$ ), BMOV ( $n = 10$ ),  $\text{HL}^3$  ( $n = 10$ ),  $\text{VO}(\text{L}^3)_2$  ( $n = 10$ ); and for  $\text{VO}(\text{L}^4)_2$ , ( $n = 5$ ), BMOV ( $n = 5$ ),  $\text{HL}^4$  ( $n = 10$ ),  $\text{VO}(\text{L}^4)_2$  ( $n = 10$ ). All drug candidates were administered by i.p. injection in a volume of  $2.5 \text{ mL kg}^{-1}$  at a dose of  $0.1 \text{ mmol kg}^{-1}$ . The control groups (CMC) received an equivalent volume of 1% CMC alone. There was no significant effect of drug administration on body weight over the treatment period in any of the trials.

#### ACKNOWLEDGMENT

The authors gratefully acknowledge the Canadian Institutes of Health Research (CHIR) for an operating grant and Kinetek Pharmaceuticals Inc. for personnel support. We also thank Dr. B.D. Liboiron for his assistance with the EPR spectra. T.S. acknowledges NSERC (Natural Sciences and Engineering Research Council) of Canada for a postgraduate fellowship, and P.B. acknowledges a NATO Science Fellowship.

# Novel Shielded Transferrin–Polyethylene Glycol–Polyethylenimine/DNA Complexes for Systemic Tumor-Targeted Gene Transfer

Malgorzata Kursa,<sup>†</sup> Greg F. Walker,<sup>‡</sup> Vanessa Roessler,<sup>†</sup> Manfred Ogris,<sup>‡</sup> Wolfgang Roedel,<sup>‡</sup> Ralf Kircheis,<sup>†,§</sup> and Ernst Wagner<sup>\*,‡</sup>

Pharmaceutical Biology-Biotechnology, Department for Pharmacy, Ludwig-Maximilians-Universitaet, Butenandtstrasse 5-13, D-81377 Muenchen, Germany, and Boehringer Ingelheim Austria, Dr Boehringer Gasse 5-11, A-1121 Vienna, Austria. Received September 20, 2002; Revised Manuscript Received November 7, 2002

Tumor-targeting DNA complexes which can readily be generated by the mixing of stable components and freeze–thawed would be very advantageous for their subsequent application as medical products. Complexes were generated by the mixing of plasmid DNA, linear polyethylenimine (PEI22, 22 kDa) as the main DNA condensing agent, PEG–PEI (poly(ethylene glycol)-conjugated PEI) for surface shielding, and Tf–PEG–PEI (transferrin–PEG–PEI) to provide a ligand for receptor-mediated cell uptake. Within the shielding conjugates, PEG chains of varying size (5, 20, or 40 kDa) were conjugated with either linear PEI22 (22 kDa) or branched PEI25 (25 kDa). The three polymer components were mixed together at various ratios with DNA; particle size, surface charge, in vitro transfection activity, and systemic gene delivery to tumors was investigated. In general, increasing the proportion of shielding conjugate in the complex reduced surface charge, particle size, and in vitro transfection efficiency in transferrin receptor-rich K562 cells. The particle size or surface charge of the complexes containing the PEG–PEI conjugate did not significantly change after freeze–thawing, while complexes without the shielding conjugate aggregated. Complexes containing PEG–PEI conjugate efficiently transfected K562 cells after freeze–thawing. Furthermore the systemic application of freeze–thawed complexes exhibited in vivo tumor targeted expression. For complexes containing the luciferase reporter gene the highest expression was found in tumor tissue of mice. An optimum formulation for in vivo application, PEI22/Tf–PEG–PEI/PEI22–PEG5, containing plasmid DNA encoding for the tumor necrosis factor (TNF- $\alpha$ ), inhibited tumor growth in three different murine tumor models. These new DNA complexes offer simplicity and convenience, with tumor targeting activity in vivo after freeze–thawing.

## INTRODUCTION

The ability of nonviral DNA complexes to deliver genes specifically to cells and tissues in vivo offers a potential therapy for many diseases that are currently considered incurable, including some disseminated tumors (1). To date, the main developmental focus for nonviral DNA complexes for systemic tumor targeting has been improving their gene transfer in vivo. Beside the need to improve delivery efficiency, the formulation of well-defined, easily prepared complexes that can be stored over long periods is also necessary for their practical administration and development as a pharmaceutical product. For tumor-specific uptake, polyplexes (2) are usually made in relatively small batches and are required to be freshly prepared before use as they form large aggregates when stored by freezing or freeze-drying (3, 4). Furthermore, nonviral-based gene delivery systems have to be administered many times, and the formation of many types of DNA complexes requires sequential reaction steps which are both laborious and inconvenient.

Polyplexes are formed by the mixing of a solution of plasmid DNA with a solution of a cationic polymer which

collapses the DNA via electrostatic interactions. Of the cationic polymers, PEI is the most popular for gene delivery as DNA/PEI complexes display high transfection efficiency in cell culture and have potential for gene delivery in vivo (5, 6). For tumor specific uptake a ligand such as epidermal growth factor (7), folate (8), or transferrin (9) is conjugated to the cationic polymer. However, in vivo PEI/DNA complexes have been shown to interact with blood components and nontarget cells, strongly reducing their tumor targeting efficiency (10). To overcome this problem a shielding molecule such as the hydrophilic PEG molecule is conjugated to the surface of the DNA complex (11). It is believed that the highly mobile and hydrated PEG strands sterically prevent nonspecific interactions with the biological environment, prolonging the circulation time of the complex in vivo (10).

Improved systemic circulation of DNA/PEI complexes by their PEGylation was first described by Ogris et al. (10) with TF–PEI 800 kDa/DNA complexes. PEG was covalently attached to the cationic polymer after DNA polymer condensation (post-PEGylation). PEGylation not only improves systemic tumor targeting but improves solubility of the DNA complexes allowing for formulations to be prepared at the higher therapeutic concentrations without aggregation (10, 12). Furthermore, PEGylation reduces the in vivo toxicity of DNA complexes containing PEI (10, 13).

<sup>§</sup> Present address: Igeneon AG, Vienna, Austria.

**Figure 1.** A schematic presentation of alternative strategies for the formation of a PEG shielded, ligand-containing DNA-polymer complex. Strategy A: DNA is condensed with a polycation (step 1), heterobifunctional PEG is covalently attached to the amino groups of the polycation at the surface (step 2), ligands are covalently attached to the distal end of the PEG chain (step 3). Strategy B: DNA-condensing agent PEI, targeting conjugate ligand-PEG-PEI and shielding conjugate PEG-PEI are mixed together (step 1), DNA in buffer is then added and mixed (step 2).

Recently, it was observed that DNA complexes with lower molecular weight PEIs (25 kDa branched, 22 kDa linear) display less systemic toxicity than the PEI 800 kDa complexes (9). Subsequently it was shown that DNA complexes of low molecular weight PEI could also be successfully post-PEGylated.

The major drawback of post-PEGylation of DNA complexes is that they require an additional sequential synthesis step which is time-consuming; furthermore, the degree of surface PEGylation is not well defined. Another strategy for the PEGylation of DNA complexes is to synthesize a copolymer of the condensing and the shielding agent prior to the mixing of DNA, for instance, polylysine-PEG (8, 14–16) and PEI-PEG (17–19) copolymers. However, the major limitation of these copolymers is that the hydrophilic part appears to hinder proper DNA condensation and particle formation (14, 17).

Work with an alternative shielding agent, transferrin, showed that although Tf-PEI (22 and 25 kDa) conjugates were not able to condense DNA either, the inclusion of extra unmodified PEI25 in the complex enabled efficient DNA condensation and particle formation (9, 20). Since post-PEGylation was not required for these complexes, they could be quickly and easily generated by the flash mixing of three components, Tf-PEI, unmodified linear PEI22, and DNA.

In this work we present novel tumor-targeting PEG shielded DNA complexes which can be formed more quickly and easily generated than post-PEGylation strategies (7) (Figure 1). Furthermore these new DNA complexes containing the PEI-PEG shielding conjugate were shown to have tumor-targeting activity after freeze-thawing.

## MATERIALS AND METHODS

**Reagents and Assays.** Branched PEI with an average molecular weight of 25 kDa (PEI25) was obtained from Sigma-Aldrich (Vienna, Austria). Linear PEI with an average molecular weight of 22 kDa (PEI22) is available from Euromedex (Exgen 500, Euromedex, Souffelweyersheim, France). For complex preparation, PEI was used as a 1 mg/mL working solution, neutralized with HCl. Liquid chromatography of conjugates was performed with a Merck-Hitachi L-6220 pump, with a L-4500A UV-vis diode array detector. PEI content of conjugate fractions was determined spectrophotometrically by ninhydrin assay at 570 nm (21) and DNA mobility shift assay by

**Table 1.** Conjugation Ratio of Shielding Conjugates Generated

conjugate	ratio (PEI:PEG)
PEI22-PEG20	1/0.9
PEI25-PEG20	1/0.9
PEI22-PEG5	1/4.4
PEI25-PEG5	1/23
PEI22-PEG40	1/0.1 <sup>a</sup> , 1/0.3 <sup>b</sup>
PEI25-PEG40	1/0.4
PEI22-ss-PEG5	1/0.7

<sup>a</sup> PEI was incubated with PEG succinimide for 1 h. <sup>b</sup> PEI was incubated with PEG succinimide for 24 h.

agarose gel electrophoresis. PEG derivatives were obtained from Shearwater Polymers (Birmingham, AL). The modification of PEI with PEG (molar ratio of PEI/PEG) in conjugates was determined by proton NMR spectrometry (400 MHz, Bruker, Germany). Succinimidyl 3-(2-pyridyldithio)propionate (SPDP) was purchased from Fluka (Buchs, Switzerland) and 2-iminothiolane from Sigma (Vienna, Austria). The amount of dithiopyridine linkers in modified PEI was determined after reduction of an aliquot with dithiothreitol (DTT) followed by absorption measurement of released pyridine-2-thione at 340 nm. The amount of free mercapto groups was determined by Ellman assay at 412 nm (22) using 5,5'-dithiobis(2-nitrobenzoic acid) (Sigma, Vienna, Austria). Transferrin (iron-free) was obtained from Biotest (Dreieich, Germany), cell culture media, antibiotics, fetal calf serum (FCS) from Life Technologies (Gaithersburg, MD). Plasmid pCMVLuc (*Photinus pyralis* luciferase under control of the CMV enhancer/promoter) described in Plank et al. (23) was purified with the EndoFree Plasmid Kit from Qiagen (Hilden, Germany). Plasmid pGSmtNF $\alpha$  coding for murine TNF $\alpha$  was purified by ELIM Biopharmaceuticals (San Francisco, CA). Endotoxin (LPS) levels were <0.1 endotoxin units/50  $\mu$ g DNA as determined by Limulus Amebocyte Lysate assay (BioWhittaker, Walkersville, MD).

**Synthesis of PEG-PEI Conjugates.** *PEI22-PEG20 and PEI25-PEG20 Conjugate.* A gel-filtered (Sephadex G-25 superfine, Pharmacia, Sweden) solution of PEI22 HCl (0.7  $\mu$ mol), at pH of 6 in 1 mL of 0.25 M NaCl, was mixed with a 2  $\mu$ mol of PEG succinimidyl propionate (methoxy-PEG-SPA; MW 20 kDa) dissolved in 0.8 mL of water. The pH of the solution was adjusted to 7.1 by the addition of 25  $\mu$ L of 2 M HEPES, pH 7.9. After 24 h, 0.6 mL of 3 M NaCl and 1.6 mL of water were added to the incubate to give a final NaCl concentration of 0.5 M. The reaction mixture was loaded on a cation-exchange column (Macro-prep High S; HR 10/10, BioRad, München, Germany) and fractionated with a salt gradient from 0.5 to 3.0 M NaCl in 20 mM HEPES pH 7.1. The product (6 mL) was eluted between 2.3 and 2.8 M NaCl. All PEI-PEG conjugates were dialyzed against 2 L of HBS (20 mM HEPES pH 7.3, containing 150 mM NaCl), and the conjugation ratio of PEI modified with PEG was determined by 400 MHz proton NMR (Table 1). The yield of the PEI22-PEG20 and PEI25-PEG20 synthesized in a similar manner based on PEI was 63% and 95%, respectively. The conjugate was diluted to 1 mg/mL PEI equivalent concentration by addition of HBS buffer, pH 7.3, and then divided into convenient small aliquots and stored at -20 °C.

*PEI22-PEG5 and PEI25-PEG5 conjugates* were prepared in analogous manner to PEI-PEG20 conjugates by mixing 0.7  $\mu$ mol of PEI HCl salt in 1 mL of 20 mM HEPES pH 7.1 with 42 equiv (in case of PEI22) or 50 equiv (in case of PEI25) of PEG succinimidyl propionate

(Methoxy-PEG-SPA; MW 5000) dissolved in 0.7 mL of DMSO. After 1 h incubation, the PEI conjugates were isolated by a cation-exchange column and dialyzed.

**PEI22-PEG40 Conjugate.** A gel-filtered solution of PEI22 (0.7  $\mu$ mol) in 1 mL of 0.25 M NaCl was mixed with a 0.8 mL aqueous solution of 2  $\mu$ mol branched PEG succinimide (branched-PEG2-NHS ester; MW 40 kDa). The solution was incubated at pH 7.1 for 1 h (a) or 24 h (b), respectively; 0.6 mL of 3 M NaCl and 1.5 mL of water were added to bring the solution to 0.5 M NaCl. The reaction mixture was loaded on a cation-exchange column (BioRad Macro-prep High S; HR 10/10) and fractionated with a salt gradient from 0.5 to 3.0 M NaCl in 20 mM HEPES, pH 7.1, buffer. The conjugate product (4 mL) was eluted between 2.6 and 2.9 M NaCl.

**PEI25-PEG40 conjugate** was similarly prepared as for PEI22-PEG40. Gel-filtered PEI25 (0.6  $\mu$ mol, HCl form) in 1 mL of 0.15 M NaCl was mixed with a 0.8 mL aqueous solution of 1.8  $\mu$ mol of branched PEG succinimide (branched-PEG2-NHS ester; MW 40 kDa). After 24 h, PEI conjugate was isolated on the cation-exchange column and dialyzed.

**PEI22ssPEG5 conjugate** was prepared as follows: to a solution of 1.4  $\mu$ mol of PEI22 as HCl salt in 1 mL of 0.25 M NaCl, 20 mM HEPES, pH 7.1, 0.27 mL of 10 mM ethanol containing of 2.9  $\mu$ mol of SPDP was added, and after purification by gel filtration (Sephadex G-25 superfine; HR 10/30 column; 0.25 M NaCl, 20 mM HEPES, pH 7.1), 5 mL of product containing 30 mg of PEI22 and 1.5  $\mu$ mol of dithiopyridine linker was obtained and quantified spectrophotometrically at 343 nm by release of thiopyridone after reduction of an aliquot with excess DTT (24). To 2 mL of this solution (0.6  $\mu$ mol of PEI), 30  $\mu$ mol of DTT in 0.1 mL of 20 mM HEPES buffer, pH 7.1, containing 0.25 M NaCl was added to yield (after gel filtration) 0.5  $\mu$ mol of PEI22 modified with 0.5  $\mu$ mol of mercaptopropionate linker. A solution of 0.6  $\mu$ mol of PEG-orthopyridyl-disulfide (methoxy-PEG-OPSS; MW 5000) in 0.1 mL of 20 mM HEPES, pH 7.1, was added under argon and incubated for 48 h and then purified by cation-exchange chromatography.

**Synthesis of Tf-PEG-PEI25 Conjugate.** To a solution of 4.1  $\mu$ mol of PEI25 (HCl form, after gel filtration with Sephadex G-25 superfine) in 1.3 mL of 0.7 M NaCl, 810  $\mu$ L of a 10 mM ethanolic solution of SPDP (8.1  $\mu$ mol) was added while mixing vigorously. After 1 h at room temperature, purification was performed by gel filtration (Sephadex G-25 superfine, HR 10/30 column; 20 mM HEPES, pH 7.1, containing 0.25 M NaCl) to give 5 mL of a solution of 3.9  $\mu$ mol of PEI25 modified with 6  $\mu$ mol of dithiopyridine linker (molar ratio of 1/1.5). Half of the solution (containing 49 mg of PEI25) was treated with 150  $\mu$ mol of DTT in 0.1 mL of 20 mM HEPES, pH 7.1, containing 0.25 M NaCl, and the reaction mixture was kept under argon for 1 h. After gel filtration (Sephadex G-25 superfine, HR 10/10 column; 0.25 M NaCl, 20 mM HEPES, pH 7.1; under argon), a solution of 1.6  $\mu$ mol of PEI25 modified with 2.7  $\mu$ mol of mercaptopropionate linker (1.7 linker for each PEI chain) was obtained.

A solution of 2.5  $\mu$ mol of transferrin (human, iron-free) in 4 mL of a 0.15 M NaCl was subjected to gel filtration with 30 mM sodium acetate pH 5.0 on a Sephadex G-25 superfine column (Pharmacia; HR 10/30). The resulting 6.6 mL of product was concentrated (speed-vac) to a volume of 2.7 mL, containing 2  $\mu$ mol of transferrin. The pH was adjusted to 7.3 by addition of sodium bicarbonate and 25  $\mu$ L of 2 M HEPES, pH 7.3. Part of the solution (0.9  $\mu$ mol) of transferrin in 1.25 mL was mixed with a

solution of 1.05  $\mu$ mol of *N*-hydroxysuccinimide-PEG-maleimide (NHS-PEG-MAL; MW 3400) in 0.1 mL of water. After 3 h at room temperature, the reaction mixture was added under argon to the mercaptopropionate-modified PEI25 solution (0.8  $\mu$ mol of PEI; 1.3  $\mu$ mol of mercaptopropionate linker) in 1.5 mL of 20 mM HEPES, pH 7.1, containing 0.25 M NaCl, at a molar ratio of 1/1.2 (maleimide linker/SH group) and kept under argon for 24 h at room temperature. The mixture was diluted with 0.9 mL of 3 M NaCl and 2.5 mL of water, and conjugate was isolated by cation-exchange chromatography (BioRad Macro-prep High S; HR 10/10 column) with a salt gradient from 0.5 to 3.0 M NaCl with a constant content of 20 mM HEPES, pH 7.1. The 8 mL of product was eluted between 2.2 and 3.0 M NaCl. After dialysis against 2 L of HBS (20 mM HEPES pH 7.3, 150 mM NaCl), 11.4 mL of conjugate consisting of 170 nmol of transferrin modified through PEG bridges with 0.4  $\mu$ mol PEI25 at a molar ratio of 1/2.4 was obtained. The yield (based on PEI25) was 52%.

Iron incorporation into transferrin was performed by addition of 1.25  $\mu$ L of 10 mM iron(III) citrate buffer (containing 200 mM citrate and adjusted to pH 7.8 by sodium bicarbonate addition) per milligram of transferrin content. The conjugate was left at 0.9 mg PEI/mL concentration, divided into convenient small aliquots, and stored at  $-20^{\circ}\text{C}$ .

**Synthesis of Tf-PEG-PEI22 Conjugate.** PEI22 (1.3  $\mu$ mol, hydrochloride salt, after gel filtration with Sephadex G-25 superfine) in 2.45 mL of 0.18 M NaCl was mixed under argon with a solution of 0.4  $\mu$ mol of 2-iminothiolane in 50  $\mu$ L of 15 mM HEPES, pH 8.5, and kept under argon for 2 h. The mixture was diluted with 1.3 mL of 3 M NaCl and 5.2 mL of water and separated by cation-exchange chromatography under argon (BioRad Macro-prep High S, HR 10/10 column; gradient elution 22–100% buffer A; buffer A, 20 mM HEPES, pH 7.1, containing 3 M NaCl; buffer B, 20 mM HEPES pH 7.1). The 4.5 mL of PEI product was eluted at a NaCl concentration of approximately 2.5–2.9 M. After gel filtration under argon with 20 mM HEPES, pH 7.1, containing 0.25 M NaCl (Sephadex G-25 superfine, HR 10/30 column), 4.3 mL solution containing 0.8  $\mu$ mol of PEI22 modified with 0.6  $\mu$ mol of thiolane linker (molar ratio of 1.5/1) was obtained.

A solution of 0.4  $\mu$ mol of transferrin in 1.6 mL of 30 mM HEPES, pH 8.5, was mixed under argon with a solution of 1.3  $\mu$ mol of 2-iminothiolane in 100  $\mu$ L of 15 mM HEPES, pH 8.5. After 3 h at room temperature, purification was performed by gel filtration under argon with HBS, pH 7.3, on a Sephadex G-50 superfine column (HR 10/10) to give 2.8 mL of a solution of 0.3  $\mu$ mol of transferrin modified with 0.55  $\mu$ mol of thiolane linker (molar ratio of 1/1.8). This solution was mixed under argon with a solution of 0.55  $\mu$ mol of PEG-bis-orthopyridyl-disulfide (PEG-[OPSS]<sub>2</sub>; MW 3400) in 0.2 mL of HBS, pH 7.3, and kept at room temperature for approximately 70 h. After gel filtration (Sephadex G-50, HR 10/30; HBS pH 7.3), 3.3 mL of product containing 0.3  $\mu$ mol of transferrin modified with PEG with 0.15  $\mu$ mol of dithiopyridine linker (molar ratio of 2/1) was obtained. The modified transferrin solution was added under argon to the thiolane-modified PEI22 solution (0.2  $\mu$ mol of PEI; 0.15  $\mu$ mol of thiolane linker) in 1.15 mL of 20 mM HEPES, pH 7.1, containing 0.25 M NaCl, at a molar ratio 1/1 (SS-pyridine linker/SH group). After 24 h at room temperature, 1.1 mL of 3 M NaCl and 2.5 mL of water were added to bring the solution to a salt concentration of about 0.5 M. The reaction mixture was loaded on a

cation-exchange column (BioRad Macro-prep High S; HR 10/10) and fractionated with a salt gradient from 0.5 to 3.0 M NaCl with a constant content of 20 mM HEPES pH 7.1. The 7.6 mL of product was eluted between 1.9 and 2.8 M salt and concentrated (speed-vac) to a volume of 4.5 mL. The resulting 4.5 mL of solution was subjected to gel filtration with HBS, pH 7.3, on a Superdex-75 column (HR 10/30) to give 6 mL of conjugate consisting of 63 nmol of transferrin modified through PEG linker with 68 nmol of PEI22 (molar ratio of 1/1.1). The yield based on PEI was 32%. The iron incorporation into conjugates was performed as described above.

**Formation of Transfection Complexes.** DNA complexes were prepared by first diluting and mixing free PEI22 with various amounts of PEG-PEI and Tf-PEG-PEI conjugates in the indicated ratios and buffer. Plasmid DNA diluted in buffer was mixed with the PEI-conjugate buffer solution. Complexes were formed at a molar ratio of PEI nitrogen atoms to DNA phosphate (N/P) of 6. Complexes were prepared in either 0.5× HBS for in vitro application or 20 mM HEPES, pH 7.1, for in vivo application. Complexes were allowed to stand for at least 20 min at room temperature before use. Final concentration of DNA in complexes for in vitro application was 10  $\mu\text{g/mL}$ , while for in vivo it was 200  $\mu\text{g/mL}$ . DNA complexes prepared at the higher DNA concentration for in vivo application (200  $\mu\text{g/mL}$ ) were shock-frozen in liquid nitrogen and stored at  $-20^\circ\text{C}$ . To obtain isosmolarity glucose stock (50% w/v) was added to give a final glucose concentration of 5% (w/v). For determining the biophysical parameters, glucose was added to the DNA complex solution either before freezing or after thawing. For all DNA complexes that are applied systemically to mice, glucose was added after thawing. DNA complexes were thawed rapidly with mixing in a water bath at  $37^\circ\text{C}$  and then placed on ice and stood at room temperature for at least 1 h before use.

For example, for in vitro transfection complexes were generated containing 20  $\mu\text{g}$  of DNA in 1 mL total volume. For this purpose, 20  $\mu\text{g}$  (60.6 nmol phosphate) of pCMV-Luc plasmid was diluted to a volume of 0.5 mL with 0.5× HBS buffer and added to 363 nmol nitrogen of PEI (including PEI conjugates) in 0.5 mL of the same buffer with rapid mixing by pipetting.

Measurement of particle size and zeta-potential. Particle size of transfection complexes was measured by laser-light scattering using a Malvern Zetasizer 3000HS (Malvern Instruments, Worcestershire, UK). For particle sizing, complexes were diluted in the appropriate buffer to give a final DNA concentration of 10  $\mu\text{g/mL}$ . For estimation of the surface charge, transfection complexes were diluted in 10 mM NaCl to give a DNA final concentration of 2  $\mu\text{g/mL}$ , and the zeta-potential was measured as previously described (25).

**Cells Culture and Transfection.** K562 suspension cells (ATCC CCL-243) were grown in RPMI 1640 medium supplemented with 10% FCS and 6 mM L-glutamine, at  $37^\circ\text{C}$  in a 5%  $\text{CO}_2$  humidified atmosphere. Cells were placed in fresh medium containing 50  $\mu\text{M}$  desferrioxamine 16 h before transfection. Before transfection, the cells were collected, resuspended in fresh medium (10% FCS, 68 mM L-glutamine), and plated in a 24-well plate at a density of  $5 \times 10^5$  cells in 1.5 mL per well. Transfection complexes (0.5 mL, 5  $\mu\text{g}$  DNA) were added to the cells, and after 4 h incubation at  $37^\circ\text{C}$ , transfection medium was replaced by 2 mL of fresh culture medium. The cells were harvested 20–22 h after transfection and lysed with 1 mL of lysis buffer (25 mM Tris-phosphate, pH 7.8, 2 mM DTT, 2 mM CDTA pH 7.8, 10% glycerol, 1% Triton

X-100) per well. Luciferase activity was determined from aliquots of the lysate using a luminometer (Lumat LB9507, Berthold, Bad Wildbad, Germany). Values are given as light units and represent the total luciferase activity per  $5 \times 10^5$  cells as mean  $\pm$  standard deviations of at least triplicates.

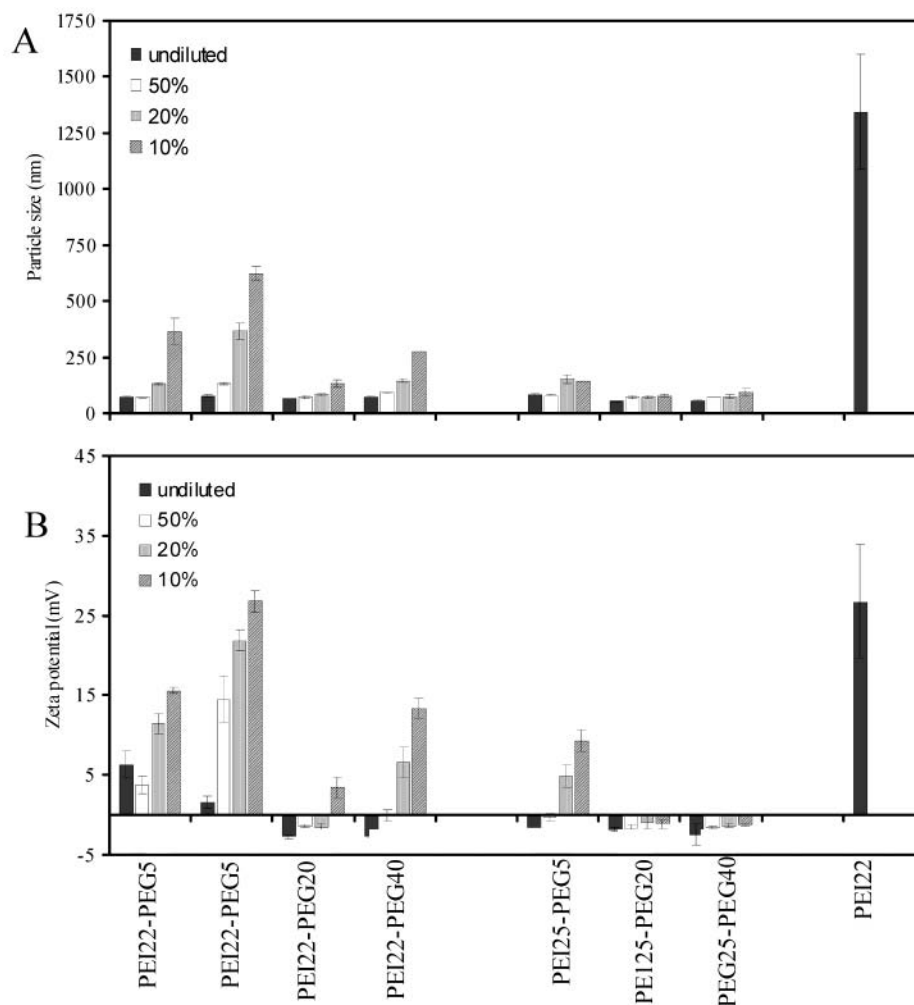

**Systemic Application of Transfection Complexes in Tumor-Bearing Mice.** A/J mice (7–8 weeks, female) were purchased from Harlan, Bicester, UK. Mice were injected subcutaneously with  $1 \times 10^6$  Neuro2a neuroblastoma cells (ATCC CCL 131). After 2 weeks, when tumors had reached approximately 10–13 mm in diameter, transfection complexes were applied. The thawed transfection complexes with the pCMVL plasmid (50  $\mu\text{g}$  DNA, at 200  $\mu\text{g/mL}$ ) coding the luciferase prepared in 20 mM HEPES, pH 7.1, were injected into the tail vein. At 24 h after injection, animals were sacrificed and the indicated tissues were resected, frozen in liquid nitrogen, and stored at  $-80^\circ\text{C}$ . Tissues were homogenized in 250 mM Tris-buffer, pH 7.5, using an IKA-Homogenizer, and frozen in liquid nitrogen, and the tissue lysates were stored at  $-80^\circ\text{C}$  until assay of luciferase activity (as described above). Luciferase background (100–200 RLU) was subtracted from each value and transfection efficacy is expressed as RLU per tumor. One million RLU correspond approximately to 2 ng of luciferase.

**Systemic Application of TNF $\alpha$  DNA Complexes in Therapeutic Models.** A/J mice were injected subcutaneously with  $1 \times 10^6$  syngeneic Neuro2a tumor cells, DBA/2 mice were injected with  $1 \times 10^6$  M-3 (ATCC CCL131) cells, and C57Bl6 mice were injected with  $1 \times 10^6$  B16F10 cells (kindly provided by Dr. Fidler, M. D. Anderson Hospital, Houston, TX). Starting at indicated time points after tumor setting, when tumors reached sizes of 5–8 mm in diameter, thawed DNA complex containing 50  $\mu\text{g}$  of plasmid pGSmuTNF $\alpha$  coding for murine TNF $\alpha$  in 20 mM HEPES, pH 7.1, and 5% (w/w) glucose was injected into the tail vein. For control animals, 0.25 mL 0.9% (w/v) NaCl was injected into the tail vein. Injections were repeated 5–7 times as indicated, and tumor sizes of the animals were monitored. Differences in tumor growth were statistically analyzed using one-way ANOVA, using GraphPad Prism software.

## RESULTS AND DISCUSSION

**Synthesis of PEG-PEI and Tf-PEG-PEI Conjugates.** Several different PEG-PEI shielding conjugates were generated by modifying amino groups of 22 kDa linear PEI or the 25 kDa branched PEI with *N*-hydroxysuccinimide ester derivatives of PEG of 5, 20, or 40 kDa. In addition, a disulfide-bridged conjugate, PEI22ssPEG5, was synthesized by reacting mercaptopropionate-modified 22 kDa PEI with 5 kDa PEG-orthopyridyl disulfide. Conjugates were purified by cation exchange chromatography, and PEG:PEI ratios were analyzed by proton NMR. These coupling efficiencies are shown in Table 1. The highest coupling ratio of 23 was generated for the PEI25-PEG5 conjugate. This is most likely due to the highly branched PEI25 core having a large number of primary amines available to react with PEG. Likewise a much lower coupling ratio of 4.4 was observed for the PEI22-PEG5 conjugate, which has a linear PEI core. The size of the PEG molecule conjugated also influences the efficiency of the coupling reaction. For copolymers with either branched or linear PEI core the coupling efficiency decreases with increasing PEG size.

For receptor-specific targeting of the complexes, transferrin was linked to either 22 kDa linear or 25 kDa

**Figure 2.** Particle size (A) and zeta-potential (B) of DNA complexes generated in  $0.5\times$  HBS at a final DNA concentration of  $20\text{ }\mu\text{g/mL}$  at a PEI/DNA charge ratio of  $N/P = 6$ . PEG–PEI conjugates were mixed with unmodified PEI22; the percentage of PEG–PEI conjugate was 50, 20, and 10 by weight relative to PEI. Measurements were made approximately 30 min after mixing of the components. Each data value represents mean  $\pm$  SD of three experiments.

branched PEI via a PEG bridging molecule to form the Tf–PEG–PEI, the targeting conjugate. The Tf–PEG–PEI25 conjugate was generated by first modifying PEI25 with SPDP and conversion into the mercaptopropionate form, reaction of transferrin amino groups with heterobifunctional ( $\alpha$ -maleimide- $\omega$ -*N*-hydroxysuccinimide ester) 3.4 kDa PEG derivative, and reacting the maleimide group at the distal end of the PEG-chain in the Tf conjugate with the thiol-functionalized PEI25. The resulting Tf–PEG–PEI25 polymer after purification contained approximately one Tf ligand on average per two PEI molecules.

In the Tf–PEG–PEI22 targeting conjugate, both PEI and transferrin were modified separately with iminothiolane. The modified transferrin was reacted with bifunctional PEG derivative PEG-bis-orthopyridyl-disulfide. The reaction mixture was subsequently reacted with the sulfhydryl groups of the iminothiolane-modified PEI22. The purified conjugate contained approximately one Tf ligand to one PEI molecule.

**Formation of DNA Complexes.** The concept of how post-PEGylated and the new PEGylated DNA particles described here are formed is presented in Figure 1. The previous post-PEGylation method involves three sequential steps (path a). First, DNA is condensed to the cationic PEI, and then PEG is covalently attached to the surface.

For receptor-mediated cell uptake, the targeting ligand is covalently attached to some of the surface-exposed PEG chains.

For the new method of PEGylation described here, complex formation requires only two quick sequential steps (path b). Unlike the postPEGylation method, conjugation of shielding and targeting agents is performed prior to DNA complex formation. The two copolymers, PEG–PEI for surface shielding and Tf–PEG–PEI for receptor-mediated cell uptake, are synthesized as described above and stored at  $-20\text{ }^{\circ}\text{C}$  until required. The two copolymers and unmodified PEI22, the main DNA condensing agent, are mixed together, followed by the addition of plasmid DNA.

To explore the effect of PEG conjugates, in the first physical characterization studies, the targeting conjugate was omitted. The shielding conjugate was mixed with PEI22 at various ratios with plasmid DNA at  $10\text{ }\mu\text{g/mL}$ . These complexes were analyzed fresh by laser-light scattering (Figure 2). The size and surface charge of these particles varied depending upon the amount and type of shielding conjugate in the complex. The particle size and zeta potential of DNA complexes generated from the various shielding conjugates is shown in Figures 2, parts A and B, respectively. Figure 2A shows that for the linear PEI shielding PEG conjugate there is an increase in particle size when its fraction is reduced in the complex.

This effect was greatest for the low molecular weight 5 kDa PEG shielding conjugates, followed by the branched 40 kDa PEG and the linear 20 kDa PEG. In contrast, it appears that decreasing amount of branched PEI shielding PEG conjugate in the complex has less effect on the particle size (Figure 2A).

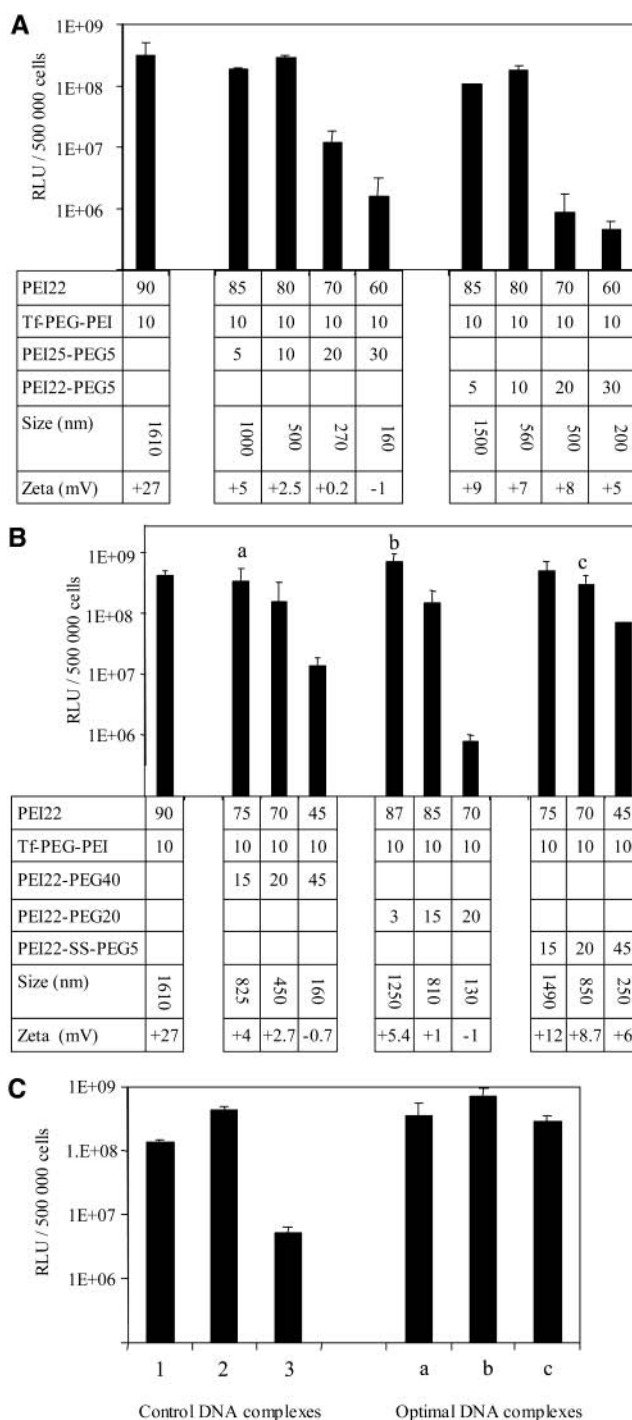

The zeta potential data (Figure 2B) is also shown to be influenced by the ratio of the linear shielding PEG conjugate in the complex, while the branched PEI shielding conjugate has lesser effect on the zeta potential. Decreasing the amount of linear PEI shielding conjugate in the complex results in an increase in the surface charge. For the branched shielding conjugate, the complexes have a surface charge near neutral with the exception of the 5 kDa PEG at the two lowest concentrations in the complexes.

**In Vitro Transfection Efficiency of DNA Complexes.** To determine the effect of the shielding conjugate on receptor-mediated cell uptake in vitro, the complexes were prepared with the targeting conjugate, Tf-PEG-PEI, which was maintained at 10% of total PEI (w/w) in the complex. Luciferase transfection efficiency was determined with freshly prepared complexes in the transferrin receptor-rich erythromyeloid cell line K562 (26, 27). Gene expression was determined by luciferase activity using a luminometer (Figure 3). Figure 3A compares the transfection efficiency of branched and linear PEI shielding conjugates, with the low molecular weight shielding PEG (5 kDa). There appears to be little difference in transfection efficiencies for both branched and linear PEI conjugates, with maximum transfection efficiency when the shielding conjugate represents 5 and 10% of the complex.

Figure 3B compares the transfection efficiencies of the linear PEI22 conjugated with 40, 20, or 5 kDa PEG. Transfection efficiency of these complexes was highest when the fraction of the shielding conjugate was at the two lowest fractions tested in the complex. The maximum transfection efficiencies for all complexes tested were similar to the control complex, which consists of PEI22 and the targeting conjugate Tf-PEG-PEI only. Although the control has a high transfection efficiency, it has a high positive surface charge of +27 mV, while the shielded conjugates have a surface charge in the range of -1 to +12 mV. The high positive surface charge on the control complex is expected to result in the complex interacting with serum proteins when applied systemically, resulting in particle aggregation and loss of systemic targeting activity (10).

On the basis of the biophysical properties of the complexes and their in vitro transfection efficiency, complexes a, b, and c (Figure 3B) were chosen as optimal. Optimum ratios for the 40 and 20 kDa PEG shielding conjugates was based on their high transfection efficiency. For the low molecular weight 5 kDa PEGylated conjugates, the complex with the highest transfection efficiency had a high surface positive charge of +12 mV and was not expected to be effective in vivo, therefore a formulation of medium PEG conjugate content was chosen.

Figure 3C gives a direct comparison of the transfection efficiency of the three optimal complexes from Figure 3B with two additional control complexes. The three optimal formulations tested all showed similar transfection efficiencies, comparable to the control complex "2" consisting of Tf-PEG-PEI/PEI22. The DNA/PEI22 control complex "1", without the targeting conjugate, has slightly lower transfection efficiency. The high transfection efficiency of the DNA/PEI complex is believed to be due to

**Figure 3.** In vitro transfection efficiency of DNA complexes. Complexes were prepared in  $0.5 \times$  HBS at a DNA concentration of  $10 \mu\text{g/mL}$ , N/P ratio of 6.0. First, the Tf-PEG-PEI conjugate was mixed with various amounts of PEI-PEG conjugate and PEI22 in 0.25 mL buffer (containing  $3.9 \mu\text{g}$  of PEI in total), and then  $5 \mu\text{g}$  of pCMVL in 0.25 mL of buffer was added. The percentages of components in the complex are based on PEI: (A) 5 kDa PEG conjugated with branched or linear core PEI; (B) linear core PEI conjugated with 40, 20, or 5 kDa PEG. (C) Transferrin is required for gene transfer to K562 cells. Control DNA complexes, 1; PEI22, without shielding and targeting conjugate, 2; PEI22 (90%) and Tf-PEG-PEI targeting conjugate (10%), without shielding conjugate, 3; PEI22 (85%) and PEI-PEG40 shielding conjugate (15%), without targeting conjugate. Optimal DNA complexes a, b, and c as described in Figure 3B. All DNA complexes were applied fresh to the K562 cells; luciferase activity of transfected K562 cells ( $5 \mu\text{g}$  DNA per 500,000 cells) is shown as mean  $\pm$  SD, of four to six experiments.

**Table 2.** Effect of Freeze–Thawing on Particle Size and Zeta Potential of DNA Complexes Formed with and without PEG–PEI Shielding Conjugate

complex	components (%)	fresh		frozen	
		size (nm)	zeta (mV)	size (nm)	zeta (mV)
non PEG–PEI shielded	Tf–PEI (25) PEI22 (75)	270 ± 34	+4.9 ± 0.7	> 1000 (aggregates)	aggregates
PEG–PEI shielded	Tf–PEG–PEI (10)	214 ± 22	+5.6 ± 1.5	271 ± 34 <sup>a</sup>	+2.8 ± 0.2 <sup>a</sup>
	PEG20–PEI22 (20)			1250 ± 118 <sup>b</sup>	+2.3 ± 0.1 <sup>b</sup>
	PEI22 (70)				

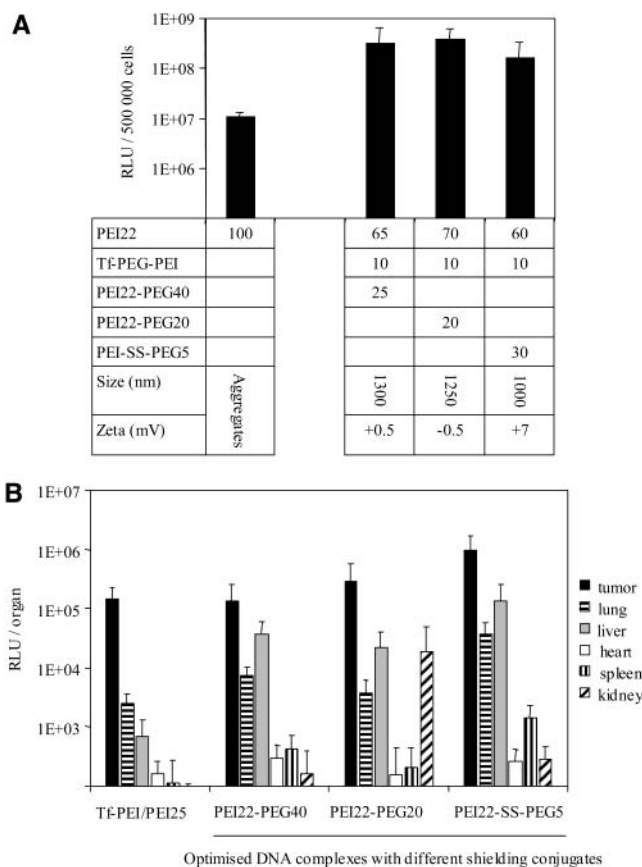

<sup>a</sup> Glucose was added after complex formation and before freezing. <sup>b</sup> Glucose was added after thawing.

its high surface charge of +31 mV (data not shown) which will facilitate its binding to the cell surface by electrostatic attraction (28). The third control “3” consists of DNA, PEI, and the shielding conjugate PEI22–PEG40, analogous to formulation “a” but lacking the targeting conjugate. The inclusion of the shielding conjugate in the complex reduced the surface charge of the complex to +10 mV (data not shown). The transfection efficiency of this complex was about 100-fold lower than the analogous complexes containing Tf ligand (Figure 3C, compare with formulation “a”). The lower transfection efficiency in comparison to the other control complexes can be attributed to the lower surface charge of the complex, resulting in reduced electrostatic interactions with the cell surface. The higher transfection rate of the transferrin targeting DNA complexes “a” indicates transferrin receptor-mediated internalization of the complexes in K562 cells, which is consistent with our previous work (26, 27, 29).

**Freeze–Thawing of DNA Complexes for in Vivo Application.** It would be of great convenience to store DNA complexes frozen and thaw them prior to their in vivo application. Since previous work demonstrated a strong correlation between the maintenance of particle size/zeta potential and retention of transfection rates (30), the biophysical parameters (particle size and zeta potential) of complexes before and after freeze–thawing was first determined. To determine whether the inclusion of PEG conjugates in the complex affords greater freeze–thawing stability, we compared Tf-targeting DNA complexes with and without PEG conjugates. The ratio of the components in the complexes is shown in Table 2.

To deliver therapeutic amounts of DNA to tumor-bearing mice, a higher concentration of DNA (200 µg/mL) is required. The physical parameters of the complexes were determined with DNA at the higher in vivo concentration of 200 µg/mL, with an N/P of 6. However complexes containing such high concentrations of DNA have been shown to have a higher tendency to aggregate (30). To prevent aggregation of DNA particles, a greater amount (20–30%) of the shielding conjugate in the complexes is required to maintain particles sizes similar to those in the earlier in vitro transfection studies (Figure 4A). In these biophysical studies, PEGylated complexes contained 20% shielding conjugate (Table 2). Complexes were prepared in 20 mM HEPES, pH 7.1, in the absence of NaCl, as previously it was shown that NaCl is a driving force for particle aggregation (30, 31). Furthermore, previous work showed that sugars (sucrose, trehalose, or maltose) were required to maintain size and transfection efficiency of DNA/polymer complexes after freeze–thawing (32). Therefore to minimize aggregation, glucose was added to the complexes after complex formation and before freezing at 5% (w/v) to obtain iso-osmolarity. The effect of adding glucose only after thawing was also investigated as indicated in Table 2.

Both PEGylated and non-PEGylated complexes freshly prepared had similar particle size and a surface charge

**Figure 4.** Transfection efficiency of optimized DNA complexes prepared with DNA at a higher concentration for in vivo application. Complexes were prepared with DNA at 200 µg/mL, N/P ratio of 6.0, in 20 mM HEPES pH 7.1, snap frozen in liquid nitrogen and stored at –20 °C. DNA complexes were thawed in glucose (5% w/v, final concentration). (A) In vitro transfection: the complexes were diluted after thawing with 20 mM HEPES, pH 7.1, to a DNA concentration of 10 µg/mL. Luciferase activity of K562 cells transfected with 5 µg pCMVL DNA per 5 × 10<sup>5</sup> cells represents the mean ± SD of four to five experiments. (B) Biodistribution of reporter gene expression after systemic gene delivery. The DNA complexes (pCMVL, 50 µg per mouse) after thawing in glucose were injected into the tail vein of Neuro2a tumor-bearing A/J mice. The control complexes (Tf-PEI/PEI25, N/P of 4.8) were freshly prepared as previously described. The biodistribution of gene expression was determined after 24 h by luciferase activity (mean ± SD, *n* = 6 animals per group).

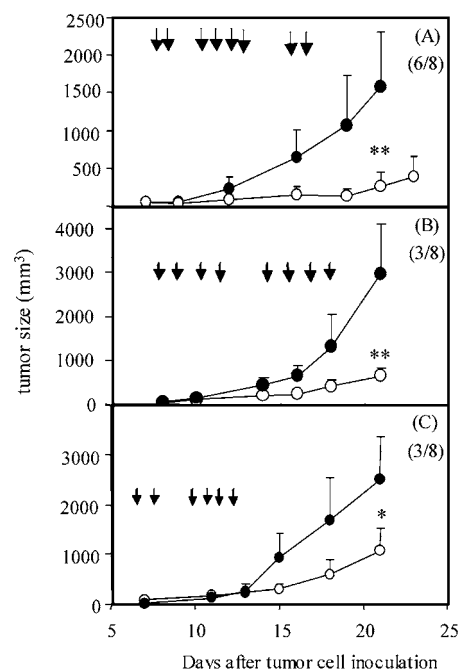

near neutral (Table 2). After freeze–thawing of these complexes, the particle size and zeta potential of the PEGylated complex was comparable to the fresh complex, while the non PEGylated complexes grew in size (Table 2). These results suggest that PEGylation can not only stabilize DNA/polymer particles in solution but also prevent aggregation upon the freeze–thawing process. Similarly, it was shown that a DNA–peptide condensing agent when PEGylated was an efficient lyoprotectant, with respect to maintaining particle size (33).

Interestingly, larger but stable PEGylated particles could be generated when glucose was only added after thawing (Table 2). Larger Tf-PEI/DNA complexes ( $\sim 1 \mu\text{m}$ ) have previously been shown to have higher transfection efficiencies (30). Therefore these large, stable DNA complexes were used to deliver plasmid DNA systemically to mice.

**Formulation of DNA Complexes for in Vivo Application.** DNA complexes were formed with the higher concentration of DNA ( $200 \mu\text{g/mL}$ ) and shielding conjugate (20–30%). Complexes were snap frozen and stored, and glucose was added to the complexes after they were thawed, as described in Table 2. Figure 4A shows the physical characteristics and in vitro transfection efficiencies of the three optimized formulations generated at the higher DNA concentration of  $200 \mu\text{g/mL}$ . The particles which we have chosen for further evaluation have a diameter of around  $1 \mu\text{m}$ , slightly larger in size than those prepared with lower amounts of DNA (compare with Figure 3). Importantly for in vivo application, the increased amount of the shielding conjugate in the complex maintains the zeta potential at near neutral. The in vitro transfection efficiencies of the optimized formulations are all much higher than the control DNA/PEI22 complex which aggregated upon the freeze/thaw process. Furthermore, there was no significant difference in the transfection efficiency of all three optimized formulations.

To test these optimized formulations in vivo (Figure 4B), each formulation was thawed, glucose added, and the formulation injected into the tail vein of A/J Neuro2a neuroblastoma tumor-bearing mice. The major internal tissues were recovered after 1 day. The control DNA/Tf-PEI/PEI25 complexes had to be prepared fresh before application as previously described (9). Figure 4B shows the luciferase protein expressed in the respective tissues. For all formulations, the highest expression was observed in the tumor cells. The highest expression in the tumor tissue was observed for PEI22-SS-PEG5 shielded formulation, with an expression level almost 1 log unit higher than the other formulations tested. The luciferase was found to be also expressed at low but significant levels in the liver, followed by the lung. The gene expression in the kidney for the PEI22-PEG20 formulation was due to expression in only 1 mouse out of 6 and in no other treatment group. It is therefore believed that this single observation is animal-specific (possibly due to a dysfunctional kidney) and not formulation-specific.

**Systemic Administration of a Therapeutic Gene (TNF $\alpha$ ).** Previously we demonstrated that freshly prepared transferrin-shielded DNA complexes mediate the expression of the highly potent and toxic protein tumor necrosis factor (TNF $\alpha$ ) in distant tumors, resulting in therapeutic effects in several murine tumor models (3, 34). On the basis of the previous luciferase experiments, we now selected the cryoconserved formulation shielded by PEI22-SS-PEG5 and tested for its ability to target the TNF $\alpha$  gene expression in distant tumors after systemic application. This was assessed by the reduction in growth and necrosis of tumors in three different murine tumor models, Neuro2a, M-3, and B16F10 (Figure 5). Complexes containing the plasmid pGSmuTNF $\alpha$  coding for murine TNF $\alpha$  were formed in 20 mM HEPES pH 7.1 and stored at  $-20^\circ\text{C}$ . Prior to injection, DNA formulations were thawed, glucose was added, and the formulation was injected into the tail vein of mice, between 5 and 7 times at the intervals indicated in Figure 5, and tumor sizes of the animals were recorded. Administration of the formulation was well tolerated by the mice; out of the 174 applications no sign of toxicity was

**Figure 5.** Tumor growth after the systemic application of Tf-PEG-PEI22/PEI22/PEI22ssPEG5/DNA (pGSmuTNF $\alpha$ ) to (A) Neuro2a tumor-bearing A/J mice, (B) M-3 tumor-bearing DBA/2 mice, or (C) B16F10 tumor-bearing C57Bl6 mice. Complexes were prepared in 20 mM HEPES, pH 7.1, using a molar PEI ratio of 1:6:3. DNA complexes were snap frozen in liquid nitrogen and stored at  $-20^\circ\text{C}$ . At indicated time points (see arrows), the DNA complex was thawed in glucose (5% w/v final concentration), and the complex ( $50 \mu\text{g}$  DNA per mouse) was injected into the tail vein of the mouse (open circles). Control mice were injected with 0.9% (w/v) NaCl (closed circles). Tumor sizes were monitored, mean  $\pm$  SD are presented;  $n = 10$  animals in Neuro2a control group,  $n = 8$  animals per group in all other control and treatment groups. Number of treatment animals with tumor necrosis is indicated in brackets. (\*)  $p < 0.1$ , (\*\*)  $p < 0.05$ , compared to control.

observed. Retardation in tumor development was observed in all three tumor models (Figure 5) accompanied with pronounced tumor necrosis. This is in agreement with transferrin-shielded DNA complexes which localized TNF $\alpha$  activity to the tumor without systemic toxicity (3). Of the models tested, the Neuro2a model showed the strongest response with regard to tumor necrosis with strong necrosis in six of the eight mice treated with the plasmid coding for TNF $\alpha$ , while for the control, two out of the 10 mice only showed weak central necrosis. For both M-3 and B16F10 tumor models, three of the eight mice showed tumor necrosis, while for the controls, no change in tumor growth was observed.

Current literature suggests that biodistribution of therapeutic particles following intravenous administration is modulated by the size of the particle and surface charge. A hydrophilic and uncharged surface on the particle reduces their uptake by the phagocytic cells of the RES and aggregation, significantly prolonging circulation time. For targeting DNA complexes to cancer cells, particles should be small enough to pass through the fenestrations in the tumor vasculature (35). These two parameters, particle size and surface hydrophilicity, can easily be modulated by this new streamlined system for generating PEGylated DNA particles. For instance, particle size and surface charge was reduced by increasing the amount of the shielding conjugate in the complex (Figure 2). The in vivo studies (Figure 4B) show that the PEGylated DNA complexes encoding TNF $\alpha$  were effective

in tumor necrosis in three different murine tumor models (Figure 5). Despite these promising *in vivo* results, the tumors were only rarely regressed and there was a variable response in the different tumor models tested. The variable response of the different tumor models to the formulation may be a reflection of the different tumor types having varying leakiness (35). Future studies will use this system to optimize size and surface charge of the transferrin-targeted formulations for targeting different tumors *in vivo*.

## CONCLUSION

This work describes a simple and quick method for the formation of PEG shielded transferrin-targeting PEI/DNA complexes. We demonstrate that the PEG shielded DNA/polymer vector can maintain its size/charge and transfection efficiency after freeze–thawing. For the first time we show that freeze–thawed polyplex vectors have systemic targeting activity toward disseminated tumors. Furthermore, the ratios of the shielding and targeting components in the complex can easily be varied, producing well defined particles with varying size and surface charge. This will enable such biophysical parameters to be easily investigated for their ability to target tumors, leading to DNA vectors which are tailor-made for their application. The simplicity of their preparation and storage in frozen form is a major step forward in the development of nonviral vectors as pharmaceutical products.

## ACKNOWLEDGMENT

We are grateful to Alexandra Schreiber and Sandra Fandl for help in the animal experiments.

# Synthesis of Maleimide-Activated Carbohydrates as Chemoselective Tags for Site-Specific Glycosylation of Peptides and Proteins

Jiahong Ni, Suddham Singh, and Lai-Xi Wang\*

Institute of Human Virology, University of Maryland Biotechnology Institute, University of Maryland, 725 W. Lombard Street, Baltimore, Maryland 21201. Received September 30, 2002; Revised Manuscript Received November 14, 2002

An array of maleimide-activated mono- and oligosaccharides were synthesized to permit site-specific glycosylation of cysteine-containing peptides and proteins. Maleimide-activated monosaccharides, in which the native  $\alpha$ - or  $\beta$ -O-glycosidic linkages found for nonreducing terminal sugars of native glycoproteins are preserved, were prepared using 2'-aminoethyl glycosides as the key intermediates. In addition, a native high-mannose type oligosaccharide, Man<sub>9</sub>GlcNAc<sub>2</sub>Asn, was converted into its maleimide-activated form by taking advantage of the existing amino group in the Asn portion. The application of these maleimide-activated carbohydrates was exemplified by the site-specific glycosylation of a 36-mer HIV-1 gp41 peptide, T20, which is a potent inhibitor against HIV infection. The chemoselective ligation was found to be rapid, highly efficient, and essentially quantitative. Tagging the biologically active peptide with a mannose and/or oligomannose moiety will be useful for targeting the drug to macrophage and dendritic cells, which are primary targets for HIV-1 infection and are expressing mannose- and oligomannose-specific receptors on their surface. In combination with site-specific mutagenesis, the maleimide-activated carbohydrates can serve as generally applicable tags for site-specific glycosylation of proteins via the highly efficient maleimide–thiol ligation reaction.

## INTRODUCTION

Protein glycosylation, the covalent attachment of carbohydrates to the side chains of proteins, is one of the most common co- and posttranslational modifications of proteins. The carbohydrate portions of glycoproteins have been implicated to play a role in many important biological recognition processes such as cell adhesion, host–pathogen interaction, and host immune responses (1–3). In addition, it is known that correct glycosylation is critical for protein expression and folding and increases protein's thermal and proteolytic stability (4). However, a thorough understanding of the functions and properties of glycoproteins has been hindered by the complexity of glycoprotein biosynthesis. Generally, natural and recombinant glycoproteins occur as a heterogeneous mixture of glycoforms that share the same peptide backbone but differ in the carbohydrate portions and/or in the sites of linkage. This micro-heterogeneity makes it extremely difficult to obtain a pure, homogeneous glycoprotein from natural and recombinant sources (5). To better understand the molecular basis of the oligosaccharides in biological processes and to exploit these molecular properties for pharmaceutical applications, e.g., drug targeting, there is an urgent need for chemical methods that will allow site-specific attachment of homogeneous and natural as well as unnatural carbohydrates to proteins. For the purpose, several nonnative chemoselective ligation methods have been developed to introduce carbohydrate moieties at specific sites of peptides and proteins (6, 7). For example, iodoacetamide-containing mono- and oligosaccharides were first employed for site-specific glycosylation of cysteine-containing peptides/proteins (8, 9). Glyco-methanethiosulfonates that are reactive to

cysteines via disulfide formation have been developed for controlled site-selective glycosylation of proteins (10). In combination with sited-directed mutagenesis to introduce cysteine residue(s) at predetermined sites, the above-mentioned methods allow regio- and glycan-specific glycosylation of some biologically important proteins (10–12). In addition, aminooxy-, hydrazide-, and thiosemicarbazide-functionalized saccharides have been prepared as versatile reagents for glycoconjugate synthesis via chemoselective formation of oxime or hydrazone linkages (13). The development of these chemoselective ligation methods significantly extends our abilities to design and synthesize novel glycoproteins and analogues for biological and biomedical applications. Nevertheless, some drawbacks exist for some current methods that limit their potentials. For example, glycosylation via nucleophilic substitution of a thiol group with iodoacetyl moieties requires an alkaline condition (pH 8–9). Under the alkaline conditions, side reactions from other nucleophiles (e.g., histidine and lysine residues) may occur (12). The effective formation of an oxime or hydrazone needs an acidic condition (pH 4–5) that may cause stability and solubility problems for certain peptides and proteins.

In an attempt to develop milder alternative approaches toward chemoselective site-specific glycosylation of peptides and proteins, we turned our attention to the highly efficient and selective ligation between maleimide and thiol functionalities. Maleimide-functionalized moieties have been widely used for selective modification and conjugation of cysteine-containing biomolecules in bioconjugate chemistry (14–16). The maleimide–thiol ligation is rapid, highly selective, and essentially quantitative under physiological conditions. Recently we have successfully exploited the potential of this highly chemoselective ligation for the synthesis of very large and complex multivalent HIV-1 peptides (17). In the design of carbo-

hydrate-based vaccine, a maleimide group was introduced into the carbohydrate antigen for final coupling to a carrier protein (18). More recently, 1-maleimido sugars were prepared and used for the synthesis of neoglycopeptides and neoglycoproteins via maleimide–thiol ligation (19). The major drawback of the reported synthesis is that the  $\beta$ -*N*-glycosidic linkage in the 1-maleimido sugars does not represent most native glycosidic forms of nonreducing terminal sugars found in native glycoproteins. In this paper, we describe a general synthesis of an array of maleimide-activated carbohydrates using 2'-aminoethyl glycosides as the key intermediates, in which the native  $\alpha$ - or  $\beta$ -*O*-glycosidic linkages found for the nonreducing terminal sugars of native glycoproteins are preserved. The preservation of native  $\alpha$ - or  $\beta$ -*O*-glycosidic linkages is important for the interactions between the terminal sugars and carbohydrate-specific lectins or cell surface receptors (20). On the other hand, a native high-mannose type oligosaccharide, Man<sub>9</sub>GlcNAc<sub>2</sub>-Asn, was converted into its maleimide-activated form by taking advantage of the existing amino group in the Asn portion. The application of these maleimide-activated carbohydrates was exemplified by the site-specific glycosylation of a 36-mer HIV-1 gp41 peptide, T20, which is a potent inhibitor against HIV infection.

## EXPERIMENTAL PROCEDURES

**General.** *N,N*-Dimethylformamide, dichloromethane, and methanol were purchased from Aldrich and stored over 4A molecular sieves. All other chemicals were purchased from Aldrich/Sigma and used as received. <sup>1</sup>H NMR spectra were recorded at 300 MHz on a QE 300 with Me<sub>4</sub>Si ( $\delta$  0) as the internal standard. <sup>13</sup>C NMR spectra were recorded at 125 MHz with a Varian 500. The ESI-MS spectra were measured on a Waters ZMD mass spectrometer. Analytical TLC was performed on glass plates coated with silica gel 60 F<sub>254</sub> (E. Merck). Carbohydrates were detected by charring with 10% ethanolic sulfuric acid. Amines were detected by ninhydrin spraying (0.3% in ethanol and acetic acid (97:3)). Flash chromatography was performed on silica gel 60 (200–400 mesh, EM Science). Analytical HPLC was carried out with a Waters 626 HPLC instruments on Waters Nova-Pak C18 column (3.9  $\times$  150 mm) at 40 °C, with a linear gradient of 0–30% (Method A) or 10–90% (Method B) acetonitrile containing 0.1% TFA in 25 min at a flow rate of 1 mL/min with UV detection (at 214 and/or 280 nm).

**2'-Chloroethyl 2,3,4-Tri-*O*-acetyl- $\alpha$ -L-fucopyranoside (9).** A mixture of L-fucose (1.64 g, 10.00 mmol), 2-chloroethanol (10 mL), and Dowex 50W-100 (H<sup>+</sup>) (1.00 g) was stirred at 80 °C for 2 h. The mixture was cooled to room temperature and filtered. The resin was washed with ethanol (2  $\times$  3 mL). The combined filtrates were evaporated at a reduced pressure. The residue was purified by flash column chromatography on silica gel using dichloromethane and MeOH (9:1) as the eluent to give a crude product, which was recrystallized with ethanol to afford a crystalline 2-chloroethyl  $\alpha$ -L-fucopyranoside (1.01 g, 45%); <sup>1</sup>H NMR (300 MHz, D<sub>2</sub>O):  $\delta$  4.92 (d, *J* = 3.9 Hz, 1 H, H-1), 4.14 (q, *J* = 6.6 Hz, 1 H, H-5), 3.96–3.73 (m, 7 H, H-2, H-3, H-4, OCH<sub>2</sub>CH<sub>2</sub>Cl), 1.20 (d, *J* = 6.6 Hz, 3 H, H-6); ESI-MS: 251.30 (M(<sup>37</sup>Cl) + Na)<sup>+</sup>, 249.30 (M(<sup>35</sup>Cl) + Na)<sup>+</sup>.

A solution of 2'-chloroethyl  $\alpha$ -L-fucopyranoside (320.0 mg, 1.41 mmol) in pyridine–acetic anhydride (1:1, v/v, 4 mL) was stirred at room temperature for 2 h, then ice (5 g) was added. The resulting mixture was stirred for 1 h

and extracted with dichloromethane (50 mL). The organic layer was separated, washed with solution of hydrogen chloride (1 M, 3  $\times$  30 mL) and brine (3  $\times$  30 mL), dried over sodium sulfate, filtered, and evaporated. The residue was purified by flash column chromatography on silica gel using dichloromethane–EtOAc (9:1, v/v) as the eluent to give the per-*O*-acetylated glycoside **9** (478.6 mg, 97%); *R*<sub>f</sub> = 0.58 (CH<sub>2</sub>Cl<sub>2</sub>–EtOAc 9:1); <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>/TMS):  $\delta$  5.40 (dd, *J* = 10.1, 3.4 Hz, 1 H, H-3), 5.33 (d, *J* = 3.9 Hz, 1 H, H-1), 5.16 (d, *J* = 3.4 Hz, 1 H, H-4), 5.13 (dd, *J* = 10.1, 3.9 Hz, 1 H, H-2), 4.27 (q, *J* = 6.6 Hz, 1 H, H-5), 3.95 (ddd = dt, *J* = 11.2, 5.6, Hz, 1 H, OCHHCH<sub>2</sub>Cl), 3.77 (ddd = dt, *J* = 11.2, 5.3, 3.4 Hz, 1 H, OCHHCH<sub>2</sub>Cl), 3.47 (dd, *J* = 5.6, 5.3, 2 H, OCH<sub>2</sub>CH<sub>2</sub>Cl), 2.19 (s, 3 H, (O)CCH<sub>3</sub>); 2.11 (s, 3 H, (O)CCH<sub>3</sub>); 2.02 (s, 3 H, HN(O)CCH<sub>3</sub>), 1.17 (d, *J* = 6.6 Hz, 3 H, H-6); ESI-MS: 377.14 (M(<sup>37</sup>Cl) + Na)<sup>+</sup>, 375.16 (M(<sup>35</sup>Cl) + Na)<sup>+</sup>, 273.17 (M – OCH<sub>2</sub>CH<sub>2</sub>Cl)<sup>+</sup>.

**2'-Azidoethyl 2,3,4-Tri-*O*-acetyl- $\alpha$ -L-fucopyranoside (10).** A suspension of the 2-chloroethyl glycoside **9** (459.0 mg, 1.30 mmol), NaI (193.6 mg, 13.00 mmol), and sodium azide (845.1 mg, 13.00 mmol) in *N,N*-dimethylformamide (6 mL) was stirred at 80 °C for 18 h. The *N,N*-dimethylformamide was evaporated at a reduced pressure, and the residue was partitioned between dichloromethane (150 mL) and water (30 mL). The organic layer was separated, washed with brine (3  $\times$  30 mL), dried over sodium sulfate, filtered, and evaporated. The residue was purified by flash column chromatography on silica gel using dichloromethane–EtOAc (9:1, v/v) as the eluent to give the per-*O*-acetylated 2-azidoethyl glycoside **10** (454.5 mg, 98%); *R*<sub>f</sub> = 0.64 (CH<sub>2</sub>Cl<sub>2</sub>–EtOAc 9:1); <sup>1</sup>H NMR (300 MHz, CDCl<sub>3</sub>/TMS):  $\delta$  5.38 (dd, *J* = 10.0, 3.3 Hz, 1 H, H-3), 5.33 (d, *J* = 3.3 Hz, 1 H, H-4), 5.13 (dd, *J* = 10.0, 3.7 Hz, 1 H, H-2), 5.12 (d, *J* = 3.7 Hz, 1 H, H-1), 4.19 (q, *J* = 6.6 Hz, 1 H, H-5), 3.87 (ddd, *J* = 10.5, 6.1, 3.2 Hz, 1 H, OCHHCH<sub>2</sub>N<sub>3</sub>), 3.62 (ddd, *J* = 10.5, 6.8, 3.4 Hz, 1 H, OCHHCH<sub>2</sub>N<sub>3</sub>), 3.47 (ddd, *J* = 13.2, 6.8, 3.2, 1 H, OCH<sub>2</sub>CHHN<sub>3</sub>), 3.38 (ddd, *J* = 13.2, 6.1, 3.4, 1 H, OCH<sub>2</sub>CHHN<sub>3</sub>), 2.18 (s, 3 H, (O)CCH<sub>3</sub>); 2.09 (s, 3 H, (O)CCH<sub>3</sub>); 2.00 (s, 3 H, HN(O)CCH<sub>3</sub>), 1.16 (d, *J* = 6.6 Hz, 3 H, H-6); ESI-MS: 382.18 (M + Na)<sup>+</sup>, 273.17 (M – OCH<sub>2</sub>CH<sub>2</sub>Cl)<sup>+</sup>.

**2'-Azidoethyl  $\alpha$ -L-Fucopyranoside (11).** The per-*O*-acetylated glycoside **10** (408.0 mg, 1.14 mmol) was treated with catalytic amount of MeONa in MeOH (10 mL) for 30 min, and then the reaction was neutralized with Dowex 50W(H<sup>+</sup>). The resin was removed by filtration and the filtrate was evaporated to give the 2-azidoethyl fucoside **11** (251.7 mg, 95%); *R*<sub>f</sub> = 0.34 (CH<sub>2</sub>Cl<sub>2</sub>–MeOH 90:10); <sup>1</sup>H NMR (300 MHz, D<sub>2</sub>O):  $\delta$  4.89 (d, *J* = 3.7 Hz, 1 H, H-1), 4.09 (m, 1 H, H-5), 3.92–3.38 (m, 7 H, H-2, H-3, H-4, OCH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub>), 1.20 (d, *J* = 6.4 Hz, 3 H, H-6); <sup>13</sup>C NMR (125 MHz, D<sub>2</sub>O):  $\delta$  98.7 (C-1), 72.0 (C-3), 69.6 (C-5), 68.1 (C-2), 67.0 (C-4), 66.9 (OCH<sub>2</sub>CH<sub>2</sub>N<sub>3</sub>), 50.6 (OCH<sub>2</sub>CH<sub>2</sub>N<sub>3</sub>), 15.5 (C-6); ESI-MS: 256.24 (M + Na)<sup>+</sup>.

**2'-Aminoethyl Glycosides. General Procedures for Hydrogenation of 2'-Azidoethyl Glycosides.** A solution of the respective 2'-azidoethyl  $\beta$ -D-galactoside (**1**) (2f),  $\alpha$ -D-mannoside (**3**) (2f),  $\beta$ -D-glucoside (**5**) (2f), 2-acetamido-2-deoxy- $\alpha$ -D-galactoside (**7**) (2f), or  $\alpha$ -L-fucoside (**11**) (1 mmol), in methanol (10 mL) containing Pd–C (30.0 mg), was stirred at room temperature under hydrogen atmosphere for 12–18 h until the disappearance of the starting material (TLC). The mixture was filtered through a pad of Celite. The solid was washed with methanol (2  $\times$  2 mL), and the combined filtrates were evaporated at a reduced pressure to give the

corresponding 2-aminoethyl glycosides **2**, **4**, **6**, **8**, and **12**, respectively.

**6'-Maleimidohexanamidoethyl Glycosides. General Procedures for the Introduction of Maleimide Functionality into the 2-Aminoethyl Glycosides.** To a stirred solution of the 2-aminoethyl glycoside (1 mmol) in MeOH (10 mL) was added a solution of 6-maleimidoheptanoic acid *N*-hydroxysuccinimide ester (1.5 mmol) in MeOH (5 mL). The reaction mixture was stirred at room temperature for 1–2 h, when TLC showed the disappearance of the starting 2-aminoethyl glycosides. The reaction mixture was concentrated to dryness. The residue was subject to flash column chromatography on silica gel using  $\text{CH}_2\text{Cl}_2$ –MeOH (4:1 to 1:1) as the eluent to give the corresponding 6-maleimidohexanamidoethyl glycosides.

**6'-Maleimidohexanamidoethyl  $\beta$ -D-Galactopyranoside (13).** Yield: 67%;  $R_f = 0.37$  ( $\text{CH}_2\text{Cl}_2$ –MeOH 80:20);  $^1\text{H}$  NMR (300 MHz,  $\text{D}_2\text{O}$ ):  $\delta$  6.82 (s, 2 H,  $\text{CH}=\text{CH}$ ),

4.38 (d,  $J = 7.8$  Hz, 1 H, H-1), 3.99–3.91 (m, 1H,  $\text{OCHHCH}_2\text{NH}$ ), 3.90 (d,  $J = 3.2$  Hz, 1 H, H-4), 3.81–3.61 (m, 4 H, H-5, H-6, H-6',  $\text{OCHHCH}_2\text{NH}$ ), 3.64 (dd,  $J = 10.1$ , 3.2 Hz, 1 H, H-3), 3.51 (dd,  $J = 10.1$ , 7.8 Hz, 1 H, H-2), 3.49 (t,  $J = 6.8$  Hz, 2 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 3.47–3.32 (m, 2 H,  $\text{OCH}_2\text{CH}_2\text{NH}$ ), 2.23 (t,  $J = 7.3$  Hz, 2 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 1.64–1.51 (m, 4 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 1.31–1.19 (m, 2 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ); ESI-MS: 439.49 ( $\text{M} + \text{Na}$ ) $^+$ , 417.49 ( $\text{M} + \text{H}$ ) $^+$ .

**6'-Maleimidohexanamidoethyl  $\alpha$ -D-Manopyranoside (14).** Yield 65%;  $R_f = 0.32$  ( $\text{CH}_2\text{Cl}_2$ –MeOH 80:20);  $^1\text{H}$  NMR (300 MHz,  $\text{D}_2\text{O}$ ):  $\delta$  6.90 (s, 2 H,  $-\text{CH}=\text{CH}-$ ), 4.84 (d,  $J = 1.6$  Hz, 1 H, H-1), 3.90 (dd,  $J = 3.2$ , 1.7 Hz, 1 H, H-2), 3.84 (dd,  $J = 12.5$ , 1.7 Hz, 1 H, H-6), 3.80–3.351 (m, 6 H, H-3, H-4, H-5, H-6',  $\text{OCH}_2\text{CH}_2\text{NH}$ ), 3.47 (t,  $J = 6.9$  Hz, 2 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 3.44–3.31 (m, 2 H,  $\text{OCH}_2\text{CH}_2\text{NH}$ ), 2.21 (t,  $J = 7.3$  Hz, 2 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 1.64–1.49 (m, 4 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 1.30–1.18 (m, 2 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ); ESI-MS: 439.36 ( $\text{M} + \text{Na}$ ) $^+$ , 417.37 ( $\text{M} + \text{H}$ ) $^+$ .

**6'-Maleimidohexanamidoethyl  $\alpha$ -L-Fucopyranoside (17).** Yield: 55%;  $R_f = 0.72$  ( $\text{CH}_2\text{Cl}_2$ –MeOH 80:20);  $^1\text{H}$  NMR (300 MHz,  $\text{D}_2\text{O}$ ):  $\delta$  6.82 (s, 2 H,  $-\text{CH}=\text{CH}-$ ), 4.84 (d,  $J = 3.7$  Hz, 1 H, H-1), 3.99 (m, 1 H, H-5), 3.81 (dd,  $J = 10.1$ , 3.1 Hz, 1 H, H-3), 3.78–3.67 (m, 3 H, H-2, H-4,  $\text{OCHHCH}_2\text{NH}$ ), 3.55–3.47 (m, 1 H,  $\text{OCHHCH}_2\text{NH}$ ), 3.47 (t,  $J = 7.1$  Hz, 2 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 3.47–3.38 (m, 1 H,  $\text{OCH}_2\text{CH}_2\text{NH}$ ), 3.38–3.30 (m, 1 H,  $\text{OCH}_2\text{CH}_2\text{NH}$ ), 2.21 (t,  $J = 7.3$  Hz, 2 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 1.63–1.49 (m, 4 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 1.30–1.19 (m, 2 H,  $\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{N}$ ), 1.18 (d,  $J = 6.6$  Hz, 3 H, H-6); ESI-MS: 423.43 ( $\text{M} + \text{Na}$ ) $^+$ , 401.38 ( $\text{M} + \text{H}$ ) $^+$ .

***N*-(6'-Maleimidohexacarbonyl) Man<sub>9</sub>GlcNAc<sub>2</sub>Asn (19).** To a solution of Man<sub>9</sub>GlcNAc<sub>2</sub>Asn **18** (**23**) (2.25 mg, 1.13  $\mu\text{mol}$ ) in phosphate buffer (pH 7.4, 50 mM) and acetonitrile (2:1, v/v, 1.5 mL) was added a solution of 6-maleimidoheptanoic acid *N*-hydroxysuccinimide ester (3.47 mg, 11.26  $\mu\text{mol}$ ) in acetonitrile (0.5 mL). The reaction mixture was stirred at room temperature for 2 h and then lyophilized to dryness. The residue was purified on reverse-phase preparative HPLC to yield the maleimide-activated product **19** (1.68 mg, 68%). The

purified **19** appeared at 10.48 min as a single peak under the HPLC condition with a linear gradient (method A) as described in General Methods. ESI-MS: 2192.17 ( $M + H$ )<sup>+</sup>, 1118.60 ( $M + 2Na$ )<sup>2+</sup>, 1096.72 ( $M + 2H$ )<sup>2+</sup>, 1015.60 ( $M - Man + 2H$ )<sup>2+</sup>, 934.41 ( $M - 2Man + 2H$ )<sup>2+</sup>, 853.35 ( $M - 3Man + 2H$ )<sup>2+</sup>, 772.28 ( $M - 4Man + 2H$ )<sup>2+</sup>, 691.21 ( $M - 5Man + 2H$ )<sup>2+</sup>, 610.06 ( $M - 6Man + 2H$ )<sup>2+</sup>.

**The Cysteine-Containing Peptide 20.** Peptide **20** was synthesized on a Pioneer Peptide Synthesizer (Applied Biosystems, Foster City, CA) using standard Fmoc-chemistry on Fmoc-PAL-PEG-PS resin, according to the reported method (17). Briefly, 4-fold excess of *N*<sup>t</sup>-Fmoc-protected amino acids were used for each coupling and HATU/DIPEA were used as the coupling reagents. The N-terminus of the peptide was capped with an acetyl group, and the C-terminus is in the amide form after release from the resin and simultaneous deprotection. The peptide was purified with HPLC and characterized by ESI-MS. The purified peptide **20** appeared at 15.84 min as a single peak under the HPLC condition with a linear gradient (method B) as described in General Methods. ESI-MS of **20**: 1532.84 ( $M + 3H$ )<sup>3+</sup>, 1149.83 ( $M + 4H$ )<sup>4+</sup>, and 920.12 ( $M + 5H$ )<sup>5+</sup>.

**Glycopeptide 21.** To a solution of peptide **20** (20 mg, 4.35  $\mu$ mol) in phosphate buffer (pH 6.6, 50 mM, 3 mL) and acetonitrile (3.0 mL) was added dropwise a solution of the maleimide-activated mannose **14** (1.21 mg, 2.90  $\mu$ mol) in DMF (242  $\mu$ L). The mixture was kept at room temperature for 1 h and lyophilized. The residue was subject to reverse-phase preparative HPLC to give the glycopeptide **21** (11.6 mg, 80%). The purified glycopeptide **21** appeared at 15.18 min as a single peak under the HPLC condition with a linear gradient (method B) as described in General Methods. ESI-MS of **21**: 1671.50 ( $M + 3H$ )<sup>3+</sup>, 1253.97 ( $M + 4H$ )<sup>4+</sup>, 1213.34 ( $M - Man + 4H$ )<sup>4+</sup>, 1003.64 ( $M + 5H$ )<sup>5+</sup>, 971.08 ( $M - Man + 5H$ )<sup>5+</sup>.

**Glycopeptide 22.** A mixture of peptide **20** (4.33 mg, 0.94  $\mu$ mol) and the maleimide-activated high-mannose oligosaccharide **19** (1.03 mg, 0.47  $\mu$ mol) in a phosphate buffer (pH 6.6, 50 mM, 1.0 mL) and acetonitrile (1.0 mL) was kept at room temperature for 1 h. After the reaction mixture was lyophilized to dryness, the residue was subject to preparative RP-HPLC to give the glycopeptide **22** (2.56 mg, 82%). The purified glycopeptide **22** appeared at 14.43 min as a single peak under the HPLC condition with a linear gradient (Method B) as described in General Methods. ESI-MS of **22**: 2262.96 ( $M + 3H$ )<sup>3+</sup>, 1698.34 ( $M + 4H$ )<sup>4+</sup>, 1657.26 ( $M - Man + 4H$ )<sup>4+</sup>, 1358.62 ( $M + 5H$ )<sup>5+</sup>, 1326.18 ( $M - Man + 5H$ )<sup>5+</sup>, 1293.80 ( $M - 2Man + 5H$ )<sup>5+</sup>, 1261.29 ( $M - 3Man + 5H$ )<sup>5+</sup>, 1229.04 ( $M - 4Man + 5H$ )<sup>5+</sup>, 1196.39 ( $M - 5Man + 5H$ )<sup>5+</sup>, 1164.08 ( $M - 6Man + 5H$ )<sup>5+</sup>, 1131.63 ( $M + 6H$ )<sup>6+</sup>.

## RESULTS AND DISCUSSION

Glycosides and oligosaccharides with a terminal amino group in the aglycon moiety are frequently used in the synthesis of neoglycoconjugates (24). One way to introduce an amino group at later stage of oligosaccharide synthesis is to use an azido group as a latent functionality, which can be easily converted into amino group through reduction (21). Therefore, to introduce maleimide functionality into carbohydrates while preserving the native  $\alpha$ - or  $\beta$ -*O*-glycosidic linkages, we chose 2'-aminoethyl  $\alpha$ - and  $\beta$ -glycosides as the key intermediates. Accordingly, the 2'-azidoethyl  $\beta$ -D-galactopyranoside (**1**),  $\alpha$ -D-mannopyranoside (**3**),  $\beta$ -D-glucopyranoside (**5**), and 2-acetamido-2-deoxy- $\alpha$ -D-galactopyranoside (**7**) were synthesized following the reported procedures (21, 22). To

**Figure 1.** Structures of 2'-azidoethyl and 2'-aminoethyl glycosides.

prepare the corresponding 2'-azidoethyl fucopyranoside (**11**) with an  $\alpha$ -L-glycosidic linkage found in native glycoproteins, L-fucose was refluxed with 2-chloroethanol under acid catalysis to give the 2'-chloroethyl  $\alpha$ -L-fucopyranoside, which was isolated as its per-acetate (**9**) after *O*-acetylation. Treatment of 2'-chloroethyl glycoside (**9**) with NaN<sub>3</sub>/NaI in DMF gave the corresponding 2'-azidoethyl per-*O*-acetylated glycoside (**10**), which was de-*O*-acetylated with MeONa/MeOH to afford the 2'-azidoethyl  $\alpha$ -L-fucopyranoside (**11**) in excellent yield. Catalytic hydrogenation of the 2'-azidoethyl glycosides **1**, **3**, **5**, **7**, and **11** was performed using palladium/charcoal as the catalyst to afford the corresponding 2'-aminoethyl glycosides **2**, **4**, **6**, **8**, and **12** in essentially quantitative yield (Figure 1). With a terminal amino group in the aglycon moiety, a maleimide moiety was readily introduced into the carbohydrates through reaction with an activated ester of maleimide. Thus, treatment of the 2'-aminoethyl glycosides **2**, **4**, **6**, **8**, and **12** with 6-maleimido-hexanoic acid *N*-hydroxysuccinimide ester in MeOH gave the 6-maleimido-hexanamidoethyl glycosides **13–17**, respectively (Table 1).

For some native glycopeptides that can be isolated from native glycoproteins to homogeneity via thorough protease digestion, the free amino group in the resulting glycopeptide or glyco-asparagine moiety can be used directly for introducing a maleimide moiety. As an example, a high-mannose type oligosaccharide, Man<sub>9</sub>GlcNAc<sub>2</sub>Asn (**18**), was prepared via thorough Pronase digestion of soybean agglutinin that was isolated from soybean flour according to the literature (23). The released Man<sub>9</sub>GlcNAc<sub>2</sub>Asn (**18**) was purified by HPLC, which is identical to an authentic sample in HPLC. Its identity was further characterized by ESI-MS [1998.73 ( $M + H$ )<sup>+</sup>, 999.69 ( $M + 2H$ )<sup>2+</sup>, and 918.65 ( $M - Man + 2H$ )<sup>2+</sup>, 837.68 ( $M - 2Man + 2H$ )<sup>2+</sup>, 756.70 ( $M - 3Man + 2H$ )<sup>2+</sup>, 675.52 ( $M - 4Man + 2H$ )<sup>2+</sup>, 594.61 ( $M - 5Man + 2H$ )<sup>2+</sup>]. Introduction of a maleimide moiety was achieved by treatment of Man<sub>9</sub>GlcNAc<sub>2</sub>Asn (**18**) with excess of the activated ester of 6-maleimido-hexanoic acid in an aqueous organic solvent (Scheme 1). After reverse-phase HPLC purification, the resulting maleimide-activated oligosaccharide (**19**) was isolated in 68% yield. The ESI-MS of **19**, showing typical ionic species at 2192.17 ( $M + H$ )<sup>+</sup>, 1118.60 ( $M + 2Na$ )<sup>2+</sup>, 1096.72 ( $M + 2H$ )<sup>2+</sup>, 1015.60 ( $M - Man + 2H$ )<sup>2+</sup>, 934.41 ( $M - 2Man + 2H$ )<sup>2+</sup>, 853.35 ( $M - 3Man + 2H$ )<sup>2+</sup>, 772.28 ( $M - 4Man + 2H$ )<sup>2+</sup>, 691.21 ( $M - 5Man + 2H$ )<sup>2+</sup>, 610.06 ( $M - 6Man + 2H$ )<sup>2+</sup>, is in good agreement with its structure. The procedure should be readily extendable to other native high-mannose type as well as complex type glyco-asparagine/glycopeptides, when their isolation from native glycoproteins is achievable (25, 26).

**Scheme 1.** Synthesis of Maleimide-Activated High Mannose Oligosaccharide

The application of the maleimide-activated mono- and oligosaccharides were exemplified by the synthesis of two neoglycopeptides. A biologically active HIV-1 gp41 peptide, T20, was chosen as the model peptide. T20 is a 36-mer peptide from the C-terminal ectodomain of HIV-1 glycoprotein gp41. It exhibits strong inhibitory activity against HIV-1 infection, and is currently in clinical trials for the treatment of HIV/AIDS (27, 28). For chemoselective ligation to maleimide-activated carbohydrates, a cysteine residue was introduced at the C-terminus of the peptide T20 during solid-phase synthesis to give the cysteine-containing peptide **20**. The ligation of the maleimide-activated mannose (**14**) and peptide **20** was readily achieved in a phosphate buffer (pH 6.6)

containing acetonitrile (Scheme 2). The neoglycopeptide **21** thus formed was purified by reverse phase HPLC. The ESI-MS of **21** revealed typical ionic species at 1671.50 ( $M + 3H$ )<sup>3+</sup>, 1253.97 ( $M + 4H$ )<sup>4+</sup>, 1213.34 ( $M - \text{Man} + 4H$ )<sup>4+</sup>, 1003.64 ( $M + 5H$ )<sup>5+</sup>, 971.08 ( $M - \text{Man} + 5H$ )<sup>5+</sup>, which confirms the identity of **21**. It should be pointed out that the peptide **20** was found to aggregate in aqueous solution even at a relatively low concentration (50  $\mu\text{M}$  and above), which prevents the ligation and gives unidentified byproducts (data not shown). We found that addition of acetonitrile in the reaction mixture efficiently prevented the aggregation of the peptide and allowed the ligation reaction to proceed smoothly (Scheme 2).

**Scheme 2. Ligation of Maleimide-Activated Mannose **14** and HIV-1 Peptide **20******Scheme 3. Ligation of Maleimide-Activated High-Mannose Oligosaccharide **19** and HIV-1 Peptide **20******Figure 2.** The ESI-MS and HPLC profile of glycopeptide **21**.

Similarly, a high-mannose oligosaccharide was conjugated to the HIV-1 peptide through chemoselective ligation of the maleimide-activated oligosaccharide **19** and peptide **20** to give the neoglycopeptide **22** (Scheme 3). The ligation proceeded rapidly and specifically to give a single product, as monitored by HPLC, even if a large oligosaccharide was involved. The HPLC and ESI-MS profile of **22** was shown in Figure 2. Typical ionic species in the ESI-MS of **22** include 2262.96 ( $M + 3H$ )<sup>3+</sup>, 1698.34 ( $M + 4H$ )<sup>4+</sup>, 1657.26 ( $M - \text{Man} + 4H$ )<sup>4+</sup>, 1358.62 ( $M +$

5H)<sup>5+</sup>, 1326.18 ( $M - \text{Man} + 5H$ )<sup>5+</sup>, 1293.80 ( $M - 2\text{Man} + 5H$ )<sup>5+</sup>, 1261.29 ( $M - 3\text{Man} + 5H$ )<sup>5+</sup>, 1229.04 ( $M - 4\text{Man} + 5H$ )<sup>5+</sup>, 1196.39 ( $M - 5\text{Man} + 5H$ )<sup>5+</sup>, 1164.08 ( $M - 6\text{Man} + 5H$ )<sup>5+</sup>, and 1131.63 ( $M + 6H$ )<sup>6+</sup>. These data are in good agreement with the structure of the neoglycopeptide **22**. The introduction of mannose and/or high-mannose oligosaccharide moiety at the C-terminus of the biologically active HIV-1 peptide should have the potential to target the drug to macrophage and dendritic cells through specific carbohydrate ligand–receptor recognition. Macrophage and dendritic cells are major target cells for HIV-1 infection and express rich mannose- and oligomannose-specific receptors on their surface (29, 30).

In summary, an array of maleimide-activated monosaccharides and a maleimide-tagged, native high-mannose oligosaccharide were synthesized. The application of these maleimide-activated carbohydrates as chemoselective tags for site-specific glycosylation of peptides via the highly efficient maleimide–thiol ligation was exemplified by the site-specific introduction of mannose and oligomannose ligands at the C-terminus of a 36-mer HIV-1 gp41 peptide, which is a potent inhibitor against HIV infection. Tagging the biologically active peptide with a mannose and/or oligomannose moiety will be useful for targeting the drug to macrophage and dendritic cells, which are primary targets for HIV-1 infection and are expressing

mannose- and oligomannose-specific receptors on their surface. In combination with site-specific mutagenesis, the maleimide-activated carbohydrates described can serve as generally applicable tags for site-specific glycosylation of proteins via the highly efficient maleimide-thiol ligation reaction.

# Solid-Phase Synthesis of Multivalent Glycoconjugates on a DNA Synthesizer

Michael Dubber and Jean M. J. Fréchet\*

Department of Chemistry, University of California, Berkeley, California 94720-1460. Received October 9, 2002

Carbohydrate–oligonucleotide conjugates and glycodendrimers were synthesized utilizing a DNA synthesizer. The synthesis of multivalent glycoconjugates on solid-phase allows custom tailoring of their structure to the requirements of biological assays within hours, as opposed to traditional approaches that require weeks or months of work in the laboratory. Therefore it will become much easier to investigate carbohydrate–protein interactions and optimize for objectives such as the receptor-mediated targeting of antisense oligonucleotides.

## INTRODUCTION

Many recognition events in biology are based on multivalent carbohydrate protein interactions (1). Numerous examples from recent years demonstrate that molecules capable of presenting multiple carbohydrates in an appropriate way to viruses, bacteria, and toxins can efficiently target or inhibit them (2). Tremendous inhibition properties have been achieved, when structurally well defined, monodisperse glycoconjugates matched the carbohydrate receptors of bacterial AB5 toxins. These toxins recognize their host cells through the simultaneous interaction of their five carbohydrate-binding proteins with gangliosides on human cell surfaces. Critical information from the X-ray crystallographic structure of AB5 toxins led to the syntheses of pentameric glycoconjugates with optimized spacer lengths that exhibited binding at a level  $10^7$ -fold higher than that for single ligands (3, 4). However, in most cases the exact structure of receptors for biologically active carbohydrates are unknown, making the screening of glycoconjugates with different structures of special interest. Recently, the chemotactic response of *Escherichia coli* to galactose-functionalized oligomers was optimized by tuning the valency of these galactose arrays (5); in another study, the inhibition of influenza viruses by sialic acid-conjugated dendritic polymers with various backbone structures was investigated (6).

Numerous attempts have been made to utilize carbohydrate–protein interactions to enhance the cellular uptake and the targeting of drug delivery vehicles by coating them with carbohydrates ligands (7). Currently, only a few examples are known in which carbohydrate ligands have been used to increase the uptake of antisense oligonucleotides (8). Carbohydrate-coated structures have been used to achieve the receptor-mediated endocytosis of antisense oligonucleotides by either complexation with mannosylated polylysine (9) or chemical ligation to galactosylated polylysine (10). However, a drawback in the synthesis of multivalent glycoconjugates is the complexity of their synthesis and the difficulty of their purification (11). This becomes even more problematic if only biocompatible connections are allowed (12). Recently, the synthesis of oligosaccharides and simple

glycoconjugates was facilitated by their automated assembly on solid phase (13). The automated synthesis of multivalent glycoconjugates on solid phase would allow their custom tailoring to the requirements of biological assays within hours, whereas solution phase strategies require weeks or months of work in the laboratory.

In the course of an ongoing antisense project with macrophages in our laboratory, it became of interest to synthesize oligonucleotides with mannosylated dendrons for receptor-mediated endocytosis. Therefore a flexible methodology to attach multivalent carbohydrate structures to oligonucleotides that allows for easy modification of the bouquet of presented carbohydrates was necessary. The most appealing way to synthesize such hybrid molecules involved the use of a consistent type of chemistry enabling the preparation of the hybrid as a whole instead of synthesizing two separate moieties using distinct carbohydrate and nucleic acid methodologies. In previous work a DNA synthesizer has been used to assemble dendritic structures that present multiple DNA strands (14, 15) or dyes (16). Branched phosphoramidites as well as mannose-containing phosphoramidites have been described in the literature for different purposes (17–21). Therefore, it was reasonable to try and complete the whole synthesis of our oligonucleotides with mannosylated glycodendrons on the DNA synthesizer. Herein we demonstrate that a standard DNA synthesizer may be used for the small-scale assembly of a variety of multivalent glycoconjugates with biological relevance, which may or may not contain DNA fragments.

## RESULTS AND DISCUSSION

The DNA synthesizer is an ideal tool for the assembly of complex, multivalent glycoconjugates from versatile components, such as spacer units, branching points, or terminal carbohydrates. Therefore it should be possible to select the combination, number, and arrangement of building blocks to create a variety of structures. Originally, DNA synthesizers were designed to assemble oligonucleotides from cyanoethyl phosphoramidites on solid supports (22). Numerous functional groups have since been introduced in the middle or at the end of the oligonucleotide by adapting the desired functionality into an appropriate phosphoramidite (23). Utilizing this approach, the synthesis of mannose, galactose, and branched functional phosphoramidites is described, followed by the

**Scheme 1. Synthesis of Carbohydrate Phosphoramidites**

assembly of an oligonucleotide with mannosylated glycodendron and other glycoconjugates.

**Phosphoramidite Syntheses.** The mannose- and galactose-derivatized phosphoramidites, **3** and **6**, respectively, were synthesized by hydroboration of the acetylated allyl glycosides, **1** and **4**, and subsequent reaction with 2-cyanoethyl tetraisopropylphosphordiamidite (Scheme 1). The hydroboration was performed with 9-BBN to achieve a stereoselective anti-Markovnikoff addition of the borane (24). Nonbasic conditions were required to retain the four ester protecting groups on the carbohydrate. Therefore, the normal hydroboration workup procedure was replaced with aqueous 3 M NaOAc and 30% H<sub>2</sub>O<sub>2</sub>; less than 1 equiv of 9-BBN was used to avoid base formation by hydrolysis of excess 9-BBN. Best results for the synthesis of phosphoramidites such as **3** and **6** were achieved by a modification of a recently published procedure with 2-cyanoethyl tetraisopropylphosphordiamidite and 4,5-dicyanoimidazole (25). Only 0.1 equiv of 4,5-dicyanoimidazole were used to avoid the formation of side products, in which both diisopropylamino groups reacted with the alcohol donor. Furthermore, the suggested aqueous workup was eliminated, and the reaction products were directly purified with dichloromethane over basic alumina, which was made less polar by increasing the Brokmann factor (26), so that the use of reactive solvents such as methanol could be avoided.

Branched functional phosphoramidite **11** was synthesized by selective extension and protection of two hydroxyl groups of 1,1,1-trihydroxymethylethane and its transformation into a phosphoramidite (Scheme 2). After allylation of two hydroxyl groups of 1,1,1-trihydroxymethylethane, the remaining third hydroxyl group was protected with the UV-active benzoyl group to facilitate reaction monitoring. The bis allyl ether **8** was hydroborated as described earlier with less than 1 equiv of 9-BBN followed by workup with 3 M NaOAc/30% H<sub>2</sub>O<sub>2</sub> to afford the diol **9**. The sterically hindered diol **9** was protected

with 4,4'-dimethoxytrityl chloride (DMTCl) using a procedure with DMTCl, NH<sub>4</sub>ClO<sub>4</sub>, and 2,4,6-trimethylpyridine, thereby generating in situ the active protection reagent 4,4'-dimethoxytrityl perchlorate (27). After debenzoylation with sodium methoxide in a THF/methanol mixture, the resulting alcohol **10** was reacted with 2-cyanoethyl tetraisopropylphosphordiamidite and 4,5-dicyanoimidazole to yield the branched phosphoramidite **11**, which was purified with basic alumina.

Spacer functionalized phosphoramidites and triple branched functional phosphoramidites are required in addition to the phosphoramidites described above to vary the spacer length and multiplicity of the targeted multivalent glycoconjugates. The previously known spacer phosphoramidite **12** and the triply branched phosphoramidite **13** meet these requirements perfectly (Chart 1) (17, 28). Following a synthetic approach different from that previously reported, we synthesized **12** by mono DMT-protection of triethylene glycol and subsequent reaction with 2-cyanoethyl tetraisopropylphosphordiamidite and 4,5-dicyanoimidazole. The triply branched phosphoramidite **13** was synthesized following the procedure for the branched phosphoramidite **11** starting with pentaerythritol triallyl ether instead of 1,1,1-trihydroxymethylethane.

**Assembly of Phosphoramidites.** With the mannose, galactose, spacer, and branched phosphoramidites in hand, all the building blocks for the synthesis of multivalent glycoconjugates on a DNA synthesizer are complete and model compounds can be assembled. Initially, the coupling parameters for each novel phosphoramidite needed to be optimized. Several simple structures were synthesized with different reaction times and flow parameters to optimize the coupling conditions for both the new carbohydrate presenting phosphoramidites and the branched phosphoramidites **3**, **6**, and **11**. The purity of the desired products was monitored by MALDI-TOF MS. It revealed that, when used in the synthesizer, all the functional phosphoramidites we prepared were much

**Scheme 2. Synthesis of Branched Phosphoramidites****Chart 1. Branched and Spacer Phosphoramidites.**

less reactive than the phosphoramidites of the four nucleotides adenosine, guanosine, cytosine, and thymidine, and that a simple increase in the normal reaction time was not sufficient to achieve complete coupling. Instead it was found that best results were obtained when the phosphoramidite-activator mixture was regularly renewed over the solid support every 1 or 2 min over a period of 6 or 18 min, respectively. Details about the use of this procedure on an Expedite 8909 synthesizer can be found in the Supporting Information.

**Assembly of Glycodendrimer 14.** The first glycoconjugates targeted was glycodendrimer **14** (Scheme 3). A solid support tagged with 6-fluorescein was used, to obtain fluorescently tagged glycoconjugates that will facilitate monitoring within biological assays. Since the Applied Biosystems Expedite 8909 synthesizer allows the assignment of letters to certain reagents together with corresponding reaction protocols, the automated synthesis became as simple as entering a "XVWVWV" code into the synthesizer computer. Typically the codes X, W, and V were assigned to reagent bottles with phosphoramidites **3**, **11**, and **12**, respectively, together with their appropriate reaction times and flow parameters. It is possible to cleave glycodendrimer **14** from the solid support and deprotect it under normal oligonucleotide

deprotection conditions, for example with aqueous ammonia, but it is more convenient to use standard carbohydrate deprotection conditions. The only protecting group used, acetate ester, becomes volatile methyl acetate, if sodium methoxide in methanol is used for the deprotection. The glycodendrimer **14** was characterized by  $^1\text{H}$  NMR spectroscopy and MALDI-TOF mass spectroscopy.

**Assembly of Oligonucleotide-Glycodendrion Conjugate 15.** The thioated oligonucleotide (5-CAAGCCATGTCTGAGACTTTG) coded for the antisense inhibition of inducible nitric oxide synthase (**29**) with mannosylated glycodendrion **15** was grown divergently in the same manner as **14** on a standard guanosine-support (Scheme 4). The standard oxidizing reagent iodine, which yields oligonucleotides with phosphate backbone, was replaced by the sulfurization reagent 3*H*-1,2-benzodithiole-3-one 1,1-dioxide to obtain a phosphorothioate backbone that increases the stability against nucleases. The deprotection was done with aqueous ammonia/methylamine 1:1 at 40 °C (**30**). The oligonucleotide-glycodendrion conjugate **15** was purified by an ethanol precipitation and subsequently characterized by MALDI-TOF mass spectroscopy and gel electrophoresis. The sterically bulky glycodendrion causes delayed elution in gel electrophoresis, and **15** behaves like a 38mer though it only has 34 negative charges. The formation of duplexes of **15** with complementary oligonucleotide strands was not hindered, due to the good solubility properties of the glycodendrion. A melting point of 44.2 °C (50 mM NaCl) was measured for the hybridization product of **15** with a complementary DNA strand with two short PEG chains at its 5' end, compared to 44.1 °C (50 mM NaCl) for the unmodified DNA strands.

**Assembly of Cluster Glycoside 16.** Galactosylated cluster glycosides were used in the first example of the exponential affinity enhancement of carbohydrate-protein interactions through multiple contacts by multivalent glycoconjugates, also known as cluster effect (**31**, **32**). Using the galactose phosphoramidite **6**, the triple branched phosphoramidite **13**, and the spacer phosphoramidite **12**, it is easy to use the DNA synthesizer to assemble such cluster glycosides with variable spacer

**Scheme 3. Synthesis of Mannosylated Glycodendrimer 14****Scheme 4. Synthesis of Thioated Antisense Oligonucleotide with Mannosylated Glycodendron 15**

lengths. The negatively charged backbone may increase inhibition potency of antisense-oligonucleotide-glycodendrimer conjugates in some cases (33) and may obstruct structural investigations with the presented cluster glycosides. In such cases it is possible to avoid the negative charges, by using methyl phosphoramidites instead of cyanoethyl phosphoramidites, though in this case the resulting structures will be mixtures of diastereomers with neutral methylphosphonate backbone. The cluster glycoside **16** with phosphate backbone was synthesized as a model compound and characterized by MALDI-TOF and  $^1\text{H}$  NMR (Scheme 5). As was the case for the syntheses of **14** and **15**, this synthesis was carried out on a 1  $\mu\text{mol}$  scale. This scale is normally sufficient to meet the amount of glycoconjugate needed for in vitro biological investigations.

**CONCLUSION**

In conclusion, a methodology for the facile, fast, and efficient synthesis of oligonucleotides with glycodendrons

for receptor-mediated endocytosis was presented. This approach also allowed the synthesis of high molecular-weight, multivalent glycoconjugates, such as glycodendrimers and cluster glycosides. The large glycoconjugates prepared are highly soluble in water and present potential high affinity ligands for carbohydrate binding proteins. The syntheses of multivalent glycoconjugates on a DNA synthesizer allows the custom-tailoring of their structure to meet the requirements of biological assays and affords the desired samples within hours, while normal approaches to the synthesis of multivalent glycoconjugates take weeks or months of work in the laboratory. Therefore, it should be possible to generate biological results much faster and optimize for instance the affinity of antisense oligonucleotides fitted with glycodendrons to their target cells.

**EXPERIMENTAL SECTION**

**General Procedures.** For the preparation of Brockmann type II or III alumina, 3% or 6% water was added

**Scheme 5. Synthesis of Galactosylated Cluster Glycoside 16**

to basic alumina type I, respectively, and the resulting material was agitated for 10 min and equilibrated overnight. Vanillin (2.5 g) in 5%  $\text{H}_2\text{SO}_4$  in ethanol (100 mL) was used as the staining reagent for phosphoramidites. Simple alcohols and unsaturated compounds were stained with basic  $\text{KMnO}_4$ -staining reagent [ $\text{KMnO}_4$ , (3 g),  $\text{K}_2\text{CO}_3$  (20 g) in 300 mL water plus 5% (w/v) aqueous  $\text{NaOH}$  (5 mL)]. Carbohydrate-containing compounds were stained with 5%  $\text{H}_2\text{SO}_4$  in ethanol. Dimethoxytrityl-containing compounds were monitored by UV light 254 nm. MALDI-TOF spectra were measured on a Voyager DE MALDI-TOF mass spectrometer from Perseptive Biosystems using 3-hydroxy picolinic acid (HPA) as a matrix [0.7 M HPA, 0.07 M ammonium citrate dibasic, acetonitrile/water 1:1].  $^1\text{H}$  NMR,  $^{13}\text{C}$  NMR, and  $^{31}\text{P}$  NMR spectra were recorded on Bruker VBAMX-400 or DRX-500 spectrometers. Melting points were measured on a Lambda 35 UV spectrometer from Perkin-Elmer with PTP 6 Peltier unit.

**Oligonucleotide Synthesis.** Assembly of the phosphoramidites was done on an Expedite 8909 synthesizer from Applied Biosystems with 1*H*-tetrazole as activator. All synthesizer reagents and controlled glass pore (CPG) supports were obtained from Glen Research. A 1  $\mu\text{mol}$  500 Å 3-(6-fluorescein)-LCAA-CPG (LCAA: Long Chain Alkylamine) was used for fluorescein-labeling of **14** and **16**, and 1  $\mu\text{mol}$  G-1000 Å-LCAA-CPG support was used for the synthesis of **15**. Optimized long coupling procedures were used for the phosphoramidites **3**, **6**, **11**, **12**, and **13**. A short coupling procedure with 16  $\mu\text{mol}$  0.06 M reagent/1  $\mu\text{mol}$  support in five equal injections over 6 min and a longer coupling procedure with 26  $\mu\text{mol}$  0.06 M reagent/1  $\mu\text{mol}$  support in eight equal injections over 18 min was used for the introduction of the more sterical hindered branched phosphoramidites **11** and **13**, as well as for the extension of branched structures. Both procedures use a larger phosphoramidite excess than normal 6  $\mu\text{mol}$  0.06 M reagent/1  $\mu\text{mol}$  support to achieve a better than 98% coupling yield.

**3-Hydroxypropyl 2,3,4,6-Tetra-*O*-acetyl  $\alpha$ -D-mannopyranoside (**2**).** Allyl 2,3,4,6 tetra-*O*-acetyl  $\alpha$ -D-mannopyranoside (**1**) (1.43 g, 3.68 mmol) was dissolved in dry THF (40 mL). 9-BBN (7 mL, 3.5 mmol) was added, and the solution was stirred for 1 day at room temperature. Ice (5 g) and 3 M  $\text{NaOAc}$  (3.5 mL) were added followed by 30% hydrogen peroxide (3.5 mL) added slowly while stirring at 0 °C in an ice bath. The solution was stirred for 8 h and then quickly saturated with  $\text{K}_2\text{CO}_3$  at 0 °C. The phases were carefully separated and the aqueous phase washed twice with THF. The combined organic layers were filtered, dried over  $\text{MgSO}_4$ , filtered, concentrated, and purified over silica gel with ethyl acetate/cyclohexane 2:1 to yield **2** as white amorphous solid (1.01 g, 68%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 400 MHz):  $\delta$  5.23

(dd,  $J$  3.2 Hz and  $J$  9.9 Hz, 1H), 5.18 (dd $\approx$ t,  $J$  9.5 Hz, 1H), 5.15 (dd,  $J$  1.8 Hz,  $J$  3.1 Hz, 1H), 4.74 (d,  $J$  1.6 Hz, 1H), 4.19 (dd,  $J$  12.3 Hz,  $J$  5.4 Hz, 1H), 4.03 (dd,  $J$  12.1 Hz,  $J$  2.5 Hz, 1H), 3.93 (m, 1H), 3.77 (m, 1H), 3.66 (t,  $J$  6.1 Hz, 2H), 3.50 (m, 1H), 2.07, 2.02, 1.97, 1.91 (each s, each 3H), 1.77 (m, 2H) ppm.  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 400 MHz):  $\delta$  170.8, 170.1, 169.9, 169.8, 97.6, 69.5, 69.1, 68.3, 66.1, 65.1, 62.5, 59.3, 32.0, 20.9, 20.8, 20.7, 20.6 ppm. Anal. Calcd for  $\text{C}_{17}\text{H}_{26}\text{O}_{11}$ : C, 50.24; H, 6.45. Found: C, 49.99; H, 6.49.

**3-(2,3,4,6-Tetra-*O*-acetyl  $\alpha$ -D-mannopyranosyloxy)-propyl (2-Cyanoethyl) (*N,N*-Diisopropyl)phosphoramidite (**3**).** To a solution of **2** (410 mg, 1.01 mmol) in dry dichloromethane were added 2-cyanoethyl tetraisopropylphosphordiamidite (0.45 mL, 1.4 mmol) and 4,5-dicyanoimidazole (12 mg, 0.1 mmol). The reaction mixture was stirred for 2 h and then directly purified by column chromatography on Brockmann Type III alumina with dichloromethane as the eluent to yield **3** as colorless viscous liquid (480 mg, 78%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 400 MHz):  $\delta$  5.34–5.24 (m, 2H), 5.22 (m, 1H), 4.80 (m, 1H), 4.28 (m, 1H), 4.08 (dd,  $J$  12.3 Hz,  $J$  2.4 Hz, 1H), 3.99 (m, 1H), 3.89–3.52 (m, 8H), 2.63 (t,  $J$  11.4 Hz, 2H), 2.14, 2.09, 2.02, 1.98 (each s, each 3H), 1.90 (m, 2H), 1.18, 1.16 (each d,  $J$  2.0 Hz, each 6H) ppm.  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 400 MHz):  $\delta$  170.6, 169.9, 169.8, 169.6, 117.5, 97.6, 69.5, 69.0, 68.3, 66.0, 64.9 (d,  $J$  6.0 Hz), 62.3, 59.9 (d,  $J$  17.5 Hz), 58.2 (d,  $J$  9.8 Hz), 42.9 (d,  $J$  12.3 Hz), 30.8 (d,  $J$  6.8 Hz), 24.6, 24.5, 24.5, 24.4, 20.8, 20.7, 20.6, 20.6, 20.3 (d,  $J$  7.2 Hz) ppm.  $^{31}\text{P}$  NMR ( $\text{CDCl}_3$ , 400 MHz):  $\delta$  146.6 ppm. Anal. Calcd for  $\text{C}_{26}\text{H}_{43}\text{N}_2\text{O}_{12}\text{P}$ : C, 51.48; H, 7.14; N, 4.62. Found: C, 51.52; H, 7.18; N, 4.65.

**3-(2,3,4,6-Tetra-*O*-acetyl  $\alpha$ -D-galactopyranosyloxy)-propyl (2-Cyanoethyl) (*N,N*-Diisopropyl)phosphoramidite (**6**).** To a solution of **5** (386 mg, 0.950 mmol) in dry dichloromethane (20 mL) were added 2-cyanoethyl tetraisopropyl phosphordiamidite (0.44 mL, 1.39 mmol) and 4,5-dicyanoimidazole (14 mg, 0.2 mmol). The reaction mixture was stirred for 2 h and directly purified by column chromatography on Brockmann type III alumina using dichloromethane as eluent, to yield **6** as colorless syrup (330 mg, 54%).  $^1\text{H}$  NMR ( $\text{CDCl}_3$ , 400 MHz):  $\delta$  5.41 (m, 1H), 5.31 (dd,  $J$  10.6 Hz,  $J$  3.4 Hz, 1H), 5.11–5.05 (m, 2H), 4.20 (m, 1H), 4.11–4.01 (m, 2H), 3.88–3.45 (m, 8H), 2.61 (dt,  $J$  6.3 Hz,  $J$  1.8 Hz, 2H), 2.10, 2.05, 2.01, 1.95 (each s, each 3H), 1.87 (m, 2H), 1.16–1.13 (m, 12H) ppm.  $^{13}\text{C}$  NMR ( $\text{CDCl}_3$ , 400 MHz):  $\delta$  170.4, 170.3, 170.2, 170.0, 117.6, 96.3, 68.2, 68.1, 68.0, 67.6, 65.1 (d,  $J$  3.6 Hz), 61.6, 60.2 (t,  $J$  18.0 Hz), 58.3 (dd,  $J$  19.5 Hz,  $J$  7.9 Hz), 43.1 (dd,  $J$  2.3 Hz,  $J$  12.5 Hz), 31.1 (t,  $J$  7.5 Hz), 24.6, 24.5, 20.8, 20.8, 20.7, 20.7, 20.4 (d,  $J$  7.0 Hz) ppm.  $^{31}\text{P}$  NMR ( $\text{CDCl}_3$ , 400 MHz):  $\delta$  146.6 ppm. Anal. Calcd for  $\text{C}_{26}\text{H}_{43}\text{N}_2\text{O}_{12}\text{P}$ : C, 51.48; H, 7.14; N, 4.62. Found: C, 51.17; H, 6.97; N, 4.27.

**4,8-Dioxa-6-[(benzoyloxy)methyl]-6-methylnona-1,10-diene (8).** 1,1,1-Trihydroxymethylethane (12.4 g, 103.5 mmol) and allyl bromide (17.9 mL, 206.8 mmol) were dissolved in DMF (60 mL), and NaH (12.0 g, 327 mmol) was added at 0 °C over 1 h. The solution was stirred for 12 h. Ice and brine (400 mL) were added at 0 °C, and the solution was extracted five times with cyclohexane (50 mL each). The combined cyclohexane fractions were dried over MgSO<sub>4</sub> and purified over silica gel using a toluene → toluene/ethyl acetate 10:1 gradient, to obtain the bis-allyl ether as a colorless viscous liquid. The syrup was dissolved in pyridine (100 mL), and benzoyl chloride (10 mL) was added at 0 °C over 10 min. The solution was stirred overnight. Methanol (5 mL) was added at 0 °C to quench the reaction, and the solution was poured into ice–water (300 mL). Dichloromethane was added, the phases were separated, and the aqueous phase was extracted twice with dichloromethane. The combined organic phases were dried (MgSO<sub>4</sub>), concentrated, and purified over silica gel with cyclohexane/ethyl acetate 9:1 to yield **8** as colorless viscous liquid (18.6 g, 59%). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz): δ 8.02 (d, *J* 8.2 Hz, 2H), 7.53 (t, *J* 7.4 Hz, 1H), 7.43 (t, *J* 7.4 Hz, 2H), 5.85 (m, 2H), 5.26 (m, 2H), 5.12 (m, 2H), 4.27 (s, 2H), 3.96 (t, *J* 1.5 Hz, 2H), 3.95 (t, *J* 1.5 Hz, 2H), 3.41 (s, 4H), 1.08 (s, 3H) ppm. <sup>13</sup>C NMR (CDCl<sub>3</sub>, 400 MHz): δ 166.4, 135.0, 132.9, 130.5, 129.6, 128.4, 116.5, 72.7, 72.3, 67.5, 40.3, 17.5 ppm. Anal. Calcd for C<sub>18</sub>H<sub>24</sub>O<sub>4</sub>: C, 71.03; H, 7.95. Found: C, 70.70; H, 7.96.

**4,8-Dioxa-6-[(benzoyloxy)methyl]-6-methylnonane-1,11-diol (9).** To a solution of **8** (5.85 g, 19.2 mmol) in dry THF (40 mL) was added 9-BBN (75.7 mL, 37.8 mmol), and the solution was stirred for 3 d at room temperature. Ice (10 g) and 3 M NaOAc (38 mL) were added followed by 30% hydrogen peroxide (37.5 mL) added slowly while stirring at 0 °C in an ice bath. The solution was stirred for 6 h and then quickly saturated with K<sub>2</sub>CO<sub>3</sub> at 0 °C. The phases were carefully separated, and the aqueous phase was washed twice with THF. The combined organic layers were filtered, dried over MgSO<sub>4</sub>, filtered, concentrated, and purified over silica gel with dichloromethane/methanol 50:3 to yield **9** as colorless viscous liquid (4.89 g, 75%). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz): δ 8.02 (d, *J* 8.3 Hz, 2H), 7.56 (t, *J* 7.4 Hz, 1H), 7.46 (t, *J* 7.4 Hz, 2H), 4.24 (s, 2H), 3.73 (t, *J* 5.5 Hz, 4H), 3.58 (t, *J* 5.5 Hz, 4H), 3.39 (s, 2H), 3.38 (s, 2H), 2.77 (s, 2H), 1.78 (m, 4H), 1.02 (s, 3H) ppm. <sup>13</sup>C NMR (CDCl<sub>3</sub>, 400 MHz): δ 166.1, 133.0, 129.6, 128.5, 73.7, 70.2, 67.5, 61.3, 40.1, 31.8, 17.8 ppm. Anal. Calcd for C<sub>18</sub>H<sub>28</sub>O<sub>6</sub>: C, 63.51; H, 8.29. Found: C, 63.15; H, 8.31.

**1,11-Bis(4,4'-dimethoxytrityloxy)-4,8-dioxa-6-(hydroxymethyl)-6-methylnonane (10).** The diol **9** (2.0 g, 5.9 mmol) was dissolved in dry CH<sub>2</sub>Cl<sub>2</sub> (100 mL). 2,4,6-Trimethylpyridine (3.16 mL, 23.8 mmol), NH<sub>4</sub>ClO<sub>4</sub> (5.43 g, 15.9 mmol), and 4,4'-dimethoxytrityl chloride (5.38 g, 15.9 mmol) were added, and the solution was stirred for 5 d. For workup, the solution was washed with saturated aqueous NaHCO<sub>3</sub> and water, dried (Na<sub>2</sub>SO<sub>4</sub>), filtered through a alumina Brockmann III pad, concentrated, and dried in high vacuum. For debenzoylation, the residue was dissolved in THF (50 mL), and NaOMe in methanol (0.1 M, 20 mL) was added. The solution was stirred overnight, concentrated, redissolved in CH<sub>2</sub>Cl<sub>2</sub> and washed with brine (2×), dried (Na<sub>2</sub>SO<sub>4</sub>), concentrated, and purified over silica gel with toluene/ethyl acetate 9:1 to yield **10** as colorless viscous liquid (3.42 mg, 69%). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz): δ 7.47–7.43 (m, 4H), 7.36–7.16 (m, 14H), 6.86–6.83 (m, 8H), 3.81 (s, 12H), 3.54 (t, *J* 6.5 Hz, 4H), 3.48 (d, *J* 5.8 Hz, 2H), 3.36 (d, *J* 8.9 Hz, 2H), 3.29

(d, *J* 8.9 Hz, 2H), 3.15 (t, *J* 6.2 Hz, 4H), 2.84 (t, *J* 5.7 Hz, 1H), 1.86 (m, 4H), 0.78 (s, 3H) ppm. <sup>13</sup>C NMR (CDCl<sub>3</sub>, 400 MHz): δ 158.7, 145.6, 136.9, 130.3, 128.5, 128.1, 127.0, 113.3, 86.1, 75.8, 69.7, 69.1, 60.6, 55.5, 40.7, 30.6, 17.8 ppm. Anal. Calcd for C<sub>60</sub>H<sub>64</sub>O<sub>10</sub>: C, 76.25; H, 6.83. Found: C, 75.85; H, 7.18.

**2,2-Bis[5-(4,4'-dimethoxytrityloxy)-2-oxapentyl]-propyl (2-Cyanoethyl) (N,N-Diisopropyl)phosphoramidite (11).** **10** (940 mg, 1.12 mmol) was dissolved in dry dichloromethane (10 mL). 2-Cyanoethyl tetraisopropyl phosphordiamidite (1.2 mL, 3.78 mmol) and 4,5-dicyanoimidazole (11.2 mg, 0.095 mmol) were added to the solution. The reaction mixture was stirred for 15 h and directly purified by column chromatography on Brockmann type II alumina using dichloromethane as eluent, to yield **11** as colorless viscous liquid (1.04 mg, 89%). <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz): δ 7.41–7.15 (m, 18H), 6.81–6.76 (m, 8H), 3.76 (s, 12H), 3.57–3.45 (m, 9H), 3.18 (s, 4H), 3.11 (t, *J* 6.3 Hz, 4H), 2.54 (t, *J* 6.7 Hz, 2H), 1.82 (m, 4H), 1.16–1.13 (m, 12H), 0.83 (s, 3H) ppm. <sup>13</sup>C NMR (CDCl<sub>3</sub>, 400 MHz): δ 158.3, 145.4, 136.7, 130.1, 128.2, 127.7, 126.6, 117.7, 113.0, 85.7, 73.2, 68.6, 66.4 (d, *J* 16.3 Hz), 60.5, 58.2 (d, *J* 18.5 Hz), 55.2, 43.0 (d, *J* 13.3 Hz), 41.1 (d, *J* 8.2 Hz), 30.3, 24.7, 24.6, 20.3 (d, *J* 6.4 Hz), 17.3 ppm. <sup>31</sup>P NMR (CDCl<sub>3</sub>, 400 MHz): δ 146.9 ppm. Anal. Calcd for C<sub>62</sub>H<sub>77</sub>N<sub>2</sub>O<sub>10</sub>P: C, 71.52; H, 7.45; N, 2.69. Found: C, 71.37; H, 7.61; N, 2.71.

#### Synthesis of Mannosylated Glycodendrimer 14.

At the DNA synthesizer, 6 coupling cycles using the functional phosphoramidites in the sequence **12**, **11**, **12**, **11**, **12**, and **3** were applied to a 1 μmol 3'-(6-fluorescein) support. The first coupling step was done with 16 μmol 0.06 M reagent in five equal injections over 6 min, the second to fifth coupling steps were done with 26 μmol 0.06 M reagent in 8 equal injections over 18 min. The product was deprotected with 0.1 M NaOMe in MeOH at 40 °C over 3 h and neutralized with Dowex 50WX2 to obtain **14** as an amorphous orange solid (2.9 mg). <sup>1</sup>H NMR (d<sub>4</sub>-MeOH, 500 MHz): δ 8.04 (m, 2H), 7.67 (s, 1H), 7.03 (d, *J* 9.2 Hz, 2H), 6.51 (m, 4H), 4.90 (s, 4H), 3.98–3.30 (m, 172H + MeOH), 1.90 (m, 20H), 1.65–1.30 (m, 7H), 0.97 (s, 9H) ppm. MALDI-TOF MS: *m/z* 4087.8 (Calcd for C<sub>139</sub>H<sub>255</sub>N<sub>107</sub>P<sub>14</sub>: 4086.1).

**Synthesis of Thioated Oligonucleotide with Mannosylated Glycodendron 15.** The iNOS-sequence (5'-CAAGCCATGTCTGAGACTTTG-3') was synthesized on a 1 μmol G-support at the DNA synthesizer using standard phosphoramidites. After the last coupling cycle, a sequence of six further coupling cycles using the functional phosphoramidites in the sequence **12**, **11**, **12**, **11**, **12**, and **3** was added. The first additional coupling step was done with 16 μmol 0.06 M reagent in five equal injections over 6 min, the second to sixth coupling steps were done with 26 μmol 0.06 M reagent in eight equal injections over 18 min. For each step the sulfurization reagent 3*H*-1,2-benzodithiole-3-one 1,1-dioxide was used to oxidize the intermediate phosphotriester. The product was deprotected with aqueous ammonia/aqueous methyllamine (1:1; 1 mL) at 40 °C over 1 h and concentrated at the SpeedVac. The crude product was subjected to a standard ethanol precipitation to yield 151 OD of **15**. A MALDI-TOF MS spectrum was obtained after precipitation of a sample with 3 volume equivalents of 3 M NH<sub>4</sub>-OAc with 0.01 M EDTA overnight at –20 °C. MALDI-TOF MS: *m/z* 10575.7 (calcd for C<sub>316</sub>H<sub>487</sub>N<sub>77</sub>O<sub>190</sub>P<sub>34</sub>S<sub>34</sub>: 10547.9).

The melting behavior of **15** with complementary DNA strand (5'-CAAAGTCTCAGACATGGCTTG-3') was analyzed by UV spectrometry in 0.05 M aqueous NaCl from

20 °C to 70 °C. A melting point of 44.2 °C (50 mM NaCl,  $2 \times 0.2$  OD) was observed for the hybridization of **15** with a complementary DNA strand with two short PEG chains at its 5' end, compared to 44.1 °C (50 mM NaCl,  $2 \times 0.2$  OD) for the unmodified DNA strands.

The mobility shift caused by the glycodendron, was monitored by gel electrophoresis using a 13% denaturing polyacrylamide gel (200 V, 45 min). The oligonucleotide was compared with thioated iNOS DNA (21 bases) and a 10 bp ladder. The iNOS oligonucleotide with mannosylated glycodendron behaved like a 38mer though it has only 34 negative charges.

**Synthesis of Galactosylated Cluster Glycoside 16.** At the DNA synthesizer, three coupling cycles using the synthesized phosphoramidites in the sequence **12**, **13** and **6** were applied to a 1  $\mu$ mol 3'-(6-fluorescein) support. All coupling steps were done with 26  $\mu$ mol 0.06 M reagent in eight equal injections over 18 min. The product was deprotected overnight with 0.06 M NaOMe in MeOH (1 mL) at 37 °C over 6 h and neutralized with Amberlite IR120 to obtain **16** as an amorphous orange solid (2.0 mg). <sup>1</sup>H NMR (*d*<sub>4</sub>-MeOH, 500 MHz):  $\delta$  8.05 (m, 2H), 7.51 (s, 1H), 7.03 (d, *J* 9.3 Hz, 2H), 6.52 (m, 4H), 4.95 (s, 3H), 3.99–3.30 (m, 92H + MeOH), 1.92 (m, 12H), 1.65–1.30 (m, 7H) ppm. MALDI-TOF MS: *m/z* 2416.2 (calcd for C<sub>87</sub>H<sub>146</sub>NO<sub>62</sub>P<sub>7</sub> 2414.90).

#### ACKNOWLEDGMENT

Financial support of this research by the Department of Energy (Basic Energy Sciences; DE-AC03-76SF00098) and the DOE's Biomolecular Program at Lawrence Berkeley National Laboratory is acknowledged with thanks.

# Structural Effects of Carbohydrate-Containing Polycations on Gene Delivery. 1. Carbohydrate Size and Its Distance from Charge Centers

Theresa M. Reineke<sup>†</sup> and Mark E. Davis\*

Division of Chemistry and Chemical Engineering, California Institute of Technology, Pasadena, California 91125. Received August 9, 2002; Revised Manuscript Received October 10, 2002

Cationic polymers have the ability to bind plasmid DNA (pDNA) through electrostatic interactions and condense it into particles that can be readily endocytosed by cultured cells. The effects that polycation structure has on toxicity and gene delivery efficiency are investigated here by synthesizing a series of amidine-based polycations that contain the carbohydrates D-trehalose and  $\beta$ -cyclodextrin (CD) within the polycation backbone. The carbohydrate size (trehalose vs CD) and its distance from the charge centers affect the gene delivery behavior in BHK-21 cells. It is found that as the charge center is further removed from the carbohydrate unit, the toxicity is increased. Also, as the size of the carbohydrate moiety is enlarged from trehalose to  $\beta$ -cyclodextrin, the toxicity is reduced. The absence of a carbohydrate in the polycation produces high toxicity. All carbohydrate polycations transfect BHK-21 cells to approximately the same level of gene expression.

## INTRODUCTION

One of the hurdles to successful application of gene therapy is the development of a viable nucleic acid delivery vehicle. Although viruses are the foremost-investigated gene transfer agents, several problems with this technology have surfaced and nonviral alternatives, such as cationic polymers, are currently being explored (1, 2). While synthetic vectors have been found to be more toxic and have lower transgene expression than viral vectors, several benefits remain. Advantages of utilizing nonviral carriers include the lack of immune and/or inflammatory responses, the lower cost and ease of manufacture on a larger scale, and the ability to carry an unlimited amount of genetic information (viruses can only contain a finite gene size within their capsid) (2–4).

Polylysine (PLL), polyethylenimine (PEI), polyamidoamine (PAA), chitosan, and other polycations have the ability to bind pDNA through electrostatic interactions and condense it into colloidal particles that have been termed polyplexes (5–9). Numerous studies have shown that these systems can carry pDNA into cultured cells. However, substantial differences in transfection efficiency and degree of toxicity have been observed. Several reviews on this topic have recently been published, and they discuss the many vectors that are currently under investigation (4, 10–14).

As various structure–property studies are completed, the influence of polycation composition on gene delivery is beginning to be identified. Numerous reports have suggested that physical and chemical differences play a significant role in the delivery efficiency and toxicity of these systems (3, 15–22). For example, Godbey and co-workers have shown that the transfection efficiency of

PEI increases as the molecular weight increases (6). Also, Murphy et al. have synthesized and studied a diverse set of peptoids and revealed that although several variations were able to bind and condense DNA, only a small subset containing a repeated cationic–hydrophobic–hydrophobic motif were able to transfect cultured cells (21). Moreover, Jones and colleagues have found that very minor structural changes in PAAs have profound effects on the DNA binding ability and colloidal stability, which in turn affected transfection efficiency of the polyplexes (16).

Hwang et al. have shown that the inclusion of  $\beta$ -cyclodextrin into a polyamidine backbone significantly lowers the toxicity associated with polymeric vectors (15). This study suggested that the presence of a large carbohydrate in the polycation backbone was responsible for a remarkable decrease in the toxicity of these systems since polyamidines lacking a carbohydrate were very toxic. Also, the spacing between the charge centers was modified (Figure 1a) and found to affect the toxicity and gene expression. The most efficient vector in the series by Hwang et al. was the  $\beta$ -cyclodextrin polycation with six methylene units between the cationic amidine groups. It was observed that a reduction in the charge separation by only 2 Å (from six to five methylenes), decreased the transfection efficiency of the  $\beta$ -cyclodextrin polycation by an order of magnitude. Furthermore, the  $\beta$ -cyclodextrin polycation with charge centers separated by eight methylenes was found to be the least toxic.

In the previous study by Hwang et al., amidine polymers lacking the repeated sugar moieties (Figure 1b) were initially examined as controls with approximately the same charge distribution along the polycation backbone as the  $\beta$ -cyclodextrin-containing polymers (15). Unfortunately, the long hydrophobic regions in these polyamidine structures are not ideal models for examining the effects of the polymer hydration and determining the parameters responsible for the cytotoxic effects of polycation vectors. Here, several polycations that contain hexamethylenediamine, D-trehalose, and  $\beta$ -cyclo-

**Figure 1.** (a) Schematic structure of the  $\beta$ -cyclodextrin polycations that were studied previously to elucidate structure–property relationships (15). The charge separation was varied by  $n = 4, 5, 6, 7, 8$ , and 10 methylene units between the amidine charge centers. (b) Schematic structure of the amidine polycations lacking a sugar moiety (15). The value of  $n$  was varied by  $n = 1$  or 4 methylene units.

dextrin were created to give further insight into the physiochemical and structural contributions of synthetic gene carriers on toxicity and gene expression in vitro. Trehalose was selected to provide a smaller carbohydrate than the CD since it contains two glucose units (as compared to the seven of the CD). Because the highest gene expression levels were obtained previously with a charge spacing of six methylene units, we chose to keep the charge separation constant at six and vary other parameters in an attempt to (i) understand and elucidate the effects of additional structural differences on the toxicity and delivery efficiency, and (ii) compare the results to our previous investigations. Here, a series of amidine polymers (AP1–AP7) were synthesized with variations in the size of the carbohydrate as well as the distance of the carbohydrate from the charge center. In this examination, each polycation was synthesized and characterized by molecular weight, binding to pDNA, size and zeta potential of the formed polyplexes, and delivery efficiency and toxicity to BHK-21 cells.

## MATERIALS AND METHODS

**Monomer and Polycation Synthesis.** All reagents were purchased from Aldrich Chemical Co. (Milwaukee, WI) with the exception of the dimethyl suberimidate·2HCl (DMS), dimethyl adipimidate·2HCl (DMA), and cysteamine, which were purchased from Pierce Chemical Co. (Rockford, IL) and  $\beta$ -cyclodextrin, which was purchased from Wacker Biochem. Corp. (Adrian, MI). Electrospray mass spectra were obtained from the Beckman Institute Mass Spectrometry Center on a Perkin-Elmer SCIEX API 365 in either positive or negative ion mode as indicated. NMR spectra were collected on a Varian 300 MHz spectrometer (75.5 MHz for  $^{13}\text{C}$ ) with trimethylsilylpropionic acid sodium salt as an internal standard. All amine products were purified using a Toyopearl SP-650M ion-exchange column using a gradient of ammonium bicarbonate (0–0.3 M) as the eluant. TLC on amine products were performed as previously described (15) and spots were detected by using 0.2% ninhydrin in ethanol. Monomers **8** and **9** (Schemes 3 and 4) as well as polymers AP1, AP4, and AP5 were synthesized as previously described (3, 15).

**6,6'-Diiodo-6,6'-dideoxy-D-trehalose 2** (Scheme 1) (23). Anhydrous D-trehalose **1** (4.00 g, 11.7 mmol) was dissolved in anhydrous dimethylformamide (100 mL) under  $\text{N}_2(\text{g})$ . Triphenylphosphine ( $\text{PPh}_3$ ) (15.325 g, 58.5 mmol) and iodine solid (11.875 g, 46.8 mmol) were added to this

reaction and heated to 80 °C for 1.5 h. This mixture was then concentrated to about 1/3 the starting volume, and methanol (150 mL) was added. Sodium methoxide was added to this solution to pH = 8 and then stirred for another 1.5 h. This mixture was then desalted with the addition of ion-exchange resin (IWT TMD-8). The resin was filtered off, and the solution was concentrated to a residue. This product was then triturated with water, and the residual  $\text{PPh}_3$  was filtered off. This solution was then extracted with  $4 \times 100$  mL of chloroform, and the aqueous layer was concentrated to yield a white solid, **2** (5.472 g, 83%). ES/MS:  $m/z$  561  $[\text{M} - \text{H}]^-$ , 689  $[\text{M} + \text{I}]^-$ .  $^{13}\text{C}$  NMR ( $\text{D}_2\text{O}$ ):  $\delta$  95.81, 76.11, 74.49, 73.51, 73.30, 9.53.

**6,6'-Diazido-6,6'-dideoxy-D-trehalose 3** (Scheme 1) (23). To a solution of **2** (2.089 g, 3.72 mmol) in dimethylformamide (40 mL) was added sodium azide (1.446 g, 22.2 mmol), and the mixture was stirred at 80 °C for 16 h. The mixture was then cooled, the residual salts were filtered, and the remaining solution was concentrated. This mixture was then dissolved in water, and ion-exchange resin (IWT TMD-8) was added to the mixture to desalt the solution. The mixture was filtered, and the aqueous solution was concentrated yielding **3** (0.534 g, 37%) ES/MS:  $m/z$  391  $[\text{M} - \text{H}]^-$ .  $^{13}\text{C}$  NMR ( $\text{D}_2\text{O}$ ):  $\delta$  96.37, 74.96, 73.66, 73.49, 73.10, 53.53.

**6,6'-Diamino-6,6'-dideoxy-D-trehalose 4** (Scheme 1) (23). **3** (0.437 g, 1.11 mmol) was dissolved in anhydrous pyridine (19 mL) under  $\text{N}_2(\text{g})$ .  $\text{PPh}_3$  (2.04 g, 7.77 mmol) was added to the mixture, and the mixture was stirred for 1 h at room temperature. Next, concentrated ammonium hydroxide (4.8 mL) was added via syringe to the mixture, and the solution was stirred at room temperature for 16 h. The pyridine was then removed, and the dry material was triturated with water. The solids were filtered off, the aqueous mixture was brought to a pH < 4, and the liquid was added to the Toyopearl column to purify. The appropriate fractions were combined and lyophilized to dryness, yielding a white solid, **4** (0.355 g, 94%). ES/MS:  $m/z$  341  $[\text{M} + \text{H}]^+$ .  $^{13}\text{C}$  NMR ( $\text{D}_2\text{O}$ ):  $\delta$  96.18, 74.44, 73.79, 73.16, 70.61, 43.07.

**6,6'-Dicysteamino-6,6'-dideoxy-D-trehalose 5** (Scheme 2). To a solution containing freshly sublimed cysteamine (0.312 g, 4.0 mmol) in degassed water (50 mL) was added **2** (0.573 g, 1.0 mmol) in four aliquots to the mixture over 30 min. The mixture was heated to 80 °C and stirred for 3 h. The heat was shut off, and the solution was stirred overnight at room temperature. This mixture was concentrated, redissolved in water, and acidified to a pH = 1.8. The mixture was then purified on the Toyopearl column and lyophilized to dryness, yielding a white solid, **5** (0.306 g, 67%). ES/MS:  $m/z$  461  $[\text{M} + \text{H}]^+$ .  $^{13}\text{C}$  NMR ( $\text{D}_2\text{O}$ ):  $\delta$  95.85, 75.25, 73.88, 43.42, 41.45, 35.13.

***N,N*-(Dithiodibutane-4,1-diyl)bis[phthalimide] 11** (Scheme 5) (26). A solution of *N*-(4-bromobutyl)phthalimide **10** (4.250 g, 15.1 mmol) was refluxed in a 1:1 mixture of methanol:water (60 mL) with  $\text{Na}_2\text{S}_2\text{O}_3$  (3.78 g, 15.2 mmol) for 4 h. Next, the Bunte salt was formed by treating the hot solution with small aliquots of iodine solid (2.22 g, 8.74 mmol) over 30 min until the brown color remained. The residual iodine was reduced by adding a small amount of  $\text{Na}_2\text{S}_2\text{O}_5$ . The solution was then cooled to room temperature and stored overnight in the refrigerator. The methanol/water layer was decanted, the solid pellet was dissolved in chloroform, and the remaining salts were removed with ion-exchange resin (IWT TMD-8). A white-yellow solid, **11** (3.78 g, 66%), remained after evaporation of the chloroform. ES/MS:  $m/z$  486  $[\text{M} + \text{H}]^+$ ,  $^{13}\text{C}$  NMR ( $\text{D}_2\text{O}$ ):  $\delta$  168.03, 133.68, 131.83, 122.98, 38.03, 37.33, 27.33, 26.28.

Scheme 1<sup>a</sup>

<sup>a</sup> Reagents and conditions: (a) PPh<sub>3</sub>, I<sub>2</sub>, DMF, 80 °C; (b) NaN<sub>3</sub>, DMF; (c) PPh<sub>3</sub>, pyridine, NH<sub>4</sub>OH.

## Scheme 2

**4,4'-Dithiobisbutane-1-amine Dihydrochloride 12** (Scheme 5) (26). **11** (3.784 g, 7.8 mmol) was refluxed in anhydrous ethanol (90 mL) and hydrazine hydrate (1.1 mL) under N<sub>2</sub>(g). The reaction was stirred for 1 h in which a white precipitate formed after about 30 min. The ethanol was then removed, and the solid was refluxed in 1 M HCl for 1.5 h to form the dihydrochloride salt. The solid hydrazide residue was filtered off, and the aqueous layer was concentrated. The crude product was purified on the Toyopearl column using a gradient of 0–1.0 M of aqueous ammonium bicarbonate. The appropriate fractions were combined and lyophilized to dryness, yielding a white product, **12** (1.38 g, 85%). ES/MS: *m/z* 209 [M + H]<sup>+</sup>, <sup>13</sup>C NMR (D<sub>2</sub>O):  $\delta$  39.63, 37.55, 26.05, 25.76.

**6<sup>A</sup>,6<sup>D</sup>-Dithiobutaneamino-6<sup>A</sup>,6<sup>D</sup>-dideoxy- $\beta$ -cyclodextrin 14** (Schemes 5 and 6). **12** (0.434 g, 2.09 mmol) was dissolved in 70 mL of degassed dH<sub>2</sub>O, and Ar(g) was bubbled through this solution for 30 min. Triscarboxyethylphosphine dihydrochloride (TCEP) (Molecular Probes, Eugene, OR) (0.719 g, 2.51 mmol) was then added to this solution, and the mixture was stirred for 1 h under Ar(g) to reduce the disulfide. The TCEP oxide was removed by quickly passing the solution through a column of Amberlite IRA-400 (OH) resin that was prepared by rinsing with several portions of He(g) sparged water. The freshly cleaved sulfhydryl form, **13**, was then immediately heated to 80 °C, and **6** (0.583 g, 0.43 mmol) was added to the solution in three aliquots over 20 min and left to stir for 4 h. The mixture was then concentrated, dissolved in water, acidified to a pH = 2.0, filtered to remove undissolved solids, and purified. The proper fractions were recovered and lyophilized to dryness to give a white solid, **14** (0.250 g, 44%). ES/MS: *m/z* 1309 [M + H]<sup>+</sup>, 1332 [M + Na]<sup>+</sup>, <sup>13</sup>C NMR (DMSO-*d*<sub>6</sub>):  $\delta$  104.39, 86.95, 83.57, 75.57, 74.53, 62.57, 43.32, 35.46, 34.91, 31.65, 29.09.

**Polymerization.** Each polycation was synthesized as previously described through condensation polymerization (Scheme 7) of an amine monomer with DMS (AP1–AP6) or DMA (AP7) (3, 15). For example, 0.102 g (0.3 mmol) of **2** was combined with DMS (0.067 g, 0.25 mmol) in a small scintillation vial. Na<sub>2</sub>CO<sub>3</sub> (0.5 M, 0.500 mL) was added, and the mixture was stirred for 16 h. This solution was then diluted with about 5 mL of water, brought to a pH < 4.0 with 0.1 M HCl, and added to a dialysis membrane (3500 MWCO for the  $\beta$ -cyclodextrin polycations and 1000 MWCO for the hexamethylenediamine and trehalose polycations). The solution was then dialyzed for 36 h with several water changes and lyophilized to dryness.

**Polycation Characterization.** Polycation molecular weights were determined by static light scattering. The

polycations were analyzed on a Waters 515 HPLC system equipped with a Wyatt Technologies Corp. DAWN EOS in conjunction with an Optilab DSP interferometric refractometer or on a Hitachi D6000 HPLC system equipped with a ERC-7512 refractive index detector and a Precision Detectors PD2020/DLS. Each sample was prepared at a concentration between 50 and 70 mg/mL and injected onto a Polymer Labs Aquagel-OH 30 column with an eluant flow rate of 0.7 mL/min. The eluant was 0.8 M ammonium acetate, brought down to a pH = 2.8 with phosphoric acid. The refractive index increment values were determined in the same eluant at 25 °C (633 nm).

**Gel Retardation Experiments.** Each polycation was examined for its ability to bind pDNA through gel electrophoresis experiments as previously described (3). pGL3-CV (1  $\mu$ g; 10  $\mu$ L of a 0.1  $\mu$ g/ $\mu$ L in DNase free water) was mixed with an equal volume of polymer at charge ratios between 0 and 5.0  $\pm$ . Each solution was incubated for approximately 30 min. Loading buffer (2  $\mu$ L) was added to each sample, and then 10  $\mu$ L of each sample was pipetted into the wells of a 0.6% agarose gel containing 6  $\mu$ g of ethidium bromide/100 mL TAE buffer (40 mM Tris-acetate, 1 mM EDTA) and electrophoresed.

**Dynamic Light Scattering and Zeta-Potential.** The polyplex size and zeta-potential were measured using a ZetaPals dynamic light scattering instrument (Brookhaven Instruments Corporation, Holtsville, NY) as previously described (15). pGL3-CV (2  $\mu$ g) was complexed with each polymer at a charge ratio of 10  $\pm$  in dH<sub>2</sub>O and allowed to stand for 30 min before diluting to 1.2 mL of dH<sub>2</sub>O. The results for each sample are reported as an average of five measurements for the polyplex size and an average of 10 data points for the zeta-potential.

**Cell Culture Experiments.** Plasmid pGL3-CV (Promega, Madison WI) containing the luciferase gene under the control of the SV40 promoter was amplified by *Escherichia coli* strain DH5 $\alpha$  and was then purified using a Novagen Ultramobius 1000 plasmid kit. BHK-21 cells were purchased from ATCC (Rockville, MD) and maintained in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% FBS, 100 units/mg penicillin, 100  $\mu$ g/mL streptomycin, and 0.25  $\mu$ g/mL amphotericin at 37 °C and 5% CO<sub>2</sub>. Media and supplements were purchased from Gibco BRL (Gaithersburg, MD). BHK-21 cells were plated at 50000 cells per well in 24 well plates and incubated for 24 h.

Sixty microliters of cationic polymer dissolved in DNase free water (Gibco BRL) was added to 60  $\mu$ L of pDNA (0.05  $\mu$ g/ $\mu$ L in DNase free water) at charge ratios of 3, 5, 10, 15, 20 (polymer +/DNA –). The mixtures were incubated for 30 min and then diluted to 600  $\mu$ L with serum free media. Twenty four hours after cell plating, the cells were transfected with 1  $\mu$ g of pGL3-CV complexed with each of the polymers (AP1–AP7) at the various charge ratios (200  $\mu$ L of each solution above) and with naked pDNA in triplicate in serum free media. After 4 h, 800  $\mu$ L of DMEM was added to each well. Twenty four hours after transfection, the media was replaced

with 1 mL of DMEM. Forty eight hours after transfection, cell lysates were analyzed for luciferase protein activity with results reported in relative light units (RLUs) as previously described (3). Toxicities were determined by a modified version of the Lowry protein assay with a Bio-Rad (Hercules, CA) DC Protein Assay Kit also as previously described (3).

## RESULTS

**Monomer and Polycation Synthesis and Characterization.** Each monomer was synthesized in accordance to the procedures described above (depicted in Schemes 1–6). All yields and spectra were in agreement with literature values where applicable. The polycations were synthesized in the same manner as previously described via AABB condensation polymerization by combining amine-functionalized comonomers with DMS or DMA in aqueous sodium carbonate as shown in Scheme 7 (3, 15). The polycation yield, molecular weight, degree of polymerization, and polydispersity index were determined by static light scattering and the results given in Table 1 for each polycation (see Figure 2 for schematics of structures).

**pDNA Binding Studies and Polyplex Characterization.** The polycations were complexed with pDNA at several charge ratios, and the point of charge neutralization was determined by agarose gel electrophoresis. All polycations bound pDNA at and above a charge ratio of 1.0 ±.

To determine both the particle size and the surface charge of the polyplexes, each polycation was complexed with pDNA at a charge ratio of 10 ± and analyzed for

particle size using dynamic light scattering and surface charge using zeta-potential. As shown in Figure 3a, the polyplexes formed by each of the polycations were all between 80 and 100 nm in diameter. In addition, the polyplex surface charge was very positive (Figure 3b), indicating an excess of polycation charge relative to the charge of the pDNA. Positive zeta-potentials provide appropriate characteristics for endocytosis of the polyplexes (24).

**In Vitro Toxicity and Transfection of the Polyplexes.** BHK-21 cells were plated in 24-well plates and transfected under serum-free conditions using 1 µg of pGL3-CV complexed with each polycation at various charge ratios. Toxicities associated with the polyplexes at various charge ratios were determined by measuring the total protein concentration in the cell lysates after 48 h following initial transfection and normalizing the data to protein levels from untransfected cells. As shown in Figure 4, at a charge ratio of 3 ± and above, the toxicity associated with AP1 becomes evident and only 20% cell survival is found. At charge ratios of both 15 and 20 ±, only 40% of the cells survived with polyplexes from AP3. AP6 displays slight toxicity to BHK-21 cells at a charge ratio of 15 and 20 ± where 70% cell survival was noticed, and AP4, AP5, and AP7 show essentially no toxicity to BHK-21 cells at all charge ratios shown in Figure 4.

IC<sub>50</sub> values for AP1, AP3, AP6, and AP7 (6.6 µM, 23 µM, 58 µM, and 71 µM, respectively) were calculated from transfection experiments (AP1 and AP3 from charge ratios of 3, 5, 10, 15, and 20 ± and AP6 and AP7 from charge ratios of 10, 20, and 50 ±). Results for AP5 (formerly denoted CDP6), CDP8, and CDP4 were obtained from the previous study (1100 µM, 2200 µM, and 380 µM, respectively) and were determined via the MTT assay (15). A comparison of all the IC<sub>50</sub> data is shown in Figure 5.

Transfection efficiencies of the polyplexes were determined by assaying for luciferase protein activity, and the results are reported in relative light units (RLUs) per mg of protein. Several polycation (+) to DNA (−) charge ratios were tested and the results are shown in Figure 6. AP3 was found to have the highest transfection efficiency at lower charge ratios. At a charge ratio of 20

±, AP2–AP7 all revealed expression levels within an order of magnitude from one another. The lowest gene expression values were obtained with AP1 where maximum transfection was reached at a charge ratio of 3 ± and significantly decreased at higher charge ratios.

## DISCUSSION

Previously, Hwang and co-workers demonstrated with  $\beta$ -cyclodextrin-containing polyamidines that interchange spacing was an important parameter, and significant differences in the toxicity and gene expression were noted for this family of delivery vehicles (15). Here, further investigation of the charge spacing is studied by systematically changing the distance from the charge center to the carbohydrate unit within the backbone to determine whether there is a relationship between this distance and toxicity and gene expression. Likewise, the carbohydrate size was varied to determine if increasing the size and therefore the degree of backbone hydration affects these parameters. Such parameter changes were accomplished through preparing a new set of carbohydrate monomers. The trehalose amine monomer **4** was synthesized in a manner similar to Garcia Fernandez et al. using slight modifications to the various steps by exploiting the greater reactivity of the primary hydroxyl groups to halogenation (23). As shown in Scheme 1, the final amine product **4** was created through a Staudinger reduction of the azide **3**. A literature preparation of the trehalose dicysteamine analogue **5** was found where the product was synthesized via a tosyl intermediate step (25). However, here a nucleophilic substitution of the iodo group with cysteamine was used and proceeded in an efficient manner as pictured in Scheme 2. The  $\beta$ -cyclodextrin monomers (**8** and **9**) were synthesized as previously described (depicted in Schemes 3 and 4) with the

exception of the dithiobutaneamino  $\beta$ -cyclodextrin derivative, **14**, that was produced by a new method (vide infra). **12** (Scheme 5) was prepared through a similar route published by Pfammatter and co-workers to create C6–C12 alkanethiols (26). The synthesis of **14**, as shown in Scheme 6, was found to be slightly complicated by the fact that the TCEP interfered with the nucleophilic substitution step with **13**, and that the reducing agent must be removed from the solution via anion-exchange chromatography in order for the desired reaction to proceed. Also, after TCEP removal, the disulfide, **12**, can reform quickly after cleavage, and therefore the substitution step must take place immediately upon disulfide reduction.

The  $\beta$ -cyclodextrin and trehalose polycations were prepared in an effort to modify the charge distribution along the polyamidinium backbone, and to compare how the size of the carbohydrate moiety affects both the toxicity and gene delivery efficiency. The structures of the polycations used in this study are illustrated in Figure 2. Molecular weights were determined by static light scattering, and results are listed Table 1. Note that as the monomer is changed, the degree of polymerization is affected; the hexamethylenediamine derivative (AP1) showed the highest degree of polymerization (DP = 10, 3.2 kDa), the trehalose polycations (AP2 and AP3) had intermediate degrees of polymerization (DP = 8, 4.5, and 5.4 kDa, respectively), and the  $\beta$ -cyclodextrin polycations (AP4–AP7) showed the lowest degrees of polymerization (DP = 5, 6.2 kDa; DP = 4, 4.9 kDa; DP = 6, 9.0 kDa; and DP = 4, 6.5 kDa). This influence is more pronounced in the  $\beta$ -cyclodextrin derivatives than in the trehalose polycations, and could be due to the steric affects of the bulk cyclodextrin cup hindering further monomer coupling during the polymerization steps.

Polyplexes formed from all the polycations were between 80 and 100 nm in diameter. Therefore, it is unlikely that differences noted in the transfection efficiency are due to changes in polyplex size. The zeta-potential measurements reveal that all polyplexes contain a large positive charge on the surface of the polyplexes. It is somewhat surprising that AP6 and AP7 have quite high values (above 50 mV).

Figure 4 shows the toxicity observed for each polycation. AP1 is clearly the most toxic, where only 20% cell survival is found at a charge ratio of  $3 \pm$  and above. This effect is likely due to the lack of a carbohydrate within the polycation structure, but some of the increase in toxicity could also be from the slightly higher degree of

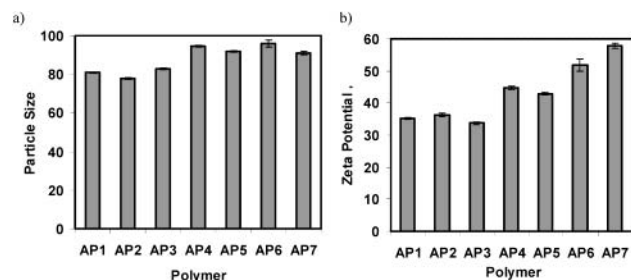

**Figure 2.** Schematic structures of the amidine polycations AP1–AP7.

polymerization. Several groups have observed the effect of higher polymer toxicity with increasing polymer molecular weight (19, 27). AP3 is more toxic to BHK-21 cells than the remaining carbohydrate polyamidine systems; cell survival decreases systematically as the charge ratio increases for AP3, and only 40% cell survival is obtained at  $20 \pm$ . In addition, AP6 also exhibits some degree of toxicity at charge ratios of 15 and  $20 \pm$ . Polycations AP2, AP4, AP5, and AP7 revealed almost no toxic effects to BHK-21 cells at charge ratios up to  $20 \pm$ , with AP2 showing only a small amount of toxicity at a charge ratio of  $20 \pm$ .

$\text{IC}_{50}$  values were calculated from a series of transfection experiments that were conducted to charge ratios as high as  $50 \pm$ . As shown in Figure 5, AP1, which lacks a carbohydrate, is clearly the most toxic of the series to BHK-21 cells ( $\text{IC}_{50} = 6.6 \mu\text{M}$ ). AP3 also displays a low  $\text{IC}_{50}$  value ( $23 \mu\text{M}$ ) and was shown to be more toxic than

AP2 in the transfection experiments. AP2 did display a small amount of toxicity at a charge ratio of  $20 \pm$  (83% cell survival), but the CD analogue, AP4, as well as AP5 did not display any toxicity. These data reinforce the idea that larger carbohydrates contribute to lowering the toxicity of polycations in BHK-21 cells.

The  $\text{IC}_{50}$  values for the  $\beta$ -cyclodextrin polycations (Figure 5), AP6 and AP7, are considerably lower ( $58 \mu\text{M}$  and  $71 \mu\text{M}$ , respectively) than those obtained in a previous study for CDP4 (Figure 1a,  $n = 4$ ), AP5 (formerly CDP6), and CDP8 (Figure 1a,  $n = 8$ ) where  $\text{IC}_{50}$  results were found to be  $380 \mu\text{M}$ ,  $1100 \mu\text{M}$ , and  $2200 \mu\text{M}$ , respectively (15). As mentioned earlier, transfection experiments revealed that AP4 and AP5 were nontoxic to BHK-21 cells up to a charge ratio of  $20 \pm$ . However, as the charge was moved further from the CD (AP6), the toxicity did increase. It is interesting to note that this effect was not as dramatic with AP7 at a charge ratio of

**Figure 3.** (a) Comparison of the hydrodynamic diameter of the polyplexes formed by complexing AP1–AP7 with pDNA as measured by dynamic light scattering. The results shown are reported as an average of five measurements. (b) The particle charge as determined by zeta-potential measurements. The results are reported as an average of 10 measurements. Polyplexes were prepared by combining 2  $\mu$ g of DNA with polycations AP1–AP7 at a charge ratio of  $10 \pm$  and diluting to 1.2 mL.

**Figure 4.** Comparison of the relative toxicities of the polycations AP1–AP7 at charge ratios of 3, 5, 10, 15, and 20  $\pm$  with BHK-21 cells. Cell survival was determined by assaying for total protein content and normalizing each sample with the protein concentration for untransfected cells. The data are reported as a mean  $\pm$  SD of three samples.

20  $\pm$  and may be because AP7 has a lower degree of polymerization than AP6 (19, 27). When transfection experiments were performed at a charge ratio of 50  $\pm$  for AP6 and AP7, the calculated  $IC_{50}$  values were similar. These data support the idea that toxicity increases as the DNA-binding charge center is further removed from carbohydrate moiety within the polycation backbone (see particularly CDP8 versus AP7 where both polycations have exactly the same composition but different arrangements of the charge centers).

All polyplexes were able to transfect BHK-21 cells with differing degrees of efficiency (Figure 6). AP1 revealed the lowest transfection efficiency, which is most likely attributable to the high degree of cell death obtained from this polycation. While all the carbohydrate-containing polymers demonstrate relatively high transfection efficiency, the best gene expression is obtained with AP3 at a charge ratio of 5  $\pm$ . Similar gene expression values resulted from polyplexes using AP2–AP7 (within the same order of magnitude at 20  $\pm$ ). Additionally, it is observed that the trehalose polyplexes reach maximum gene expression levels at lower charge ratios than the  $\beta$ -cyclodextrin polyplexes. The CD-containing polyplexes exhibited escalating gene expression levels with increasing charge ratio, which may be due to the lower degrees of polymerization for the  $\beta$ -cyclodextrin polymers. This trend has also been observed by Plank et al. with branched cationic peptides, where optimum transfection

**Figure 5.** Comparison of the  $IC_{50}$  values calculated for CDP4, CDP6 (AP5), CDP8, AP1, AP3, AP6, and AP7.  $IC_{50}$  values for CDP4, CDP6, and CDP8 were obtained from the previous study (15) and values for AP1, AP3, AP6, and AP7 were calculated from transfection experiments.

**Figure 6.** Comparison of transfection efficiencies of the AP1–AP7 polyplexes at charge ratios of 3, 5, 10, 15, and 20  $\pm$  with BHK-21 cells as determined by luciferase protein activity. Data are presented as a mean  $\pm$  SD of three replicates.

shifted to higher charge ratios with decreasing peptide length (28).

In conclusion, a series of polycations containing hexamethylenediamine, D-trehalose, and  $\beta$ -cyclodextrin were synthesized and studied for their toxicity and gene delivery efficiency in BHK-21 cells. It is found that the distance of the charge center from the carbohydrate unit in the polycation backbone affects the toxicity to BHK-21 cells. Also, it appears that the size of the carbohydrate moiety affects toxicity since the  $\beta$ -cyclodextrin polycations all display lower toxicity than the trehalose polycations. Further structure–property studies are ongoing in order to fully understand these effects. In Part 2 of this study, we investigate a series of polyquaternary ammonium vectors that are analogous to the amidine systems studied herein, and compare the effects of charge type on toxicity and delivery efficiency in cell culture.

#### ACKNOWLEDGMENT

We thank Insert Therapeutics, Inc. for partial support of this project. T.M.R. would like to thank the NIH for a National Research Service Award (1-F32 GM64919-01). Also, we are grateful to Swaroop Mishra for amplifying the pDNA and Jeremy Heidel for helpful discussions regarding the cell culture experiments and performing some of the toxicity studies on polymers AP6 and AP7.

# TECHNICAL NOTES

## Structural Effects of Carbohydrate-Containing Polycations on Gene Delivery. 2. Charge Center Type

Theresa M. Reineke<sup>†</sup> and Mark E. Davis\*

Division of Chemistry and Chemical Engineering, California Institute of Technology, Pasadena, California 91125. Received August 9, 2002

Recent polycation structure–gene delivery studies reveal that subtle changes in the molecular structure of polycations have substantial influences on DNA-binding and condensation and on in vitro toxicity and gene delivery efficiency. In Part 1 of this structure–property study using carbohydrate-containing polycations (1), it is demonstrated that as the amidine charge center is removed further from the carbohydrate unit within the polycation structure, the toxicity increases. Inclusion of larger carbohydrate species within the polycation backbone also reduces the toxicity. Here, the effect that polycation charge center type has on toxicity and gene delivery efficiency is investigated. A series of quaternary ammonium polycations containing *N,N,N,N*-tetramethyl-1,6-hexanediamine, D-trehalose, and  $\beta$ -cyclodextrin are synthesized in order to elucidate the effects of charge center type (by comparison to the data given in Part 1) on gene delivery. In all cases, it is found that the quaternary ammonium analogues exhibit lower gene expression values and similar toxicities to their amidine analogues. Additionally, transfection experiments conducted in the presence of chloroquine reveal increased gene expression from quaternary ammonium containing polycations and not from their amidine analogues.

### INTRODUCTION

Cationic polymers are under investigation as alternatives to viral systems for the delivery of therapeutic genes (1–6). Several recent reports have indicated that structural differences in polycations have a considerable effect on nucleic acid condensation, polyplex stability, toxicity, and cellular uptake (1, 7–21). In Part 1 of our study (1), efforts aimed at elucidating structure–property relationships between carbohydrate-containing polyamides and their ability to deliver plasmid DNA (pDNA) are described. It was found that the structure indeed played a role in the toxicity of the polycation in cultured cells, and as the charge center was moved away from the carbohydrate unit within the polycation backbone, the toxicity increased (1). In addition, by increasing the size of the carbohydrate moiety, a reduction in the toxicity was observed.

The identification of subtle structure–property relationships prompted us to further investigate other changes within this family of polycations in hopes of enhancing the understanding of how charge variations affect the properties of carbohydrate-containing, polycationic, gene delivery vectors. A number of studies have recently indicated that there is a relationship between charge center type, toxicity, and delivery efficiency. For instance, van de Wetering et al. investigated a series of cationic methacrylate and methacrylamide polymers and determined that small changes in the structure and charge type did not have a large effect on the pDNA condensing

properties, although substantial changes in the cytotoxicity and transfection capabilities were observed (14). Molecular modeling studies were used to help clarify their findings, and it was discovered that polycations having a low number of interactions with DNA possessed higher gene expression. Wolfert and co-workers also investigated a family of polymethacrylates for the influence of charge spacing, charge type, and molecular weight and found that as the pendant charge was further removed from the polymer backbone, pDNA condensation was less efficient (21). In addition, gene expression levels were influenced by charge type where polymethacrylates containing quaternary ammonium charges exhibited low transfection efficiency.

Here, we describe the synthesis and characterization of a new family of carbohydrate-containing polyquaternary ammonium vectors. The polycations were synthesized from *N,N,N,N*-tetramethyl-1,6-hexanediamine, D-trehalose, and  $\beta$ -cyclodextrin in an effort to create a group of polycations related to the amidine carbohydrate polycations (1) and to compare the results of transfection experiments between the two polycation families.

### MATERIALS AND METHODS

**Monomer and Polycation Synthesis.** All reagents were purchased from Aldrich Chemical Co. (Milwaukee, WI) with the exception of the dimethylaminoethanethiol that was obtained from Research Organics, Inc. (Cleveland, OH) and the  $\beta$ -cyclodextrin, which was purchased from Wacker Biochem Corp (Adrian, MI). Electrospray mass spectra were obtained from the Beckman Institute Mass Spectrometry Center on a Perkin-Elmer SCIEX API 365 in positive ion mode. NMR spectra were collected on a Varian 300 MHz spectrometer (75.5 MHz for <sup>13</sup>C)

**Scheme 1****Scheme 2**

with trimethylsilylpropionic acid sodium salt as an internal standard. All amine products were purified over a Toyopearl SP-650M ion-exchange column using a gradient of ammonium bicarbonate (0–0.3 M) as the eluant. TLC on amine products were performed as previously described and spots were detected by using  $\text{I}_2$  (**8**). 6,6'-diiodo-6,6'-dideoxy-D-trehalose **1** and 6A,6B-diiodo-6A,6B-dideoxy- $\beta$ -cyclodextrin **4** were synthesized as previously described in Part 1 of this study (**1**, **7**, **8**).

*N,N,N,N*-Tetramethyl-6,6'-diamino-6,6'-dideoxy-D-trehalose **2** (Scheme 1). **1** (0.364 g, 0.648 mmol) was dissolved in 25 mL of 2.0 M dimethylamine in methanol. The reaction was stirred at 70 °C for 6 h, stirred at room-temperature overnight, and then concentrated. The residue was redissolved in 25 mL of water, brought to a pH = 1.8, and then purified on the cation exchange column. The appropriate fractions were combined and lyophilized to dryness yielding a white solid, **2** (0.134 g, 52%). ES/MS:  $m/z$  397  $[\text{M} + \text{H}]^+$ , 419  $[\text{M} + \text{Na}]^+$ .  $^{13}\text{C}$  NMR ( $\text{D}_2\text{O}$ ):  $\delta$  95.93, 74.77, 74.69, 73.21, 71.16, 62.13, 46.80.

*N,N,N,N*-Tetramethyl-6,6'-diaminoethanethio-6,6'-dideoxy-D-trehalose **3** (Scheme 1). To a flask containing 60 mL of degassed  $\text{dH}_2\text{O}$  was added dimethylaminoethanethiol (0.693 g, 6.6 mmol). Under constant stirring, **1** (0.606 g, 1.10 mmol) was then added in 4 equal installments over 30 min and then stirred at 75 °C for 5 h. This mixture was then concentrated to a residue, resuspended in 20 mL of  $\text{dH}_2\text{O}$ , and acidified to a pH = 1.8. After purification with the Toyopearl column, the appropriate fractions were combined and lyophilized to dryness yielding a white product, **3** (0.347 g, 61%) ES/MS:  $m/z$  517  $[\text{M} + \text{H}]^+$ .  $^{13}\text{C}$  NMR ( $\text{D}_2\text{O}$ ):  $\delta$  95.27, 74.97, 74.84, 73.58, 73.43, 59.96, 46.07, 35.23, 31.33.

*N,N,N,N*-Tetramethyl-6A,6B-diamino-6A,6B-dideoxy- $\beta$ -cyclodextrin **5** (Scheme 2). **4** (2.169 g, 1.6 mmol) was dissolved in 2 M dimethylamine in methanol (77 mL) and was stirred at 70 °C. After 7 h the reaction was cooled to room temperature and stirred overnight. The methanol was evaporated, the crude product redissolved in methanol, evaporated again, and pumped on overnight to remove residual dimethylamine. The crude product was

**Figure 1.** Schematic structures of the quaternary ammonium polycations QP1–QP4.

### Scheme 3

then dissolved in water, acidified to pH = 2.0, and purified yielding a white solid, **5** (0.528 g, 28%). ES/MS:  $m/z$  1190  $[M + H]^+$ ,  $^{13}\text{C}$  NMR ( $\text{D}_2\text{O}$ ):  $\delta$  104.16, 103.47, 86.39, 83.64, 82.84, 82.70, 75.45, 74.43, 74.30, 71.82, 62.72, 61.56, 47.26.

*N,N,N,N*-Tetramethyl-6<sup>A</sup>,6<sup>D</sup>-diaminoethanethio-6<sup>A</sup>,6<sup>D</sup>-dideoxy- $\beta$ -cyclodextrin **6** (Scheme 2). To a flask containing  $\text{dH}_2\text{O}$  was added dimethylaminoethanethiol (0.630 g, 6.0 mmol), and the mixture was stirred at 80 °C. Next, **4** (1.350 g, 1.0 mmol) was added to this mixture in 4 aliquots over 30 min and then stirred for an additional 4.5 h at temperature. The mixture was then dried in vacuo, resuspended in water, acidified to a pH = 1.5, and purified on the ion exchange column. Fractions containing the product were combined and lyophilized yielding a white solid, **6** (0.53 g, 53%). ES/MS:  $m/z$  1310  $[M + H]^+$ ,  $^{13}\text{C}$  NMR ( $\text{D}_2\text{O}$ ): 104.79, 104.55, 87.53, 84.34, 75.88, 74.65, 63.11, 60.95, 46.98, 35.95, 32.23

**Polymerization.** The polycations QP1–QP4 (see Figure 1) were synthesized via Menschutkin polymerization (Scheme 3) by combining a ditertiary amine comonomers with dibromohexane and mixing the reaction in a solvent for 3 days at temperature (22). For example, **3** (0.103 g, 0.20 mmol) was combined in a small scintillation vial with 0.6 mL of a 4:1 dimethylformamide:methanol solution. Next, 1,6-dibromohexane (0.055 g, 0.23 mmol) was added, and the mixture was stirred for 3 days at 40 °C. The solution was then suspended in a 50% solution of methanol in  $\text{dH}_2\text{O}$ , added to a 1000 MWCO dialysis membrane (Spectrum Laboratories) (1000 MWCO was used for the tetramethyl-1,6-hexanediamine and trehalose polycations, 2000 MWCO membranes were used for the  $\beta$ -cyclodextrin analogues), dialyzed in 30% methanol

in water for 3 h to remove residual dibromohexane, and then dialyzed exhaustively with several water changes for 72 h.

**Polycation Characterization.** Polycation molecular weights were determined by static light scattering. The polycations were analyzed on a Waters 515 HPLC system equipped with a Wyatt Technologies Corp. DAWN EOS in conjunction with an Optilab DSP interferometric refractometer or on a Hitachi D6000 HPLC system equipped with a ERC-7512 refractive index detector and a Precision Detectors PD2020/DLS. Each sample was prepared at a concentration between 50 and 70 mg/mL and injected onto a Polymer Labs Aquagel-OH 30 column with an eluant flow rate of 0.7 mL/min. The eluant was 0.8 M ammonium acetate, brought down to pH = 2.8 with formic acid. The refractive index increment values were determined in the same eluant at 25 °C (633 nm).

**Gel Retardation Experiments.** Each polycation was examined for its ability to bind pDNA through gel electrophoresis experiments as previously described (7). A 1  $\mu\text{g}$  amount of pGL3-CV (10  $\mu\text{L}$  of a 0.1  $\mu\text{g}/\mu\text{L}$  in DNase free water) was mixed with an equal volume of polymer at charge ratios between 0 and 5.0  $\pm$ . Each solution was incubated for approximately 30 min. A 2  $\mu\text{L}$  volume of loading buffer was added to each sample, and then 10  $\mu\text{L}$  of each sample was pipetted into the wells of a 0.6% agarose gel containing 6  $\mu\text{g}$  of ethidium bromide/100 mL TAE buffer (40 mM Tris-acetate, 1 mM EDTA) and electrophoresed.

**Dynamic Light Scattering and Zeta-Potential.** The polyplex size and zeta-potential were measured using a ZetaPals dynamic light scattering instrument (Brookhaven Instruments Corporation, Holtsville, NY) as

**Table 1. The Polycation Percent Yield, Refractive Index Increment, Molecular Weight, Polydispersity, and Degree of Polymerization Data for the Carbohydrate-Containing Quaternary Ammonium Polycations QP1–QP4 (Figure 1) As Determined by Static Light Scattering**

polycation	yield, %	dn/dc	$M_w$ (kDa)	$M_w/M_n$	degree of polymerization
QP1	53	0.149	12.5	1.68	30
QP2	38	0.154	6.0	1.53	14
QP3	32	0.162	3.4	2.60	12
QP4	37	0.140	9.8	1.30	6

previously described (7, 8). A 2  $\mu$ g amount of pGL3-CV was complexed with each polymer at a charge ratio of  $10 \pm$  and allowed to stand for 30 min before diluting to 1.2 mL of dH<sub>2</sub>O. The results for each sample are reported as an average of five measurements for the polyplex size and an average of 10 data points for the zeta-potential.

**Cell Culture Experiments.** Plasmid pGL3-CV (Promega, Madison WI) containing the luciferase gene under the control of the SV40 promoter was amplified by *Escherichia coli* strain DH5 $\alpha$  and was then purified using a Novagen Ultramobius 1000 plasmid kit. BHK-21 cells were purchased from ATCC (Rockville, MD) and maintained in Dulbecco's Modified Eagle Medium (DMEM) supplemented with 10% FBS, 100 units/mg penicillin, 100  $\mu$ g/mL streptomycin, and 0.25  $\mu$ g/mL amphotericin at 37 °C and 5% CO<sub>2</sub>. Media and supplements were purchased from Gibco BRL (Gaithersburg, MD). BHK-21 cells were plated at 50000 cells per well in 24 well plates and incubated for 24 h.

A 60  $\mu$ L volume of polycation dissolved in DNase free water (Gibco BRL) was added to 60  $\mu$ L of plasmid DNA (0.05  $\mu$ g/ $\mu$ L in DNase free water) at charge ratios of 3, 5, 10, 15, 20 (polymer +/DNA –). The mixtures were incubated for 30 min and then diluted to 600  $\mu$ L with serum free media. Twenty four hours after cell plating, the cells were transfected with 1  $\mu$ g of pGL3-CV complexed with each of the polymers above (QP1–QP4) at the various charge ratios (200  $\mu$ L of each solution above) and with naked pDNA in triplicate in serum free media. After 4 h, 800  $\mu$ L of DMEM was added to each well. Twenty four hours after transfection, the media was replaced with 1 mL of DMEM. Forty eight hours after transfection, cell lysates were analyzed for luciferase protein activity with results reported in relative light units (RLUs) as previously described (7). Toxicities were determined by a modified version of the Lowry protein assay with a Bio-Rad (Hercules, CA) DC Protein Assay Kit also as previously described (7).

Transfections were also completed with polyplexes prepared from pDNA and polycations AP3 and QP3 at charge ratios of 3, 5, and  $10 \pm$  in the presence of chloroquine. These experiments were carried out using the same procedure above with the exception that chloroquine was added at concentrations of 0, 50, 100, and 200  $\mu$ M to the serum free media in which the polyplexes were diluted in.

## RESULTS

**Monomer and Polycation Synthesis and Characterization.** Each monomer was synthesized in accordance to the procedures described above (depicted in Schemes 1 and 2). Monomers were prepared via nucleophilic substitution of the halogenated analogue with the corresponding amine derivative. All of the polycations were prepared via the Menshutkin reaction by combining the tertiary amine-functionalized comonomers with dibromohexane in a solution of dimethylformamide and

**Figure 2.** Comparison of the hydrodynamic diameter of the polyplexes formed by complexing QP1–QP4 with pDNA as measured by dynamic light scattering (illustrated by the bars on the graph). The results shown are reported as an average of five measurements. The particle charge is denoted by (◆) as determined by zeta-potential measurements. The results are reported as an average of 10 measurements. Polyplexes were prepared by combining 2  $\mu$ g of DNA at a charge ratio of  $10 \pm$  and diluting to a total volume 1.2 mL.

methanol as shown in Scheme 3. Polymerizations proceeded accordingly with the exception of monomer 5, which would not undergo polymerization. The reaction of 5 with 1,6-dibromohexane was attempted in several solvent combinations without success. The polymer yield, molecular weight, degree of polymerization, and polydispersity index were determined by static light scattering, and the results are given in Table 1 for each polycation.

**pDNA Binding Studies and Polyplex Characterization.** The polycations were complexed with pDNA at several charge ratios between 0 and  $5.0 \pm$  and the point of charge neutralization determined by agarose gel electrophoresis. All polycations bound and neutralized pDNA at and above a charge ratio of  $1.0 \pm$ .

To determine both the particle size and the surface charge of the polyplexes, each polycation was complexed with pDNA at a charge ratio of  $10 \pm$  and analyzed for particle size using dynamic light scattering and surface charge using zeta-potential. As shown in Figure 2, the polyplexes formed by each of the polycations were all between 90 and 110 nm. In addition, the surface charge of these the polyplexes was positive indicating an excess of polycation charge relative to the charge of the pDNA. Positive zeta-potentials provide for endocytosis with cultured cells (23).

**In Vitro Toxicity and Transfection of the Polyplexes.** BHK-21 cells were plated in 24-well plates and transfected under serum-free conditions using 1  $\mu$ g of pGL3-CV complexed with each polycation at charge ratios of 3, 5, 10, 15, and  $20 \pm$ . Toxicities associated with the polyplexes at various charge ratios were determined by measuring the total protein concentration in the cell lysates after 48 h following initial transfection and normalizing the data with protein levels from untransfected cells. As shown in Figure 3, at a charge ratio of  $3 \pm$ , the toxicity associated with polymer QP1 becomes evident where about 70% cell survival is obtained. At a charge ratio of  $20 \pm$ , only about 30% of the cells survived. Polycation QP3 also shows elevated toxicity levels, and at a charge ratio of  $20 \pm$ , approximately 40% of the cells survived. Polycations QP2 and QP4 were essentially nontoxic to BHK-21 cells. Toxicity comparisons between AP and QP type polycations are shown in Figure 4.

**Figure 3.** Comparison of the relative toxicities of the carbohydrate quaternary ammonium polymers QP1–QP4 at charge ratios of 0, 3, 5, 10, 15, and 20 with BHK-21 cells. Cell survival was determined by assaying for total protein content and normalizing each sample with the protein concentration for untransfected cells. The data are reported as a mean  $\pm$  SD of three samples.

**Figure 4.** Toxicity comparison of analogous AP and QP polyplexes at a charge ratio of  $20 \pm$  in BHK-21 cells. Data were normalized to untransfected cells for each study.

Transfection efficiencies of the polyplexes were determined by assaying for luciferase protein activity, and the results are reported in relative light units (RLUs) per mg of protein. Several polycation (+) to DNA (–) charge ratios were tested, and the results are shown in Figure 5. QP4 is found to have the highest transfection efficiency, but only at higher charge ratios. Both QP1 and QP2 give similar gene expression values at lower charge ratios; however, at  $20 \pm$ , QP2 exhibits higher expression (likely due to the high toxicity of QP1). The lowest gene expression was obtained from QP3. Transfection efficiency comparisons between AP and QP type polycations are illustrated in Figure 6.

Transfections were also conducted in the presence of 0, 50, 100, and  $200 \mu\text{M}$  chloroquine in serum free media with naked pDNA and with polyplexes formed with polymers AP3 and QP3 at charge ratios of 3, 5, and  $10 \pm$ . Polycations AP3 and QP3 were compared in this experiment because of the large difference in gene expression values obtained for these polycations (Figure 6). As depicted in Figure 7, for almost all cases, the addition of chloroquine to transfection experiments using polyplexes formed from AP3 actually resulted in a

**Figure 5.** Comparison of transfection efficiencies of the QP1–QP4 polyplexes with BHK-21 cells at charge ratios of 0, 3, 5, 10, 15, and  $20 \pm$  as determined by luciferase protein activity. Data are presented as a mean  $\pm$  SD of three replicates.

**Figure 6.** Comparison of transfection efficiencies for the analogous AP and QP polyplexes with BHK-21 cells as determined by luciferase protein activity. Data points represent the maximum transfection for each vector.

decrease in gene expression (most likely due to an increase in cell death from the associated toxicity of chloroquine). It is shown that at charge ratios of both 3 and  $5 \pm$ , the addition of  $200 \mu\text{M}$  of chloroquine did cause a small increase in gene expression. However, for polymer QP3, a substantial increase in gene expression is observed at both charge ratios of 3 and  $5 \pm$ . At a charge ratio of  $3 \pm$ , gene expression increases systematically with increasing concentration of chloroquine, and at a concentration of  $200 \mu\text{M}$ , a 63-fold increase in gene expression is observed. At a charge ratio of  $5 \pm$ , an overall 20-fold increase in gene expression is noted. At a charge ratio of  $10 \pm$ , gene expression levels do not increase with QP3 and this is likely due to the high degree of cell death (between 20 and 40% cell survival) that is observed at this charge ratio.

## DISCUSSION

A series of carbohydrate-containing polycations with quaternary ammonium DNA-binding centers were synthesized to study the effect of charge center type on toxicity and gene delivery efficiency. The effect of charge center type was assessed by comparing the results obtained to those from polycations possessing amidine

**Figure 7.** The effects of chloroquine on the transfection efficiency of polyplexes formed with polycations AP3 and QP3. Chloroquine concentrations of 0, 50, 100, and 200  $\mu\text{M}$ , and polycation charge ratios of 3, 5, and 10  $\pm$  were tested with BHK-21 cells.

charges (investigated in Part 1). Synthesis of the tertiary amine monomers is accomplished through the substitution of the diiodo-carbohydrate molecule with the corresponding nucleophile as depicted in Schemes 1 and 2. Polymerizations of the tertiary amine comonomers with dibromohexane proceed efficiently through Menshutkin quaternization, as shown in Scheme 3, with the exception of monomer **5**, which did not react. Previous synthetic studies with this type of polymerization reaction by Rembaum and co-workers indicate that solvent is an important variable in the kinetics of formation (22). Polymerization of **5** was attempted with several batches of monomer as well as in several solvent systems including dimethylformamide, methanol, water, and dimethyl sulfoxide without success. The polymerization of **5** may not be possible due to the steric hindrance around the amine from the bulky cyclodextrin unit. All other monomers were successfully polymerized (Figure 1). Polycation data such as molecular weights, degrees of polymerization, and polydispersity indices are displayed in Table 1. Clearly, the degree of polymerization is dependent on the structure of the diamine.

As expected, all polycations neutralize pDNA above a charge ratio of 1.0 according to agarose gel electrophoresis experiments. Polyplexes prepared from the quaternary ammonium polymers QP1–QP4 were analyzed using dynamic light scattering and found to be less than 110 nm (QP4 forms the largest polyplexes at 110 nm). zeta-potential measurements show that all polyplexes have high positive surface charge (Figure 2).

Toxicity studies (Figure 3) reveal that QP1 (lacks a carbohydrate unit) is the most toxic polycation to BHK-21 cells where only 30% cell viability is observed at a charge ratio of 20  $\pm$ . In addition, the trehalose polymer, QP3 is found to be relative toxic (40% cell survival at 20  $\pm$ ). These observations are consistent to those found with polyamides (Part 1) where the amidine analogue of QP3 (AP3) was found to be the most toxic of the carbohydrate-containing polycations. QP2 exhibits only slight toxicity with 90% cell viability at 20  $\pm$ , and QP4 is essentially nontoxic. Figure 4 shows the toxicity comparison between the amidine and the quaternary ammonium polycations. Both polycations that lack a carbohydrate, AP1 and QP1, are the most toxic to cells. Note that these polycations

have higher degrees of polymerization and this may influence the toxicity. However, since QP1 is approximately 3 times longer than AP1, and their toxicities to BHK-21 cells are similar, the toxicity of these non-carbohydrate polycations may not be influenced by chain length in the range investigated here. A similar trend exists between the both polycation families where toxicity increases as the charge center is moved further away from the carbohydrate moiety (AP2, AP3, QP2, QP3). However, the effect is not as severe with the  $\beta$ -cyclodextrin polycations. In general, the toxicity does not appear to significantly vary between each analogous quaternary ammonium and amidine polycation (Figure 4).

Transfection efficiencies as determined by luciferase protein activity show that QP3 generally gives lower transfection efficiency than QP1, QP2, and QP4 (Figure 5). QP4 reveals increasing gene expression with increasing polycation amount. This effect is also noted with  $\beta$ -cyclodextrin polyamides and may be attributed to the slight membrane disruption ability of cyclodextrins (24). Figure 6 shows a comparison of the transfection efficiencies for both families of polycations (polyamides and the polyquaternary ammonium). The data displayed in Figure 6 are for the maximum transfection. In every case with carbohydrate-containing polycations, it is observed that the quaternary ammonium polycations give lower gene expression values than the amidine analogues, and the largest difference is noted between AP3 and QP3.

Transfections with AP3 and QP3 polyplexes were performed with the lysosomotropic agent, chloroquine (Figure 7). Chloroquine is known to promote endosomal release of some types of polyplexes. In Part 1 (1), it was noticed that AP3 exhibited the highest transfection efficiency in the series of amidine polymers. However, here it is shown that the quaternary ammonium analogue of AP3 (QP3) displays the lowest transfection efficiency. If this discrepancy is due to the inability of the quaternary ammonium polycations to be released from the endosomes, then the addition of chloroquine may affect the gene expression. There is not a significant increase in gene expression in the presence of chloroquine for AP3, while for QP3 at charge ratios of 3 and 5  $\pm$ , gene expression increases with chloroquine concentration (Figure 7). These results could indicate that the amidine

analogues have improved endosomal escape properties relative to the quaternary ammonium analogues. An exception to this finding is QP4, where at a charge ratio of  $20 \pm$ , relatively high transfection efficiency is noted. As previously mentioned, this may be due to the slight membrane disruption ability of the  $\beta$ -cyclodextrin moiety that may contribute to increase the endosomal escape (24).

Reports by Wolfert et al. also reveal that quaternized methacrylate polymers transfected poorly as compared to methacrylate polymers that contain secondary amine DNA-binding centers (21). These studies indicate that although quat-based polyplexes produce efficient intranuclear transcription following injection into *Xenopus* oocytes, the lack of transfection could be attributed to the absence of pH responsiveness of the quaternized polycation. In addition, van de Wetering et al. also observed low transfection efficiency from a quaternized methacrylate polymer (14). The inability of the quaternized derivatives to escape from the endosomes was confirmed by an experiment in where they added an endosome-disruptive agent (adenovirus) during the transfection experiment that led to a substantial increase in transfection efficiency.

In conclusion, a series of quaternary ammonium polymers containing *N,N,N,N*-tetramethyl-1,6-hexanediamine, D-trehalose, and  $\beta$ -cyclodextrin were synthesized and studied for their ability to bind pDNA and to deliver pDNA to BHK-21 cells. The results obtained indicate that the charge center type does not considerably influence the toxicity since no significant difference in toxicity was noted between the polycation families (quaternary ammonium versus amidine). However, it was found that the charge center type does have a significant influence on gene delivery efficiency since the amidine polycations consistently exhibit higher gene expression than their quaternary ammonium analogues. This result may be due in part to the inability of quat-based polyplexes to escape from endosomes since the addition of chloroquine to transfection experiments increased gene expression for QP3 but not with AP3.

#### ACKNOWLEDGMENT

We thank Insert Therapeutics, Inc. for partial support of this project. T.M.R. would like to thank the NIH for a National Research Service Award (1-F32 GM64919-01). We are grateful to Jeremy Heidel for his help with some of the chloroquine transfection experiments and Swaroop Mishra for amplifying the pDNA.

# A Concise Synthesis of the 3-*O*- $\beta$ -D- and 4'-*O*- $\beta$ -D-Glucuronide Conjugates of *trans*-Resveratrol

David A. Learmonth\*

Laboratory of Chemistry, Department of Research & Development, BIAL, À Avenida da Siderurgia Nacional, 4745-457 S. Mamede do Coronado, Portugal. Received July 22, 2002;  
Revised Manuscript Received October 7, 2002

*trans*-Resveratrol ((*E*)-3,4',5-trihydroxystilbene, **1**) is a phytoalexin produced naturally in plants and grape skins as a stress metabolite protecting against fungal attack. Widespread interest in this apparently structurally simple molecule and synthetic stilbene analogues has arisen in recent years due to the discovery of its antioxidant, antiinflammatory, and anti-carcinogenic activities, among others. Although *O*-conjugation with glucuronic acid in vivo is known to represent a significant metabolic pathway for polyphenolic compounds in general and **1** in particular, preclinical studies have been hampered by the lack of chemically pure, completely characterized reference standards of both regioisomeric 3-*O*- $\beta$ -D- and 4'-*O*- $\beta$ -D-glucuronide conjugates of **1** for adequate identification and quantification of these significant metabolites. The present work describes a concise, convergent synthesis of both 3-*O*- $\beta$ -D- and 4'-*O*- $\beta$ -D-glucuronide conjugates of **1** using a strategy based on a novel Heck coupling of iodoaryl-*O*- $\beta$ -D-glucuronate esters with appropriately substituted styrenes, such that highly pure multimilligram to gram quantities of both the 3-*O*- $\beta$ -D- and 4'-*O*- $\beta$ -D-glucuronide conjugates of **1** can now be conveniently synthesized.

## INTRODUCTION

*trans*-Resveratrol ((*E*)-3,4',5-trihydroxystilbene, **1**) (Figure 1) is an intriguing polyhydroxy-stilbene derivative of apparent structural simplicity that has been detected in several plants (1), peanuts (2), and most abundantly in the skins of red grapes (3), where it is produced as a phytoalexin (plant antibiotic) as part of the defense mechanism against attack by the fungal grapevine pathogen *Bortrytis cinerea* (4). Widespread interest concerning resveratrol is manifested by an increasing number of reports describing its broad range of biological activities. Indeed, initial motivation behind research into **1** began with the discovery of its presence in appreciable (pharmacologically significant) concentrations in red wines, which was upheld as an explanation for the so-called "French Paradox" (5, 6), where despite a diet rich in fat and alcohol, the expected increase in coronary heart disease among the wine-drinking French population is not observed. Consequently, a series of sensitive chromatographic methods have been developed to quantify its concentration in red wines from various regions (7–10). To date, **1** has been shown to exhibit an impressive array of antioxidative (11), anticarcinogenic (12), anti-inflammatory (13), and cardioprotective (5) properties. For example, studies have shown that **1** inhibits the initiation, promotion, and progression of cancer (13), inhibits platelet aggregation and coagulation (14), and acts as a vasorelaxant by inhibiting the contractile response of the aorta to noradrenaline (15). The various relevant physiological properties of **1** have been reviewed and summarized in considerable depth (16).

Despite the enthusiastic push toward reaching clearer assessment of resveratrol's potential health protecting properties in humans, studies of its in vivo metabolism

**1**

**Figure 1.** Chemical structure of resveratrol **1**.

have left doubts remaining as to the exact nature of its metabolic profile. Although *O*-conjugation of structurally related polyhydroxylic substrates, such as for example the flavanoids, with glucuronic acid is known to represent a major metabolic pathway for such compounds (17), it was somewhat surprising therefore to fail to discover suitable literature precedent for the chemical synthesis of the regioisomeric 3-*O*- $\beta$ -D- and 4'-*O*- $\beta$ -D-glucuronide conjugates (**2** and **3**, respectively) (Figure 2) of **1** for unequivocal identification and quantification of these conjugates in preclinical metabolic studies. Indeed, two distinct *O*-glucuronide conjugates were detected in a bioavailability study of **1** in the rat, but it was not possible to elucidate the exact position of conjugation or clearly ascertain the relative extent of conjugation at each position. Consequently, enzymatic deconjugation with a  $\beta$ -glucuronidase was required to liberate free **1** for more exact quantification (18). Although chemical synthesis of the naturally occurring 3-*O*- $\beta$ -glycoside (piceid) of **1** has been previously reported (19, 20), two drawbacks of this synthesis are apparent from the outset. The traditional Wittig phosphorus ylid chemistry employed therein to install the central carbon–carbon double bond gave predominantly what would be in this case, the unwanted *cis*-isomer (*cis*/*trans*, 2.3:1 ratio), and equally unfortunately, chromatographic separation of the *cis*/*trans* geometric isomers was difficult, contributing to diminish the overall yield of the desired *trans*-stilbene even

further. Second, the deprotection procedure described for cleavage of a methoxyl protecting group in the last step (large excess of sodium ethanethiolate in DMF at 140 °C for 10 h) was considered incompatible with the presence of the rather sensitive *O*- $\beta$ -glucuronide substituent. Elsewhere, despite the considerable number of reported methods for chemical synthesis of **1** itself and related derivatives (21–24), there has appeared to date only a single recent report of enzymatic glucuronidation of **1** and its *cis*-isomer using human liver microsomes (25). Unfortunately, this enzymatic method allows for the preparation of only very low quantities of the required glucuronide conjugates, and this lack of appropriate methodology rendered necessary the development of efficient regio- and stereoselective chemical synthesis of both the 3-*O*- $\beta$ - and 4'-*O*- $\beta$ -D-glucuronide conjugates of **1** using a strategy based on a novel Heck coupling of iodoaryl-*O*- $\beta$ -D-glucuronate esters with appropriately substituted styrenes.

#### EXPERIMENTAL PROCEDURES

**Chemistry.** Melting points were measured in open capillary tubes on an Electrothermal Model 9100 hot stage apparatus and are uncorrected. NMR spectra were recorded on a Bruker Avance DPX (400 MHz) Spectrometer with solvent used as internal standard, and data are reported in the following order: chemical shift (ppm), multiplicity (s, singlet; d, doublet; t, triplet; m, multiplet; dd, double doublet; br, broad), number of protons, and approximate coupling constant in Hertz. IR spectra were measured with a Bomem Hartmann & Braun MB Series FTIR spectrometer using KBr tablets (see Table 1). Analytical HPLC was performed on an automated Agilent 1100 Series HPLC, using LiChrospher 100 RP-18 (5 $\mu$ m) LiChroCart 250–4 Cartridges (Merck) in combination with acetonitrile/water (1% formic acid) mixtures. Analytical TLC was performed on precoated silica gel plates (either Merck 60 Kieselgel F<sub>254</sub> or Merck RP-18 F<sub>254s</sub>) and visualized with UV light. Preparative chromatography was done on Merck 60 Kieselgel (0.063–0.2 mm). Elemental analyses were performed on a Fisons EA 1110 CHNS instrument and all analyses are consistent with theoretical values to within  $\pm 0.4\%$  unless otherwise indicated. Solvents and reagents were purchased from Aldrich, E. Merck, and Fluka. 3,5-Diacetoxystyrene **7** was prepared as previously reported by Guiso et al (26) from commercially available 3,5-dihydroxybenzaldehyde. 4-Ac-

etoxystyrene **12** was purchased from Aldrich and used as received. 3,5-Dihydroxyiodobenzene **9** was prepared from commercially available 3,5-dimethoxyaniline via Sandmeyer reaction (59% yield) and demethylation (57% HI, 90% yield) as previously described by Deboves et al (27). The trichloroacetimidate **5** was prepared according to the procedure of Fischer et al. (28).

**4-Iodo-*O*-2,3,4-triacetyl- $\beta$ -D-glucuronopyranosidobenzene Methyl Ester (6).** To a stirred and cooled (ice–water bath) solution of 4-iodophenol **4** (0.66 g, 2.98 mmol) and trichloroacetimidate **5** (2.0 g, 4.18 mmol) in dry dichloromethane (20 mL) under argon was added anhydrous boron trifluoride diethyl etherate (0.59 g, 4.18 mmol) dropwise. The resulting solution was allowed to stir at room temperature for 1 h and then poured onto ice–water (30 mL). The phases were separated, and the aqueous phase was extracted by dichloromethane (10 mL). The combined organic layers were washed by water (40 mL) and brine (40 mL), dried over anhydrous magnesium sulfate, filtered, and evaporated (40 °C, water aspirator pressure) to leave a pale orange residue that solidified on standing. Recrystallization (dichloromethane/2-propanol) afforded colorless crystals (1.30 g, 66%) of mp 161–162 °C. Anal. (C<sub>19</sub>H<sub>21</sub>IO<sub>10</sub>) C, H.

IR (KBr) 1756 cm<sup>−1</sup> (broad, C=O).

<sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  7.61 (d, 2H, *J* = 8.9 Hz), 6.79 (d, 2H, *J* = 8.9 Hz), 5.40–5.25 (m, 3H), 5.12 (d, 1H, *J* = 7.3 Hz), 4.18 (m, 1H), 3.75 (s, 3H), 2.08 (s, 3H), 2.07 (s, 3H), 2.06 (s, 3H). <sup>13</sup>C NMR (CDCl<sub>3</sub>)  $\delta$  170.7, 169.9, 169.8, 167.3, 157.1, 139.1, 119.9, 99.5, 73.2, 72.2, 71.6, 69.5, 53.6, 21.2, 21.1.

**(*E*)-1-(3,5-Diacetoxyphenyl)-2-(4'-*O*-2,3,4-triacetyl- $\beta$ -D-glucuronopyranosidophenyl)ethene Methyl Ester (8).** To a stirred solution of 3,5-diacetoxystyrene **7** (0.31 g, 1.42 mmol) and the iodoaryl-*O*- $\beta$ -D-glucuronate ester **6** (1.14 g, 1.74 mmol) in dimethylformamide (15 mL) at room temperature under argon were added benzyltriethylammonium chloride (0.32 g, 1.42 mmol), tributylamine (0.69 g, 3.73 mmol), and palladium (II) acetate (15.3 mg, 0.068 mmol). The resulting pale orange solution was stirred at 110 °C for 30 min and then allowed to cool to room temperature. The mixture was poured into water (50 mL) with stirring causing formation of a pale yellow precipitate, which was filtered off and washed with water (5 mL). The precipitate was dissolved in dichloromethane (20 mL), and the organic layer was washed by water (20 mL), 2N HCl (10 mL), water again (10 mL), and brine (20 mL), then dried over anhydrous magnesium sulfate, filtered, and evaporated (40 °C, water aspirator pressure) to leave an orange/brown foam. Chromatography over silica gel (petroleum ether/ethyl acetate, 1:1) afforded the major product as an off-white solid that was triturated with diethyl ether to afford a white powder (0.49 g, 55%) of mp 152–154 °C. Anal. (C<sub>31</sub>H<sub>32</sub>O<sub>14</sub>) C, H.

IR (KBr) 1759 cm<sup>−1</sup> (broad, C=O).

<sup>1</sup>H NMR (DMSO-*d*<sub>6</sub>)  $\delta$  7.58 (d, 2H, *J* = 8.7 Hz), 7.29 (d, 1H, *J* = 16.4 Hz), 7.26 (d, 2H, *J* = 2.1 Hz), 7.14 (d, 1H, *J* = 16.4 Hz), 7.02 (d, 2H, *J* = 8.7 Hz), 6.88 (t, 1H, *J*

= 2.1 Hz), 5.7 (d, 1H,  $J$  = 8.0 Hz), 5.47 (t, 1H,  $J$  = 9.7 Hz), 5.11 (dd, 1H,  $J$  = 8.0 and 9.7 Hz), 5.07 (t, 1H,  $J$  = 9.7 Hz), 4.72 (d, 1H,  $J$  = 9.7 Hz), 3.64 (s, 3H), 2.28 (s, 6H), 2.02 (s, 3H), 2.01 (s, 3H), 2.00 (s, 3H).  $^{13}\text{C}$  NMR (DMSO- $d_6$ )  $\delta$  170.6, 170.4, 170.1, 170.1, 168.1, 157.1, 152.2, 140.5, 132.6, 130.6, 129.2, 126.6, 118.0, 117.6, 97.8, 72.1, 72.0, 71.5, 70.0, 53.7, 21.8, 21.3, 21.2.

**(E)-1-(3,5-Dihydroxyphenyl)-2-(4'-O- $\beta$ -D-glucuronopyranosidophenyl)ethene (3), (trans-Resveratrol-4'-O- $\beta$ -D-glucuronide).** To a stirred and cooled (ice–water bath) suspension of the glucuronate ester **8** (0.39 g, 0.61 mmol) in methanol (9 mL) was added dropwise aqueous 1 N sodium hydroxide solution (9 mL, 9 mmol). The resulting mixture was stirred in the cold for 30 min and then at room temperature for 15 min. The resulting solution was diluted with water (6 mL), and sufficient Amberlyst 15 ion-exchange resin was added with stirring to maintain pH  $\sim$ 2–3. The resin was then filtered off and washed with water (3 mL). The combined filtrate was evaporated (60 °C, water aspirator pressure). Toluene (5 mL) was added to the residue and re-evaporated. The residue was dried at room temperature over phosphorus pentoxide under high vacuum overnight. The resulting solid was triturated with diethyl ether (3 mL) and filtered to give a pale beige solid (0.21 g, 84%), which decomposed without melting above 230 °C. Anal. ( $\text{C}_{20}\text{H}_{20}\text{O}_9$ ) C,H.

IR (KBr) 3383 (very broad, OH) and 1730  $\text{cm}^{-1}$  (C=O).

$^1\text{H}$  NMR (DMSO- $d_6$ )  $\delta$  9.22 (br s, 2H), 7.52 (d, 2H,  $J$  = 8.7 Hz), 7.00 (d, 2H,  $J$  = 8.7 Hz), 6.99 (d, 1H,  $J$  = 16.4 Hz), 6.92 (d, 1H,  $J$  = 16.4 Hz), 6.41 (d, 2H,  $J$  = 1.7 Hz), 6.13 (t, 1H,  $J$  = 1.7 Hz), 5.46 (d, 1H,  $J$  = 3.75 Hz), 5.25 (br, 1H), 5.07 (d, 1H,  $J$  = 7.5 Hz), 3.90 (d, 1H,  $J$  = 9.6 Hz).  $^{13}\text{C}$  NMR (DMSO- $d_6$ )  $\delta$  171.2, 159.5, 157.5, 140.0, 132.1, 128.7, 128.3, 128.3, 117.3, 105.5, 103.1, 100.8, 76.8, 76.4, 74.0, 72.4.

**3-Hydroxy-5-iodo-O-2,3,4-triacetyl- $\beta$ -D-glucuronopyranosidobenzene Methyl Ester (10).** To a stirred and cooled (ice–water bath) solution of 3,5-dihydroxyiodobenzene **9** (2.36 g, 10 mmol) and the trichloroacetimidate **5** (4.79 g, 10 mmol) in dry dichloromethane (50 mL) under argon was added boron trifluoride diethyl etherate (1.42 g, 10 mmol) dropwise. The resulting mixture was allowed to stir at room temperature for forty minutes and then poured onto ice–water (30 mL). The phases were separated and the aqueous phase was extracted by dichloromethane (10 mL). The combined organic layers were washed by water (40 mL) and brine (40 mL), dried over anhydrous magnesium sulfate, filtered, and evaporated (40 °C, water aspirator pressure) to leave a pale yellow foam. Chromatography over silica gel (petroleum ether/ethyl acetate 2:1) afforded the major product as a white solid, (1.93 g, 35%) of mp 186–188 °C. Anal. ( $\text{C}_{19}\text{H}_{21}\text{IO}_{11}$ ) C,H.

IR (KBr) 3332 (OH) and 1748  $\text{cm}^{-1}$  (broad, C=O).

**RESULTS AND DISCUSSION**

It has been previously shown that *O*-glucuronidation of **1** is a major metabolic pathway in the rat, giving rise to two *O*-conjugated glucuronide metabolites, which unfortunately could not be unambiguously characterized (18). Of course, *O*-glucuronidation of **1** is certainly expected to represent a major metabolic pathway in other species, including humans and hence synthesis of the individually pure *O*-glucuronide standards would greatly assist metabolic and pharmacokinetic studies of **1**. Although a number of chemical methods exist for preparation of *O*-glucuronide conjugates (29), synthesis of the individual resveratrol 3-*O*- $\beta$ -D- and 4'-*O*- $\beta$ -D-conjugates **2** and **3** represents a particular challenge, due to the presence of three equally reactive hydroxyl groups shared between two phenyl rings, separated by a highly conjugated central carbon-carbon double bond, structural features which effectively combine to complicate many protection/deprotection strategies. As such, direct methods of selective mono-*O*-glucuronidation of **1** were not considered. Alternatively, a convergent strategy was devised, where the two phenyl constituents of the stilbenic skeleton of glucuronides **2** and **3** were to be constructed separately, i.e a phenyl ring of the molecule containing the acetyl protected *O*- $\beta$ -D-glucuronide moiety and an appropriately *O*-substituted styrene, giving rise to two suitably functionalized synthons which could then theoretically be cross-coupled via a palladium catalyzed olefinic arylation, more commonly known as the Heck reaction (30, 31).

Starting with synthesis of resveratrol-4'-*O*- $\beta$ -D-glucuronide **3**, preference for the use of the aryl iodide was based on generally enhanced reactivity over bromides in the Heck reaction thereby also providing the possibility to employ phosphine-free conditions. Accordingly, the

reaction of commercially available 4-iodophenol **4** with Schmidt's trichloroacetimidate **5** proceeded smoothly under boron trifluoride catalysis to give in a completely stereoselective fashion (exclusive  $\beta$ -anomer formation) the acetyl protected *O*- $\beta$ -D-glucuronate ester **6** in good yield (66%). Preparation of the required diacetoxy olefin **7** was achieved as described (26) without incident. This olefin was in fact used in a Heck-mediated synthesis of **1** with 4-acetoxyiodobenzene (26), although when investigating this same reaction in this laboratory, the long reaction time and conditions (17 h at reflux) caused extensive deacetylation and decomposition, and the overall yield of **1** was rather low. In accordance, initial attempts to couple the glucuronate ester **6** with the olefin **7** under similar Heck conditions ( $\text{Pd}(\text{OAc})_2$ ,  $\text{Et}_3\text{N}$  or  $\text{Bu}_3\text{N}$ , DMF or  $\text{CH}_3\text{CN}$ , 100–120  $^\circ\text{C}$ ) were frankly disappointing, giving rise to mostly decomposition products (possibly again through extensive deacetylation) and eventually furnishing the desired protected stilbene derivative **8** in rather unsatisfactory yields (12–20%). The use of tetraalkylammonium halides (in particular chlorides) has been found to significantly accelerate certain Heck reactions (32) (Jeffery modification), and it was therefore extremely gratifying to find that the addition of one molar equivalent of benzyltriethylammonium chloride (used instead of the standard additive, tetrabutylammonium chloride) relative to the olefin greatly improved the situation; in fact, after only 30 min at 110  $^\circ\text{C}$ , the reaction had proceeded cleanly, and the desired protected (*E*)-stilbene **8** could be obtained exclusively in considerably improved yield (55%). To the best of the author's knowledge, this is the first reported example of the successful use of this type of aryl-*O*- $\beta$ -D-glucuronate ester in a Heck coupling reaction. Thereafter, deprotection of the acetyl protecting groups of the both the glucuronide and phenolic hydroxyl groups was easily achieved using aqueous 1 N sodium hydroxide in methanol. Acidic workup (Amberlyst 15 ion-exchange resin) and evaporation of the solvents afforded resveratrol-4-*O*- $\beta$ -D-glucuronide **3** in both good yield (84%) and excellent purity (HPLC, >99%) with minimum purification necessary (Scheme 1).

Thus, for the synthesis of resveratrol-3-*O*- $\beta$ -D-glucuronide **2**, 3,5-dihydroxyiodobenzene **9** and commercially available 4-acetoxystyrene **12** were considered suitably convenient starting materials. Aryl iodide **9** was prepared from commercially available 3,5-dimethoxyaniline as previously described (27) (attempts to convert another readily available precursor, 3,5-dimethoxychlorobenzene,

**Scheme 2. Synthesis of Resveratrol-3-*O*- $\beta$ -D-glucuronide **2**<sup>a</sup>**

<sup>a</sup> Reagents: (a) **5**, BF<sub>3</sub>·OEt<sub>2</sub>, CH<sub>2</sub>Cl<sub>2</sub>, 0 °C to room temperature, 40 min (35%); (b) Ac<sub>2</sub>O, pyridine, DMAP, CH<sub>2</sub>Cl<sub>2</sub>, 0 °C, 30 min, (83%); (c) Pd(OAc)<sub>2</sub>, BnEt<sub>3</sub>N<sup>+</sup>Cl<sup>-</sup>, Bu<sub>3</sub>N, DMF, 120 °C, 40 min, (45%); (d) (i) 1N NaOH (aq), MeOH, 0 °C for 30 min, room temperature for 40 min, 45 °C for 30 min, (ii) Amberlyst 15 ion-exchange resin (92%).

into the corresponding iodide by reaction with magnesium and iodine gave inconsistent results in agreement with observations made by another group (33). Attempted mono-acetylation of **9** (1 equiv Ac<sub>2</sub>O, Py, DMAP, CH<sub>2</sub>Cl<sub>2</sub>) gave a three-component mixture, containing predominantly diacetylated product and starting material rather than the desired mono-acetate. More encouraging however, was the completely stereoselective reaction of **9** with 1 equiv of Schmidt's trichloroacetimidate **5**, again under boron trifluoride catalysis, which allowed isolation of the mono-*O*- $\beta$ -D-glucuronate ester **10** in moderate yield (35%). Some unreacted **9** (~25%) could be recovered by chromatography and recycled. Since the presence of free hydroxyl groups is preferably avoided in the Heck reaction, **10** was *O*-acetylated to give fully protected **11**. Heck coupling of **11** with the styrene **12** under similar conditions used beforehand (Pd(OAc)<sub>2</sub>, Bu<sub>3</sub>N, BnEt<sub>3</sub>NCl, DMF, 120 °C) proceeded rapidly (40 min) and without significant decomposition, affording exclusively the protected (*E*)-stilbene **13** in now quite acceptable yield (45%). Subsequent acetyl-group deprotection of **13** was achieved under similar basic conditions as before, and the free glucuronide **2** could be isolated in excellent yield (92%) and purity (>99% homogeneous by HPLC) again with minimal purification (Scheme 2).

**CONCLUSIONS**

Short, efficient chemical methods suitable for the stereo- and regioselective, multimilligram to gram scale synthesis of highly pure individual 3-*O*- $\beta$ -D- and 4'-*O*- $\beta$ -D-glucuronide conjugates **2** and **3** of resveratrol **1** have been developed, based on a novel Heck coupling of iodoaryl-*O*- $\beta$ -D-glucuronate esters with *O*-protected styrenes. These compounds will find use in the more accurate determination of the metabolic and pharmacokinetic profile of **1** in several species, including humans. It is further hoped that the methodology herein described

will be found useful for the synthesis of *O*- $\beta$ -D-glucuronide conjugates of related polyhydroxy stilbenes.

# Biohydrogen Production from Sucrose Using the Visible Light Sensitization of Artificial Zn Chlorophyll-*a*

Yumi Takeuchi and Yutaka Amao\*

Department of Applied Chemistry, Oita University, Dannoharu 700, Oita 870-1192, Japan.

Received July 24, 2002; Revised Manuscript Received November 1, 2002

A photoinduced hydrogen production system that couples sucrose degradation with invertase and glucose dehydrogenase (GDH) and hydrogen production with colloidal platinum as a catalyst using visible light-induced photosensitization of artificial Zn chlorophyll-*a* (Zn Chl-*a*) has been developed. Continuous hydrogen gas production over more than 240 min was observed when the reaction mixture containing sucrose, invertase, GDH, nicotinamide adenine dinucleotide (NAD<sup>+</sup>), Zn Chl-*a*, methyl viologen (MV<sup>2+</sup>, an electron relay reagent), and colloidal platinum was irradiated by visible light. Zn Chl-*a* was superior to that of Mg Chl-*a* in photostability and photosensitization activity.

## INTRODUCTION

Hydrogen production systems from bioresources is important in environmental and energy development research (1–5). Some renewable biomass resources are starch, cellulose, sucrose, and lactose. These polysaccharides are hydrolyzed to form monosaccharides such as glucose. Thus, the conversion of glucose to hydrogen would be a useful new enzymatic pathway. Some studies on hydrogen production from glucose using an enzymatic pathway have been reported (6–10). Hydrogen production from glucose utilizing a combination of glucose dehydrogenase (GDH) and hydrogenase has been reported (11, 12). However, enzymatic photoinduced hydrogen production from other monosaccharides oligosaccharides or polysaccharides has received little attention. Glucose was obtained from sucrose by using invertase enzymatically. Thus, hydrogen production from oligosaccharides, such as sucrose, can be attained using a combination of invertase, GDH, and hydrogenase or some other hydrogen-evolving catalyst.

On the other hand, some photoinduced hydrogen production systems consist of electron donor, photosensitizer, electron carrier, and catalyst. (13–19). For hydrogen-evolving catalyst, colloidal platinum (17–19) and hydrogenase from *Desulfovibrio vulgaris* (Miyazaki) (13–16) are widely used in hydrogen production systems. Especially, colloidal platinum is stable against long-term irradiation. In photoinduced hydrogen production systems with visible light, as water-soluble zinc porphyrins have an absorption band in the visible light region (380–600 nm), these porphyrins have been widely used as an effective photosensitizer (13, 14). Especially, zinc tetraphenylporphyrin tetrasulfonate (ZnTPPS) is useful as a photosensitizer (13, 14). However, the molar absorption coefficient of zinc porphyrins in the visible light region (500–600 nm) was lower than that in the near ultraviolet light region (380–400 nm). On the other hand, Mg chlorophyll-*a* (Mg Chl-*a*), which acts as the effective photosensitizer in the photosynthesis of green plants (20), has an absorption maximum at 670 nm. Thus, Mg Chl-*a*

is attractive as a visible photosensitizer. So far, photoinduced hydrogen production systems with chemically modified chlorophyll and hydrogenase (21, 22), and chlorophyll derivatives (23–25), were reported previously. However, Mg Chl-*a* purified from green plants is unstable to irradiation. On the other hand, zinc bacteriochlorophyll *a* was found in an aerobic bacterium, *Acidiphilium rubrum* (26). As zinc porphyrins are stable to irradiation and effective photosensitizers, zinc chlorophylls are attractive as stable visible photosensitizers. Some studies on the preparation and characterization of the zinc chlorophyll and bacteriochlorophylls have been reported (20, 27).

In photoinduced hydrogen production with systems consisting of an electron donor, photosensitizer, electron relay, and catalyst, photoexcited photosensitizer reacts with the electron relay to form the reduced electron relay, hydrogen evolves by the proton reduction with the catalyst, and then the oxidized photosensitizer is reduced by the electron-donating reagent such as reduced nicotinamide adenine dinucleotide (NADH). Thus, the electron donor, NADH is the sacrificial reagent, and the oxidized electron donor, NAD<sup>+</sup> is consumed in the reaction system. If NADH is regenerated, the photoinduced hydrogen production system is accomplished without NAD<sup>+</sup> consumption. As GDH uses NAD<sup>+</sup> as a cofactor, photoinduced hydrogen production with GDH, electron donor, photosensitizer, electron relay reagent, and catalyst can be attained. We previously reported visible light-induced hydrogen production from sucrose using the photosensitization of Mg Chl-*a* (28). Thus, an effective photoinduced hydrogen production can be accomplished using Zn Chl-*a* as photosensitizer instead of Mg Chl-*a*.

In this work, we describe the visible light-induced hydrogen production system coupling sucrose degradation with invertase and GDH, and hydrogen production with colloidal platinum using the photosensitization of artificial Zn Chl-*a* in the presence of methyl viologen (MV<sup>2+</sup>) as an electron relay reagent as shown in Scheme 1.

## EXPERIMENTAL PROCEDURES

**General.** Mg Chl-*a* from *spirulina*, invertase from yeast, and GDH from *Bacillus* sp. were purchased from Wako Pure Chemical Industries Ltd. (Osaka, Japan).

\* To whom correspondence should be addressed. Phone: +81-97-554-7972. Fax: +81-97-554-7972. E-mail: amao@cc.oita-u.ac.jp.

**Scheme 1. Visible Light-Induced Hydrogen Production System Coupling the Sucrose Degradation with Invertase and GDH and Hydrogen Production with Colloidal Platinum Using the Photosensitization of Zn Chl-*a* in the Presence of MV<sup>2+</sup>**

NAD<sup>+</sup> and NADH were purchased from Oriental Yeast Co. Ltd. MV<sup>2+</sup> dichloride and cetyltrimethylammonium bromide (CTAB) were purchased from Tokyo Kasei Co. Ltd (Tokyo, Japan). Hydrogen hexachloroplatinate hexahydrate and sodium citrate dihydrate were obtained from Kanto Chemical Co. Ltd (Tokyo, Japan). The other chemicals were analytical grade or the highest grade available. One unit of GDH activity was defined as the amount of enzyme that reduced 1.0  $\mu\text{mol}$  of NAD<sup>+</sup> to NADH by glucose per minute. One unit of invertase activity was defined as the amount of enzyme that produced 1.0  $\mu\text{mol}$  of glucose by sucrose per minute.

**Preparation of Zn Chl-*a*.** Zn Chl-*a* was synthesized by refluxing Mg Chl-*a* (50 mg, 56  $\mu\text{mol}$ ) with about 10 mol equiv of zinc acetate in 100 mL of methanol at 80 °C for 5 h. The insertion of zinc ion into the porphyrin ring of Chl-*a* was monitored by visible absorption spectroscopy. During the reaction, the characteristic absorption bands of Zn Chl-*a* at 421 and 662 nm increased and the absorbance bands at 433 and 668 nm of Mg Chl-*a* decreased gradually. After the mixture was cooled to room temperature, the solvent was removed by rotary evaporation, and then the reaction mixture was washed with water to remove the unreacted zinc acetate. Finally, Zn Chl-*a* was precipitated in water. Zn Chl-*a* was collected by filtration and washed with water. The purification was performed by recrystallization (water–methanol). Zn Chl-*a* and Mg Chl-*a* were solubilized with 10 mmol dm<sup>-3</sup> of CTAB, since Zn Chl-*a* and Mg Chl-*a* are insoluble in aqueous solution.

**Preparation of Colloidal Platinum.** Colloidal platinum was prepared by reduction of hexachloroplatinate solution with sodium citrate. The reduction procedure was similar to the previously reported method (17). A solution of 400 mL of water containing 30 mg of hydrogen hexachloroplatinate hexahydrate was refluxed using a mantle heater and magnetic stirrer for 1.5 h, and then a solution of 30 mL of water containing 600 mg of sodium citrate dihydrate was added and refluxed with a magnetic stirrer at 100 °C for 4 h. The particle size of colloidal platinum prepared was estimated to be 1.5 nm. In general, the colloidal platinum activity decreased with increase the particle size (more than 2.0 nm) (17). The prepared colloidal platinum has the ability to release 0.7  $\mu\text{mol}$  of hydrogen in the reaction system of 10  $\mu\text{L}$  of colloidal platinum,  $1.2 \times 10^{-5}$  mmol of methyl viologen, and  $7.7 \times 10^{-5}$  mmol of sodium dithionite in 4.0 mL of 50 mmol dm<sup>-3</sup> Tris-HCl buffer (pH 7.4) at 30 °C for 10 min. One unit of colloidal platinum activity was defined as the release of 1.0  $\mu\text{mol}$  of hydrogen per minute.

**Spectroscopic Measurements.** The UV–vis absorption spectrum of Zn Chl-*a* was recorded using a spectrophotometer (Multispec-1500 Shimadzu). The molar coefficients at the absorption maxima of Zn Chl-*a* were determined by the linear plot of absorbance versus Zn

**Figure 1.** UV–vis absorption spectra of Zn Chl-*a* (solid line) and Mg Chl-*a* (dashed line) in methanol solution. The concentrations of Zn Chl-*a* and Mg Chl-*a* were 79 and 16  $\mu\text{mol dm}^{-3}$ , respectively.

Chl-*a* concentration. The fluorescence emission spectrum of Zn Chl-*a* was measured using a spectrofluorophotometer with a 150 W xenon lamp as a visible excitation light source (RF-5300PC Shimadzu). The excitation and emission band-passes were 5.0 nm, respectively. The excitation wavelength was 600 nm. In these experiments, the absorbance at the excitation wavelength was kept constant at 0.2 for all the sample solutions.

**NADH Formation with Sucrose, Invertase, and GDH.** The reaction was started by addition of NAD<sup>+</sup> (0.80  $\mu\text{mol}$ ) solution to the sample solution containing sucrose (16  $\mu\text{mol}$ ), invertase (4.0 units), and GDH (5.0 units) in 3.0 mL of 10 mmol dm<sup>-3</sup> potassium phosphate buffer (pH 7.0). The reduction of NAD<sup>+</sup> to NADH by GDH was monitored using a UV–vis spectrophotometer at 340 nm, with a molar extinction coefficient of  $6.3 \times 10^3$  mol dm<sup>3</sup> cm<sup>-1</sup>.

**Photoreduction of MV<sup>2+</sup>.** Photoreduction of MV<sup>2+</sup> was tested in the reaction mixture containing NAD<sup>+</sup>, sucrose, Zn Chl-*a*, MV<sup>2+</sup>, invertase, and GDH. The reaction system consisted of NAD<sup>+</sup> (15  $\mu\text{mol}$ ), sucrose (0.30 mmol), Zn Chl-*a* (4.5 nmol), MV<sup>2+</sup> (1.2  $\mu\text{mol}$ ), invertase (4.0 units), and GDH (5.0 units) in 3.0 mL of 10 mmol dm<sup>-3</sup> potassium phosphate buffer (pH 7.0). The sample solution was deaerated by repeated freeze–pump–thaw cycles and irradiated with a 200 W tungsten lamp at a distance of 3.0 cm, with a light intensity of 200 J m<sup>-2</sup> s<sup>-1</sup>, at 30 °C. The light of the wavelength less than 390 nm was removed by a Toshiba L-39 cutoff filter (Tokyo, Japan). The reduction of MV<sup>2+</sup> was monitored using a UV–vis spectrophotometer at 605 nm, with the molar extinction coefficient of  $1.3 \times 10^4$  mol dm<sup>3</sup> cm<sup>-1</sup> (29).

**Visible Light-Induced Hydrogen Production.** The photoinduced hydrogen production from sucrose was carried out as follows. The sample solution containing NAD<sup>+</sup> (15  $\mu\text{mol}$ ), sucrose (0.30 mmol), Zn Chl-*a* (4.5 nmol), MV<sup>2+</sup> (1.2  $\mu\text{mol}$ ), colloidal platinum (0.5 units), invertase (4.0 units), and GDH (5.0 units) in 3.0 mL of 10 mmol dm<sup>-3</sup> potassium phosphate buffer (pH 7.0) was deaerated by freeze–pump–thaw cycle six times, and substituted by argon gas. The amount of hydrogen evolved was measured by a Shimadzu GC-14B gas chromatograph (detector: TCD, column temperature: 40 °C, column: active charcoal with the particle size 60–80 mesh, carrier gas: nitrogen gas, carrier gas flow rate: 24 mL min<sup>-1</sup>).

## RESULTS AND DISCUSSION

**UV–vis Absorption Spectrum of Zn Chl-*a*.** Figure 1 shows the UV–vis absorption spectra of Zn Chl-*a* and Mg Chl-*a* in methanol solution. The absorption bands of

**Figure 2.** Fluorescence emission spectra of Zn Chl-*a* (solid line) and Mg Chl-*a* (dashed line) in methanol solution. The excitation wavelength was 600 nm. The concentrations of Zn Chl-*a* and Mg Chl-*a* were 0.6 and 0.4 mmol dm<sup>-3</sup>, respectively.

Zn Chl-*a* were 421 nm attributed to Soret band and 662 nm attributed to Q-band. On the other hand, the absorption bands of Mg Chl-*a* were 433 nm attributed to Soret band and 668 nm attributed to Q-band. In comparison of the absorption spectra of Zn Chl-*a* and Mg Chl-*a*, a blue-shift in the absorption bands of Zn Chl-*a* was observed.

#### Fluorescence Emission Spectrum of Zn Chl-*a*.

Figure 2 shows fluorescence emission spectra of Zn Chl-*a* and Mg Chl-*a* in methanol solution. The fluorescence emission peak of Zn Chl-*a* and Mg Chl-*a* were 664 and 678 nm, respectively. In comparison of the fluorescence emission spectra of Zn Chl-*a* and Mg Chl-*a*, the blue-shift in the emission peak of Zn Chl-*a* was observed as well as that in the absorption spectra. The energies of the first excited singlet states of Zn Chl-*a* and Mg Chl-*a* were calculated from the average value of the frequencies of the longest wavelength of absorption maxima and the shortest wavelength of the fluorescence emission maxima. The energies of the first excited singlet states of Zn Chl-*a* and Mg Chl-*a* were 1.50 and 1.47 eV, respectively.

**NADH Formation with Sucrose, Invertase, and GDH System.** When the sample solution containing sucrose, invertase, GDH, and NAD<sup>+</sup> was incubated, the initial rate of NADH formation, which was determined by the amount of NADH with incubation for 15 min, was estimated to be  $(3.4 \pm 0.1) \times 10^{-8}$  mol min<sup>-1</sup>. After 80 min incubation,  $0.77 \pm 0.03$  μmol of NADH was formed. The yield of conversion of NAD<sup>+</sup> to NADH in this system was ca. 100%. When the sample solution containing glucose (16 μmol), GDH, and NAD<sup>+</sup> (without sucrose and invertase) was incubated, the initial rate of NADH formation was estimated to be  $(4.2 \pm 0.1) \times 10^{-8}$  mol min<sup>-1</sup>. After 80 min incubation,  $0.77 \pm 0.02$  μmol NADH was formed, and the yield of conversion of NAD<sup>+</sup> to NADH in this system also was ca. 100%. These results show that glucose formation from sucrose (process 1 in Scheme 1) with invertase proceeded rapidly.

**Stability of Zn Chl-*a* against Irradiation.** The photostability of Zn Chl-*a* in the reaction mixture was investigated. The photostability was tested by irradiation with visible light using a 200 W tungsten lamp (light intensity of 200 J m<sup>-2</sup> s<sup>-1</sup>). Figure 3 shows the absorbance changes at 662 nm attributed to the absorption maximum of Zn Chl-*a* (A) and at 670 nm attributed to the absorption maximum of Mg Chl-*a* (B) with irradiation time. The absorbance decrease of Zn Chl-*a* was slower than that of Mg Chl-*a* in solution as shown in curves A and B, indicating that the degradation rate of Zn Chl-*a* was suppressed compared with that of Mg Chl-*a* against

**Figure 3.** Photostability of Zn Chl-*a* solution under anaerobic conditions. Curves A and B are CTAB solubilized Zn Chl-*a* and Mg Chl-*a* aqueous solution, respectively. Samples were irradiated with visible light using 200 W tungsten lamp at a distance of 3.0 cm (light intensity of 200 J m<sup>-2</sup> s<sup>-1</sup>).

**Figure 4.** The time dependence of the MV<sup>2+</sup> concentration under steady-state irradiation with visible light using 200 W tungsten lamp at a distance of 3.0 cm (light intensity of 200 J m<sup>-2</sup> s<sup>-1</sup>). (Closed circle): The sample solution consisting of invertase (4.0 units), GDH (5.0 units), NAD<sup>+</sup> (15 μmol), sucrose (0.30 mmol), Zn Chl-*a* (4.5 nmol), and MV<sup>2+</sup> (1.2 μmol) in 3.0 mL of 10 mmol dm<sup>-3</sup> potassium phosphate buffer (pH = 7.0). (Open circle): Mg Chl-*a* (3.0 nmol) was used as photosensitizer instead of Zn Chl-*a*. (Closed square): In the absence of NAD<sup>+</sup>.

irradiation. Thus, Zn Chl-*a* was superior to Mg Chl-*a* in photostability.

**Photoreduction of MV<sup>2+</sup>.** Figure 4 shows the time dependence of the MV<sup>2+</sup> concentration in the system containing NAD<sup>+</sup>, sucrose, Zn Chl-*a*, MV<sup>2+</sup>, invertase, and GDH with visible light irradiation (closed circle). The absorbance at 605 nm, absorption band of MV<sup>2+</sup>, increased with irradiation time. After 80 min irradiation, 0.69 μmol of reduced MV<sup>2+</sup> was produced, and the yield of MV<sup>2+</sup> to MV<sup>+</sup> was estimated to be ca. 58%. The photoreduction rate was independent of the concentrations of NAD<sup>+</sup>, sucrose, invertase, and GDH. On the other hand, the reduction rate depends on the concentrations of Zn Chl-*a* and MV<sup>2+</sup>. Thus, the rate-limiting step in the MV<sup>2+</sup> reduction (processes 1, 2, and 3 in Scheme 1) is the photoinduced electron-transfer process from the photoexcited Zn Chl-*a* (\*Zn Chl-*a*) to MV<sup>2+</sup> (process 3 in Scheme 1). For the system using Mg Chl-*a*, 0.21 μmol of reduced MV<sup>2+</sup> was produced, and the yield of MV<sup>2+</sup> to MV<sup>+</sup> was estimated to be ca. 33% after 80 min irradiation (open circle). Thus, the photosensitization activity of Zn Chl-*a* was superior to that of Mg Chl-*a*. On the other hand, MV<sup>2+</sup> was not reduced without NAD<sup>+</sup> in the above system (closed square). There is no direct electron transfer between sucrose or glucose formed with invertase and MV<sup>2+</sup>, and between Zn Chl-*a* and MV<sup>2+</sup>. Thus, the visible light-induced MV<sup>2+</sup> reduction proceeded by

**Figure 5.** Time dependence of hydrogen production under steady-state irradiation with visible light using 200 W tungsten lamp at a distance of 3.0 cm (light intensity of  $200 \text{ J m}^{-2} \text{ s}^{-1}$ ). (Closed circle): The sample solution consisting of invertase (4.0 units), GDH (5.0 units)  $\text{NAD}^+$  (15  $\mu\text{mol}$ ), sucrose (0.30 mmol), Zn Chl-*a* (4.5 nmol),  $\text{MV}^{2+}$  (1.2  $\mu\text{mol}$ ), and colloidal platinum (0.5 unit) in 3.0 mL of 10 mmol  $\text{dm}^{-3}$  potassium phosphate buffer (pH = 7.0). (Open circle): Mg Chl-*a* (3.0 nmol) was used as photosensitizer instead of Zn Chl-*a*. (Closed square): In the absence of  $\text{NAD}^+$ .

coupling the sucrose degradation with invertase and GDH (processes 1 and 2 in Scheme 1) and  $\text{MV}^{2+}$  reduction using the photosensitization of Zn Chl-*a* (process 3 in Scheme 1).

**Visible Light-Induced Hydrogen Production.** As the  $\text{MV}^{2+}$  photoreduction system containing  $\text{NAD}^+$ , sucrose, Zn Chl-*a*,  $\text{MV}^{2+}$ , invertase and GDH was achieved, the photoinduced hydrogen production system was investigated. Figure 5 shows the time dependence of the photoinduced hydrogen production in the system containing  $\text{NAD}^+$ , sucrose, Zn Chl-*a*,  $\text{MV}^{2+}$ , colloidal platinum, invertase, and GDH by the visible light. By irradiation, hydrogen evolved continuously over more than 240 min. The amount of hydrogen production was estimated to be 7.0  $\mu\text{mol}$  after 240 min irradiation. It indicated that 14  $\mu\text{mol}$  of proton, that was 3111 times the amount of Zn Chl-*a* (4.5 nmol) in the sample solution, was reduced to hydrogen molecules. Therefore, the Zn Chl-*a* appeared to serve as the system for transferring electrons from  $\text{NADH}$ , which was formed from sucrose, to a more reductive hydrogen molecule. On the other hand, the hydrogen also was not evolved in the absence of  $\text{NAD}^+$  in the above system (closed square). There is no direct electron transfer between sucrose or glucose formed with invertase and colloidal platinum, and among Zn Chl-*a*,  $\text{MV}^{2+}$  and colloidal platinum. These results suggest that visible light-induced hydrogen production proceeded by coupling the sucrose degradation with invertase and GDH (processes 1 and 2 in Scheme 1) and the hydrogen production with colloidal platinum using the photosensitization of Zn Chl-*a* (processes 3 and 4 in Scheme 1). For the system using Mg Chl-*a*, the amount of hydrogen production was estimated to be 3.0  $\mu\text{mol}$  after 240 min irradiation. It indicated that 6.0  $\mu\text{mol}$  of proton, that was 2000 times the amount of Mg Chl-*a* (3.0 nmol) in the sample solution, was reduced to hydrogen molecules. Thus, the Zn Chl-*a* has a high activity of photosensitization compared with that of Mg Chl-*a* in the photoinduced hydrogen production system.

Next let us focus on the relationship between the photoreduction of  $\text{MV}^{2+}$  and the photoinduced hydrogen production using Zn Chl-*a* and colloidal platinum. The formation of  $\text{MV}^{+}$  reached a constant after 20 min irradiation as shown in Figure 4. This result suggests that the cycle of  $\text{MV}^{2+}$  and  $\text{MV}^{+}$  was stable. As shown

in Figure 5, on the other hand, the photoinduced hydrogen production was proportional to irradiation time. As indicated from Figures 4 and 5, an efficient hydrogen or electron relay in the system may lead to efficient hydrogen production.

In conclusion, a hydrogen production system that couples sucrose degradation with invertase and GDH and hydrogen production with colloidal platinum using visible light-induced photosensitization of artificial Zn Chl-*a* was developed, and continuous hydrogen gas was gained. Moreover, Zn Chl-*a* was superior to Mg Chl-*a* in photo-stability and photosensitization activity. Renewable biomass resources are effectively used to produce an environmentally clean energy source, hydrogen gas. However, since sucrose is expensive as a renewable biomass or clean energy source, hydrogen production from cellulose, which is an inexpensive renewable biomass, is desirable. Further research will be directed toward a photoinduced hydrogen production system that utilizes cellulose and cellulase instead of sucrose and invertase in process 1 of Scheme 1.

## In Memoriam: Claude Hélène

One of the fathers of triple helix antigene targeting has died. Just a week after his 65th birthday and a few days after a grand symposium celebrating this occasion, held in Paris, in the Natural History Museum that also hosts his laboratory, Claude Hélène is no longer with us. Those of us who knew Claude will remember him as a very generous scientist and human being. Claude Hélène started out as a photobio-physicist but very early turned his attention to the properties and function of nucleic acids. Claude Hélène's scientific contributions are numerous, but there are two that particularly stand out. His first major contribution was the discovery that a tripeptide (LysTrpLys) binds to abasic sites in DNA by intercalation and catalyzes strand scission (*Nature* **1981**, 292, 858–859). Some years later he entered the emerging field of gene targeting by antisense oligonucleotides and was a central player in shaping this field. However, the finding in 1987 (in parallel with Peter Dervan) that short homopyrimidine oligonucleotides via triple helix formation can sequence specifically target double-stranded DNA (*Nucleic Acids Res.* **1987**, 15, 7749–7760) had the most impact on the fields of bioorganic chemistry, DNA recognition, and gene therapeutic drug discovery. The follow-up studies in the Hélène lab of this seminal discovery during the past 15 years showed that this process could be improved by chemical design to a stage where “proof of principle” in cells was obtained. Claude Hélène's impact on the field of gene targeting has been tremendous. He and his laboratory constantly sought the key experiments to rigorously show the path to the final goal: controlling gene function by design. Through a large number of international collaborations he was always very alert to implement the newest and most promising technologies to reach this goal, and he defined the forefront of the field.

Many of us will remember the special atmosphere when visiting Claude Hélène in his laboratory in the unique setting at the Museum of Natural History with plants and exotic animals “in the backyard”. Being with Claude Hélène and discussing science was always an inspiring experience, and at the numerous meetings he attended, Claude Hélène was always ready with penetrating and visionary questions. The discovery of the sequence-specific triple helix recognition of duplex DNA had very profound influence on my own research, as this demonstrated for the first time a way to digitally read the sequence of double-stranded DNA in the major groove. The triple helix principle was the direct inspiration that triggered us to consider alternative ways of chemically connecting the sequence-reading nucleobases in the major groove of the DNA, that eventually lead to the discovery of PNA. From that point on much of our research was paralleling that of Claude Hélène's group, including several collaborative projects. As in an ideal world, to Claude, science was not a competition but a universal effort toward a common goal.

I feel privileged to have known Claude Hélène and fortunate to have been able to pay tribute to a unique scientist at his 65th birthday symposium, a symposium that duly reflected the impact of the field he was instrumental in giving birth to.

A great scientist and human being is no longer among us: A grave loss for the scientific community. His wisdom, great spirit, foresight, and warmth will be deeply missed.

## Comment on "In Vitro and in Vivo Evaluation of a Technetium-99m-Labeled Cyclic RGD Peptide as a Specific Marker of $\alpha_v\beta_3$ Integrin for Tumor Imaging"

*Sir:* In the article by Zi-Fen Su et al. recently published in *Bioconjugate Chemistry* (1), a technetium-99m-labeled RGD-4C peptide was introduced as a radioactive tracer for imaging  $\alpha_v\beta_3$  expression. However, in two tumor models this compound showed only marginal accumulation in tumor bearing nude mice. We have recently developed two radiolabeled RGD-peptides (2, 3) that demonstrated a markedly higher and receptor-specific accumulation in tumor-bearing animals (tumor/blood ratio greater 8 compared to less than 2 in the study by Su et al.). These tracers have been successfully used to image noninvasively  $\alpha_v\beta_3$ -positive tumors in vivo. Therefore, our findings differ significantly from the data reported by Su et al. Thus, the statement of the authors (page 568) that their work confirms and explains our previous findings is obviously not correct.

Su et al. determined an association constant of  $7 \times 10^{-6} \text{ M}^{-1}$  for binding of Tc-99m-RGD to the  $\alpha_v\beta_3$  integrin. Because of this low affinity it is not surprising that uptake of Tc99m-RGD by  $\alpha_v\beta_3$ -positive tumors was only marginal in vivo. However, it is important to note that other radiolabeled  $\alpha_v\beta_3$ -specific ligands have shown markedly higher affinity. For example the association constant of an iodine-labeled DTPA RGD has been reported as  $10 \times 10^{-9} \text{ M}^{-1}$  (4). The  $\text{IC}_{50}$  values of Galacto-RGD and Gluco-RGD developed by our group are  $5 \times 10^{-9} \text{ M}$  and  $40 \times 10^{-9} \text{ M}$ , respectively. Therefore, the conclusion of the authors (abstract, last sentence) that RGD peptides generally bind with low affinity to  $\alpha_v\beta_3$  is not correct. The in vitro data of the study by Su et al. only indicate that labeling of RDG-4C with technetium-99m using HYNIC as a chelator results in peptides with only modest affinity that appear not suitable for in vivo imaging.

In addition, the results of the in vivo experiments are difficult to interpret because the expression of  $\alpha_v\beta_3$  by

the tumor or endothelial cells was not evaluated by immunohistochemistry or Western blotting. Thus, it is unclear whether the low accumulation in the tumor is due to the low affinity of the tracer or due to low expression of  $\alpha_v\beta_3$  in the tumor tissue.

## Response to Comment on "In Vitro and in Vivo Evaluation of a Technetium-99m-Labeled Cyclic RGD Peptide as a Specific Marker of $\alpha_v\beta_3$ Integrin for Tumor Imaging"

*Sir:* The report in question (1) describes an investigation into the properties of  $^{99m}\text{Tc}$ -RGD-4C for tumor imaging. As is evident therein, our results were disappointing in that unsatisfactory tumor targeting was observed in two xenografts (LS174T and ACHN) in nude mice. In the conclusion of that report, we state that other investigators imaging the same receptor with cyclic RGD peptides have also experienced "marginal" results and, as an example, we cited the work of Dr. Haubner et al. (2). In retrospect, it was somewhat unfair to do so since the peptides are quite different. Whereas the RGD-4C used in our investigation was cyclized via two disulfide bridges, the RGD of Haubner et al. was cyclized via an amide bond. While Haubner et al. labeled with radioiodine via an attached tyrosine, we radiolabeled with  $^{99m}\text{Tc}$  via hynic/tricine. Furthermore, the RGD of Haubner et al. was glycosylated to improve pharmacokinetics. Finally, the tumor models used by Haubner et al. are reported to show a high expression of the receptor whereas the receptor concentration of the LS174T and ACHN tumors are unknown and were not measured by us. Under these conditions, the tumor uptake reported by Haubner et al. was decidedly superior at about 3%ID/g and could be inhibited vs about 0.7% ID/g in our case with no difference from control. But whether both studies are "marginal" is best left to the readership to decide.

In the final sentence of our abstract, we conclude that "RGD peptides may have limitations as tumor imaging

agents" because of low receptor numbers or low binding affinities. We recognize that binding affinities considerably higher than the micromolar value of our radiolabeled RGD-4C have been reported for other RGD peptides. Whether due to higher affinities or higher receptor numbers, we would be delighted to be proven wrong.

## An Efficient and Versatile Synthesis of BisPNA–Peptide Conjugates Based on Chemoselective Oxime Formation

Philippe Neuner,<sup>†</sup> Pasquale Gallo,<sup>†</sup> Laura Orsatti,<sup>‡</sup> Laura Fontana,<sup>†</sup> and Paolo Monaci<sup>\*,†</sup>

Department of Molecular & Cell Biology and Department of Pharmacology, I.R.B.M. P. Angeletti, Pomezia (Roma), Italy. Received September 25, 2002

Oligomers with two identical peptide nucleic acid sequences joined by a flexible hairpin linker (bisPNA) can stably bind to specific DNA sequences without altering plasmid supercoiling, thus offering a unique opportunity to attach various functional entities to high molecular weight DNA. Current synthetic approaches, however, severely limit the possibility to link peptides or other chemical moieties (i.e., sugars, oligonucleotides, etc.) to bisPNA. Here we report a novel strategy for the synthesis of bisPNA–peptide conjugates in which chemoselective ligation of bisPNA to peptides was accomplished through oxime formation between an oxy-amine-containing peptide and a bisPNA–methyl ketone (complementary modifications can also be used). The described synthesis is highly efficient, does not require a protection strategy, and is carried out under mild aqueous conditions. Through this methodology long peptide sequences in either C to N or N to C polarity can be linked to bisPNA. In addition, this protocol makes the conjugation of cysteine-containing peptides feasible and allows disulfide bond formation to be controlled. This same approach can be exploited to link oligonucleotides, sugars, or other chemical entities to bisPNA.

### INTRODUCTION

Plasmid-based, nonviral gene delivery systems are a promising therapeutic approach for gene therapy and genetic immunization protocols (1–3). However, the poor efficiency and specificity of gene transduction obtained in vivo hampers the full exploitation of their potential in clinical settings. Several key steps can be identified along the route leading to gene expression: DNA condensation, efficient and specific targeting of cell surface receptors, cellular uptake, escape from the endosome/lysosome, stability against nucleases, intracellular distribution, efficient recruitment of transcription factors, etc. In many cases specific peptide sequences have been shown to increase the efficiency of one or more of these steps (4–8). However, conjugating peptides to DNA is not a straightforward procedure. A stable modification of plasmid DNA in its supercoiled form is often required, multiple copies of the peptides with defined polarity need to be conjugated, and the modification must not interfere with plasmid transcriptional activity.

Peptide nucleic acid (PNA) is a DNA analogue in which repeating *N*-(2-aminoethyl)glycine units replace the deoxyribose-phosphate backbone (9, 10). Due to the neutral charge of its backbone, PNA hybridizes to complementary DNA with affinity and specificity higher than the corre-

sponding DNA–DNA hybrid (11). A bisPNA molecule is an oligomer with two identical PNA sequences joined by a flexible hairpin linker (11–13). Binding of bisPNA to its DNA target is sequence-specific, stoichiometric, extremely stable, and essentially irreversible under physiological conditions (11, 14). Of note is that a bisPNA molecule targets a specific site on DNA, invades duplex DNA, and displaces the complementary DNA strand to form a stable PNA:DNA:PNA triplex hybrid, without affecting the supercoiled form of plasmid DNA (11). These properties identify bisPNA as a preferential method to efficiently link molecules with various functional properties at specific sites on supercoiled plasmid DNA. For example, fluorescein or rhodamine can be linked to bisPNA and the ensuing conjugate used to bind irreversibly and specifically to a binding site cloned into a plasmid to track distribution in vivo (14).

With the aim of improving plasmid-mediated gene transduction, peptides emerge as the most interesting class of molecules to link to bisPNA. Current methods for preparing bisPNA–peptide conjugates are based on collinear synthesis of the hybrid molecule, which present some drawbacks to its general application (15). For instance, synthesis is limited to C to N polarity of the peptide and is rather inefficient for long peptide sequences. In addition, the collinear synthesis of peptides containing cysteine residues is not feasible, since formation of disulfide bridges cannot be controlled. Finally, linking to bisPNA chemical moieties other than peptides, such as carbohydrates or oligonucleotide, clearly require alternative synthesis protocols.

Recently, Felgner and co-workers described an approach in which sulfhydryl-containing peptides are conjugated to streptavidin maleimide, and the resulting streptavidin conjugates are then bound to a biotin–bisPNA-labeled plasmid (16). Alternatively, the same peptides can be directly coupled to a maleimide–bisPNA conjugate bound to plasmid DNA. This approach can also be extended to oligonucleotides containing free SH groups, but not to peptides containing cysteine residues.

As a further step toward broadening the applications of bisPNA conjugates, we describe an alternative and more versatile synthetic approach to conjugate peptides and other molecules to bisPNA based on chemoselective ligation of an amino-oxy peptide to a bisPNA–methyl ketone which circumvents the limitations listed above.

## RESULTS AND DISCUSSION

We adopted a novel synthesis approach to link peptides to bisPNA. An amino-oxy peptide was conjugated to bisPNA–methyl ketone through an oxime forming ligation (Figure 1). The amino-oxy group could be displayed either at the C or at the N terminus of the peptide. Complementary modifications (i.e., amino-oxy group at the N-terminus of the bisPNA and methyl ketone group at the N or C terminus of the peptide) can also be used.

**Solid-Phase Synthesis of the Amino-oxy Peptides.** Four different peptides were linked to a bisPNA molecule (Table 1). We chose peptides with specific biological properties, which differed in length, presence of cysteine residues, and polarity of conjugation to bisPNA. NL1.1 and NL4c are 24 and 22 aa long peptides, respectively, which specifically bind to HER2/neu, a tyrosine-kinase

receptor which is overexpressed in 30–50% of human breast, gastric, and colon tumors (17, 18). These peptides have been identified by screening phage-displayed random peptide libraries (19, unpublished data). Of note, NL4c contains two cysteine residues forming a disulfide bridge. Both peptides must be linked C to N to bisPNA. VP16 is 13 aa minimal transcription activator domain derived from herpes simplex virus protein 16 (20). Just two VP16 peptides bound to DNA through a GAL4 DNA binding domain are sufficient to activate transcription from a downstream promoter (20).

We thus attempted to generate a minimal transcription activator by linking two or three VP16 peptides with the N to C polarity to bisPNA. Binding of this bisPNA chimera to plasmid DNA could enhance transcription from a downstream promoter without requiring the recruitment of intracellular transcription activators.

Peptides NL1.1, NL4c, VP16<sub>2</sub>, and VP16<sub>3</sub> were synthesized by standard Fmoc chemistry. GGG linker sequences were added to the C-terminus of NL1.1 (11 residues) and NL4c (12 residues) to facilitate the interaction of the peptides with the target promoter (21). An amino-oxy group was incorporated at the C terminus of NL1.1 and NL4c peptide by coupling the (amino-oxy) acetyl functionality at the  $\epsilon$ -amine side chain of an extra C-terminal Lys residue, as described by Canne et al. (15). Similarly, an amino-oxy group was incorporated at the N terminus of peptide VP16<sub>2</sub> and VP16<sub>3</sub>. Peptides were purified by HPLC and their structure verified by mass spectroscopy.

**Solid-Phase Synthesis of the BisPNA–Methyl Ketone.** All reagents including Boc-PNA-C(Z), Boc-PNA-T, Boc-AEEA-ODCHA spacer (L = 2-aminoethoxy-2-

**Figure 2.** HPLC and mass analysis of the purified bisPNA-methyl ketone.

ethoxyacetic acid), and HBTU were obtained from PerSeptive Biosystems (Framingham, MA). MBHA-resin was obtained from Calbiochem-Novabiochem AG (Laufelfingen, Switzerland). A bisPNA-methyl ketone oligomer (mKetone-NH-LL-TCTCTCTC-LLL-JTJTJT-CONH<sub>2</sub>) designed to bind the DNA sequence 5'-GAGAGAGAGA-3' was synthesized by hand on MBHA-resin (215 mg; substitution = 45.5  $\mu$ mol/g; 10  $\mu$ mol scale) essentially as described (22). Pseudoisocytosine J, an analogue of C which encourages a pH-independent specific formation of the Hoogsteen triplex hybrid, was synthesized as described by Egholm et al. (11).

In a typical procedure, 40  $\mu$ mol of monomers (4 equiv), *N,N*-diisopropylethylamine (6 equiv/monomer) and HBTU (0.9 equiv/monomer) were dissolved in 800  $\mu$ L of a mixture *N*-methylpyrrolidinone/pyridine (1:1). After 3 min of preactivation, the reaction mixture was applied to the resin, coupling was allowed to proceed for 4 h, and resin was washed with DMF/DCM (twice for 3 min each). Prior to the next coupling step, the Boc-protected amino terminus was deprotected with a mixture of TFA/*m*-cresol (95:5; twice for 4 min each). After completion of the bisPNA sequence, the methyl ketone moiety was introduced by activating 4-acetylbutyric acid (100  $\mu$ mol) as symmetric anhydride with DIC (50  $\mu$ mol) in DCM. After

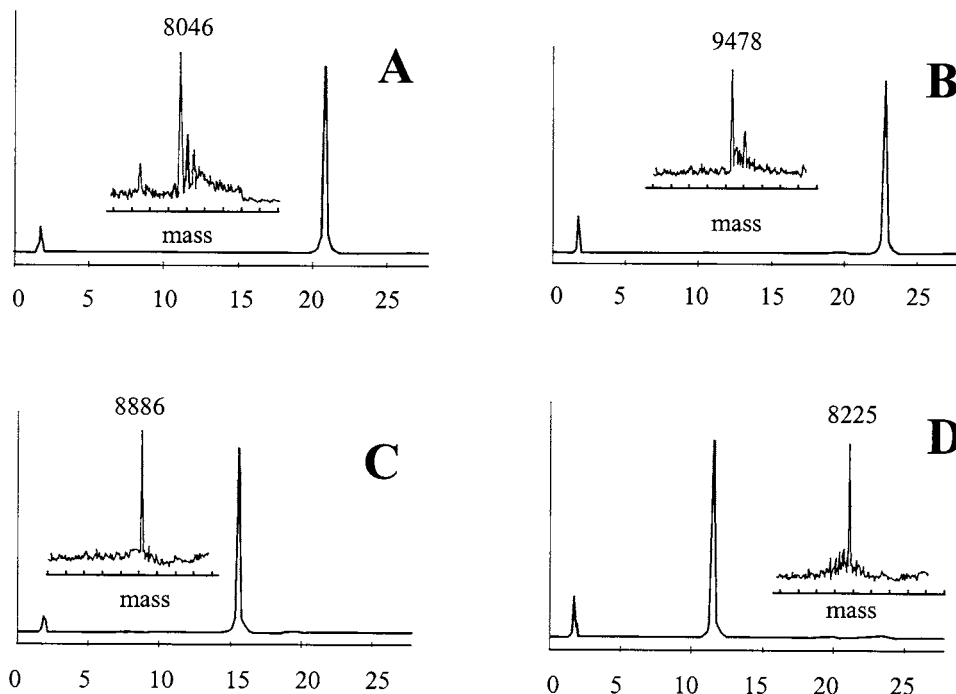

**Table 2.** Experimental and Calculated Mass for the BisPNA-Peptide Chimera

	M (experimental)	M (calculated)
BisPNA-NL1.1	8886.00	8887.65
BisPNA-NL4	8225.00	8227.27
BisPNA-VP16 <sub>2</sub>	8046.00	8047.32
BisPNA-VP16 <sub>3</sub>	9478.00	9479.91

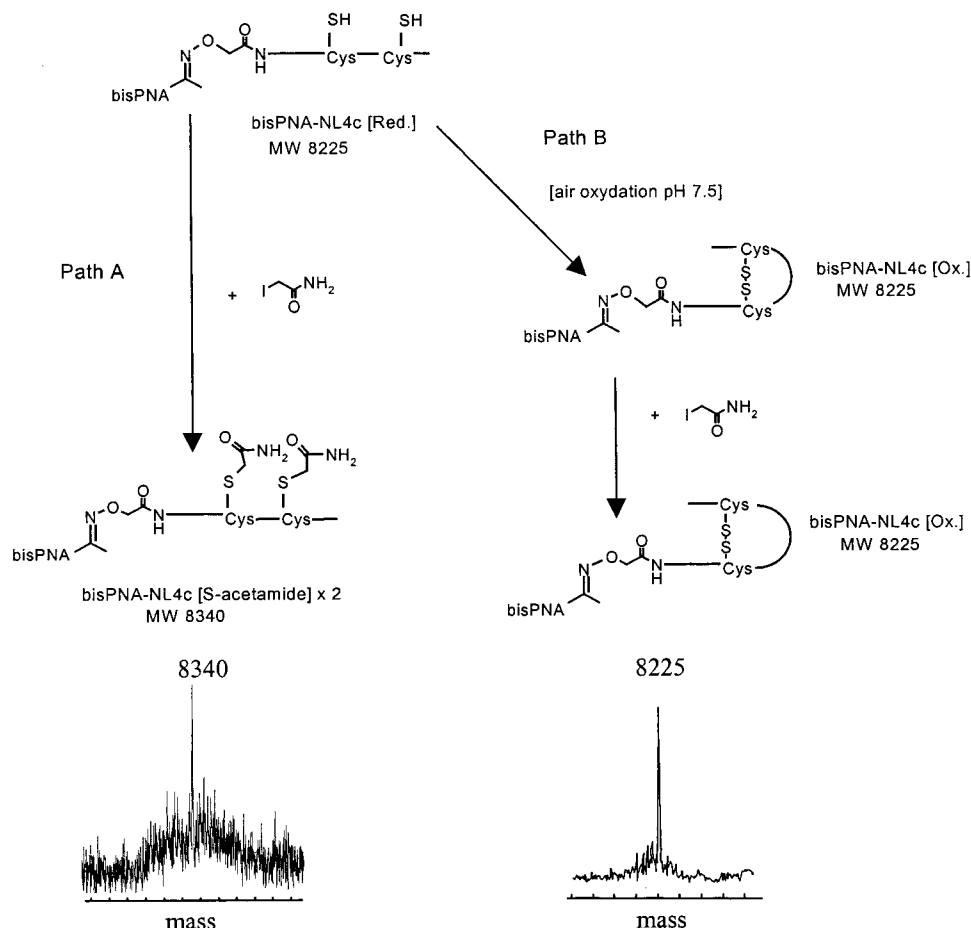

activation for 15 min, the mixture was diluted with DMF (1 mL), added to the PNA-resin, and coupled for 60 min. The resin was washed with DMF/DCM, dried, and transferred to a screw cap vial. The product bisPNA was deprotected and concomitantly cleaved from the resin by treatment with a mixture of TFMSA/TFA/*m*-cresol (18:73:9; 1 mL) for 2 h at 0 °C. The solid was separated by filtration and the filtrate poured into 10 volumes of ice cold Et<sub>2</sub>O. Centrifugation yielded a pellet, which was purified by HPLC. M (calculated) for C<sub>204</sub>H<sub>282</sub>N<sub>78</sub>O<sub>73</sub> = 4995.00; M (experimental) = 4994.00 (Figure 2).

**Synthesis of the BisPNA-Peptide Conjugate: Oxime-Forming Ligation.** Purified bisPNA-methyl ketone was mixed with the amino-oxy peptide to generate the oxime-linked bisPNA-peptide conjugate. The amino-oxy group was displayed either at the C (NL1.1 and NL4c) or at the N terminus (VP16<sub>2</sub> and VP16<sub>3</sub>) of the peptide (Figure 1).

In a typical experiment, bisPNA-methyl ketone **1** was coupled to the amino-oxy peptide **2** via oxime ligation (15). The bisPNA-methyl ketone (0.2  $\mu$ mol) was dissolved in 250  $\mu$ L of 0.1 M sodium acetate buffer (pH 4.2). Two equivalents (0.4  $\mu$ mol) of the amino-oxy peptide and 20  $\mu$ L of DMF were added to the resulting solution. Coupling reaction was allowed to proceed for 12 h, and the resulting conjugate was readily purified by semipreparative reverse-phase HPLC and lyophilized to give a white solid. Preparative RP C18 HPLC purification was performed using a SymmetryPrep C18 (7.8  $\times$  150 mm) reverse-phase column (Waters, Milford, MA). Eluant A: 99.9% water, 0.1% TFA; eluant B: 10% water, 89.9% acetonitrile, 0.1% TFA; a linear gradient of 5%-30%

eluant B over 25 min at a flow rate of 3.0 mL/min monitored at 260 nm. The average yield was usually 15–20% of purified chimeras. Final product was analyzed for purity by mass determination by LC/Quadrupole ion trap mass spectrometer Finnigan-MAT (San Jose, CA, Figure 3). Experimentally derived and calculated mass for the four bisPNA-peptides products are listed in Table 2.

As for the bisPNA-NL4c chimera, the crude product was purified by HPLC after oxime ligation, and the desired fractions were lyophilized. The resulting solid was resuspended at a concentration of 1 mg/mL in distilled water and air-oxidized overnight to allow intramolecular disulfide bridge formation. Oxidation of the NL4c peptide cysteine residues was assessed by adding a small excess of iodoacetamide to an aliquot of the purified bisPNA-NL4c chimera before and after air oxidation (Figure 4, paths A and B, respectively). Mass analysis of the iodoacetamide reaction product derived from path A showed an increase in mass of 114 (2 × 57), corresponding to the two acetamide adducts of the reduced bisPNA-NL4c chimera, whereas no mass variation was detected for the oxidized bisPNA-NL4c.

**Figure 5.** Specific binding of bisPNA-VP16 chimeras to target sequence. Three and six pmoles of bisPNA-methyl ketone (lanes 2, 3 and 9, 10), bisPNA-VP16<sub>2</sub> (lanes 4, 5 and 11, 12) or bisPNA-VP16<sub>3</sub> (lanes 6, 7 and 13, 14) were incubated at 37 °C for 15 min with approximately 1.5 pmol of the [ $\alpha$ -<sup>32</sup>P]-labeled double stranded oligonucleotide in 20  $\mu$ L of HBS buffer (10 mM Hepes, 50 mM NaCl, pH 7.0). Lanes 2–7 and lanes 9–14 refer to reactions with target or control oligonucleotide, respectively. Additional control reactions were included in the absence of bisPNA (lanes 1 and 8, with target and control oligo, respectively). Five microliters of 20% glycerol was added, and the samples were fractionated on a 5% polyacrylamide gel in TBE buffer (45 mM Tris-borate, 1 mM EDTA, pH = 7.5) at 10 V/cm for 3–4 h at 4 °C. Gel was dried and autoradiographed on Kodak XR5 film with intensifying screen.

**Figure 6.** BisPNA-peptide chimeras bind the target sequence within supercoiled plasmid DNA. Increasing amounts (35, 70, 140, and 280 pmol) of bisPNA-methyl ketone (empty circles, lanes 4–7), bisPNA-VP16<sub>2</sub> (filled squares; lanes 8–11), or bisPNA-VP16<sub>3</sub> (filled triangles; lanes 12–15) were incubated with 1.12 pmol of pGGLuc plasmid DNA in 40  $\mu$ L of HBS buffer for 45 min. The binding of these bisPNA derivatives was challenged, adding 32 pmol of bisPNA-fluorescein to the reaction and incubating for additional 20 min. Control reactions with bisPNA fluorescein (lane 1), pGGLuc (lane 2), or bisPNA-fluorescein conjugated with pGGLuc (lane 3) were also included. Seven microliters of 20% glycerol were added, and the samples were fractionated on a 0.8% agarose gel in TBE buffer (90 mM Tris-borate, 2 mM EDTA, pH 7.5). The incubations were performed at 37 °C and the samples run at room temperature. Gels were scanned using a GS-700 Imaging Densitometer BIORAD (Hercules, CA). Quantitation of the PNA-fluorescein conjugated was performed with a MacIntosh G3 computer using the program Molecular Analyst.

**Characterization of the BisPNA-Peptide Conjugates.** We wanted to assess the DNA-binding properties of these bisPNA-peptide chimeras. To this end we synthesized two double-stranded oligonucleotides containing the bisPNA binding sequence (target oligo) and the same sequence with two mutations (control oligo) (Table 3; binding sequence is indicated in bold and mutation are underlined). Two different amounts of bisPNA-methyl ketone, bisPNA-VP16<sub>2</sub>, or bisPNA-VP16<sub>3</sub> were incubated with target or control oligonucleotide (2 and 4 molar ratios).

Formation of the DNA:bisPNA-VP16 complex was detected by a gel mobility shift assay (Figure 5). Both bisPNA-VP16<sub>2</sub> and bisPNA-VP16<sub>3</sub> chimeras bound the target oligonucleotide in a manner indistinguishable from that of the reference bisPNA-methyl ketone molecule (Figure 5, lanes 2–7). By contrast, no binding could be detected to control oligonucleotide in the same conditions (Figure 5, lanes 9–14).

Next, we tested the ability of the same chimeras to bind the target binding sequence in the context of a supercoiled plasmid DNA. We used plasmid pGGLuc (Gene Therapy Systems, San Diego, CA) which bears a CMV immediate early promoter driving the expression of a luciferase reporter gene. This plasmid contains 10 binding sites for bisPNA molecule immediately after the translational termination site. We preincubated pGGLuc plasmid DNA with increasing amounts of bisPNA-methyl ketone, bisPNA-VP16<sub>2</sub>, or bisPNA-VP16<sub>3</sub>. Then, a fixed amount of bisPNA-fluorescein was allowed to bind plasmid DNA. Increasing the amount of either bisPNA derivatives reduced fluorescence-labeling of the plasmid (Figure 6).

These results indicate that bisPNA-VP16<sub>2</sub> or bisPNA-VP16<sub>3</sub> retains the binding properties of the reference bisPNA-methyl ketone and similarly prevented bisPNA-fluorescein binding to its target site on supercoiled plasmid DNA.

#### ACKNOWLEDGMENT

In summary, the data we report in this paper demonstrate that bisPNA-peptide conjugate can be prepared by post-assembly conjugation of an amino-oxy peptide with a bisPNA-methyl ketone molecule. The reaction is simple, efficient, and versatile, since it can be applied to linking long peptides, with or without cysteine residues, in both polarities, to bisPNA. The same approach can be extended to linking other chemical moieties to bisPNA, namely to oligonucleotides. The synthetic approach we describe makes generating several different bisPNA-peptide conjugates limited only by the efficiency of synthesis of the individual components. Indeed, bisPNA-peptide chimeras appear particularly suited for providing plasmid DNA with new functions (e.g., targeting specific cell types, subcellular localization, transcription activating domain, etc.) which could improve the efficiency of gene expression, *in vitro* and *in vivo*.

#### ACKNOWLEDGMENT

We wish to thank Antonello Pessi for useful discussion, Marco Finotto for the synthesis of the modified peptides, and Janet Clench for proofreading the manuscript.

## Can Nuclear Localization Signals Enhance Nuclear Localization of Plasmid DNA?

Takeshi Nagasaki,<sup>\*,†</sup> Teruhiko Myohoji,<sup>†</sup> Taro Tachibana,<sup>†</sup> Shiroh Futaki,<sup>‡</sup> and Seizo Tamagaki<sup>†</sup>

Department of Applied and Bioapplied Chemistry, Graduate School of Engineering, Osaka City University, SORST (JST), Osaka, 558-8585, Japan, and Institute for Chemical Research, Kyoto University, Uji, Kyoto 611-0011, Japan. Received September 9, 2002; Revised Manuscript Received November 22, 2002

Nonviral vectors are safer and more cost-effective than viral vectors but are significantly less efficient, and thus, increasing the efficiency of nonviral vectors remains an important objective. One way to overcome this problem is by stimulating the nuclear localization of exogenous genes. Nuclear localization signals (NLSs) are known to be involved in the active transport of exogenous proteins and probes into the nucleus. However, stimulation of nuclear localization of plasmid DNA has yet to be confirmed completely. In the present study, we prepared plasmid DNA–NLS peptide conjugates and adjusted spacer length and number introduced in an attempt to increase transfection efficiency. In comparison to conjugates with unmodified plasmid DNA and short spacers, we found that NLS–plasmid DNA conjugates with covalent bonding by diazo coupling through PEG chain (MW 3400) stimulated complexation with the nuclear transport proteins importin  $\alpha$  and importin  $\beta$ . Evaluation of transfection showed higher expression efficiency with plasmid DNA–NLS peptide conjugates than with unmodified plasmids. However, evaluation of intracellular trafficking after microinjection into the cytoplasm showed plasmid DNA–NLS peptide conjugates only within the cytoplasm; there was no NLS–plasmid stimulation of nuclear localization. Our findings suggest that stimulation of plasmid nuclear localization cannot be achieved merely by changing spacer length or chemically modifying plasmid DNA–NLS peptide conjugates. An additional mechanism must be involved.

### INTRODUCTION

Gene therapy has been seriously investigated in the United States as a clinical treatment for genetic diseases such as adenosine deaminase (ADA) deficiency since 1990. Numerous studies have subsequently investigated the use of gene therapy for treatment of cancer, infections (such as AIDS), and other lifestyle-related diseases. The key to efficient transfection and expression of exogenous genes into cells is the use of “vectors” (gene carriers). Retrovirus and adenovirus vectors have conventionally been used because of their high efficiency. However, reports of a patient death due to an adenovirus vector in the United States in 1999 led to renewed interest in developing nonviral vectors to further increase safety (1). The increasing use of gene therapy in clinical practice also makes the development of nonviral vectors important with regard to cost and availability.

Nonviral vectors can broadly be divided into lipoplexes (lipid/DNA complexes) and polyplexes (polymer/DNA complexes) (2). However, the transfection and expression efficiencies of these nonviral vectors are much lower than those of viral vectors. The low efficiency of these vectors is also the most significant problem when they are used

for gene therapy. This necessitates research and development of nonviral vectors with higher efficiency by using nanoparticles consisting of complexes of nucleic acids and polycations such as dendrimer polymers or lipid aggregates (liposomes).

Nonviral vectors must overcome several intracellular barriers before mRNA transcription (3–5). The greatest barrier facing both polyplexes and lipoplexes is the nuclear membrane (6–9). Nuclear localization efficiency significantly influences expression efficiency.

Recent studies have shown that intranuclear transport of large molecules such as proteins and nucleic acids is a selective process through nuclear pore complexes that involves energy dependent carrier proteins (10–15). Several investigations have focused on the nuclear-cytoplasm transport system used by biological organisms as a means of stimulating nuclear localization of exogenous genes (16, 17). Some studies have reported dramatic increases in expression efficiency using NLS modified linear DNA (18, 19), but similar results with plasmid DNA have not been reported to date (20–22).

The clinical application of gene therapy requires the development of highly efficient plasmid DNA delivery systems that can be synthesized both easily and in large quantities. The availability of plasmid DNA–NLS peptide conjugates providing reliable intranuclear transport would be of enormous benefit. In this regard, we must first consider why previous research has failed to achieve these goals. In plasmid DNA–NLS peptide conjugates

designed to date (20–22), suboptimal spacer lengths between the cationic NLS and anionic DNA have resulted in a strong interaction between the NLS and plasmid and burying of the NLS within the negative charges. This interferes with recognition of transport proteins. Furthermore, the localization of large plasmid molecules may require insertion of multiple NLSs, whereas overfull chemical modification cause the inhibition of the transcriptional process. Therefore, our research has focused on developing a convenient method to produce plasmid DNA–NLS peptide conjugates with a more optimum spacer length and where the number of insertions can be regulated. The objective is the development of a highly efficient nonviral gene delivery system.

**EXPERIMENTAL METHODS**

**Materials.** 5(and 6)-Carboxyltetramethylrhodamine *N*-hydroxysuccinimide ester was purchased from Molecular Probes (Eugene, OR). *N*-(6-Maleimidocaproyloxy)-succinimide was purchased from Dojindo Lab. (Kumamoto, Japan). Maleimido-peg-carboxylic acid *N*-hydroxysuccinimide<sup>1</sup> ester was purchased from Shearwater (Huntsville, AL). Di-*tert*-Butyl dicarbonate and *N*-(9-fluorenylmethyloxy-carbonyloxy)succinimide were purchased from Peptide Lab. (Osaka, Japan). Recombinant GST fusion Importin  $\alpha$  and importin  $\beta$  were prepared as reported previously (12). Lipofectin was purchased from Invitrogen Corp. (Carlsbad, CA). Other reagents and solvents were purchased from Aldrich.

**Plasmids.** pGL3-control (pGL3) was purchased from Promega (Madison, WI). pEGFP-N1 (pGFP) was purchased from Clontech (Palo Alto, CA). Plasmid DNAs were amplified in *Escherichia coli* and purified by Endo-Free Plasmid Kit (Qiagen, Hilden, Germany).

**Rhodamine-Labeled NLS Peptide.** The NLS peptide, from SV-40 large T antigen, used in this study was manually synthesized by the Fmoc solid-phase method on a Rink amide resin as reported previously (23). After the elongation of the NLS sequence PKKKRKVEDPYC, 4-amino butyric acid was introduced as a spacer between the NLS and a fluorescent residue. Finally, the amino

group was labeled with 5(and 6)-carboxyltetramethylrhodamine succinimidyl ester. The protecting groups and the resin were removed with TFA in the presence of H<sub>2</sub>O (10%), phenol (5%), ethanedithiol (5%), and thioanisole (5%) at room temperature for 3 h. After addition of diethyl ether, the crude product was precipitated and then purified by RP-HPLC.

**Preparation of Plasmid DNA–NLS Peptide Conjugates.** Diazocoupling (24–26) and photoactivation (27–32) have been reported as the covalent modifications of DNA. In this study plasmid DNA–NLS peptide conjugates were prepared by the diazo coupling method according with Scheme 1. Synthesized conjugates were purified with ultrafiltration (Centricon Plus-10; nominal molecular weight limit = 10 kDa, Millipore, Bedford, MA). The number of NLS linked to one plasmid was determined by absorbance at 260 nm and fluorescent intensity (ex = 546 nm, em = 576 nm). The fluorescence polarization of rhodamine linked to the NLS was measured by BEACON 2000 spectrometer (Pan Vera, Madison, WI) in order to estimate the type of binding of the NLS to plasmid. PEGylated NLS (NLS-peg) prepared with the NLS peptide and PEG-maleimide (Mw. 5000, Shearwater, Huntsville, AL) was also examined for the fluorescence polarization method as a comparison.

**Importin Binding Assay.** Binding to importin  $\alpha$  in the presence of importin  $\beta$  was performed according to Wils et al. (22), with the following method: all assays were performed in binding buffer (20 mM HEPES, pH 7.0, 110 mM potassium acetate, 2 mM magnesium acetate, and 0.1 mg/mL bovine serum albumin). The GST fusion importin  $\alpha$  with and without importin  $\beta$  (1 mg per 10 mL of beads, respectively) was incubated with 0.25 mL of glutathione-sepharose beads (Amasham, Piscataway, NJ) in binding buffer (0.25 mL) for 30 min at room temperature. The beads were collected by centrifugation at 2000*g* for 30 s and washed five times with binding buffer (0.25 mL). The beads slurry (80  $\mu$ L) was incubated with 2  $\mu$ g of plasmid DNA–NLS peptide conjugate for 30 min at room temperature. The beads were collected by centrifugation at 2000*g* for 30 s. The supernatant was removed, and 30  $\mu$ L was used to analyze the presence of unbound DNA (this fraction is called the unbound fraction). The beads were washed five times with 0.25 mL of binding buffer and centrifuged at 2000*g* for 30 s. Finally, beads were resuspended with 50  $\mu$ L of the dissociation solution (0.1 M EDTA, 10% sodium lauryl sulfate) and vortexed deliberately at room temperature

<sup>1</sup> Abbreviations: PEG, poly(ethylene glycol); GST, glutathione *S*-transferase; GFP, green fluorescent protein; SV, simian virus; Fmoc, 9-fluorenylmethoxycarbonyl; TFA, trifluoroacetic acid; RP-HPLC, reversed-phase high performance liquid chromatography; DMEM, Dulbecco's modified Eagle's medium; FBS, fetal bovine serum; PBS, phosphate buffered saline; DAPI, 4',6-diamidino-2-phenylindole.

**Table 1. Synthesized NLS–Plasmid DNA Conjugates**

conjugate	used plasmid	ratio of reactants diazonium salt/ plasmid (mol/mol)	no. of insertions
2.8 NLS–peg–pGFP	pEGFP–N1	3.0	2.8
3.8 NLS–peg–pGFP	pEGFP–N1	10	3.8
1.9 NLS–C5–pGFP	pEGFP–N1	3.0	1.9
2.4 NLS–peg–pGL3	pGL3–control	3.0	2.4
5.1 NLS–peg–pGL3	pGL3–control	15	5.1
1.7 NLS–C5–pGL3	pGL3–control	3.0	1.7

for 1 h. After centrifugation at 2000*g* for 30 s, the supernatant was removed as the bound fraction. The bound and unbound fractions were analyzed by electrophoresis on 0.6% agarose gel, and DNA was stained with ethidium bromide.

**Transfection.** COS-1 cells ( $3\text{--}4 \times 10^4$  cells for an each well) were grown to just before confluence in a 24-wells culture plates in DMEM with 10% FBS and 100 U/mL penicillin and 100  $\mu\text{g}/\text{mL}$  streptomycin in an atmosphere of 5%  $\text{CO}_2$  at 37 °C and washed twice with 0.5 mL of PBS. Complexation and transfection were performed as described in the protocol of Lipofectin with 1  $\mu\text{g}$  of plasmid DNA (pGL3–control)–NLS peptide conjugate for each well. Luciferase assays were performed as described in the protocol of Steady-Glo Luciferase Assay System (Promega, Madison, WI). Luciferase relative light units (RLU) were analyzed by luminometer (Fluoroskan Ascent-FL, Thermo Labsystems, Finland). The protein concentrations of the cell lysates were measured as described in the protocol of NanoOrange Protein Quantitation Kit (Molecular Probes, Eugene, OR) using bovine serum albumin as a standard. The light unit values shown in the table represent the specific luciferase activity (RLU/mg protein) which is standardized for total protein content of the cell lysate. The measurement of transfection efficiency was performed in triplicate.

**Microinjection.** COS-7 cells were grown at 37 °C in a 5%  $\text{CO}_2$  incubator on coverslips. The solutions of 1 mg/mL plasmid DNA–NLS peptide conjugates were injected into the cytoplasm via glass micropipets. Injections were carried out under visual control on a fixed stage of an inverted phase contrast microscope (Diaphoto, Nikon, Tokyo, Japan) using a micromanipulator MMO-220N and a microinjector IM-16 (Narishige, Tokyo, Japan). Following injection, the cells were incubated for 20 min to 6 h at 37 °C in a 5%  $\text{CO}_2$  incubator. The cells were then washed with PBS, fixed with 5% HCHO, and examined by fluorescence microscopy. Images of the samples were collected by fluorescence microscopy on an Olympus IX-70 (Tokyo, Japan) attaching a confocal scan unit CSU-10 (Yokogawa, Tokyo, Japan) with ORCA-ER CCD Camera (Hamamatsu Photonics, Hamamatsu, Japan) using a 40  $\times$  Uapo/340 objective with NA 0.9.

## RESULT

### Preparation of Plasmid DNA–NLS Conjugates.

For synthesis of the conjugates, we used a C<sub>5</sub> alkyl chain as a short spacer and poly(ethylene glycol) (PEG; 71 units, 3400 Da) as a long spacer. We also adjusted the equivalents of diazonium salt reacted per molecule of plasmid. Table 1 lists the synthesized plasmid DNA–NLS peptide conjugates with their spacers and number of insertions. The number introduced could easily be adjusted by changing the ratio of reactants. Appended NLSs were limited to a maximum of five introductions to prevent decreased expression due to interference with transcription.

**Figure 1.** Measurement of fluorescence polarization of plasmid DNA–NLS peptide conjugates in the absence (gray bar) and presence (white bar) of excess PEI. To estimate the type of binding of the NLS to plasmid, the fluorescence polarization (ex = 546 nm, em = 576 nm) of rhodamine linked to the NLS was measured in 10 mM Tris-HCl buffer (pH 7.5) at room temperature.

**Characterization of Conjugates.** The introduced NLSs were basic peptides, and thus, in addition to conjugation by covalent bonding, it was also possible for complexes to be formed by noncovalent bonding through polyionic complexation (33). To confirm the type of bonding, we measured fluorescence polarization of rhodamine linked to the NLS upon addition of PEI (polyethylenimine), which has a higher affinity for plasmid DNA. Figure 1 shows the fluorescence polarization in the presence and absence of PEI. The parameter utilized in this method is the fluorescence polarization value (*P*). The *P* value, being a ratio of light intensities, is a dimensionless number. Polarization values are also expressed in millipolarization units (1 polarization unit = 1000 mp units). The *P* value was greatest for rhodamine-linked 1.9 NLS–C5–pGFP. The difference of the *P* value between 1.9 NLS–C5–pGFP and 2.8 NLS–peg–pGFP was nonsignificantly small. Even in the presence of PEI, there was almost no change in fluorescence polarization of these NLS-conjugated plasmids (decrease of <5%). However, when NLS–peg and pEGFP–N1 were combined, the fluorescence polarization obviously decreased. In the presence of PEI, the decrease in fluorescence polarization was greater than that observed with 2.8 NLS–peg–pGFP.

**Importin Protein Binding Assay.** We adsorbed GST-fused importin  $\alpha$  and importin  $\beta$  on glutathione beads and then evaluated the binding affinity of NLS-conjugated plasmid to the beads. The unbound supernatant fraction and bound plasmid were recovered from the beads after the treatment in the presence of surfactant and then electrophoresed on 0.6% agarose gel (Figure 2). We had done in the presence and absence of both importins  $\alpha$  and  $\beta$  in order to confirm nonspecific binding of NLS conjugates to a glutathione-sepharose gel. The amount of bound plasmid was greater with the presence versus absence of GST-fused importin  $\alpha$  and importin  $\beta$ . As the amount bound decreased with the presence of only GST-fused importin  $\alpha$  (data not shown), we could confirm the importance of ternary complex with importin  $\alpha$ , importin  $\beta$ , and NLS. The amount of bound plasmid with 5.1 NLS–peg–pGL3 was obviously greater compared with 2.4 NLS–peg–pGL3. When compared to the short spacer, the long peg spacer slightly increased the affinity of the conjugate to importin proteins.

**Transfection.** NLS–peg–pGL3 was also transfected to COS-1 cells to evaluate the influence of NLS on expression efficiency (Table 2). When compared to intact plasmid, the NLS–plasmid conjugate increased expression efficiency. Furthermore, similar to the results for binding of NLS-conjugated plasmid to beads, a higher

**Figure 2.** Interaction between glutathione-sepharose beads and plasmid DNA–NLS peptide conjugates in the absence (a) and presence (b) of GST-fused importin  $\alpha$  and  $\beta$ . Glutathione-sepharose beads (80  $\mu$ L) were incubated for 30 min at room temperature with plasmid DNA–NLS peptide conjugates (2  $\mu$ g) in the presence and absence of GST-fused importin  $\alpha$  and  $\beta$  (8  $\mu$ g, respectively). Bound and unbound fractions were analyzed by 0.6% agarose gel electrophoresis and ethidium bromide staining. (1) 5.1 NLS–peg–pGL3, (2) 2.4 NLS–peg–pGL3, (3) intact pGL3, (4) 1.7 NLS–C5–pGL3, and (5) unfractionated pGL3 control.

used plasmid	transfection efficiency (RLU/mg protein)
pGL3 control	$(4.02 \pm 0.33) \times 10^5$
1.7 NLS–C5–pGL3	$(5.44 \pm 0.50) \times 10^5$
2.4 NLS–peg–pGL3	$(1.32 \pm 0.22) \times 10^6$
5.1 NLS–peg–pGL3	$(1.69 \pm 0.36) \times 10^6$

<sup>a</sup> Nonmodified plasmid and NLS–plasmid DNA conjugates were used for transfecting COS-1 cells with Lipofectin. The luciferase expression was estimated after 48 h of incubation.

number introduced and longer spacer increased expression efficiency. However, the rate of increase was insignificant compared to the  $\geq 150$ -fold increases in efficiency reported when one NLS is inserted into linear DNA (19).

**Cytoplasmic Microinjection.** The effects of NLS on stimulation of nuclear localization of NLS–plasmid were also evaluated with microinjection of plasmid DNA–NLS peptide conjugates (2.8 NLS–peg–pGFP and 3.8 NLS–peg–pGFP) into the cytoplasm of COS-7 cells. Cells were fixed with 5% HCHO after 20 min, 2 h, or 6 h. However, no relationship between the number of NLS insertions and spacer length or time was observed. Rhodamine-labeled NLS–plasmid was observed only in the cytoplasm (Figure 3a–c). There was no NLS–plasmid stimulation of nuclear localization.

## DISCUSSION

In comparison to conjugates with unmodified plasmid DNA and short spacers, we found that plasmid DNA–NLS peptide conjugates with covalent bonding by diazo coupling through PEG-chain-stimulated complexation with the nuclear transport proteins importin  $\alpha$  and importin  $\beta$  using importin proteins binding assay. Higher number introduced and longer spacers led to more

**Figure 3.** Cytoplasmic microinjection of plasmid DNA–NLS peptide conjugate. COS-7 cells were cytoplasmically microinjected with plasmid DNA–NLS peptide conjugate (3.8 NLS–peg–pGFP) and fixed after 20 min (a), 2 h (b), or 6 h (c). PEGylated NLS–peptide localized in nuclei (d). N indicates nucleus. Bar indicates 25  $\mu$ m.

favorable complex formation. Our findings confirmed that sufficient spacing from the anionic surface of the plasmid (a large molecule) and separation of the cationic peptide increased recognition of transport proteins.

Evaluation of transfection showed higher expression efficiency with plasmid DNA–NLS peptide conjugates than with unmodified plasmids. Furthermore, it was confirmed that a higher number introduced and longer spacer increased expression efficiency similar to the results for binding of NLS–conjugated plasmid to beads. However, evaluation of intracellular trafficking after microinjection into the cytoplasm showed NLS–plasmid only within the cytoplasm; there was no NLS–plasmid stimulation of nuclear localization.

In agreement with previous studies, our findings showed that plasmid DNA–NLS peptide conjugates increased the expression efficiency of plasmid DNA using nonviral vectors. The rate of increase correlated with the number of NLS insertions and the use of a longer PEG spacer. We also observed similar findings for complexation with the transport proteins importin  $\alpha$  and importin  $\beta$ . However, the rate of increase in expression efficiency was unremarkable. Microinjection of the plasmid DNA–NLS peptide conjugates, even with use of a long PEG spacer, did not produce nuclear localization of the plasmid. In conclusion, our findings suggest that because of the interaction of large molecules such as plasmids with nuclear pore complexes, efforts to stimulate nuclear localization by modifications using NLSs may not be successful, regardless of number of insertions or spacer length. On the basis of this knowledge, our efforts will now be directed at improving nuclear localization by direct conjugation of plasmids and transport proteins.

## ACKNOWLEDGMENT

This study was supported by a Grant-in-Aid for Scientific Research on Priority Area (No. 14030080) from the Ministry for Education, Culture, Sports, Science, and

Technology, Japan, and a Scholarship for Engineering Research from Graduate School of Engineering, Osaka City University.

# Synthesis of Structurally Identical Fluorine-18 and Iodine Isotope Labeling Compounds for Comparative Imaging

Zizhong Li,<sup>\*,†</sup> Yu-Shin Ding,<sup>†,‡</sup> Andrew Gifford,<sup>†</sup> Joanna S. Fowler,<sup>‡</sup> and John S. Gatlley<sup>†</sup>

Medical Department and Chemistry Department, Brookhaven National Laboratory, Upton, New York 11978.  
Received September 30, 2002; Revised Manuscript Received December 9, 2002

The synthesis of a benzophenone-based labeling compound designed for comparative imaging studies with both in vivo positron emission tomograph (PET) and single-photon computed tomography (SPECT) and ex vivo autoradiography is described. The new compound can be labeled with either F-18 or iodine radioisotopes to give two different radioisotopomers: *N*-[2-fluoro-5-(3-[I-131]iodobenzoyl)benzyl]-2-bromoacetamide (**1**) and *N*-[2-[F-18]fluoro-5-(3-iodobenzoyl)benzyl]-2-bromoacetamide (**2**). Compound **1** and **2** have a 2-bromoacetyl group, which can be used to conjugate with biomolecules through a nucleophilic substitution reaction. Compound **1** was synthesized from the corresponding tributyltin derivatives via an oxidative destannylation reaction, and compound **2** was prepared via a four-step radiosynthesis (nucleophilic aromatic substitution, reduction, oxidation, and alkylation) starting from 4-(*N,N,N*-trimethylammonio)-3-cyano-3'-iodobenzophenone triflate. A remarkably high radiochemical yield (>90%) was achieved for the F-18 nucleophilic aromatic substitution under mild conditions (room temperature in less than 10 min), indicating the structural advantage of the designed molecule to facilitate the F-18 for trimethylammonium substitution in the presence of two electron-withdrawing groups (nitrile and carbonyl). The overall radiosynthesis time for compound **2** is less than 3 h after end of bombardment (EOB) with an unoptimized radiochemical yield of about 2% (not decay corrected) and specific activity of 0.8 Ci/ $\mu$ mol at EOB. The radiolabeling precursors for compound **1** and **2** were synthesized via a carbon–carbon bond-forming reaction between 2-substituted-5-lithiobenzonitrile and 3-substituted benzaldehyde derivatives. Compounds **1** and **2** should allow us to label biomolecules with F-18 or iodine isotopes and gives structurally identical products, which are expected to have identical biological properties and should be useful for comparative imaging studies.

## INTRODUCTION

Antisense oligonucleotides represent a group of newly developed therapeutic agents (Tseng and Brown, 1994). They take advantage of highly specific base-pair interaction to inhibit expression of disease-related genes in a selective and sequence-specific manner (Zamecnik and Stephenson, 1978). Radioisotope-labeled antisense oligonucleotides (Kühnast et al., 2000; Kobori et al., 1999; Lange et al., 2002) are also being explored as radiotracers for imaging in tissue targeted by the antisense mechanism. In theory, almost any gene sequence could be selectively imaged with a labeled antisense oligonucleotide. However, in living systems, gene targeting in the nucleus is far more complex due to enzymatic oligonucleotide degradation and the difficulty for the naked oligonucleotide to penetrate the cellular barrier (Crooke et al., 2000; Mahato et al., 1997; Hass et al., 1998). Nevertheless, oligonucleotides have become more and more attractive as imaging probes, stimulated by the recent introduction of several therapeutic oligonucleotides into clinical trials (Lebedeva and Stein, 2001; Pawlak et al., 2000; Hnatowich, 2000 and 1999). Permeation peptides, such as Tat-peptides, are also important because of their ability to cross cell membranes and to deliver therapeutic or diagnostic agents into the cell (Schwarze and Dowdy, 2000; Schwarze et al., 1999; Lindgren et al., 2000). On

the basis of the fact that most permeation peptides contain arginine- and lysine-rich sequences and are highly basic, they were thought to enter the cell through a nonspecific “inverted micelles” mechanism (Prochiantz, 2000). A recent study of the permeable barrier of epithelial cells to Tat-peptides, however, suggests the existence of a cell-specific mechanism (Violini et al., 2002). Permeation peptides or their conjugates with other functional molecules such as oligonucleotides, fluorescent probes, and radionuclides are currently being developed as possible imaging probes (Bullok et al., 2002).

Positron emission tomography (PET) is a medical imaging method, which uses positron-emitting radioisotope-labeled compounds to trace biochemical transformations and the movement of drugs in living systems (Eckelman et al. 2000; Fowler et al. 1999; Burn et al. 1999). Since it is impossible to obtain subcellular distribution information directly from population-based PET imaging, comparative imaging studies are necessary for evaluating the bioavailability of drugs whose function depend on their ability to enter the cells. First the molecule is labeled with a positron-emitting radioisotopes, such as fluorine-18 or carbon-11 or  $\gamma$ -emitting radioisotopes to conduct in vivo PET or single-photon computed tomography (SPECT) studies. Then the same molecule is labeled with fluorescent probe to obtain ex vivo subcellular fluoresce imaging or low-energy isotopes such as Auger-emitters I-125 or Br-77 to obtain in vitro higher resolution autoradiography and relate these to PET or SPECT imaging. The nonlinear signals, aggregation, and quenching both in vivo and in vitro associated

<sup>‡</sup> Chemistry Department.

with fluorescent probe-labeled biomolecules plus the potentially significant structural perturbation associated with a fluorescent probe to the parent compound makes radiolabeling method a better choice in terms of quantitative biochemical analysis. Labeling biomolecules with different radioisotopes is usually accomplished by linking them to different labeling compounds (Dolle et al., 1996; Bullok et al., 2002), result in molecules with different properties, and could compromise the biological properties of the parent biomolecules. For example, different chemical modification involved in the "tag on" labeling procedure may not interfere with the hybridization between the antisense oligonucleotide and target mRNA. Different labeling compounds, however, alter oligonucleotide cell membrane transport and its clearance from nontarget tissue (Hnatowich, 2000 and 1999), and oligonucleotides labeled with different labeling compounds may also have different cellular accumulation (Zhang et al., 2000). Different cellular uptake and similar subcellular localization were also observed between single-labeled and dual-labeled Tat-peptides (Bullok et al., 2002).

In this paper, we report, for the first time, the synthesis and radiolabeling of organic compounds: *N*-[2-fluoro-5-(3-[I-131]iodobenzoyl)benzyl]-2-bromoacetamide (**1**) and *N*-[2-[F-18]fluoro-5-(3-iodobenzoyl)benzyl]-2-bromoacetamide (**2**). The molecule contains a 2-bromoacetyl group,

which has been used previously to label oligonucleotides (Dolle et al., 1996) and peptides and proteins (Kilbourn et al., 1987) through a nucleophilic substitution reaction. Therefore, the pair of isotopomers should allow us to label biomolecules with F-18 or iodine isotopes and gives structurally identical products, which are expected to have identical biological properties and should be useful for comparative imaging studies.

## EXPERIMENTAL SECTION

**General.** All reactions were conducted under an argon atmosphere using glassware previously dried in an oven at 120 °C. Methylene chloride was freshly distilled from calcium hydride (CaH<sub>2</sub>) and tetrahydrofuran (THF) from benzophenone ketyl under an argon atmosphere. Hexane was dried over 4 Å molecular sieves. Flash column chromatography was performed using silica gel 60 Å (230–400 mesh). Silica gel thin-layer chromatography was done on plates (silica gel 60 Å, F254, 0.15 mm on glass). NMR spectra were recorded on a Bruker 400 MHz NMR instrument. Unless otherwise noted, samples were dissolved in chloroform-*d* (CDCl<sub>3</sub>) with tetramethylsilane (TMS) as an internal standard for proton NMR and the central peak of CDCl<sub>3</sub> signal at 77.0 ppm as the carbon-13 NMR reference.  $\delta$ : chemical shift in ppm; *J*: coupling constant in Hz. Mass spectra was measured by UCR Mass Spectrometry Facility, Department of Chemistry, UC Riverside.

**3-Tributyltinbenzaldehyde (11).** To a solution of 2-(3-bromophenyl)-1,3-dioxolane **9** (22.9 g, 100 mmol) in THF at –78 °C was added butyllithium (*n*-BuLi) (46 mL of 2.5 M in hexanes, 115 mmol) dropwise via syringe. After the mixture was stirred at –78 °C for 2 h,

tributyltin chloride (32 mL, 118 mmol) was added dropwise. After the mixture was stirred at –78 °C for 1.5 h, the reaction was slowly warmed to room temperature. Hydrochloric acid (1 N, 20 mL) was added. After the mixture was stirred at room temperature for 6 h, water (10 mL) and ether (30 mL) was added. The organic layer was washed with two additional portions of water (2 × 20 mL) and then dried over sodium sulfate, filtered, and concentrated. Flash chromatography (eluted with hexanes/ethyl acetate: 95/5, v/v) purification provided aldehyde **11** (32 g, 81%) as colorless oil: <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>)  $\delta$  7.93 (m, 1 H), 7.76 (td, *J* = 6.7, 1.0 Hz, 1 H), 7.70 (td, *J* = 7.2, 1.0 Hz, 1 H), 7.45 (t, *J* = 7.4 Hz, 1 H), 1.6 (m, 6H), 1.3 (m, 6 H), 1.0 (m, 6 H), 0.86 (t, *J* = 7.3 Hz, 9 H); <sup>13</sup>C NMR (100 MHz, CDCl<sub>3</sub>)  $\delta$  195.9, 146.3, 145.3, 140.4, 138.3, 132.2, 131.131.8, 30.3, 16.4, 12.4. MS (EI) *m/z* (%): 395 (M<sup>+</sup>, 1), 339 ([M – C<sub>4</sub>H<sub>9</sub>]<sup>+</sup>, 98), 283 ([M – C<sub>4</sub>H<sub>9</sub> – C<sub>4</sub>H<sub>9</sub>]<sup>+</sup>, 59), 225 ([M – C<sub>4</sub>H<sub>9</sub> – C<sub>4</sub>H<sub>9</sub> – C<sub>4</sub>H<sub>9</sub>]<sup>+</sup>, 100).

**4-Fluoro-3-cyano-3'-tributyltinbenzhydrol (5).** To a solution of 5-bromo-2-fluorobenzonitrile **3** (2.5 g, 12.5 mmol) in a mixture of THF (60 mL) and hexanes (20 mL) at –110 °C (ether, liquid nitrogen) was added *n*-BuLi (5.75 mL of 2.5 M in hexanes, 14.4 mmol) dropwise via syringe. After the mixture was stirred at –110 °C for 40 min, a solution of aldehyde **11** (5.0 g, 12.7 mmol) in THF (10 mL) was added. After the mixture was stirred at –110 °C for 1 h, the reaction was slowly warmed to room temperature. Hydrochloric acid (1 N, 20 mL) was added, the organic layer was washed with water (3 × 10 mL) and dried over sodium sulfate, filtered, and concentrated to yield an oil product, which was purified by flash chromatography (eluted with ethyl acetate/hexanes: 5/95 v/v) to give **5** (5.8 g, 89%) as colorless oil. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>)  $\delta$  7.60 (dd, *J* = 6.0, 2.0 Hz, 1 H), 7.54 (m, 1 H), 7.35 (td, *J* = 6.6, 1.2 Hz, 1 H), 7.31 (d, *J* = 2.2 Hz, 1 H), 7.25 (t, *J* = 7.1 Hz, 1 H), 7.15 (td, *J* = 6.6, 1.2 Hz, 1 H), 7.09 (t, *J* = 7.0 Hz, 1 H). <sup>13</sup>C NMR (100 MHz, CDCl<sub>3</sub>)  $\delta$  165.0 (d, <sup>1</sup>*J*<sub>C–F</sub> = 164 Hz), 146.1, 143.7, 144.6, 139.4, 137.3, 135.8 (d, <sup>3</sup>*J*<sub>C–F</sub> = 8.3 Hz), 134.0, 131.1, 129.0, 119.0 (d, <sup>2</sup>*J*<sub>C–F</sub> = 19.6 Hz), 116.7, 104.0 (d, <sup>3</sup>*J*<sub>C–F</sub> = 16.0 Hz), 77.8, 31.8, 30.0, 16.4. HRMS (DCI): Calcd C<sub>26</sub>H<sub>36</sub>FNOSn (M – H) 516.1724, found 516.1715.

**4-Fluoro-3-aminomethyl-3'-tributyltinbenzhydrol (6).** To a suspension of lithium aluminum hydride (1.0 g, 26.4 mmol) in dry THF was added a solution of **5** (3.6 g, 7.0 mmol) in THF (10 mL) at 0 °C under argon. The disappearance of the starting material was monitored by TLC. After 16 h stirring, the reaction was quenched by the addition of water (2 mL), followed by sodium hydroxide solution (2 mL, 3 M) and water (2 mL). The resulting mixture was stirred at room temperature for 10 min, filtered, dried over sodium sulfate, and concentrated. The crude product was purified by a flash chromatography (eluted with ethyl acetate); yield 1.46 g (40%) of **6** as colorless oil. <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>)  $\delta$  7.41 (m, 1 H), 7.33 (m, 2 H), 7.24 (m, 2 H), 7.17 (m, 1 H), 6.93 (dd, *J* = 8.8, 9.6 Hz, 1 H), 1.51 (m, 6 H), 1.32 (m, 6 H), 1.05 (m, 6 H), 0.89 (t, *J* = 7.3 Hz, 9 H); <sup>13</sup>C NMR (100 MHz, CDCl<sub>3</sub>)  $\delta$  160.2 (d, <sup>1</sup>*J*<sub>C–F</sub> = 245 Hz), 143.3, 142.4, 140.3 (d, <sup>3</sup>*J*<sub>C–F</sub> = 3.8 Hz), 135.8, 134.7, 129.3 (d, <sup>2</sup>*J*<sub>C–F</sub> = 15.9 Hz), 128.1, 127.5 (d, <sup>3</sup>*J*<sub>C–F</sub> = 4.8 Hz), 127.0 (d, <sup>4</sup>*J*<sub>C–F</sub> = 8.3 Hz), 126.3, 115.2 (d, <sup>2</sup>*J*<sub>C–F</sub> = 22.0 Hz), 75.5, 40.5 (d, <sup>3</sup>*J*<sub>C–F</sub> = 4.1 Hz), 29.2, 27.4, 14.9, 9.9. HRMS (DCI): Calcd C<sub>26</sub>H<sub>39</sub>FNOSn (M – H) 520.2037, found 520.2051.

**4-Fluoro-3-aminomethyl-3'-tributyltinbenzophenone (7).** To a solution of **6** (1.3 g, 2.5 mmol) in methylene chloride (15 mL) was added pyridinium chlo-

rochromate (PCC) (1.08 g, 5 mmol) in small portions. The suspension was stirred at room temperature for 30 min. Aqueous sodium hydroxide (3 M) was added, and the aqueous layer was extracted with ether. The organics were combined, dried over sodium sulfate, filtered, and concentrated. Flash chromatography (eluted with ethyl acetate) provided **7** (1.14 g, 88%) as colorless oil.  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.88 (dd,  $J = 7.33, 2.20$  Hz, 1 H), 7.85 (m, 1 H), 7.66 (m, 2 H), 7.42 (t,  $J = 7.48$  Hz), 7.08 (dd,  $J = 8.57, 9.57$  Hz, 1 H), 1.5 (m, 6 H), 1.3 (m, 6 H), 1.1 (m, 6 H), 0.89 (t,  $J = 7.1$  Hz, 9 H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  196.0, 163.6 (d,  $^1J_{\text{C-F}} = 253$  Hz), 142.8, 140.59, 137.6, 136.8, 134.2, 131.5 (d,  $^3J_{\text{C-F}} = 6.36$  Hz), 131.1 (d,  $^3J_{\text{C-F}} = 9.26$  Hz), 130.7 (d,  $^2J_{\text{C-F}} = 15.8$  Hz), 129.6, 127.7, 115.2 (d,  $^2J_{\text{C-F}} = 22.62$  Hz), 40.5 (d,  $^3J_{\text{C-F}} = 3.2$  Hz), 29.1, 27.4, 14.9, 9.9, MS (EI)  $m/z$  (%): 504 ( $[\text{M} - \text{NH}_2]^+$ , 100), 462 ( $[\text{M} - \text{C}_4\text{H}_9]^+$ , 14), 229 ( $[\text{M} - \text{SnBu}_3]^+$ , 6).

**[N-[6-Fluoro-3-(3-tributyltinbenzoyl)benzyl]-2-bromoacetamide (8).** To a solution containing **7** (1.14 g, 2.2 mmol) and *N*-methylmorpholine (244 mg, 2.42 mmol) in dry methylene chloride was added dropwise bromoacetyl bromide (488 mg, 2.42 mmol) at 0 °C. The reaction mixture was stirred overnight. The reaction was quenched with ice. The organic layer was washed with water (2  $\times$  2 mL), dried over sodium sulfate, and concentrated to dryness, and the residue was chromatographed on silica gel (eluted with hexanes/ethyl acetate, 95:5, v/v) gave 1.1 g (yield 78%) of compound **8** as colorless oil, it solidified as a white waxlike solid upon storage in the refrigerator.  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.86 (dd,  $J = 7.33$  Hz,  $J = 2.20$  Hz, 1 H), 7.85 (m, 1 H), 7.73 (ddd,  $J = 2.20, 5.1, 7.4, 1$  H), 7.66 (td,  $J = 1.1, 7.2$  Hz), 7.61 (m, 1 H), 7.39 (t,  $J = 7.49$  Hz), 7.12 (dd,  $J = 8.63, 9.43$  Hz), 6.9 (broad t,  $J = 4.90$  Hz, 1 H), 4.55 (d,  $J = 6.0$  Hz, 2 H), 4.10 (s, 2 H), 1.5 (m, 6 H), 1.3 (m, 6 H), 1.1 (m, 6 H), 0.89 (t,  $J = 7.3$  Hz, 9 H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  195.7, 165.5, 163.5 (d,  $^1J_{\text{C-F}} = 253$  Hz), 143.0, 140.8, 137.6, 136.6, 134.4 (d,  $^3J_{\text{C-F}} = 3.1$  Hz), 132.2 (d,  $^3J_{\text{C-F}} = 5.40$  Hz), 132.1 (d,  $^3J_{\text{C-F}} = 4.50$  Hz), 129.7, 127.7, 125.0 (d,  $^2J_{\text{C-F}} = 15.50$  Hz), 115.4 (d,  $^2J_{\text{C-F}} = 22.0$  Hz), 40.5 (d,  $^3J_{\text{C-F}} = 3.6$  Hz), 29.1, 28.9, 27.4, 13.7, 9.8. HRMS (FAB): Calcd  $\text{C}_{28}\text{H}_{39}\text{BrFNO}_2\text{Sn}$  (M + H) 640.1248, found 640.1223.

**2-(*N,N*-Dimethylamino)-5-bromobenzonitrile (13).** To a 150 mL round-bottom flask was added 2-amino-5-bromobenzonitrile **12** (1.97 g, 10 mmol), *N,N*-dimethylformamide (DMF) (50 mL), iodomethane (10 mL), and sodium carbonate (2.11 g, 20 mmol). The reaction mixture was sealed off in the flask and kept in 110 °C oil bath for 24 h. After the mixture was cooled to room temperature, ethyl acetate (100 mL) was added and the mixture was washed with water (4  $\times$  20 mL) and dried over sodium sulfate. Filtration and removal of the solvent gave **13** as yellowish solid (1.9 g, 84%).  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.48 (d,  $J = 2.52$  Hz, 1 H), 7.38 (dd,  $J = 9.0$  Hz,  $J = 2.43$  Hz, 1 H), 6.69 (d,  $J = 9.0$  Hz, 1 H), 3.0 (s, 6 H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  153.90, 136.78, 136.42, 118.32, 109.92, 101.84, 42.95. MS (CI)  $m/z$  (%): 225 (M, 25), 145 (M - Br, 10).

**4-(*N,N*-Dimethylamino)-3-cyano-3'-iodobenzhy-drol (14).** To a solution of **13** in THF/hexanes (50 mL/15 mL) was added *n*-BuLi (1.17 mL, 1.2 eq, 2.5 M in hexanes) at -110 °C under argon. After the mixture was stirred at -110 °C for 1 h, a solution of 3-iodobenzylaldehyde (679 mg, 2.96 mmol) in THF (5 mL) was added via a glass syringe. TLC indicated complete reaction in 10 min. The resulting mixture was allowed to warm slowly to room temperature. Ether (20 mL) was added,

and the reaction mixture was washed with water (3  $\times$  10 mL), dried over sodium sulfate, filtered, and concentrated under reduced pressure on a rotary evaporator. The resulting oil was purified by flash column chromatography on silica gel (hexanes/ethyl acetate, 80/20 to 70/30 v/v) to give **14** as colorless oil (775 mg, 84%):  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.69 (m, 1 H), 7.58 (m, 1 H), 7.43 (d,  $J = 2.26$  Hz, 1 H), 7.31 (dd,  $J = 8.8$  Hz,  $J = 2.27$  Hz, 1 H), 7.26 (m, 1 H), 7.05 (t,  $J = 7.8$  Hz, 1 H), 6.80 (d,  $J = 8.8$  Hz, 1 H), 5.63 (s, 1 H), 3.02 (s, 6 H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  154.66, 145.65, 136.90, 135.35, 133.95, 133.17, 132.03, 130.44, 125.71, 119.72, 116.93, 100.36, 94.72, 43.00. HRMS (DEI): Calcd  $\text{C}_{16}\text{H}_{15}\text{IN}_2\text{O}$  378.0229, found 378.0230.

**4-(*N,N*-Dimethylamino)-3-cyano-3'-iodobenzophe-none (15b).** To a solution of 4-(*N,N*-dimethylamino)-3-cyano-3'-iodobenzhy-drol **14** (770 mg, 2 mmol) in methylene chloride (100 mL) was added PCC (878 mg, 4 mmol). TLC indicated the reaction was completed after stirring at room temperature for 2 h. The reaction mixture was filtered through a plug of silica gel. The product was eluted from the silica gel by hexanes/ethyl acetate (80/20: v/v). Evaporation of the solvent gave a mixture of **15a** and **15b** with a ratio of 2 to 8 from proton NMR analysis. The mixture was dissolved in DMF (100 mL) in a 250 mL round-bottom flask, and iodomethane (10 mL) and sodium carbonate (1.5 g) were added. The reaction mixture was sealed off in the flask and kept in a 110 °C oil bath overnight. After the mixture was cooled to room temperature, ethyl acetate (100 mL) was added and the organic phase was washed with water and dried over sodium sulfate. Filtration and removal of the solvent gave pure **15b** as yellowish solid (600 mg, 79% from **14**):  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.98 (t,  $J = 1.5$  Hz, 1 H), 7.91 (d,  $J = 2.23$  Hz, 1 H), 7.86 (ddd,  $J = 8.0$  Hz,  $J = 1.8$  Hz,  $J = 1.0$  Hz, 1 H), 7.82 (dd,  $J = 11.11$  Hz,  $J = 2.24$  Hz, 1 H), 7.59 (ddd,  $J = 7.6$  Hz,  $J = 1.5$  Hz,  $J = 1.0$  Hz, 1 H), 7.18 (t,  $J = 7.6$  Hz, 1 H), 6.81 (d,  $J = 9.0$  Hz, 1 H), 3.23 (s, 6 H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  191.70, 155.98, 140.88, 139.78, 139.52, 138.07, 135.05, 130.10, 128.53, 125.76, 119.55, 115.14, 96.51, 94.30, 42.60. HRMS (FAB): Calcd  $\text{C}_{16}\text{H}_{15}\text{IN}_2\text{O}$  378.0229, found 378.0230. HRMS (DEI): Calcd  $\text{C}_{16}\text{H}_{13}\text{IN}_2\text{O}$  376.0072, found 376.0072.

**4-(*N*-Methylamino)-3-cyano-3'-iodobenzophe-none (15a).** To a solution of the mixture of **15a** and **15b** (**15a/15b**: 2/8, 20 mg) in methylene chloride (10 mL) was added pyridinium chlorochromate (50 mg, 0.23 mmol). After being stirred at room temperature for 3 days, the reaction mixture was filtered through a plug of silica gel and the product was eluted from the silica gel by hexanes/ethyl acetate (80/20: v/v). Evaporation of the solvent under reduced pressure to give a yellowish solid which was purified on silica gel (hexanes/ethyl acetate: 70/30) to give pure **15a** (10 mg, 51%) as white solid:  $^1\text{H}$  NMR (400 MHz, acetone- $d_6$ )  $\delta$  7.99 (t,  $J = 1.5$  Hz, 1 H), 7.86 (m, 3 H), 7.60 (td,  $J = 7.7, 1.8$  Hz,  $J = 1.5$  Hz, 1 H), 7.23 (t,  $J = 7.7$  Hz, 1 H), 6.76 (d,  $J = 8.8$  Hz, 1 H), 6.1 (broad s, 1 H), 3.0 (d,  $J = 5.0$  Hz, 6 H).

**4-(*N,N,N*-Trimethylammonio)-3-cyano-3'-iodoben-zophenone Triflate (16).** To a solution of 4-(*N,N*-dimethylamino)-3-cyano-3'-iodobenzophenone **15b** (186 mg, 0.5 mmol) in dry methylenechloride (1 mL) was added methyl trifluoromethanesulfonate (283  $\mu\text{L}$ ,  $d = 1.45$ , 2.5 mmol, 5.0 equiv) via syringe. The reaction was stirred for 3 days at 80 °C. The solvent and the excess methyl trifluoromethanesulfonate were evaporated, and the residue was dried under vacuum and purified by C18 Cartridges (water/acetonitrile: 90/10 v/v), giving 65 mg (40%) of pure compound **16** as white solid.  $^1\text{H}$  NMR (400

MHz, acetone- $d_6$ )  $\delta$  8.56 (d,  $J$  = 9.0 Hz, 1 H), 8.53 (d,  $J$  = 2.1 Hz, 1 H), 8.34 (dd,  $J$  = 8.9 Hz, 2.1 Hz, 1 H), 8.15 (t,  $J$  = 1.3 Hz, 1 H), 8.11 (m, 1 H), 7.85 (m, 1 H), 7.41 (t,  $J$  = 7.88 Hz, 1 H), 4.21 (s, 9 H).  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  191.3, 148.5, 142.6, 139.6, 138.3, 137.8, 135.9, 130.9, 129.6, 123.8, 116.1, 106.4, 93.9, 57.3. HRMS (FAB/ACN/NBA): Calcd  $\text{C}_{17}\text{H}_{16}\text{IN}_2\text{O}$  391.0307, found 391.0325.

**4-Fluoro-3-cyano-3'-iodobenzhydrol (17).** To a solution of 5-bromo-2-fluorobenzonitrile **3** (2.0 g, 10 mmol) in THF (80 mL) was added butyllithium (4.4 mL, 2.5 M in hexanes, 11 mmol) at  $-110^\circ\text{C}$ . After the mixture was stirred at  $-110^\circ\text{C}$  for 1.5 h, a solution of 3-iodobenzaldehyde (2.55 g, 11 mmol) in THF (5 mL) was added dropwise via a syringe. The reaction mixture was stirred at  $-110^\circ\text{C}$  for 2 h and warmed slowly to room temperature. The resulting mixture was washed with water (3  $\times$  20 mL) and dried over sodium sulfate. The solvent was evaporated under reduced pressure on a rotary evaporator. The residual yellow oil was purified by silica gel column (elute: hexanes/ethyl acetate: 80/20 v/v) to offer 2.1 g (61%) expected product **17**.  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.5 to 7.7 (m, 4 H), 7.26 (d,  $J$  = 7.82 Hz, 1 H), 7.13 (t,  $J$  = 8.68 Hz, 1 H), 7.04 (t,  $J$  = 7.80 Hz, 1 H), 5.68 (s, 1 H), 4.0 (s, 1 H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  162.5 (d,  $J_{\text{C-F}}$  = 258.9 Hz), 145.3, 140.8, 137.2, 135.5, 133.6 (d,  $J_{\text{C-F}}$  = 8.5 Hz), 131.4, 130.7, 126.0, 116.6 (d,  $J_{\text{C-F}}$  = 19.8 Hz), 114.1, 109.7, 101.2 (d,  $J_{\text{C-F}}$  = 15.6 Hz), 94.89, 73.70. HRMS (DCI): Calcd  $\text{C}_{14}\text{H}_9\text{IFNO}$  352.9713, found 352.9718.

**4-Fluoro-3-cyano-3'-iodobenzophenone (18a).** To a solution of **17** (2.1 g, 5.9 mmol) in methylene chloride (100 mL) was added pyridinium chlorochromate (4.0 g, 18.6 mmol). After being stirred at room temperature for 2 h, the reaction mixture was filtered through a plug of silica gel. Removal of the solvent gave **18a** as white waxlike solid (1.8 g, 87%).  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  8.0 to 8.1 (m, 3 H), 7.98 (d,  $J$  = 7.8 Hz, 1 H), 7.68 (d,  $J$  = 8.8 Hz, 1 H), 7.38 (t,  $J$  = 8.0 Hz, 1 H), 7.27 (t,  $J$  = 7.8 Hz, 1 H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  191.86, 165.6 (d,  $J_{\text{C-F}}$  = 266.8 Hz), 142.4, 138.8, 138.4, 137.8 (d, 135.5,  $J_{\text{C-F}}$  = 9.0 Hz), 136.0, 134.3 (d,  $J_{\text{C-F}}$  = 3.6 Hz), 130.7, 129.3, 117.4 (d,  $J_{\text{C-F}}$  = 20.4 Hz), 113.2, 102.7 (d,  $J_{\text{C-F}}$  = 16.2 Hz), 94.9. HRMS (DEI): Calcd  $\text{C}_{14}\text{H}_7\text{IFNO}$  350.9556, found 350.9567.

**4-Fluoro-3-aminomethyl-3'-iodobenzhydrol (19a).** To a stirred solution of **18a** (351 mg, 1 mmol) in dry THF (10 mL) was added borane ( $\text{BH}_3$ ) (6 mL, 1 M in THF) using a glass syringe at room temperature. After the initial reaction subsided, the reaction mixture was refluxed for 8 h in a water bath. Excess  $\text{BH}_3$  was quenched by careful addition of ethanol (20 mL) to the cooled reaction mixture. The solvent was removed by rotary evaporation. The residue was dissolved in ethyl acetate and filtered through a plug of silica gel, and the plug was eluted with hexanes/ethyl acetate/methanol (80/20/5: v/v/v, 100 mL) followed by ethyl acetate (150 mL). The product was eluted from the silica gel with methanol (150 mL). Evaporation of methanol resulted in a waxlike solid (270 mg, 76%):  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.69 (t,  $J$  = 1.8 Hz, 1 H), 7.55 (td,  $J$  = 7.85, 1.2 Hz, 1 H), 7.24 (m, 1 H), 7.13 (m, 1 H), 7.01 (t,  $J$  = 7.64 Hz, 1 H), 6.96 (dd,  $J$  = 8.4, 6.5 Hz, 1 H), 5.55 (s, 1 H), 3.7 (s, 2 H), 3.0 (broad s, 3 H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  160.6 (d,  $J_{\text{C-F}}$  = 245.8 Hz), 147.0, 140.3 (d,  $J_{\text{C-F}}$  = 4.32 Hz), 136.8, 135.8, 130.62, 129.7 (d,  $J_{\text{C-F}}$  = 15.2 Hz), 127.9 (d,  $J_{\text{C-F}}$  = 5.0 Hz), 127.4 (d,  $J_{\text{C-F}}$  = 8.4 Hz), 126.15, 115.7 (d,  $J_{\text{C-F}}$  = 21.8 Hz), 95.0, 74.7, 40.5 (d,  $J_{\text{C-F}}$  = 3.5 Hz). HRMS (DEI): Calcd  $\text{C}_{14}\text{H}_9\text{IFNO}$  (M - H) 355.9947, found 355.9955.

**4-Fluoro-3-aminomethyl-3'-iodobenzophenone (20a).** To a solution of **19a** (270 mg, 0.75 mmol) in

methylene chloride (20 mL) was added pyridinium chlorochromate (326 mg, 0.87 mmol). After being stirred at room temperature for 1 h, the reaction mixture was washed with aqueous sodium hydroxide solution (3 M, 2  $\times$  1 mL) and dried over sodium sulfate. The organic layer was filtered through a plug of silica gel. The product was eluted from the silica gel with ethyl acetate (150 mL). Removal of the solvent provided **20a** as yellowish oil (180 mg, 67%).  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  8.10 (m, 1 H), 7.92 (m, 2 H), 7.69 (m, 2 H), 7.25 (t,  $J$  = 7.7 Hz, 1 H), 7.15 (t,  $J$  = 7.64 Hz, 1 H), 3.7 (s, 2 H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  193.8, 162.3 (d,  $J_{\text{C-F}}$  = 253.2 Hz), 141.3, 139.5, 138.5, 133.3, 131.5 (d,  $J_{\text{C-F}}$  = 6.3 Hz), 131.1 (d,  $J_{\text{C-F}}$  = 9.6 Hz), 130.1, 129.0, 115.5 (d,  $J_{\text{C-F}}$  = 22.3 Hz), 109.66, 94.22, 40.5 (d,  $J_{\text{C-F}}$  = 3.1 Hz). MS (CI)  $m/z$  (%): 355 (M, 20).

**N-[6-Fluoro-3-(3-iodobenzoyl)benzyl]-2-bromoacetamide (21).** To a solution of **20a** (36 mg, 0.1 mmol) in 4 mL of methylene chloride was added *N*-methylmorpholine (12  $\mu\text{L}$ , 0.12 mmol) and bromoacetyl bromide (9.5  $\mu\text{L}$ , 0.11 mmol). After being stirred at room temperature for 5 h, the reaction was quenched with water (0.5 mL). The organic layer was separated and washed with water (2  $\times$  0.5 mL) and dried over sodium sulfate. The solvent was removed under vacuum and the residue was chromatographed on silica gel (elute: hexanes/ethyl acetate: 80/20 to 70/30) to give **21** as white solid (38 mg, 80%):  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ )  $\delta$  7.80 (t,  $J$  = 1.7 Hz, 1 H), 7.65 (m, 1 H), 7.54 (dd,  $J$  = 2.3, 7.2, 1 H), 7.47 (ddd,  $J$  = 2.3, 5.0, 7.2 Hz, 1 H), 6.95 (t,  $J$  = 7.82 Hz), 6.92 (dd,  $J$  = 8.56, 9.45 Hz), 6.69 (broad, 1 H), 4.30 (d,  $J$  = 6.4 Hz, 2 H), 3.62 (s, 2 H);  $^{13}\text{C}$  NMR (100 MHz,  $\text{CDCl}_3$ )  $\delta$  193.5, 165.8, 163.5 (d,  $J_{\text{C-F}}$  = 255 Hz), 141.5, 139.2, 138.6, 133.4, 132.1 (d,  $J_{\text{C-F}}$  = 5.5 Hz), 132.0 (d,  $J_{\text{C-F}}$  = 9.3 Hz), 130.2, 129.1, 125.2 (d,  $J_{\text{C-F}}$  = 15.42 Hz), 115.9 (d,  $J_{\text{C-F}}$  = 22.1 Hz), 94.2, 38.1 (d,  $J_{\text{C-F}}$  = 3.6 Hz), 29.0. MS (CI)  $m/z$  (%): 475 (M, 5), 397 (M - Br, 40).

**Radiosynthesis. Analytical Methods.** TLC was done on plates (Sigma-Aldrich, highly purified silica gel, 60 Å, F254, 0.25 mm on polyester). HPLC analysis and purification were performed under following conditions: UV detection at 254 nm; radioactivity detectors Geiger Muller detector. Column A: C18  $\mu\text{Bondpak}$  Waters (300  $\times$  3.9 mm, 10  $\mu\text{m}$ ); Column B: semipreparative C18 Phenomenex phenosphere 5 (ODS-2 250  $\times$  10.00 mm, 5  $\mu\text{m}$ ). Solvent A: acetonitrile/aqueous ammonium acetate solution (40 mM): 50/50, v/v; Solvent B: acetonitrile/aqueous ammonium acetate solution (40 mM): 80/20, v/v. Flow rate: 1 mL/min for column A; 5 mL/min for column B.

**Preparation of N-[2-Fluoro-5-(3-iodo[ $I$ -131]benzoyl)benzyl]-1-bromoacetamide (1).** To a stock solution of sodium iodide[ $I$ -131] (Dupont-New England Nuclear) was added a solution of *N*-[6-fluoro-3-(3-tributyltinbenzoyl)benzyl]-2-bromoacetamide **8** (20  $\mu\text{L}$ , 1% in ethanol) followed by hydrochloric acid solution (10  $\mu\text{L}$ , 0.5 M) and a solution of chloramine-T (10  $\mu\text{L}$ , 2% solution in water). After 2 min reaction, the product **1** was purified by a Radio-RP-HPLC ( $t_R$  = 15 min, Column A, solvent A). The radiochemical yield varied from 86% to 99% and the radiochemical purity was >99%.

**Preparation of N-[2-Fluoro[ $F$ -18]-5-(3-iodobenzoyl)benzyl]-1-bromoacetamide (2).** [ $^{18}\text{F}$ ]Fluoride in 0.3 to 0.5 mL of aqueous 0.01 M potassium carbonate from the  $\text{H}_2^{18}\text{O}$  target was delivered to a silicon-coated glass tube charged with a stirring bar and a mixture of tetrabutylammonium hydroxide (40  $\mu\text{L}$ , 40% in water) and dry ice (1.0 to 2.0 g), and the water was azeotropically evaporated at  $120^\circ\text{C}$  under a argon stream and then

cooled to room temperature. 4-(*N,N,N*-Trimethylammonio)-3-cyano-3'-iodobenzophenone triflate **16** (2.0 mg) dissolved in acetonitrile (0.3 mL) was added. The solution was stirred at room temperature for 10 min to give compound **18b**. The radiochemical yield of the substitution is greater than 92% determined by radio-TLC ( $R_f = 0.4$ , eluant: ethyl acetate/hexanes: 8/92 v/v) and HPLC ( $t_R = 3.6$  min, Column B, Solvent B). The reaction mixture was then diluted with ethyl acetate (4 mL) and washed with water ( $2 \times 0.5$  mL) (less than 30% activity was lost in the water), dried over sodium sulfate, and filtered through a silica gel cartridge (17% of the total activity was lost on silica gel and dry agent). The resulting solution was concentrated to dryness at 120 °C with a stream of argon. The residue was dissolved in THF (0.2 mL), and borane (0.2 mL, 1.0 M in tetrahydrofuran) was added. The reaction vial was then tightly closed and heated at 120 °C for 10 min and then cooled to room temperature to give compound **19b**. The yield of the reduction varied from 60% to 78% as determined by radio RP-HPLC ( $t_R = 10.0$  min, column B, solvent B). The excess borane was quenched with ethanol (0.2 mL), and the solvent was evaporated with a stream of argon at room temperature. The residue was redissolved in methylene chloride (3 mL). The solution was washed with aqueous sodium hydroxide (0.2 mL, 1 N) and water (1 mL). The organic layer was loaded on a silica cartridge, and the product was eluted with methanol (6 mL). The resulting solution was evaporated to dryness, a solution of PCC (10 mg) in methylene chloride (1 mL) was added, and the mixture was stirred at room temperature for 15 min to give compound **20b**. The resulting yellow-brown reaction mixture was washed with aqueous sodium hydroxide and water. The yield of the oxidation varied from 65% to 90% as determined by radio RP-HPLC ( $t_R = 13.0$  min, column B, solvent B). The solvent was evaporated, and the residue was dissolved in methylene chloride. After addition of bromoacetyl bromide solution (100  $\mu$ L, 1.0 M in methylene chloride), the cloudy solution was stirred at room temperature for 2 min to give compound **2**, and the solvent was evaporated, the residue was dissolved in a mixture of acetonitrile and water (1/1, v/v) and purified by an RP-HPLC ( $t_R = 10.35$  min, column B, solvent A). In a typical run, 0.75 mCi compound **2** was obtained from 44 mCi [ $^{18}$ F]fluoride, in 2 h 45 min synthesis time with a specific activity of 0.74 Ci/ $\mu$ mol. The radiochemical purity of compound **2** was >99% from radio-TLC ( $R_f = 0.31$ , eluant: ethyl acetate/hexanes: 30/70 v/v) and HPLC ( $t_R = 10.35$  min, column B, solvent A).

## RESULTS AND DISCUSSION

The synthesis of iodine labeling precursor, *N*-[2-fluoro-5-(3-tributyltinbenzoyl)benzyl]-2-bromoacetamide **8** is shown in Scheme 1. Tributyltin is a very useful functional group in iodine labeling since it allows us to introduce iodine isotopes in high radiochemical yields through an oxidative destannylation reaction (Arano et al., 1994; Zalutsky and Narula, 1987 and 1988). Moreover, an iodine atom at the meta position of a carbonyl group has higher resistance toward *in vivo* deiodination (Zalutsky and Narula, 1987) thus increasing the overall *in vivo* stability of radiolabel. 4-Fluoro-3-nitrile-3'-tributyltinbenzhydrol **5** was obtained at -110 °C in a mixture of tetrahydrofuran and hexanes (3:1, v/v) from a coupling reaction between 3-tributyltinbenzaldehyde **11** and 2-fluoro-5-lithiobenzonitrile **4**, which was generated from 5-bromo-2-fluorobenzonitrile **3** through a bromine-lithium exchange reaction (Ding et al., 1996; Parham and Lawrence,

**Scheme 1<sup>a</sup>**

<sup>a</sup> Key: (a) *n*-BuLi, THF/hexanes (3/1, v/v), -110 °C; (b) **11**, -110 °C to room temperature; (c) LiAlH<sub>4</sub>, THF, 0 °C to room temperature; (d) PCC, CH<sub>2</sub>Cl<sub>2</sub>, rt; (e) bromoacetyl bromide, *N*-methylmorpholine, CH<sub>2</sub>Cl<sub>2</sub>, 0 °C to room temperature; (f) Na<sup>131</sup>I, chloramine-T, rt, 2 min.

1976). Compound **5** could not be synthesized at a temperature of -78 °C in THF due to a side reaction between the nitrile group and organometallic reagent. Parham (Parham and Lawrence, 1976) suggested that the *o*-lithiobenzonitrile generated at a reaction temperature of -78 °C by *n*-butyllithium is relatively stable; however, the side reaction between *o*-lithiobenzonitrile and *n*-butyl bromide and the reaction between nitrile group and *n*-butyllithium become significant at an elevated temperature. The nitrile group in compound **3** is presumably more vulnerable to nucleophilic reagents due to the electron-withdrawing property of the fluorine atom in the ortho position; therefore, compound **5** can only be synthesized at a lower temperature and in a less polar reaction medium. The aryllithium **10** (Scheme 2), on the other hand, is relatively stable and can be prepared at -78 °C by bromine-lithium exchange reaction. The reaction of **10** with tributyltin chloride followed by *in situ* deprotection with hydrochloric acid gave aldehyde **11** in 81% overall yield. Compound **11** can also be synthesized from 2-(3-bromophenyl)-1,3-dioxolane **9** through Grignard reaction (Al-Diab et al., 1982); the yield, however, was poor in our hands.

4-Fluorobenzonitrile can be rapidly reduced by lithium aluminum hydride at 120 °C to give a quantitative yield of corresponding amine (Dolle et al., 1996). No desired product, however, was isolated when the same conditions were applied to reduce compound **5**. At a lower temperature, starting from 0 °C to room temperature over 16 h, 4-fluoro-3-aminomethyl-3'-tributyltinbenzhydrol **6** was isolated in an acceptable yield (40%) (Scheme 1). The reduction at high temperature may cause the cleavage of the carbon-tin bond to produce an uncharacterizable mixture.

Pyridinium chlorochromate was used to oxidize benzhydrol **6** to the corresponding ketone **7** (Scheme 1). A

simple filtration through a plug of silica gel usually is a very efficient way to separate the product from the inorganic oxidizing reagent. Compound **7**, however, could not be isolated by this method, probably due to the formation of complexes between chlorochromate and aryl- and alkylamines (Kasmai et al., 1995). We found that compound **7** can be released from the complex by treating the reaction mixture with 3 M sodium hydroxide followed by purification by silica gel column chromatography. Compound **7** was then treated with bromoacetyl bromide in the presence of *N*-methylmorpholine to afford radioiodolabeling precursor **8** in 78% yield. Radioiodination was accomplished by treating compound **8** with sodium iodide (I-131) using chloramine-T as the oxidizing reagent followed by a reverse phase HPLC separation. Pure *N*-[2-fluoro-5-(3-[I-131]iodobenzoyl)benzyl]-2-bromoacetamide **1** was obtained in 86–99% radiochemical yield.

4-(*N,N,N*-Trimethylammonio)-3-cyano-3'-iodobenzophenone triflate **16** was synthesized as the precursor for F-18 labeling (Scheme 3) starting from 2-amino-5-bromobenzonitrile **12**. *N*-Methylation of **12** with iodomethane in the presence of sodium carbonate in DMF gave 2-(*N,N*-dimethylamino)-5-bromobenzonitrile **13** in 84% yield. Unlike compound **3**, the dimethylamino group in compound **13** stabilized the nitrile group toward the nucleophilic reaction, and metal halide exchange reaction of compound **13** with butyllithium proceeded at -78 °C in THF smoothly and produced stable 2-(*N,N*-dimethylamino)-5-lithiobenzonitrile which then reacted with 3-iodobenzylaldehyde to give 4-(*N,N*-dimethylamino)-3-cyano-3'-iodobenzhydrol **14** in 84% yield. Compound **14** was converted into a mixture of 4-(*N*-methylamino)-3-cyano-3'-iodobenzophenone **15a** and 4-(*N,N*-dimethylamino)-3-cyano-3'-iodobenzophenone **15b** in a ratio of about 20 to 80 by PCC oxidation. The ratio of the products depends on the reaction time; **15b** disappeared in 3 days, and pure **15a** was isolated using a silica gel column. The loss of a methyl group in the course of oxidation is due to a known oxidative demethylation reaction by chromate (Hostetler et al., 1999). The separation of **15a** from **15b** by silica gel column chromatography was not successful. Pure **15b** was obtained by remethylation **15a** in the mixture with iodomethane in DMF in the presence of sodium carbonate. Quaternization of *N,N*-dimethylaniline derivatives with methyl triflate usually proceeds

rapidly at room temperature to offer quantitative yield. However, prolonged heating was required for the methylation of compound **15b** (80 °C in a sealed ampule for 3 days) to yield 30 to 40% of product **16**. The electron-withdrawing carbonyl and nitrile groups and the unfavorable steric hindrance caused by the ortho position nitrile group appears to be responsible. The carbonyl or nitrile group, however, is routinely introduced into aryl-trimethylammonium to activate the aromatic ring for nucleophilic aromatic substitution by F-18 (Ding et al., 2000 and 1990). The presence of both in compound **16** makes the trimethylammonium group very labile toward fluoride substitution. In fact, quantitative fluoride substitution was accomplished in acetonitrile at room temperature in less than 5 min using 1.0 equiv of tetrabutylammonium fluoride as fluoride source to give compound **18a**, which can also be synthesized from **3** (Scheme 4). This efficient substitution reaction with fluoride is very unusual since fluoride ion is not a strong nucleophile. However, in this case the displacement of the trimethylammonium group is facilitated by the presence of the two electron-withdrawing groups (nitrile and carbonyl). Compound **18** can be reduced by borane in refluxing THF to give 4-fluoro-3-aminomethyl-3'-iodobenzhydrol **19a** in 76% yield. Upon PCC oxidation, 4-fluoro-3-aminomethyl-3'-iodobenzophenone **20a** was obtained in 67% and alkylation with bromoacetyl bromide to produce compound *N*-[6-fluoro-3-(3-iodobenzoyl)benzyl]-2-bromoacetamide **21** in 80% yield. Compound **21** is the parent compound for the radiolabeled compounds **1** and **2** and serves as a reference compound in the radiosynthesis.

Initially, 4-nitro-3-cyano-3'-iodobenzophenone **16a** (Scheme 5) instead of **16** was proposed for the F-18 labeling precursor. However, we were not able to synthesize **16a** from 2-nitro-5-bromobenzonitrile **13a** under various temperature and solvent combinations. The nitrile group in 2-nitro-5-bromobenzonitrile **13a** was presumably activated by the ortho nitro group and very labile to nucleophilic reaction with *n*-butyllithium, and the 2-nitro-5-lithiobenzonitrile **4b** could not be generated through the bromine–lithium exchange reaction. Of course, the nitro group itself may also react with a strong base like butyllithium. On the basis of our results, it seems to be reasonable to conclude that the stability of the nitrile group in **3**, **13**, and **13a** toward the nucleophilic

Scheme 5

reaction is in the order of **13** > **3** > **13a**, which is consistent with the electron-withdrawing property of the amino, fluoro, and nitro group.

The F-18 labeling starting from compound **16** is shown in Scheme 4. The F-18 substitution reaction in acetonitrile at room temperature afforded **18b** in less than 10 min with a radiochemical yield (RCY) of 90 to 92%. To our best knowledge, this is the first example of a rapid room-temperature high yield F-18 substitute reaction, which makes compound **16** an ideal labeling precursor (Ding et al., 1990 and Fowler and Wolf, 1997). Borane reduction at 120 °C in 15 min yielded **19b** in 68% RCY. PCC oxidation at room temperature in 10 min gave **20b** in 68% RCY. Alkylation with bromoacetyl bromide at room temperature in 2 min followed by reverse phase HPLC purification afforded the F-18 labeled product **2**. The overall radiosynthesis from **16** takes less than 3 h after EOB with an unoptimized radiochemical yield of about 2% and specific activity of 0.8 Ci/μmol at EOB. The application of compound **2** to the F-18 labeling of oligonucleotides, peptides, and proteins is currently under investigation in our laboratory.

In summary, we have developed routes to synthesize novel precursor compounds, which can be used to label biomolecules with both F-18 and iodine radioisotopes and give structurally identical products. In the course of this project, we found that (1) nitrile and carbonyl groups at ortho and para positions in aryltrimethylammonium trifluoromethanesulfonate has an additive activation effect which facilitates the F-18 substitution reaction, and the F-18 labeling can proceed at room temperature. (2) The stability of nitrile group in 2-substitute-5-lithiobenzonitrile derivatives toward the nucleophilic agent de-

pends on the electronic properties of the 2-position substituent and in the order of dimethylamino > fluoro > nitro.

#### ACKNOWLEDGMENT

Financial support for this research was provided by the U.S. Department of Energy under the contract No. AC02-98CH10886. The assistance of C. Shea and V. Garza in the radiosynthesis, Y. Xu in the HPLC condition development, M. Schueller in the Cyclotron operation, and D. Schlyer and R. Ferrier in the radionuclides production is acknowledged.

# Conjugation of an Antisense Oligodeoxynucleotide to Ribonuclease H Results in Sequence-Specific Cleavage and Intracellular Inhibition of HCV Gene Expression

Toshiko Fukuma, Cherie M. Walton, Catherine H. Wu, and George Y. Wu\*

Department of Medicine, Division of Gastroenterology-Hepatology, University of Connecticut Health Center, Farmington, Connecticut. Received October 24, 2002; Revised Manuscript Received December 12, 2002

A recombinant *E. coli* ribonuclease H (RNase H) was chemically coupled to an antisense oligodeoxynucleotide (ODN) against the 5'-noncoding region (5'-NCR) of the hepatitis C virus. Purity of the conjugates was confirmed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) as a band corresponding to approximately 23 kDa. Conjugate function was tested by the cleavage of a HCV RNA transcript including the 5'-NCR and core region and showed HCV sequence-specific cleavage by the appearance of an expected ~1000 nt fragment of RNA. Cleavage was not seen by RNase H alone, or ODN alone. Delivery studies using <sup>32</sup>P- and <sup>125</sup>I-labeling showed that while RNase H failed to enter cells, the conjugate was efficiently taken into the cells. To assess intracellular effects, a cell line, Huh-7/CMV-NCRCΔluc, which expresses HCV mRNA (nt 1–585) fused to a marker gene, was transfected with the conjugate. Reporter gene expression was suppressed by 51.2% with the conjugate compared to only 39.7% by ODN alone, 35.8% by a mixture of RNase H plus ODN, and not at all by RNase H alone. In conclusion, the RNase H-ODN conjugate effectively cleaved an HCV transcript in vitro and inhibited expression of an HCV-marker fusion construct in a liver-derived cell line.

## INTRODUCTION

Ribonuclease H (RNase H) is an endonuclease that cleaves only the RNA strand of RNA-DNA hybrids (1). However, it does not have sequence-specific properties. It has been isolated from *Escherichia coli* (2, 3) as well as human cells (4, 5). *E. coli* RNase H1 is composed of a single polypeptide chain with 155 amino acids, and its properties are well characterized (6–8).

Antisense oligodeoxynucleotides (ODNs) can hybridize with target RNA molecules in a sequence-specific manner, blocking translation and resulting in reduction of protein synthesis including that of several viruses (9–14). Antisense ODNs against the 5'-noncoding region (5'-NCR) and core region of hepatitis C virus (HCV) genome were used to inhibit the HCV-directed expression in vitro (15, 16) in human hepatoma cell lines (17–19) and in an animal model infected with an HCV-vaccinia virus recombinant (20).

Although endogenous RNase H is suggested to have a role in inhibition of gene expression by ODNs (21–24), the normal RNase H expression level in mammalian cells is low. To obtain high, intracellular concentrations of RNase H and to colocalize it with ODNs, we sought to link RNase H to ODN to form a conjugate. The aim was to synthesize an RNase H-ODN conjugate targeting HCV, test sequence-specific cleavage using HCV RNA transcript in vitro, and study its *intracellular* activity in a human liver cell line that expresses HCV mRNA.

## MATERIALS AND METHODS

**Purification of RNase H.** *E. coli* strain MIC1066 expressing a mutant RNase H (C63S, C133A) was a generous gift from Dr. Robert Crouch, NIH. RNase H was purified as previously described (25, 26).

**Antisense ODN Design.** A 14-mer HCV 5'-NCR sequence specific antisense ODN was designed against a target sequence based on the predicted secondary structure of the HCV genome, nt 325–338 (5'-CUCGUA-GACCGUGC-3'). A 12-base oligonucleotide (5'-GCAGGGT-GAAGC-3') specific for the DR1 site on HBV adw strain was prepared as a negative oligonucleotide control. The ODN was 5'-amino modified, and the backbone phosphorothioate was modified (HHMI/Keck Oligonucleotide Synthesis Facility, Yale University).

**RNase H-ODN Conjugate Synthesis.** RNase H-ODN conjugate was synthesized as previously described (25, 26). Briefly, 360 nM ODN and 50-fold molar excess water-soluble cross-linker, Sulfo-GMBS. RNase H-ODN conjugates were purified by anion exchange column, HiTrap Q (Amersham Pharmacia Biotech Inc., Piscataway, NJ). SDS-PAGE analysis was performed, and bands were visualized by Coomassie Brilliant Blue.

**<sup>32</sup>P-Labeling of ODN and <sup>125</sup>I-Labeling of RNase H.** DNA-labeling of RNase H-ODN conjugate and ODN were performed by 3'-OH end-labeling with α<sup>32</sup>P-ATP using terminal deoxynucleotidyl transferase according to manufacturer's instructions (Promega, Madison, WI). Labeled products were analyzed on SDS-polyacrylamide (15%)/urea (8 M) gels, followed by autoradiography. Protein-labeling of RNase H and RNase H-ODN conjugate were performed with <sup>125</sup>I by the chloramine-T method and analyzed by SDS-PAGE (15%) and autoradiography.

**Plasmids and in Vitro Transcription.** To evaluate the cleavage properties of RNase H-ODN conjugate, an in vitro cleavage substrate was prepared. The plasmid, p90/HCVFLong pU, containing a full length HCV cDNA (Genotype Ia, Dr. Charles M. Rice, Rockefeller University, NY), was digested with restriction enzymes Xba I/BamHI to generate a 1,357 bp fragment. This fragment was subcloned into pUC18, resulting in pUC18/T7-HCV (nt 1–1357). As a control, an HBV RNA template was also created from an adw R9 plasmid (Dr. T. J. Liang, NIH) resulting in a fragment of 1182 nt (26). In vitro transcription was performed using conventional T7 RNA polymerase reaction (Life Technologies, Grand Island, NY).

**In Vitro Transcript Cleavage Assay.** To assess cleavage, 0.5  $\mu$ M HCV RNA of in vitro transcript and varying concentrations of RNase H-ODN conjugate with ranging 6 nM–0.6  $\mu$ M, was incubated at 37 °C for 1 h in cleavage buffer [40 mM Tris-HCl, pH 7.4, 4 mM MgCl<sub>2</sub>, 1 mM DTT, 150 mM NaCl, 1  $\mu$ L anti-RNase (Ambion, Austin, TX)]. To RNase H-ODN conjugate samples, 25 mM *N*-ethylmaleimide (NEM) was added to prevent the nonspecific cleavage by unconjugated RNase H (27). The effect of the chelating agents EDTA and EGTA were also tested. Appearance of expected cleaved fragments was sought using 0.7% agarose 2.2 M formaldehyde gels. RNA bands were visualized by ethidium bromide staining.

**Cell Lines and RNase H-ODN Conjugate Transfection.** A cell line, Huh-7/CMV-NCRCLuc was used to test the inhibition of HCV mRNA. This cell line was established by transfecting the plasmid pRc/CMV-NCRCLuc that contains HCV cDNA nt 1–585 upstream of a firefly luciferase gene under the control of CMV promoter (28). Huh-7/CMV-luc, which expresses luciferase gene driven by a CMV promoter, was used as a control. These cell lines were cultured in DMEM supplemented with 10% FBS and 250  $\mu$ g/mL G418. HepG2 derived cells, HepG2 2.2.15, that produce unrelated HBV viral proteins, were also used as controls (29).

Transfections of ODN, RNase H, and RNase H-ODN conjugate into the cells were performed by a polycationic lipid method. Cells ( $2 \times 10^5$ ) were seeded on 24-well tissue culture dishes and incubated for 24 h prior to the transfection. Various amounts of RNase H-ODN conjugates ranging from 0  $\mu$ g to 1.6  $\mu$ g were mixed with LipofectAMINE (DOSPA plus DOPE, Invitrogen, Carlsbad, CA) in OPTI-MEM I (Life Technologies). Final protein concentrations ranged from 0  $\mu$ M to 0.3  $\mu$ M. Control samples of ODN alone, RNase H alone, and a mixture of RNase H and ODN were also prepared in the identical molar ratios as present in RNase H-ODN conjugate. Cells were incubated at 37 °C with 5% CO<sub>2</sub>. At 12 h after transfection, culture medium was replaced. Cells were harvested at 3, 6, 12, 24, and 48 h after transfection, and luciferase assays were performed.

**Delivery Studies.** <sup>32</sup>P-labeled ODN and <sup>125</sup>I-labeled RNase H were used to assess delivery of the conjugate, ODN and RNase H in Huh-7/CMV-NCRCLuc cells. Transfections were performed at 0.15  $\mu$ M using radiolabeled materials as described above. Cells were harvested at 3, 6, 12, 24, and 48 h after transfection. Tissue culture medium was collected and cell layers were washed three times with ice-cold PBS, stripping solution (PBS, pH 5, 10 mM EDTA) followed by lysis buffer. All solutions, and cell lysates were collected. <sup>32</sup>P-radioactivity was scintillation counted and <sup>125</sup>I-radioactivity was measured with gamma counter. Background cell-associated radioactivity was measured by binding assays incubating cells with radiolabeled materials at 4 °C for 2 h. The delivery was

**Figure 1.** SDS-PAGE analysis of the purified RNase H and RNase H-ODN (HCV) conjugate. Purified RNase H and RNase H-ODN (3  $\mu$ g) were separated by 15% SDS-PAGE and stained with Coomassie Brilliant Blue. Lane 1, RNase H; lane 2, RNase H-ODN (HCV) conjugate. Migration of the protein size markers is shown on the left.

assessed by intracellular accumulation, the sum of uptake and elimination from the cells. It was calculated by subtraction of background from total cell-associated amount. Results were expressed as means  $\pm$  SD ( $n = 6$ ).

**Reporter Gene Assays.** Luciferase assays were performed using a commercial kit (Promega) with a luminometer model, LB9501. Total cell protein was determined by Bio-Rad protein assay kit (Bio-Rad, Hercules, CA). Luciferase activity measurements were performed in duplicate, and normalized to the total protein concentration of each sample. Results are expressed as means  $\pm$  SD of four independent experiments. The HBs antigen was quantified by Abbott ELISA according to manufacturer's instructions (Abbott Laboratories, Abbott Park, IL).

**Statistical Analyses.** Statistical analyses were performed using Student's *t*-test with *p* values of  $<0.05$ .

## RESULTS

**RNase H-ODN Conjugate Synthesis.** Figure 1 shows that recombinant mutant RNase H (C63S/C133A-RNase H) was generated from *E. coli* (lane 1). Recombinant RNase H mutant protein alone migrated at distance consistent with its known size of 18 kDa (lane 1). Chemical coupling of RNase H to ODN (HCV) was confirmed by SDS-PAGE analysis of the purified conjugate, showing a band with slower migration (lane 2). RNase H and ODN were found to be linked in a 1:1 molar ratio as calculated from spectrometer readings and Bio-Rad protein assays.

**Purity of <sup>32</sup>P-Labeled ODN and <sup>125</sup>I-Labeled RNase H.** Figure 2A shows an autoradiograph of SDS-polyacrylamide/urea gel analysis of the <sup>32</sup>P-ODN (HCV) and RNase H-(<sup>32</sup>P)ODN (HCV) conjugate. In lane 1, <sup>32</sup>P-ODN alone migrated rapidly due to its lower molecular weight. In contrast, lane 2 shows the slower migration of RNase H conjugate, with no free <sup>32</sup>P-ODN detectable in the purified conjugate.

Figure 2B shows an autoradiograph of SDS-PAGE analysis of the <sup>125</sup>I-RNase H and <sup>125</sup>I-RNase H-ODN (HCV) conjugate. <sup>125</sup>I-RNase H and <sup>125</sup>I-RNase H-ODN conjugate migrated differently with estimated molecular weights as shown in Figure 1. Unconjugated <sup>125</sup>I-RNase H contamination in <sup>125</sup>I-RNase H-ODN conjugate was not detectable.

**In Vitro Cleavage Assay.** Cleavage assay results using RNase H-ODN (HCV) conjugates are shown in Figure 3A and 3B. The untreated substrate (in vitro

**Figure 2.** SDS-PAGE analysis using radiolabeled materials. Migration of the protein size markers are shown on the left of both panels. (A)  $^{32}\text{P}$ -labeled ODN (HCV) and RNase H-ODN (HCV) conjugate with  $3 \times 10^5$  cpm radioactivity each were separated on a 15% polyacrylamide/8 M urea gel, and followed by autoradiography. Lane 1, ODN; lane 2, RNase H-ODN conjugate. (B)  $^{125}\text{I}$ -labeled RNase H and RNase H-ODN with  $1 \times 10^5$  cpm radioactivity each were separated on 15% SDS-PAGE and washed overnight, followed by autoradiography. Lane 1, RNase H; lane 2, RNase H-ODN conjugate.

**Figure 3.** Cleavage assay analyses on 2.2 M formaldehyde gels (0.7% agarose). (A) Cleavage assay with 1357 nt HCV transcripts using different RNase H-ODN (HCV) conjugate concentrations. Lane 1, RNA size marker; lane 2, RNase H 600 nM; lane 3, ODN 600 nM; lane 4, RNase H plus ODN 200 nM; lane 5, RNase H plus ODN 60 nM; lane 6, RNase H plus ODN 6 nM; lane 7, Conjugate 600 nM; lane 8, Conjugate 200 nM; lane 9, Conjugate 60 nM; lane 10, Conjugate 6 nM and lane 11, 1357 nt HCV transcript alone. (B) (Lane 1–3, 1182 nt HBV transcript; Lane 4 and 5, 1357 nt HCV transcript.) Lane 1, Conjugate 600 nM; lane 2, Conjugate 60 nM; lane 3, Conjugate 6 nM; lane 4, Conjugate 600 nM plus 25 mM EGTA and lane 5, Conjugate 600 nM plus 25 mM EDTA.

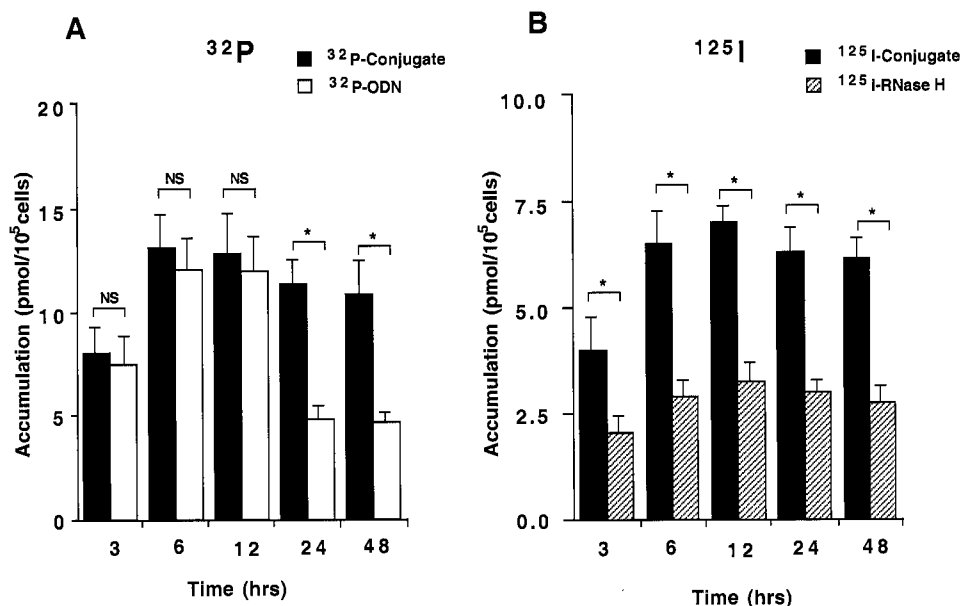

transcript) ran as an approximately 1400 nt band (panel A, lane 11). The reaction mixture incubated with RNase H-ODN conjugates showed HCV cleavage by the presence of an expected  $\sim 1000$  nt fragment. RNase H-ODN conjugate cleaved target transcript in a dose-dependent manner at conjugate concentrations between 60 nM and 600 nM (panel A, lanes 7–10). At concentrations higher than 600 nM, nonsequence-specific cleavage occurred (data not shown). Reaction mixtures containing RNase H plus ODN showed slightly higher cleavage activity than that of RNase H-ODNs conjugates with identical mole equivalents of components (panel A, lanes 4–6). Cleavage was not seen by RNase H alone (panel A, lane 2), or ODN alone (panel A, lane 3), confirming that the observed results with conjugated RNase H were not due to nonspecific RNase H activity or contamination with a nonspecific nuclease. A control HBV transcript of ap-

proximately 1200 nt, completely unrelated in sequence to HCV RNA, was also not cleaved by RNase H-ODN conjugate (panel B, lane 1–3), confirming the requirement for specific HCV sequences to obtain cleavage. The *in vitro* cleavage reaction of HCV transcript was inhibited by 25 mM EDTA (panel B lane 5), a  $\text{Mg}^{2+}$  chelator, but was not inhibited by 25 mM EGTA which binds  $\text{Ca}^{2+}$ , not  $\text{Mg}^{2+}$  (panel B, lane 4). This is consistent with the requirement of RNase H for only  $\text{Mg}^{2+}$ .

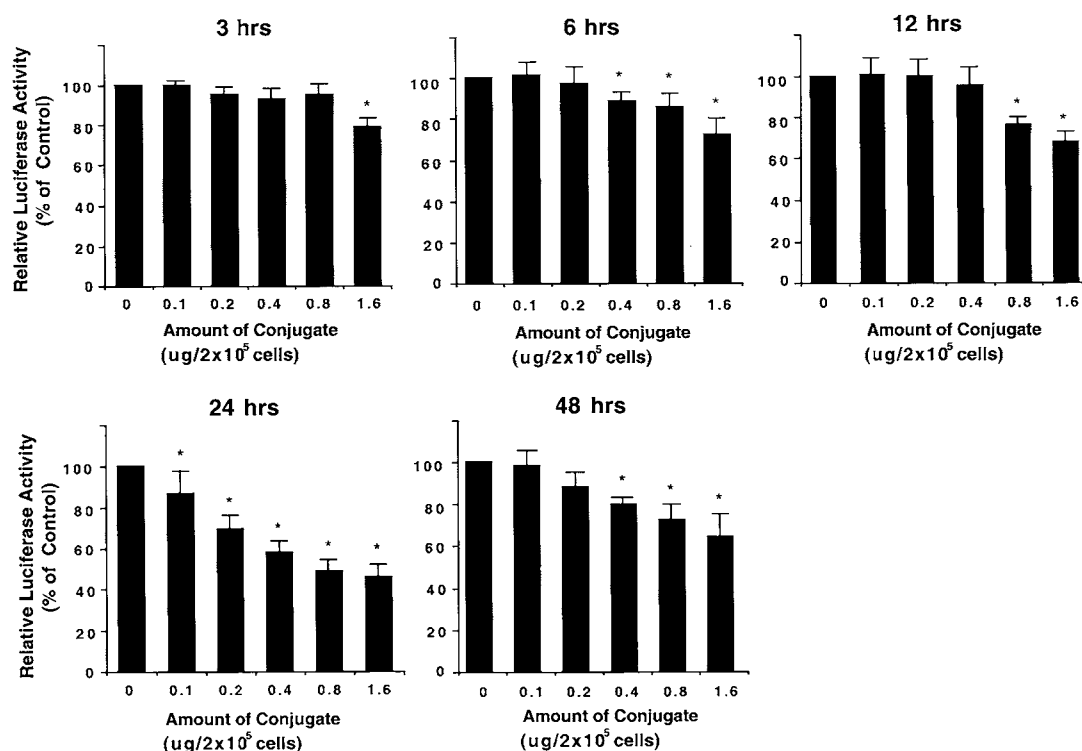

**Delivery of Radiolabeled RNase H-ODN Conjugates (HCV) into the Cells.** Delivery studies were performed to determine whether RNase H-ODN conjugate could be taken into the cells by polycationic lipid. Figure 4A shows the delivery of  $^{32}\text{P}$ -radiolabeled RNase H-ODN conjugate (HCV) and ODN (HCV) alone. Intracellular accumulation, subtraction of background from total cell-associated amount, was taken to represent the delivery of the conjugate or ODN. Background was less than 1.0 pmol/ $10^5$  cells in both groups. Peak accumulation of the conjugate, and ODN alone, were  $13.1 \pm 1.4$  pmol/ $10^5$  cells and  $12.0 \pm 1.3$  pmol/ $10^5$  cells, which correspond to 69.8% and 64.0% of total added amount, respectively, at 6 h after transfection. Thus, conjugated RNase H-ODN was transfected into cells as efficiently as ODN alone. The ODN alone treated cells showed a decline in accumulation to  $4.9 \pm 0.9$  pmol/ $10^5$  cells at 24 h, while conjugate levels remained at  $11.4 \pm 1.3$  pmol/ $10^5$  cells and relatively constant through 48 h, suggesting that more conjugated ODN survived longer than ODN alone in the cells. Figure 4B showed the delivery of  $^{125}\text{I}$ -labeled RNase H-ODN conjugate and RNase H alone. Both groups showed a maximum accumulation at 12 h, with values of  $7.0 \pm 0.58$  pmol/ $10^5$  cells for the conjugate and  $3.3 \pm 0.46$  pmol/ $10^5$  cells for RNase H alone. Beyond the 12 h point, accumulation was unchanged up to 48 h in both groups. These data indicate that intracellular accumulation of conjugated RNase H was more than twice as much as RNase H alone at all time points. At any time point, the differences between two groups were statistically significant ( $p < 0.05$ ).

**Reporter Luciferase Activity in Liver-Derived Cell Lines in the Presence of RNase H-ODN Conjugate (HCV).** A cell line, Huh-7/CMV-NCRC $\Delta$ luc, that expresses a fusion transcript of HCV nt 1–585/luciferase, was tested to investigate whether RNase H-ODN conjugate was functional in these cells. If the RNase H-ODN (HCV) conjugate was effective in cleaving the HCV target, the resulting recombinant HCV-luciferase activity should be inhibited to an extent greater than that amount of ODN alone. Figure 5 shows effects of reporter HCV-luciferase activity by RNase H-ODN conjugates (HCV) at varying times after transfection. RNase H-ODN conjugate inhibited HCV-luciferase expression in a dose dependent manner. The overall maximum suppression was seen at 24 h after transfection at all concentrations. With 1.6  $\mu\text{g}$  (0.3  $\mu\text{M}$ ), 0.8  $\mu\text{g}$  (0.15  $\mu\text{M}$ ), 0.4  $\mu\text{g}$  (0.075  $\mu\text{M}$ ), 0.2  $\mu\text{g}$  (37.5 nM), and 0.1  $\mu\text{g}$  (18.8 nM) of RNase H-ODN conjugate, reporter gene activity was suppressed by 52.0%, 51.2%, 42.0%, 30.6%, and 13.5%, respectively, relative to the lipid-treated control samples. At the 24 h point, suppression was statistically significant compared to the control samples at all conjugate concentrations ( $p < 0.05$ ).

**Effect of RNase H-ODN Conjugate (HCV) on HCV Reporter Gene Expression.** Figure 6 shows the effects of HCV-luciferase activity at 24 h after treatment with RNase H-ODN conjugate. With increasing RNase H-ODN conjugate (HCV) concentrations, inhibition was

Intracellular accumulation was determined by the subtraction of background from the total cell associated amount as described in Materials and Methods. Data represent means  $\pm$  SD ( $n = 6$ ). (A) Intracellular accumulation of RNase H-ODN conjugate and ODN by  $^{32}\text{P}$ -labeling. (B) Intracellular accumulation of RNase H-ODN conjugate and RNase H by  $^{125}\text{I}$ -labeling. \*,  $p < 0.05$ .

**Figure 5.** Effect on the reporter HCV-luciferase activity by RNase H-ODN (HCV) conjugates in Huh-7/CMV-NCR $\Delta$ luc cells. Cell lysates treated with RNase H-ODN (HCV) conjugate in six different concentrations were harvested at indicated times after transfection. Indicated RNase H-ODN conjugate amounts were added as shown on the horizontal axis, and corresponding concentrations are shown in parentheses: 0.16  $\mu\text{g}$  (0.3  $\mu\text{M}$ ), 0.8  $\mu\text{g}$  (0.15  $\mu\text{M}$ ), 0.4  $\mu\text{g}$  (0.075  $\mu\text{M}$ ), 0.2  $\mu\text{g}$  (37.5 nM), 0.1  $\mu\text{g}$  (18.8 nM), 0  $\mu\text{g}$  (0  $\mu\text{M}$ ) as described in Materials and Methods. Data represent means  $\pm$  SD ( $n = 4$ ). Each experiment was performed in duplicate. \*,  $p < 0.05$ .

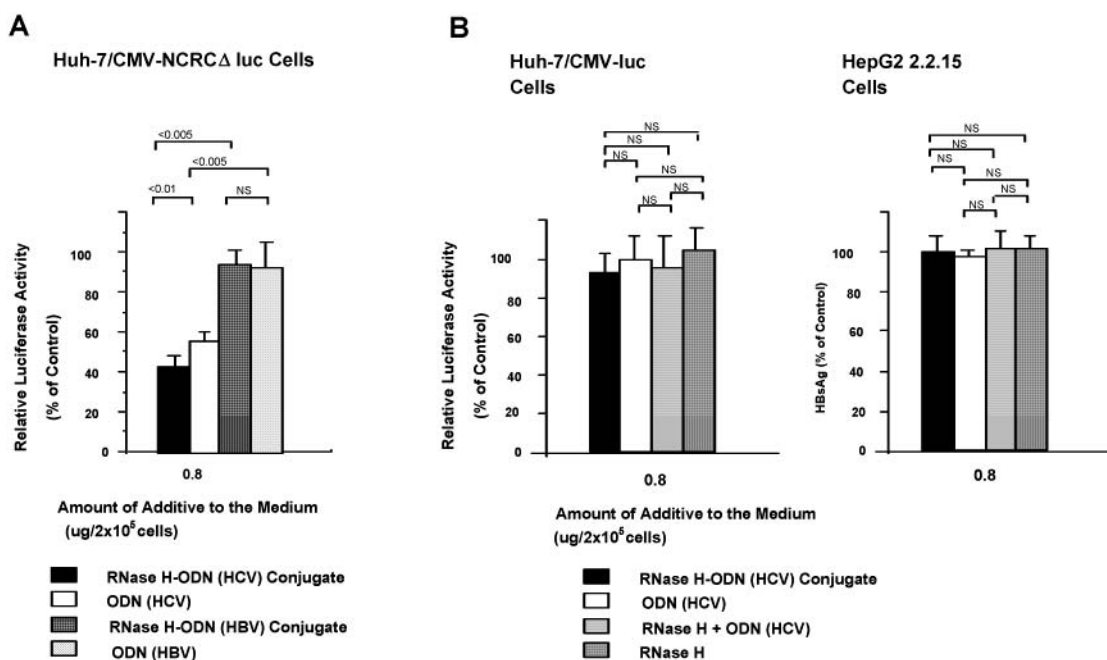

increased, but no further increase was seen above 0.8  $\mu\text{g}$  (0.15  $\mu\text{M}$ ) conjugate administration per  $2 \times 10^5$  cells. At this dose, RNase H-ODN conjugate suppressed reporter gene activity by 51.2% compared to lipid-treated controls, while ODN alone inhibited by 39.7%. Similarly, the mixture of RNase H plus ODN suppressed reporter gene expression by 35.8%, while RNase H alone failed to inhibit at all. ODN alone did show substantial inhibition

as expected, but less than that produced by conjugate. The mixture of RNase H and ODN did not show any additional effect above that of ODN alone, confirming the importance of the linkage of the 2 components to obtain increased efficiency. A control conjugate coupled to ODN (HBV) did not suppress the reporter gene expression (Figure 7A), or control cells lacking HCV sequences were not inhibited by the HCV conjugate (Figure 7B), confirm-

**Figure 6.** Effect of concentration of RNase H-ODN (HCV) conjugates and controls on the reporter HCV-luciferase activity at 24 h. Cells were harvested at 24 h after treatment. Assays using Huh-7/CMV-NCRC $\Delta$  luc cells. Data represent means  $\pm$  SD ( $n = 4$ ). Each experiment was performed in duplicate.  $p$  values are shown over each set of bars.

**Figure 7.** Assays using control cell lines and control conjugate coupled to HCV irrelevant ODN. (A) A control study using an ODN specific for HBV related sequence on Huh-7/CMV-NCRC $\Delta$  luc cells. (B) Huh-7/CMV-luc cells that contain luciferase, but lack HCV sequences, (left) and HepG2 2.2.15 cells (right) that both lack HCV and luciferase sequences. Data represent means  $\pm$  SD ( $n = 4$ ). Each experiment was performed in duplicate.  $p$  values are shown over each set of bars.

ing that the observed inhibition was not due to nonspecific effects. At  $0.15 \mu\text{M}$ , the conjugate suppressed reporter luciferase activity by only 6% in control Huh-7/CMV-luc cells (Figure 8), while at  $0.3 \mu\text{M}$ , twice the maximal effective dose, it caused considerable suppression by 18% (data not shown), suggesting nonspecific effects at the higher concentration. At  $0.15 \mu\text{M}$ , only RNase H-ODN (HCV) conjugate, but not ODN (HCV) alone, produced significant suppression at 6 and 12 h.

These results indicated that the suppression of HCV-luciferase expression was due to the presence of RNase H-ODN (HCV) conjugate. Inhibition of reporter gene activity by RNase H-ODN (HCV) conjugate was significantly greater than treatment with ODN (HCV) alone and had no evidence of nonspecific effects on expression of an unrelated gene.

## DISCUSSION

*E. coli* RNase H1 has been extensively studied regarding three-dimensional structure (30), and amino acid residues which are involved in catalytic and substrate-binding sites have been determined (8, 31). On the basis of the information, Kanaya et al. developed a mutant RNase H-conjugate having all cysteine residues replaced with alanine residues, and a newly introduced Cys-135. This cysteine was covalently linked to ODN resulting in sequence-specific RNA cleavage by the RNase H-ODN conjugate (32, 33). Ma et al. developed another mutant, C63S/C133A-RNase H, in which Cys-13 was available for the cross-linking with 5'-amino modified ODN. This mutant RNase H had 90% RNA cleavage activity compared to the wild-type RNase H. After the covalent linkage at Cys-13 with a mouse  $\beta$ -globin-specific 8-mer

**Figure 8.** Time course of the reporter HCV-luciferase activity in the presence of RNase H–ODN (HCV) conjugates and controls. Cells were treated with 0.8  $\mu$ g (0.15  $\mu$ M) conjugate or 0.15  $\mu$ M of each material and harvested at indicated time after transfection. Data represent means  $\pm$  SD ( $n = 4$ ). Each experiment was performed in duplicate.  $p$  values are shown over each set of bars.

antisense-ODN, they showed successful sequence-specific cleavage of murine  $\beta$ -globin mRNA in vitro. In their study, only 0.3% of original nonspecific cleavage activity was retained (25). We used the same mutant C63S/C133A-RNase H for conjugation of ODN against HCV. In our in vitro cleavage assay, the cleavage of target HCV RNA transcript in the presence of conjugate produced fragments consistent with sequence-specific recognition of the antisense ODN and RNA cleavage function by RNase H. Consistent with the previous report that the RNase H activity was decreased by the conjugation with ODN in vitro, our results showed that conjugate was less active than a combination of RNase H and ODN in test tube studies. The decrease of RNase H cleavage activity when conjugated to ODN may be due to change of exposure of active site residues to the target RNA by attachment of ODN to the enzyme in tertiary structure (25, 26, 32). Our results also confirmed  $Mg^{2+}$  dependency of the conjugate activity consistent with known properties of *E. coli* RNase H1 alone (2, 26).

Zabner et al. showed that COS cells took up approximately 60% of the fluorescence-labeled DNA added after 6 h exposure using cationic lipid. They also suggested that gold-labeled DNA was internalized by endocytosis (34). Intracellular ODN that had been introduced directly to the cytoplasm by microinjection was found to be eliminated gradually with time (35). However, in a pharmacokinetic study using polycationic lipid mediated delivery, the cell-associated amount of radiolabeled phosphorothioate ODN was found to increase up to 6 h (36), an observation that is consistent with our results. In contrast, Shi et al. showed that the cellular accumulation of phosphorothioate ODN increased up to 24 h. The difference may be due to different cell lines or labeling with FITC (37). In contrast to ODN alone, internalized RNase H–ODN conjugate was constant through 48 h. This may be due to decreased susceptibility of ODN to nuclease degradation when present in the form of a conjugate to RNase H. Our data further suggest that  $^{32}P$ -labeled RNase H–ODN conjugate had a higher accumulation over time compared to  $^{125}I$ -labeled conjugate and likely represents differences in the sum of uptake, degradation, and elimination of the 2 labeled forms in the cells. Our results also demonstrated that

the accumulation of RNase H–ODN conjugate was nearly twice as great as RNase H alone.

The expression level of two classes of RNase H, RNase H1 and H2, in mammalian cells is very low, and the enzyme is primarily localized in the nucleus (38, 39). Thus, RNA–ODN heteroduplexes are candidates for cleavage by RNase H, mostly in the nucleus. Because HCV replication occurs in the cytoplasm (40), it is reasonable to deliver an RNase H-antisense conjugate into the cytoplasm to inhibit HCV gene expression.

In conclusion, we have synthesized an RNase H–ODN conjugate which has substantial cleavage activity in vitro. When introduced into a liver-derived cell line, it resulted in specific suppression of HCV-directed marker gene expression and thus may be a useful tool in studying structure and function relationships of HCV RNA inside living cells.

Tumor-targeted drug delivery is an attractive strategy in cancer treatment. We have previously reported a paclitaxel model conjugate using a bombesin receptor-recognizing peptide in which the drug cytotoxicity against H1299 human nonsmall cell lung cancer was enhanced compared to unconjugated taxol. In an effort to expand the development of tumor-recognizing taxanes, paclitaxel (PTX, taxol) was conjugated to the *anti*-epidermal growth factor receptor (*anti*-EGFR) monoclonal antibody (MAb) Erbitux (C225) to serve as a model MAb-mediated drug delivery compound. Thus, paclitaxel was derivatized at its 2'-hydroxy function by introduction of a succinate linker, and the carboxyl group of the latter was covalently attached to C225 through amide bond formation. The final product conjugate (PTXC225) was analyzed mass spectrometrically for assessment of the drug-to-antibody ratios. Cytotoxicity screening of the drug-antibody conjugate against A431, UM-SCC-1, and UM-SCC-6 cells indicated an enhancement in cytotoxic effect of paclitaxel as compared to those of the free drug, the intact antibody, and a physical mixture of the two (*the controls*). In A431 cells, the conjugate showed  $25.2\% \pm 2.2\%$  of apoptosis induction as compared to little or no apoptosis caused by the controls. Biodistribution analysis of the PTXC225 in tumor-implanted nude mice and a tyrosine-kinase assay showed that conjugation of the drug did not interfere with the immunoreactivity of the antibody. The 24-h tumor uptake of C225 and PTXC225 were  $11.7\% \pm 6.0\%$  and  $7.1\% \pm 3.6\%$  of the injected dose per gram of tissue (%ID/g), respectively, which were not significantly different. Also, in A431-implanted nude mice, the conjugate and C225 showed tumor growth inhibition effects of 57.2% and 41.2%, respectively, against a saline-treated control, which were not significantly different from each other. This lack of difference in the *in vivo* antitumor activity of the MAb-delivered drug and free PTX may be due to either a relatively low dose of the antibody-delivered drug (346  $\mu\text{g/kg}$ ), or an untimely release of it, or both. The tumor growth inhibition pattern of the conjugate, however, was identical to that of C225, indicating that the attachment of PTX did not affect the antigen-binding and growth inhibitory features of the MAb. These preliminary results demonstrate the potential of tumor-targeted delivery of taxol as a promising strategy in cancer treatment and warrant further work to develop more suitable drug–MAb linkers as well as improved dosage and treatment protocols.

## INTRODUCTION

Although a powerful and important modality in cancer treatment, the effectiveness of chemotherapy is limited by the efficiency of the delivery of the drug to the tumor site(s), systemic toxicity, and side-effects of the agents used. The delicate balance between the toxicity and side-effects prevention, and producing the maximum therapeutic efficacy, is usually hard to achieve and requires long and tedious protocol development procedures which may jeopardize patient survival and quality of life. Development of antitumor drug delivery systems capable of tipping this balance in favor of a positive outcome of the therapy without worsening the side-effects would be highly desirable.

A potential strategy in achieving this goal may be drug delivery through a tumor-specific mechanism (1–3). Targeted treatment of neoplastic disease has advanced considerably in the last two decades, after the establishment of monoclonal antibody (MAb)<sup>2</sup> technology by Kohler and Milstein (4). An early realization of this technology was in the development of radiolabeled Mabs, which have reached clinical use for imaging and therapy

(5, 6), with some still under study for future clinical applications (7). Drug-MAb conjugates have also been studied in cancer therapy, albeit to a lesser extent, and the field is still open to much improvement (8, 9). Conjugates of the widely used anticancer drug doxorubicin have been reported (8–12) in attempts to both ameliorate the significant toxicities of this drug and to enhance its efficacy. Hamann and co-workers have reported conjugates of the antitumor antibiotic calicheamicin with the anti-CD33 MAb P67.6 for treatment of acute myeloid leukemia (13, 14).

After our initial report on the synthesis and in vitro cytotoxicity evaluation of the first taxol-MAb conjugate (15), Correa and Pagé (16), and Guillemard and Saragovi (17), reported preparation and cell growth inhibition studies of PTX-BCM43/2E5 conjugate, and PTX-MC192 and PTX-5C3 conjugates, respectively. The latter report also included an in vivo tumor growth inhibition experiment for one conjugate (PTX-MC192). With the exception of two time-points and only in one cell line, the  $IC_{50}$  values of Correa and Pagé were close to or higher than those of free paclitaxel. In the other report, enhancement in cytotoxicity of roughly 26–33% against B104 rat neuroblastoma cells, with respect to free paclitaxel, were reported with only 9% improvement in in vivo tumor inhibition in a nude mice model bearing sc B104 xenografts (17).

The interest to develop tumor-targeting drug-MAB conjugates stems from a duality in character of most antitumor agents, that is, the ability to eradicate cancer cells and toxicity to normal tissue. Despite their potential and an impressive clinical record, taxane drugs also suffer from dose-limiting toxicities. An added drawback of the native taxol is its extremely low aqueous solubility, a mere 0.25 mg/mL. This has led to the currently used Taxol formulation (Bristol-Myers Squibb, Princeton, NJ) of this drug consisting of 30 mg of PTX in 5 mL of a 50/50 mixture of Cremophore EL (polyethoxylated castor oil, a solubilizing surfactant) and dehydrated ethanol, which yields a homogeneous parenteral preparation. Likewise, the clinical formulation of docetaxel (Taxotere, Rhone-Poulenc Rorer, Collegeville, PA) uses polysorbate 80 and 13% ethanol in water. Both formulations have been reported to cause medium to severe hypersensitivity reactions (HSRs). Cremophore EL has been reported to cause histamine release resulting in severe allergic reactions (18, 19). In fact, the early clinical trials of taxol were delayed due to the HSRs until an effective premedication regimen was developed (20). Because of these problems, the National Cancer Institute recommended a 24-h infusion protocol for taxol before which time the patient was premedicated with antiallergy drugs. In addition to HSRs, some major side effects are associated with the use of taxanes (21–25). A peripheral neuropathy is induced by PTX, which becomes more severe by cumulative dosing, and an arthralgia-myalgia syndrome resulting 2–5 days after administration of taxol which is more pronounced with shorter infusion schedules (26). Other systemic toxicities include cardiac arrhythmias, alopecia, mucositis, and fatigue (20). Skin and nail toxicities such as onycholysis, dermatitis, and reactive erythema (27, 28) and cardiac conduction disturbances (29) are among other side effects resulting from the toxicities of this drug. Research on the design and development of water-soluble and tumor-specific taxane drugs, which could be formulated without the use of allergenic excipients and possess higher therapeutic indices without increasing the effective dose, is therefore well justified.

We have reported the first PTXMAb and PTX-peptide conjugates designed for tumor-targeted delivery of this agent and have demonstrated the enhanced cytotoxic properties of the drug in controlled in vitro experiments (15, 30, 31). Here, we report accounts of synthesis, cytotoxicity, apoptosis induction, biodistribution, and a preliminary antitumor activity evaluation of a PTXMAb conjugate using the human-mouse chimeric anti-EGFR antibody C225 (32, 33).

## EXPERIMENTAL SECTION

**General Procedure for the Synthesis of PTXMAb Conjugates.** Paclitaxel (Hande Tech, Houston, TX) was derivatized according to the procedure of Deutsch et al., by succinic anhydride in pyridine, to paclitaxel-2'-succinate (PTXSX) (34). The carboxyl function of the PTXSX (2 mg, 2.1  $\mu$ mol) was activated by the addition of NHS (0.27 mg, 2.3  $\mu$ mol) and EEDQ (0.52 mg, 2.1  $\mu$ mol) in dry DMF (250  $\mu$ L) and at 0 °C for 1 h. The DMF solution of the activated ester (15.5  $\mu$ L, containing 0.13  $\mu$ mol of PTXNHS) was then added to a precooled (0 °C) solution of C225 (2 mg, 0.013  $\mu$ mol) in 600  $\mu$ L of PBS (25 mM, pH 8.1). The solution was stirred at this temperature for 1 h at which time the reaction progress was confirmed by MALDI-TOF MS and using BSA as a MW calibrator. The conjugate was purified by dialysis in DPBS (4  $\times$  2 L) at a MW cutoff of 50 kDa. The protein content of all samples were measured by the method of Lowry (35). The PTXC225 conjugates used in this work had a drug-to-MAb molar ratio of 1.6 or 2 by MALDI. In the following in vitro and in vivo experiments, the molar concentrations of the unconjugated PTX and C225 controls were adjusted according to these ratios as indicated.

**Tumor Cell Lines.** A431 human epidermoid cancer cells were obtained from the American Type Culture Collection (Manassas, VA). The A431 cell line was maintained in Dulbecco's modified Eagle's medium (DMEM): F12 (50:50) containing 7% FBS. The head and neck squamous cell carcinoma lines (UM-SCC-1 and UM-SCC-6) were maintained in DMEM containing 10% FBS. All cell lines were supplemented with L-glutamine, penicillin, and streptomycin and incubated at 37 °C in 5% CO<sub>2</sub>. The UM-SCC-1 and UM-SCC-6 lines were provided by Dr. Thomas Carey (University of Michigan).

**Assessment of EGFR Recognition and Receptor Phosphorylation.** A431 cells were plated in six-well plates at a density of 100 000 cells/well and allowed to grow for 48 h. The cells were treated with 1  $\mu$ g/mL each of C225 or PTXC225 conjugate for 24 h, after which time they were exposed to 10 nM EGF (Sigma Chemical Co., St. Louis, MO) for 5 min. Cell lysates were collected in lysis buffer (0.025 M Tris-HCl, pH 7.5, 0.25 M NaCl, 0.005 M EDTA, 1% (v/v) NP-40, 0.001 M phenylmethylsulfonyl fluoride, 2  $\mu$ g/mL aprotinin, 2  $\mu$ g/mL leupeptin, 0.001 M sodium orthovanadate, 0.05 M sodium fluoride and 0.03 M sodium pyrophosphate, as described previously (36). Equal amounts of protein (5  $\mu$ g) were loaded per lane and separated by 10% SDS-PAGE and transferred to Immobilon-P membrane (Millipore Corp., Bedford, MA).

The immunoblots were blocked in 10% milk/Tris-buffered saline with Tween-20 (TBS-T) (20 mM Tris-HCl, pH 7.5, 137 mM NaCl, 0.05% Tween-20) for 1 h at room temperature. The membrane was incubated with the primary antibody, anti-EGFR (Sigma Chemical Co.), or anti-phosphotyrosine (Santa Cruz Biotechnology Inc, Santa Cruz, CA) in 3% milk/TBS-T overnight at 4 °C.

The secondary *anti*-mouse IgG-HRP antibody (Sigma Chemical Co.) was incubated with the membrane at room temperature for 1 h. The blots were developed by chemiluminescence (Amersham Life Sciences Inc, Arlington Heights, IL).

**In Vitro Cell Proliferation Assay.** The cells were plated in 24-well plates at a density of 10 000 cells/well and allowed to grow for 48 h, at which time (day 0) the cells were treated with C225 (3.2 nM), PTX (6.4 nM), C225 (3.2 nM) + PTX (6.4 nM), or PTXC225 conjugate (3.2 nM for a PTX:Mab of 2) for 24 h. The treatments were removed on day 1 and were replaced with drug-free medium. The cells were counted on day 4 and normalized to the percent of untreated cells. Each treatment was done in quadruplicate.

**Apoptosis-Induction Assay.** An Annexin V-FITC Apoptosis Detection kit (BioVision, Inc., Palo Alto, CA) was used to examine the induction of apoptosis. A431 cells were plated at a density of 40 000 cells per well in six-well plates. After 24 h, fresh culture medium was added to the appropriate wells containing the following agents: C225 (3.2 nM), PTX (6.4 nM), C225 (3.2 nM) + taxol (6.4 nM), or PTXC225 conjugate (3.2 nM for a PTX:C225 of 2). At 24 h posttreatment, the agents were removed and replaced with drug-free medium. The cells were collected 72 h later according to the manufacturer's protocol. Briefly, the trypsinized cells were pooled with the corresponding culture medium containing nonadherent cells. The cells were separated from the medium by centrifugation at 300*g* for 5 min. The cell pellets were suspended in 500  $\mu$ L ice-cold 1 $\times$  binding buffer. Annexin V FITC and propidium iodide were added to the cell suspension followed by a 10 min incubation at room temperature in the dark. The cells were collected by flow cytometry and analyzed by CellQuest v3.1 software (Becton Dickinson, San Jose, CA), and results are presented as percent average cell count  $\pm$  SD. All treatments were done in triplicate.

**<sup>125</sup>I-Labeling.** A standard iodogen radiolabeling method was used (37). Briefly, 10 mg of iodogen was dissolved in 1 mL of chloroform and 5 mL of this solution was dispensed into a vial containing a polystyrene bead. The bead was then dried under an argon flow. Sodium [<sup>125</sup>I]-iodide (5 mCi/bead) was added, followed by 5 $\times$  (v/v) of a pH 6 phosphate buffer. The C225 or PTXC225 was added, and the mixture was incubated for 15 min. The labeled MAb was purified on a PD-10 column (Pharmacia, Uppsala, Sweden) eluted with 0.1% HSA in DPBS.

**Animal Model.** Athymic nude female *nu/nu* mice with a BALB/c background were obtained from the National Cancer Institute Frederick Research Laboratory (Frederick, MD) and were kept under sterile conditions. Procedures to minimize discomfort, pain, and distress were in accord with the Animal Resource Program at the University of Alabama at Birmingham, accredited by the American Association for Accreditation of Laboratory Animal Care. The A431 cells were harvested and suspended in sterile PBS at a concentration of  $7.5 \times 10^8$  viable cells/mL. Cell viability was determined by trypan blue dye exclusion. Viable cells ( $10^7$ ) in sterile PBS were injected sc into the right flank.

**Biodistribution of C225 and PTXC225.** Groups of mice (six per group) with established 7-day sc tumors received 5  $\mu$ Ci of the labeled antibody or conjugate as an iv bolus injection. At 4 and 24 h postinjection, the animals were exsanguinated after anesthesia and dissected. Samples of blood, heart, lung, liver, stomach, small intestine, spleen, kidney, skin, bone, muscle, uterus,

**Figure 1.** Schematic representation of a PTXMAB conjugate in which the linkage is through the 2'-hydroxy group of the drug.

#### Scheme 1

pancreas, and tumor were blotted dry, weighed, and counted for the uptake of radioactivity in a well-type gamma counter (Minaxi-gamma 5000 series, Packard, Chicago, IL). Results of biodistribution were expressed as mean  $\pm$  SD % ID/g (percent injected dose per gram of tissue) at 4 and 24 h postinjection.

**In Vivo Tumor Growth Inhibition Study.** Athymic nude female mice ( $n = 6$ , *nu/nu*, 19–22 g body weight) were implanted sc with A431 cells ( $5 \times 10^6$ ) on the right flank. At day 10, tumors were measured by vernier calipers, and tumor volumes were calculated and mice were sorted into three groups, evenly distributing tumors by volume size. The animals were injected ip with saline, C225 (894  $\mu$ g), and the PTXC225 (894  $\mu$ g) conjugate with a PTX:Mab of 1.6 (8.05  $\mu$ g PTX). Tumor sizes were monitored and increases in fractional tumor volumes (FTVs) were calculated from the following equation:

$$\text{FTV} = \text{Vol}_{\text{dn}} / \text{Vol}_{\text{d1}}$$

where  $\text{Vol}_{\text{dn}}$  and  $\text{Vol}_{\text{d1}}$  are volumes at days  $n$  and 1, respectively.

**Statistical Methods.** The %ID/g values were compared between the group with injection of C225 antibody and the group injected with the PTXC225. Group difference may indicate there exists interaction of C225 and PTX. Two sample  $t$  tests were used to detect the difference (38). If both groups have substantially different percentage of dose/gram, the  $p$  value produced by the  $t$  test will be small ( $<0.05$ ). The summary statistics of change in tumor size from baseline by group and assessment day are provided. Furthermore, regression analysis was utilized to compare the trend in change of tumor size relative to the baseline (i.e., initial time) tumor size across time.

All statistical analyses were carried out using Statistical Analysis System, version 6.12 (38).

## RESULTS

**Synthesis of the Model PTX–C225 Conjugate.** The conjugates of PTX with C225 (Figure 1) were prepared by derivatizing the 2'-hydroxy function of the drug with succinic anhydride, according to the procedure of Deutch (Scheme 1) (34). The activated PTX was coupled to the MAb using NHS and EEDQ at a basic pH (Scheme 2).

Scheme 2

To develop a standard protocol for the conjugation reaction, the yields of product recovery and the number of substituted drugs per C225 (the PTX:Mab ratio) under different activation and coupling times, reactants molar ratios, buffers, and also at two different temperatures (0 °C and 25 °C) were studied. Molecular weight measurements and determination of the PTX:Mab ratio were carried out by MALDI-TOF MS. A typical increase in the MW of the MAb as a result of PTX conjugation is shown in Figure 2. The conjugate of Figure 2 (not used in this work) shows a measured molecular weight increase of 2925 Da by MALDI MS which refers to a PTX:C225 ratio of 3 using the equation of footnote a, Table 1. Reaction conditions and the experimentally measured drug-to-antibody molar ratios (PTX:C225) are shown in Table 1.

**Drug Cytotoxicity Studies.** To evaluate the effect of antibody attachment on the cytotoxicity of PTX, the conjugates were screened against three different cell lines: A human epidermoid carcinoma, A431, and two human head-and-neck carcinomas, UM-SCC1 and UM-SCC6. Each assay used the molar concentrations of antibody-conjugated drug, calculated from the MALDI-TOF MS analyses, and used this value to determine molar concentrations of the unconjugated drug, the C225, and their mixture.

**A431 Cell Line.** The C225 antibody is characterized as having the ability to block the ligand binding site of the EGFR, and thereby, blocking EGF-induced receptor tyrosine phosphorylation. Immunoblot analysis was performed to ensure that PTX conjugated to C225 antibody had no detrimental effect on its ability to bind to the EGF receptor. The A431 cells were treated with 1  $\mu$ g/mL concentrations of either the C225 or the PTXC225

**Table 1. Experimental<sup>a</sup> PTX:C225 Molar Ratios (MRs) for PTXC225 Conjugates Prepared at Different Reactant Molar Ratios and in Two Different Buffer Systems**

reaction	PTXSX:C225 <sup>b</sup>	MR (PBS) <sup>c</sup>	MR (carb) <sup>d</sup>
1	1:1	0	0
2	5:1	1.2 $\pm$ 0.6	0
3	10:1	2.2 $\pm$ 0.2	1.1 $\pm$ 0.3
4	20:1	4.5 $\pm$ 1.1	2.7 $\pm$ 1.7

<sup>a</sup> Measured from  $MR = \frac{MW_{conjugate} - MW_{C225}}{MW_{PTXSX}}$  using MALDI-measured MWs. <sup>b</sup> Reactant molar ratios. <sup>c</sup> Phosphate-buffered saline, 25 mM, pH 8.1. <sup>d</sup> Carbonate buffer, 25 mM, pH 9.1.

conjugate for 24 h prior to EGF stimulation. Cell lysates were separated by SDS-PAGE and probed with *anti*-EGFR or *anti*-phosphotyrosine antibodies. Both the unconjugated C225 and PTXC225 prevented the phosphorylation of EGFRs as shown in Figure 3.

For the cytotoxicity screening, the cells were treated separately with equimolar amounts of the drug, the C225, the mixture of the two, and the PTXC225 conjugate, and the percent survival of the cells for each treatment was determined by counting the posttreatment populations. The percent cell survival of each treatment, as a measure of cytotoxicity, were  $81.0 \pm 3.5$ ,  $87.0 \pm 11.0$ ,  $68.0 \pm 8.0$ , and  $30.0 \pm 0.58$ , for paclitaxel, C225, the mixture, and the PTXC225 conjugate, respectively (Figure 4a).

**SCC1 and SCC6 Cell Lines.** This experiments was carried out to test the conjugate against other EGFR-positive cell lines. Squamous head-and-neck SCC1 and SCC6 cells were used in the screening assays through the same protocol as for A431 cells above. In SCC1 cells percent survival rates of  $78.0 \pm 9.5$ ,  $89.0 \pm 5.5$ ,  $64.0 \pm 6.5$ , and  $37.0 \pm 3.5$ , for PTX, C225, the mixture, and the PTXC225, respectively, were obtained as shown in Figure 4b. In SCC6 cells percent survival rates of  $76.0 \pm 8.5$ ,  $93.0 \pm 4.9$ ,  $73.0 \pm 5.8$ , and  $46.0 \pm 4.5$  were observed for the same order of treatment (Figure 4c).

**Apoptosis Induction Studies.** The apoptotic activity of the conjugated drug in A431 cells, both at mole-corrected fixed concentrations of the conjugate and PTX,

**Figure 2.** MALDI-TOF MS of C225 (B) and PTXC225 conjugate (C). The increase in the MW confirms addition of the drug. Numbers shown refer to the center of the peaks. BSA (MW 66 kDa) was used as a MW calibrator. Peaks A and D are the doubly charged molecular ions displaying the half-MWs of B and C, respectively.

**Figure 3.** Inhibition of EGFR kinase activity. (a) A 24-h exposure of A431 cells to C225 or PTXC225 did not alter the EGFR protein levels. (b) EGF-activated EGF tyrosine kinase activity was similarly reduced by both C225 and PTXC225. The cells were treated with C225 and PTXC225, followed by treatment with either *anti*-EGFR (a) or *anti*-phosphotyrosine (b) antibodies. Antibody-free cells were used as controls. Sample cells were treated with equimolar concentrations of C225 and PTXC225.

and at increasing concentrations of the latter, were investigated. The constant-concentration experiment evaluated the effect of 3.3 nM each of C225 and the conjugate, 6.6 nM of the unconjugated PTX, and a mixture of C225+PTX (3.3 nM and 6.6 nM, respectively, for a PTX:C225 of 2). Induction of apoptosis was observed by PTXC225 in  $25\% \pm 2.2\%$  of the cells. As shown in Figure 5a, little or no enhancement in apoptosis induction was noted by the unconjugated PTX, the C225, or their mixture. The variable-concentration assay showed approximately 16.5 nM of the free drug was needed to induce apoptosis to a similar extent as did the PTXC225 conjugate at 3.2 nM (Figure 5b).

**Biodistribution Studies.** To assess the effect of conjugation and the presence of the drug moiety on the C225 tumor and normal tissue uptake, the biodistribution of the  $^{125}\text{I}$ -labeled conjugate ( $^{125}\text{I}$ -PTXC225) was compared to that of the  $^{125}\text{I}$ -C225. Radioiodination of both proteins through a standard protocol (37) afforded the labeled molecules as evidenced by radio-detected size-exclusion HPLC. The labeled MAb and the conjugate were injected iv into athymic nude mice carrying sc A431 xenografts, tissues were removed at 4 and 24 h postinjection, and the radioactivity uptake, in %ID/g (Figure 6) were measured. For both C225 and PTXC225, the normal tissue uptake decreased from 4 to 24 h while tumor uptake increases. The tumor concentrations of  $^{125}\text{I}$ -C225 was  $7.0 \pm 2.1$  and  $11.7 \pm 6.0$  at 4 and 24 h after injection, while the corresponding values for  $^{125}\text{I}$ -PTXC225 were  $6.3 \pm 1.8$  and  $7.1 \pm 3.6$ . The tumor %ID/g values for the conjugate and C225 were not significantly different ( $p$  values of 0.563 and 0.131, for 4 and 24 h, respectively). The blood concentrations of  $^{125}\text{I}$ -C225 were  $28.7 \pm 2.8$  and  $15.7 \pm 4.1$  at 4 and 24 h after injections, and the corresponding values for  $^{125}\text{I}$ -PTXC225 were  $20.8 \pm 2.9$  and  $10.8 \pm 2.4$ .

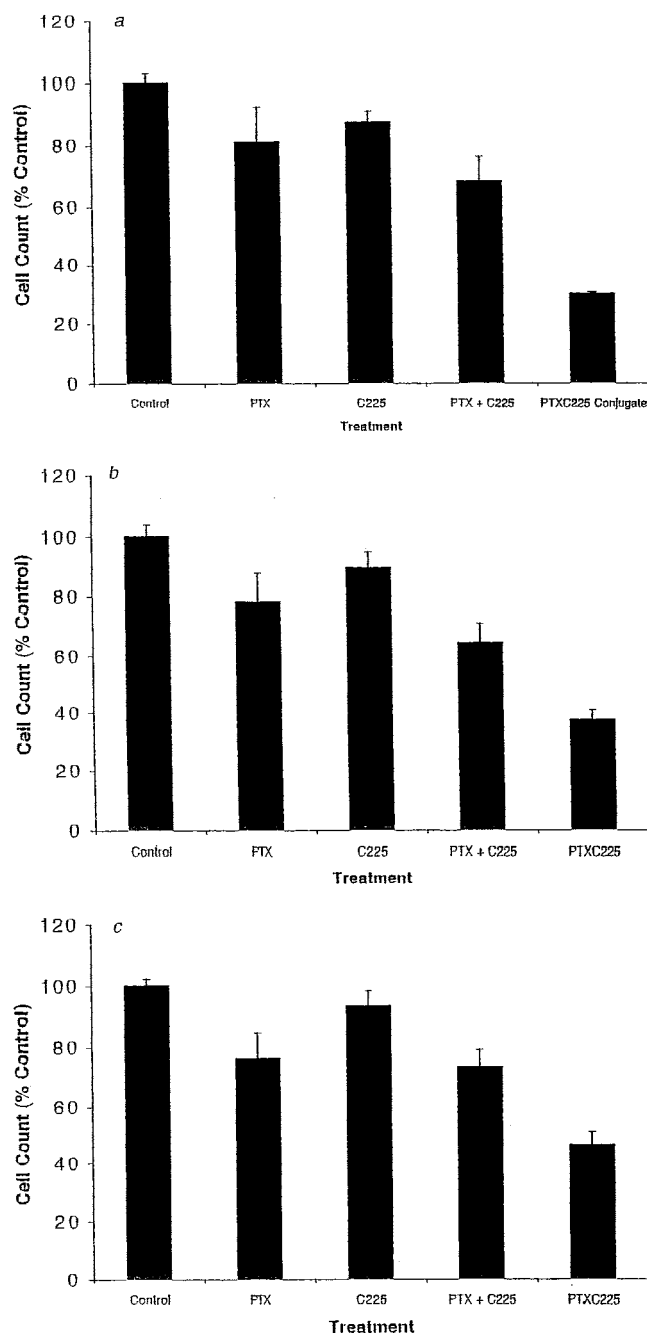

**Tumor Growth Inhibition Studies.** The tumor-inhibiting effect of the PTXC225 conjugate was examined in two groups of athymic nude female mice, implanted sc with A431 cells. The mice were treated with a single ip injection of saline, C225, or PTXC225 at equimolar amounts, and the tumor growth was monitored daily as shown in Figure 7. The summary statistics of change in tumor size from baseline by group and assessment day

are shown in Table 2. The trend in time for mean tumor size change in Group 1 was significantly larger than Group 3 ( $p = 0.0155$ ), but Group 2 was not significantly different from Group 3 ( $p = 0.720$ ).

## DISCUSSION

We report here a tumor-specific method of delivery of paclitaxel through covalent conjugation of the drug to a monoclonal antibody. The *anti*-EGFR MAb C225 used in this work is internalized into the cells after binding to EGFRs (39). We rationalized, therefore, that this clinically relevant MAb would be a suitable model in this study for internally delivering the drug which acts through a mitosis-directed mechanism. This conjugation also resulted in solubilization of the paclitaxel nucleus which suffers from an extremely low aqueous solubility ( $\approx 0.25$  mg/mL). It was found that conjugation of up to two PTX molecules per antibody keeps the drug completely solubilized in aqueous media at antibody concentrations usually used for in vitro and in vivo experiments. During the development of this work, we used conjugate solutions within a concentration range of 0.25–2.2 mg/mL. More recently, we have prepared completely soluble PTXC225 batches for therapy experiments in animal models with conjugate concentrations of up to 10 mg/mL (Safavy, A., unpublished results). Taxol solubility, however, seemed to be limited by the drug-to-antibody ratio, as a conjugate with a PTX:MAb ratio of more than 3, usually resulted in either immediate or delayed precipitation of the protein. On the other hand, a 2:1 molar ratio seemed to be sufficient for effective cell killing as demonstrated by the in vitro cytotoxicity experiments.

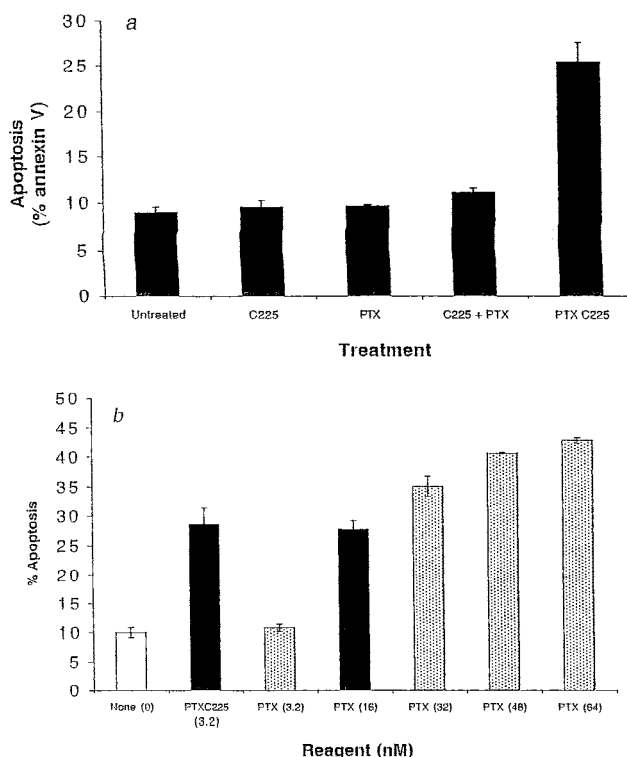

Because of reasons not clear at this time, the coupling of PTXSX to nucleophilic groups, such as amines, seemed to involve a highly reagent-selective mechanism. We examined several coupling reagents routinely used in peptide synthesis for amide bond formation (40), including DCC, DCC/HOBT, HBTU, BOP, and EEDQ, to couple this drug to the antibody. For each reagent, a two-step coupling reaction was carried out in which PTXSX was first activated and then added to C225 in basic buffer. The progress and the extent of the reaction were followed by MALDI MS (Figure 2), which from works reported

**Figure 4.** Inhibition of cell proliferation in (a) A431, (b) SCC-1, and (c) SCC-6. The cells were treated for 24 h with equimolar concentrations of PTX, C225, PTX + C225, and PTXC225. All cells were counted on day 4. Inhibition is represented as a measure of percent survival normalized against the untreated population. Each graph depicts three to four independent experiments done in quadruplicate with the mean  $\pm$  SEM plotted.

previously by our (41) and other (42) laboratories, is well established as a powerful, reliable, and most importantly, direct tool for the assessment of and monitoring reactions to attach small molecules to antibodies and other large proteins. With the exception of EEDQ, we could not detect a MW increase for C225 with any of the above coupling reagents. Since, at this time, only synthesis and biological evaluation of the PTXC225 were of interest, no in-depth mechanistic studies were carried out to uncover the reason for this observation at a molecular level.

Temperature did not seem to have any significant effect on the outcome of the PBS reaction. In the pH 9.1 carbonate, only small MW increases were observed

**Figure 5.** Induction of apoptosis by PTXC225. (a) Human A431 cells were treated with equimolar concentrations of PTX, C225, PTX+C225, and the PTXC225 for 24 h and analyzed on day 3. (b) To determine the approximate concentration of PTX which induces the same level of apoptosis as PTXC225, increasing concentrations of PTX were compared to a constant dose of PTXC225 within the same time frame as in part a.

probably due to a fast decomposition of the PTX activated ester. The maximum increase in the MW occurred within 1 h from addition of the activated PTXSX and a longer reaction time did not have any effect on the extent of drug substitution.

On the basis of these observations, PTXSX-C225 coupling reactions in PBS (pH 8.1) and carbonate (pH 9.1) buffers, and at four PTXSX:C225 molar ratios, were studied (Table 1). When carried out at 0 °C and for 1 h, the 10:1 conjugation (Reaction 3, Table 1) showed a suitable drug-to-antibody ratio ( $2.2 \pm 0.2$ ). The criteria for selection of standard conditions (suitability) was based on the retention of the solubility of the antibody and preservation of its original antigen-binding properties. Later experiments determined that Reaction 3 (Table 1) could meet these criteria.

The physical identification of the drug–MAB conjugate is of critical importance, as an error in the measurement of the drug:MAB ratio will create errors in the calculation of the applied in vitro and in vivo doses, resulting in turn, in further complications such as low therapeutic indices or high toxicities. To this end, application of a direct method of measurement will have obvious advantages (42).

MALDI MS is a tool for direct MW analysis which yields a clear measure of substituent-to-MAB (S:A) ratio in real time (43) and has been used in the conjugation of small molecules to antibodies. In the development of a protocol for covalent attachment of unprotected hydroxamic acids to antibodies, we reported the application of this technique to optimize the reaction conditions and directly determine the S:A for the bifunctional chelating agent, trisuccin (41). Siegel et al. have used MALDI MS

**Figure 6.** Biodistribution of C225 (■) and PTXC225 (□) in nude mice bearing sc A431 xenografts. Bars show the uptake of each organ in %ID/g for  $^{125}\text{I}$ -C225 and  $^{125}\text{I}$ -PTXC225 at (a) 4 h, and (b) 24 h postinjection. Each tissue is abbreviated as follows: Blood, BL; heart, HT; lung, LU; liver, LI; stomach, ST; small intestine, SI; spleen, SP; kidney, KD; skin, SK; bone, BN; muscle, MU; uterus, UT; pancreas, PA; tumor, TU.

**Figure 7.** Tumor growth inhibition by a single injection of C225 and the PTXC225 conjugate. Female nude mice with sc A431 implants were given ip injections of saline, C225, or PTXC225 at a mg/kg body weight of 38.9 for C225 and 0.32 for PTX. Tumor sizes were monitored daily.

to determine the carbohydrate content as well as the S:A for metal chelators and anticancer drugs mitoxantrone, calicheamicin, and doxorubicin (42). It was shown in the present work also that MALDI MS was an unambiguous and efficient technique to evaluate the conditions for PTX-C225 conjugation and to directly measure the PTX:C225 ratios.

The efficiency of a drug-MAb conjugate in targeted drug delivery is, among other factors, determined by the preservation of antigen recognition of the MAb. The fact that the PTXC225 conjugate prepared by this method induced EGFR phosphorylation in A431 cells (Figure 3) and showed biodistribution patterns similar to that of

**Table 2.** Summary Statistics of Relative Change from Baseline for Tumor Size

group	day 3	day 7	day 10
1, saline ( $n = 6$ )	$0.8(\pm 0.3)^{ab}$	$2.1(\pm 0.6)$	$3.1(\pm 0.7)$
2, C225 ( $n = 6$ )	$0.5(\pm 0.2)$	$0.7(\pm 0.3)$	$0.9(\pm 0.3)$
3, PTXC225 ( $n = 5$ )	$0.5(\pm 0.1)$	$0.9(\pm 0.1)$	$1.0(\pm 0.1)$

<sup>a</sup> Entries refer to mean( $\pm$ standard error). <sup>b</sup> At day 3 for saline group, the summary statistics are based on  $n = 7$ .

the unconjugated C225 (Figures 6a and 6b) demonstrated that conjugation of up to two molecules of PTX per MAb did not affect the antibody-antigen binding site and that the conjugate was still capable of targeting PTX to EGFR-overexpressing tumors.

The in vitro cell proliferation of conjugated taxol was enhanced compared to the free drug. The fact that the enhancement in efficacy was due to a targeted delivery mechanism, and not from a synergistic interaction between paclitaxel and the MAb, was demonstrated by inclusion of a mixture of unconjugated paclitaxel and C225 which showed 56%, 42%, and 37% less growth inhibition against A431, SCC1, and SCC6 cells, respectively (Figures 4a-c).

Induction of apoptosis has been reported for taxanes and is another important feature of these drugs (44). It was demonstrated that the apoptosis-inducing effect of PTX is amplified by the antibody-mediated delivery of the drug whereas the unconjugated PTX, the C225, or their mixture, induced apoptosis in a negligibly small fraction of the cells (Figure 5a). Furthermore, to estimate the concentration of the free drug to produce the same apoptotic effect, a variable-concentration assay was also carried out. This experiment demonstrated that about a 5-fold molar increase in the concentration of PTX was required to induce apoptosis to the same extent as did the PTXC225 conjugate (Figure 5b).

As mentioned above, an important issue in the design of any tumor-directed drug conjugate is preservation of the receptor-recognizing ability of the targeting moiety and the effect of the drug conjugation on the in vivo biodistribution pattern of the molecule. These are important variables as a reduced receptor affinity will result in therapeutically insignificant tumor localization of the drug. At the same time, an impaired receptor recognition of the conjugate may increase the possibility of high normal tissue uptake, and thereby, high systemic toxicity.

To comply with these considerations, the biodistribution of radiolabeled C225 and PTXC225, in mice implanted sc with A431 cells, were studied at two time points (4 and 24 h). The conjugate displayed the same tissue uptake pattern as did C225, indicating that the chemistry of conjugation and the attachment of PTX to the MAb molecule did not significantly alter the biodistribution of the antibody (Figure 6).

The growth of A431 subcutaneous tumors was inhibited by both C225 and the conjugate (Figure 7). On day 10 postinjection the C225-treated mice (group 2) showed a growth inhibition of 41.2%, as compared to the saline-treated control (group 1), whereas the PTXC225-treated mice (group 3) showed an inhibition of 57%. Although growth inhibition induced by the conjugate was significant against the control group ( $p = 0.015$ ), it was not significantly different from that of the C225 group ( $p = 0.720$ ). Since the in vitro results clearly show an advantage for the antibody-mediated delivery of PTX, the lack of a significant difference between C225 and the conjugate in the in vivo model may be explained by either an insufficient dose of the drug, or an untimely release of

it, or both. It is also important to note that the equivalent dosage of PTX in the conjugate was only 346  $\mu\text{g}$  per kg of body weight which was administered in one single injection. This amount is far less than the usual therapeutic dosage ( $\approx 40$ –200 mg/kg) of other conjugates of this drug which are not tumor-directed (45–48). Furthermore, based on our earlier results, the succinate ester used here to link the PTX nucleus to C225, was anticipated to have suitable drug release kinetics; a PTX–PEG–peptide conjugate had shown a drug release half-life of about 113 min at 37 °C and in the presence of human plasma (30). It is possible, however, that this half-life is not long enough to survive the tumor localization time of C225. That is, by the time the PTXC225 conjugate, with a relatively large molecular weight, is localized in the tumor, a significant portion of the drug will have been already cleaved and lost. To this end, new linkers with expected improved release features have been designed and are under investigation. At this time, the tumor growth inhibition results reinforce those of the cytotoxicity and biodistribution experiments, in that the covalent attachment of PTX to the antibody does not remove its tumor binding and cytotoxicity properties.

The work reported in this article demonstrates the potential of tumor-directed drug delivery for the important taxane drugs, represented here by paclitaxel, and warrants further research toward the improvement of these conjugates. Such a strategy may imply the following benefits for this treatment modality: (1) Specific, therefore more efficient, delivery of the drug to primary, as well as micrometastatic tumors, (2) reduction of the administered doses due to the tumor-specific drug delivery, and thereby, lowering drug toxicity and side effects, (3) elimination of allergenic surfactants and excipients used in the current clinical formulations of taxanes, (4) a high-impact first-line therapy through targeted delivery of PTX may reduce the chances of drug resistance formation, spread of metastases, and side effects resulting from prolonged exposure of the patient to the drug, and (5) more economic formulation of the taxane drugs due to a lowered effective dose.

#### ACKNOWLEDGMENT

Assistance of the Department of Radiation Oncology, UAB, in the form of a Seed Grant is acknowledged. We would also like to thank Lori Coward and Marion Kirk (UAB Comprehensive Cancer Center Mass Spectroscopy Shared Facility) for their assistance in MW determinations. The assistance of Susanne H. Randall (tumor growth experiments) and Soneshia McMillan (manuscript preparation) are also acknowledged.

#### NOTE ADDED AFTER ASAP POSTING

The version of this paper posted January 28, 2003, had corrections omitted. These corrections are as follows: The contributing departments from the University of Alabama at Birmingham are the Departments of Radiation Oncology and Surgery. The value on line 13 of the abstract is  $25.2 \pm 2.2\%$ . The abbreviation for standard deviation of the mean is SDM. In the Experimental Section, under Animal Model, the number of viable cells is  $10^7$ . Also in the Experimental Section, under In Vivo Tumor Growth Inhibition Study, the units are micrograms: C225 (894  $\mu\text{g}$ ), PTXC225 (894  $\mu\text{g}$ ), (8.05  $\mu\text{g}$  PTX). In the caption of Figure 7, line 4, PTXC225 is actually PTX. On the same page, last paragraph, the text is changed to "...Figure 7). On day 10 postinjection, the C225-treated...". In Literature Cited, the authors of

reference 4 are Kohler, G., and Milstein, C. In reference 37, the compound name in the title is 1,3,4,6-tetrachloro-3 $\alpha$ ,6 $\alpha$ -diphenylglycouril. The corrected version of this paper was posted on February 5, 2003.

# Nanoparticulate DNA Packaging Using Terpolymers of Poly(lysine-*g*-(lactide-*b*-ethylene glycol))

Susan Park<sup>†,‡</sup> and Kevin E. Healy<sup>\*,†</sup>

University of California at Berkeley, Departments of Bioengineering and Materials Science and Engineering, 459 Evans Hall, Berkeley, California 94720-1762, and Northwestern University, Department of Biomedical Engineering, McCormick School of Engineering and Applied Science, 2145 Sheridan Rd., Tech E310, Evanston, Illinois 60208. Received October 8, 2002; Revised Manuscript Received January 9, 2003

Terpolymers of poly(lysine-*g*-(lactide-*b*-ethylene glycol)) (pK-pLL-pEG) were synthesized by using ring-opening polymerization and functional end-group grafting. Synthesis was characterized with gel permeation chromatography, proton nuclear magnetic resonance spectroscopy, and a trinitrobenzene sulfonic acid binding assay. Polymer association behavior with DNA was investigated using an ethidium bromide exclusion assay, static light scattering, and scanning electron microscopy. Polylactide molecular weight was varied to investigate its impact on DNA association and resulting complex characteristics. Polylysine ( $M_w = 8800$ , DP = 42) modified with either 7400 or 10 870  $M_w$  pLL-pEG reduced the minimum amount of primary amines necessary for complete condensation by 23% and 48%, respectively, compared to unmodified polylysine (pK42). Complexes formed with the highest molecular weight terpolymer demonstrated significantly ( $p < 0.1$ ) greater resistance to DNase I than lyophilized pK42-DNA particles. This study suggests that modification of pK42 with pLL-pEG diblock copolymers impacts polylysine's associative and binding behavior to DNA and resulting particle characteristics. Modulation of terpolymer composition in complexes can enable control over intracellular plasmid dissociation rates to improve transfection efficiency.

## INTRODUCTION

Gene therapy is one field that has exploited spontaneous polycation assembly with DNA as an alternative to packaging plasmids within either viral vectors or liposomes. Some of these systems include those based on polyamidoamines (dendrimer), polyacrylates, polyamino acids, and polyethyleneimine (1–4). Recent investigations have found that the gross morphology of condensates is surprisingly insensitive to large variances in polymer microarchitecture as well as DNA size, within 400 to 1 million base pairs (1, 5, 6). However, there is some evidence that polycation associative behavior can vary according to the form of DNA present (7). Free DNA that has a hydrodynamic radius on the order of microns can be condensed into complexes by highly branched polymers (e.g., polyethyleneimine) as well as more simple multivalent cations (e.g.,  $\text{Co}(\text{NH}_3)_6^{3+}$ ). The resulting particles are consistently on the order of 50–300 nm in diameter and can often appear as torroids, rods, and large aggregates; however, the predominance of each is affected by condensation parameters as well as polymer composition (1, 8).

The type of polycation used can have a dramatic effect on cytotoxicity, cellular response, and intracellular trafficking of the complexes (9–11). Two polymers that have generated the most publications in the literature are polyethyleneimine (pEI) and polylysine (pK). Polyethyleneimine is a polymer that can be found in linear or in hyperbranched form. The latter contains 1°, 2°, and 3° amines at a respective ratio of 1:2:1. The different  $pK_a$ 's

of the amines on branched pEI give it an usually high buffering capacity across a wide pH range as well as the ability to effectively condense DNA employing its protonated amines (1). Both forms of pEI have been shown to exhibit high levels of transfection (4, 11–14). It has been hypothesized that pEI's high transfection efficiency can be attributed to its large buffering capacity that neutralizes lysosomal pH and induces lysis via the resulting change in ionic osmolarity (14, 15). Unfortunately, pEI's membrane permeabilizing ability has raised concern about its cytotoxicity under conditions necessary for transfection (16, 17). Even though pEI is considerably less toxic when associated with DNA, it is not degradable, and its intracellular fate, as well as any other long-term implications on normal cellular transcriptive processes, is not yet known.

Polylysine (pK) is a polyamino acid that possesses side chains with terminal amines, which are protonated at physiological pH. It is an attractive option for gene therapy techniques since it is synthesized from a non-cytotoxic, naturally occurring monomer. The molecular weight of pK has some effect on particle diameter, with the smallest pK (DP = 19) forming particles of about 30 nm in diameter and the largest (DP = 1075) forming complexes about 120–300 nm (18). However, time-resolved static light scattering investigation of high molecular weight pK-DNA complexes revealed that they can aggregate into supramolecular particles of several micrometers in diameter (19). Furthermore, the molecular weight of polylysine used can have a significant effect on cell toxicity, transfection efficiency, and biodistribution (20).

The tenacity of electrostatic association between DNA and polycations should be considered when developing synthetic vectors for gene therapy. It has been shown that

<sup>‡</sup> Northwestern University.

increasing pK molecular weight interfered with in vitro RNA transcription and was associated with a decrease in plasmid unpackaging rates as well as a protracted reporter expression (21, 22). In addition, higher transfection efficiencies were observed when 40% of the  $\epsilon$ -amines on pK were neutralized with sugar residues when compared to unsubstituted pK (23, 24).

Overall, pK has been shown to be a less effective transfection vehicle compared to PEI. Observations on intracellular trafficking of pK-plasmid complexes indicate that they are sequestered into endosomes and nuclear localization is not as prevalent when compared to complexes formed with PEI (9, 21). However, functionalization of pK with targeting ligands that induce receptor-mediated endocytosis can improve transfection efficiency significantly (22, 25, 26). In addition, reporter expression levels can be increased dramatically by conjugating fusogenic peptides derived from virus glycoproteins. These pH responsive peptides undergo a conformational change in acidic pH and then can disrupt lysosomal membranes (27–29). Other agents that combat endosomal degradation, such as chloroquine or hemolytic polymers, can be added to abet transfection (2, 30).

Block or graft copolymers have also been investigated with respect to their interaction with DNA and have often employed hydrophilic moieties to disguise complexes from recognition and subsequent sequestration by the reticuloendothelial system. When poly(ethylene glycol) (pEG) was bound to various polycations, the resulting complexes demonstrated improved colloidal stability and extended in vivo circulation lifetimes (17, 25, 31–34). The benefit of coupling pEG is not only due to greater particle hydrophilicity, but also diminished protein adsorption that activates phagocytosis.

To address some of the aforementioned issues, we have developed a polylysine-based ( $M_w = 8800$ , DP = 42) terpolymer grafted with diblock polymer components. A terminal pEG segment ( $M_w = 3400$ ) was employed to improve complex stability as well as to provide end-group functionality for conjugation of bioactive molecules, such as targeting ligands and fusogenic peptides that increase transfection specificity and efficiency. The intermediate segment of our terpolymer is a hydrolytically labile poly-L-lactide (pLL) block, which is intended to aid in protection of DNA from intracellular degradation as well as to promote premature DNA condensation through hydrophobic interactions. We hypothesize that a reduction in the amount of lysine moieties required for complete condensation will increase the rate of DNA unpackaging that is necessary for plasmid transcription. DNA release will also be contingent on the rate of pLL degradation and could possibly enable tailoring of transfection profiles by modulating the molecular weight of the pLL and/or pK segments. This investigation focuses on the synthesis and characterization of pK-pLL-pEG terpolymers as well as its interaction with plasmid DNA. The molecular weight of the pLL segment was varied to assess its impact on terpolymer association and complex characteristics.

## MATERIALS AND METHODS

A heterofunctional poly(ethylene glycol) ( $\text{NH}_2$ -pEG-OH,  $M_w = 3400$ ) bearing a terminal amino and hydroxyl group was purchased from Shearwater Corporation (Huntsville, AL). All other chemicals were purchased from Sigma-Aldrich (St. Louis, MO) and were used as received unless otherwise noted. The DNA used was

supercoiled  $\Phi$ X174 RF DNA (5386 bp) from Promega (Madison, WI).

**PEG Functionalization.** The amino end of 3400  $M_w$   $\text{NH}_2$ -pEG-OH was protected by reaction with a 6 molar excess of *N*-(9-fluorenylmethoxycarbonyloxy)succinimide (osu-fmoc) in dioxane for 4 h. The resulting fmoc-pEG was purified by repeated precipitation into cold ether until the characteristic succinimidyl proton peak at 2.82 ppm (in  $\text{CDCl}_3$ ) was undetectable by proton nuclear magnetic resonance spectroscopy ( $^1\text{H}$  NMR, Bruker AMX300). Percent substitution was calculated using the ratio of the fmoc doublet at 7.88–7.90 ppm with respect to the pEG peak at 3.63 ppm (in  $\text{CDCl}_3$ ). The polymer was dried under vacuum overnight.

**Diblock Copolymer Synthesis and Characterization.** L-Lactide was purified by recrystallization from toluene and dried under vacuum for 1 h immediately before use. A 0.5M stock solution of stannous octoate in anhydrous toluene was prepared and used at a constant lactide monomer:initiator ratio (M/I) of 300. The L-lactide and fmoc-pEG were reacted at monomer:hydroxyl (M/OH) ratios of 40 and 75 to control pLL molecular weight. To produce the diblock copolymer of lowest molecular weight, a M/OH of 75 was used and the reaction stopped after 2 h. A 20% w/v solution of the above reactants in anhydrous toluene was prepared in a sealed reaction vessel in a dry nitrogen atmosphere. Polymerization of L-lactide proceeded under refluxing toluene at 100 °C under a gentle flow of dry nitrogen for 6 h. The copolymer (pLL-pEG-fmoc) was purified by repeated dissolution in dioxane and precipitation into cold ether. Molecular weight characterization by size exclusion chromatography with multiangle laser light scattering (SEC-MALLS) was performed using an Agilent 1100 HPLC with 2 Polymer Laboratories mixed E columns in series and methylene chloride as the mobile phase. The detectors used included a multi-angle light scattering detector, refractive interferometer (Wyatt Technology Corporation, Santa Barbara, CA) and a photodiode array detector (Agilent Technologies, Mountainview, CA). The  $dn/dc$  values for each copolymer in methylene chloride were determined experimentally using a refractive interferometer (Wyatt). For comparison, proton nuclear magnetic resonance spectroscopy ( $^1\text{H}$  NMR) was also used to calculate molecular weight by using the known molecular weight of pEG as an internal standard.

The hydroxyl on the polylactide end of the diblock copolymer was then functionalized to be amine reactive (su-pLL-pEG-fmoc). Disuccinimidyl carbonate (DSC) (0.5M) and 4-dimethyl aminopyridine (DMAP) (0.5M) at a 6 molar excess in anhydrous dimethylformamide was added to the copolymer dissolved in anhydrous dioxane. The solution was stirred for 6 h under a dry nitrogen atmosphere and purified by precipitation into cold ether until the aromatic DMAP protons (in  $\text{CDCl}_3$ ) at 6.45 and 8.20 ppm disappeared. Percent substitution was calculated using the ratio of the reappeared succinimidyl peak area at 2.82 ppm to that of pEG at 3.63 ppm (in  $\text{CDCl}_3$ ).

**Terpolymer Synthesis and Characterization.** The terpolymer of poly(lysine-*g*-(lactide-*b*-ethylene glycol)) was synthesized by coupling of su-pLL-pEG-fmoc to the  $\epsilon$ -amines on poly-L-lysine (pK) ( $M_w = 8800$ , DP 42) at a 1:1 molar ratio in dimethyl sulfoxide. The nomenclature for the resulting terpolymers is pK42-Xk, where pK with a degree of polymerization of 42 has been grafted to a pLL-pEG diblock copolymer with a combined molecular weight of approximately X000.

Proton NMR in DMSO- $d_6$  was used to determine the amount of pK present in each terpolymer. For comparison, a binding assay using trinitrobenzyl sulfonic acid (TNBS) was performed using a modified standard protocol (35). In short, the copolymer was dissolved in DMSO (1 or 2 mg/mL) and reacted with an excess of TNBS in an overall reaction solution of 75% DMSO and 25% sodium bicarbonate buffer (pH 8.5). The reaction was performed at 37 °C for 1 h, after which 6M HCl was immediately added. The solution absorbance was then read at 436 nm and the amount of  $\epsilon$ -amines per milligram of polymer was calculated using a calibration curve made with known amounts of pK42.

**Particle Formation and Characterization.** *Complex Formation.* Complexes were formed by adding a pK or pK–pLL–pEG in DMSO to approximately 5  $\mu$ g of DNA in ultrapure water (UPW, 18 M $\Omega$  cm) in Teflon vials. The total volume of DMSO used was kept below 10% v/v to minimize solvent effects on condensation (8). After 20 min, an additional volume of water was added, and the solutions were lyophilized. Complexes were resuspended in UPW for further characterization unless otherwise noted.

*Degree of Condensation.* Ethidium bromide (EB) was used as an indicator of condensation since it becomes intensely fluorescent upon intercalating with free DNA but cannot bind to condensed DNA (36). Particles were made and resuspended as described above, mixed with 1mM EB, and read in a black 96 well plate using a microplate fluorimeter (Molecular Devices, Sunnyvale, CA) (ex: 339 nm, em: 610 nm, cutoff: 515 nm). The autofluorescence of free EB was subtracted from each sample value and then normalized to the maximum fluorescence obtained for DNA with no polymer added. DNA condensation was considered to be complete when the percent relative fluorescence units (RFU) reached background levels.

*Determination of complex apparent  $M_w^*$  and  $r_g^*$ .* Static light scattering of complexes was performed using a multiangle light scattering detector (Wyatt) in microbatch mode to assess particle apparent molecular weight ( $M_w^*$ ) and apparent radius of gyration ( $r_g^*$ ). The UPW mobile phase was filtered with 0.02  $\mu$ m syringe filters, and light scattering measurements were obtained every 2 s using a flow rate of 0.2 mL/min. Sample dilutions were carefully made by weight, and the final concentration was considered to be the total amount of DNA plus polymer. The data used for analysis was limited to that from seven low-angle detectors (36–90°), since these low angles are the most critical to obtain the apparent molecular weight and  $r_g^*$  of complexes. The lowest measurable angles at 14° and 26° were excluded since low-angle detectors were the most sensitive to contaminating particles and were easily saturated. Samples were run in triplicate, and each run produced at least 20 data points. Only those data with a Debye fit of less than 10% error were used for further analysis. Complexes were also visualized by cold field emission scanning electron microscopy (Hitachi S-5000) using an accelerating voltage of 5kV. Samples were prepared by depositing drops of resuspended particles onto silicon wafers, freeze-drying and coating with 8–10 nm of carbon.

*Resistance to DNase Degradation.* The ability of particles to resist degradation by bovine pancreatic DNase I was assessed by agarose gel electrophoresis. Particles were made as described above except at a 5-fold increase in concentration and then evenly aliquoted into microvials before lyophilization. Dulbecco's complete phosphate buffered saline (PBS, Gibco BRL) was used for

# Scheme 1. Synthesis of pK–pLL–pEG Terpolymers

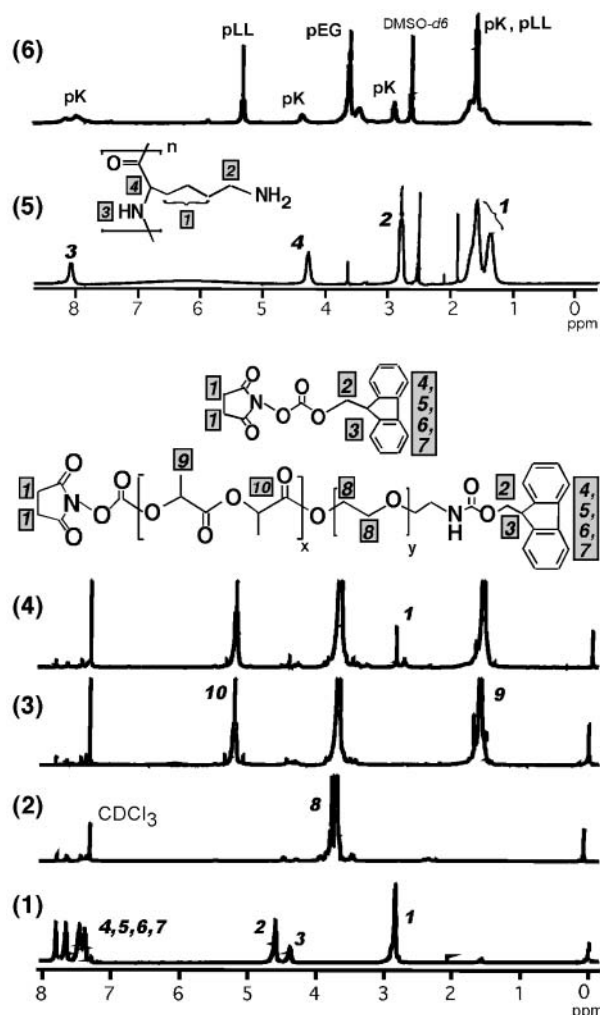

resuspension, and 2.5 units of DNase I (Pharmacia, Piscataway, NJ) were added for varying amounts of time. The reaction was stopped with 2 or 3  $\mu$ L of 6N NaOH/0.5M EDTA and run on a 0.8% agarose gel for 40 min at 4.0V/cm. The running buffer was an alkaline 20mM tris-acetate solution with 1mM EDTA (pH 12). The DNA was visualized by staining with 0.5 $\mu$ g/mL ethidium bromide in 1X TAE buffer for 20 min and subsequent destaining for 15 min. The gels were then stained with 0.1% Coomassie Brilliant Blue in UPW, methanol, glacial acetic acid (5:4:1 v/v/v) for 4 min and destained overnight in a solution mixed at a ratio of 15:4:1, respectively. Scanalytics gel analysis software was used on digital gel images to determine the extent of DNA degradation for each well. Since DNA concentration is proportional to fluorescence intensity, the amount of intact DNA was considered to be the intensity area that did not migrate past the negative control (0 min.). The value was then normalized to the total intensity in the lane (intact + degraded) in order to compensate for unavoidable fluctuations in sample loading concentration.

## RESULTS

**Synthesis Characterization.** The synthesis is depicted in Scheme 1, and its progression and purification

**Figure 1.** Representative proton nuclear magnetic resonance spectra of pK42-7k used to monitor the progression, purification and degree of end-group substitution after each reaction step. Spectra 1-6 correspond to the molecules numbered in Scheme 1. Peak shifts for spectra 1-4 ( $\text{CDCl}_3$ ): 1, 2.82 (s, 4H); 2, 4.56 (d, 2H); 3, 4.33 (t, 1H); 4, 7.77 (d, 2H); 5, 7.62 (d, 2H); 6, 7.42 (t, 2H); 7, 7.35 (t, 2H); 8, 3.63 (s, 4H); 9, 1.56 (d, 3H); 10, 5.13 (q, 1H). Peak shifts for spectrum 5 ( $\text{DMSO}-d_6$ ): 1, 1.56 (s, 4H) & 1.33 (s, 2H); 2, 2.76 (s, 2H); 3, 8.05 (d, 1H); 4, 4.25 (s, 1H).

was monitored primarily by proton NMR characterization after each step (Figure 1). The characteristic proton peaks for osu-fmoc are shown in spectrum 1, and after coupling to the terminal amine of  $\text{NH}_2\text{-pEG-OH}$ , the characteristic ether peak appeared at 3.63 ppm (spectrum 2, peak #8). The disappearance of the succinimidyl peak at 2.82 ppm indicated that unreacted osu-fmoc was removed and the degree of fmoc substitution on pEG was assessed to be above 85% (data not shown). Varying the lactide monomer:pEG hydroxyl ratio for ring opening polymerization or the reaction time easily enabled control over the pLL segment length. Lactide polymerization was indicated by shifts in its methine (from 5.02 to 5.13 ppm) and methyl (from 1.62 to 1.56 ppm) groups (spectrum 3). Succinimidyl functionalization of pLL-pEG-fmoc resulted in the reappearance of a peak at 2.82 ppm (spectrum 4, peak #1). Spectra of the final terpolymer after grafting su-pLL-pEG to pK revealed all relevant peaks after purification (spectrum 6).

There was good corroboration between molecular weight data obtained by  $^1\text{H}$  NMR using the known molecular weight of pEG as an internal standard and SEC-MALLS

**Figure 2.** Cold field emission scanning electron microscopy on complexes coated with  $\sim 10$  nm carbon. Complexes were made at an amine to phosphate charge ratio (N:P) of 1.0. The scale bars equal 500 nm in all images.

**Table 1. Diblock Mw Results**

pLL-pEG	$^1\text{H}$ NMR (g/mol)	MALLS (g/mol)	PDI
5k	3692	5800	1.02
7k	7648	7628	1.02
11k	11094	10440	1.06

**Table 2.  $1^\circ$  Amine Content and Ethidium Bromide Assay Results**

	$\mu\text{mol NH}_2/\text{mg polymer}$ [% subst]		
	TNBS	$^1\text{N}$ NMR	N:P <sub>min</sub>
pK42	—	—	0.81
pK42-5k	$3.55 \pm 0.20$	3.20 [1.8%]	0.91
pK42-7k	$1.99 \pm 0.15$	1.81 [4.3%]	0.62
pK42-11k	$1.00 \pm 0.09$	1.05 [6.7%]	0.42

(Table 1). Polydispersity indices for all pLL-pEG diblocks were below 1.1, and a peak corresponding to unreacted pEG-fmoc was not revealed by any of the three detectors (data not shown). The TNBS binding assay, developed to determine the amount of amines present in the pK-pLL-pEG terpolymer, agreed very well with data obtained with  $^1\text{H}$  NMR (Table 2). Results from  $^1\text{H}$  NMR were used to calculate the amount of amines added for all subsequent DNA condensation experiments.

**Minimum Amine:Phosphate Charge Ratio Determination.** The progression of DNA condensation was studied by measuring the relative EB fluorescence. The minimum polymer amine:DNA phosphate charge ratio (N:P<sub>min</sub>) necessary for complete condensation is summarized in Table 2. Polylysine (pK42) was able to condense DNA at a N:P<sub>min</sub> of 0.81, while pK42-5k required a slightly higher N:P<sub>min</sub> of 0.91. However, when larger pLL segments were present in pK42-7k and pK42-11k, the N:P<sub>min</sub> decreased substantially to 0.62 and 0.42, respectively. Scanning electron micrographs revealed heterogeneous submicron complexes where the population size varied between 50 and 500 nm (Figure 2). The carbon coating did not seem to severely obstruct morphology since samples with thinner ( $\sim 1$  nm) platinum coatings showed similar images with a backscattering detector (not shown).

**Static Light Scattering of Complexes.** Static light scattering investigation of complexes provided information about the apparent  $M_w^*$  and radius of gyration ( $r_g^*$ ) by measuring the excess Rayleigh ratio ( $R_e$ ) values

**Figure 3.** A representative Debye fit to static light scattering data used to calculate apparent  $M_w^*$  and  $r_g^*$  of complexes. This plot is for pK42–11k complexes (N:P = 0.5) where  $M_w^* = (1.216 \pm 0.064) \times 10^6$  g/mol and  $r_g^* = 112.5 \pm 9.3$  nm.

scattered from particle solutions and fitting a second-order Debye curve at zero concentration limits according to the following relation:

$$\frac{R_\theta}{K^*c} = M_w P(\theta) \quad (1)$$

where

$$K^* = \frac{4\pi^2 n^2 \left(\frac{dn}{dc}\right)^2}{\lambda^4 N_A}$$

The particle scattering function,  $P(\theta)$ , is defined by

$$P(\theta) = 1 - \alpha_1 \left(\frac{4\pi}{\lambda} \sin \theta/2\right)^2 + \alpha_2 \left(\frac{4\pi}{\lambda} \sin \theta/2\right)^4 - \dots \quad (2)$$

where the coefficient  $\alpha_x$  is proportional to  $\int r^{2x} dM$  and is relevant to particle shape. The root-mean-square radius ( $\langle r_g^2 \rangle$  or rms) of the molecule can be derived from

$$\langle r_g^2 \rangle = 3\alpha_1$$

The concentration ( $c$ ) and angle of measurement ( $\theta$ ) are known parameters, while  $K^*$  contains constants for incident light wavelength ( $\lambda$ ), solvent refractive index ( $n$ ) and Avogadro's number ( $N_A$ ). The refractive index increment ( $dn/dc$ ) for each component in UPW was measured experimentally, except for pLL, which was estimated to have a  $dn/dc$  value approximately equal to that of pEG due to their similar indices of refraction (data not shown). The overall  $dn/dc$  values for particles of varying compositions were calculated using the relation:  $dn/dc_{\text{total}} = \sum x_i (dn/dc)_i$  where  $x_i$  denotes the weight percent of species  $i$ . When eq 1 is plotted as  $R_\theta/K^*c$  versus  $\sin^2(\theta/2)$ , the molecular weight ( $M_w$  or  $M_w^*$ ) can be calculated by extrapolation of the curve to zero angle, and the radius of gyration ( $r_g$  or  $r_g^*$ ) is determined by the initial slope. Figure 3 illustrates a typical Debye plot for pK42–11k (N:P = 0.5) used to determine the apparent  $M_w^*$  and  $r_g^*$ .

Analysis of the naked  $\Phi$ X174 plasmid resulted in values of 135 nm for  $r_g^*$  and  $3.57 \times 10^6$  D for  $M_w^*$ , which agreed extremely well with the theoretical value of  $3.55 \times 10^6$  D when using the common conversion of  $6.6 \times 10^5$  D = 1 kbp (37). Particles made with pK42 showed an order of magnitude increase in apparent  $M_w^*$  at low charge ratios (Figure 4a). When condensation was complete, as indicated by the accompanying EB curve (% RFU), the apparent  $M_w^*$  decreased dramatically. Values for  $r_g^*$  generally remained stable despite the fact that a decrease was expected. Particles made with each of the terpolymers did not show as extreme an increase in

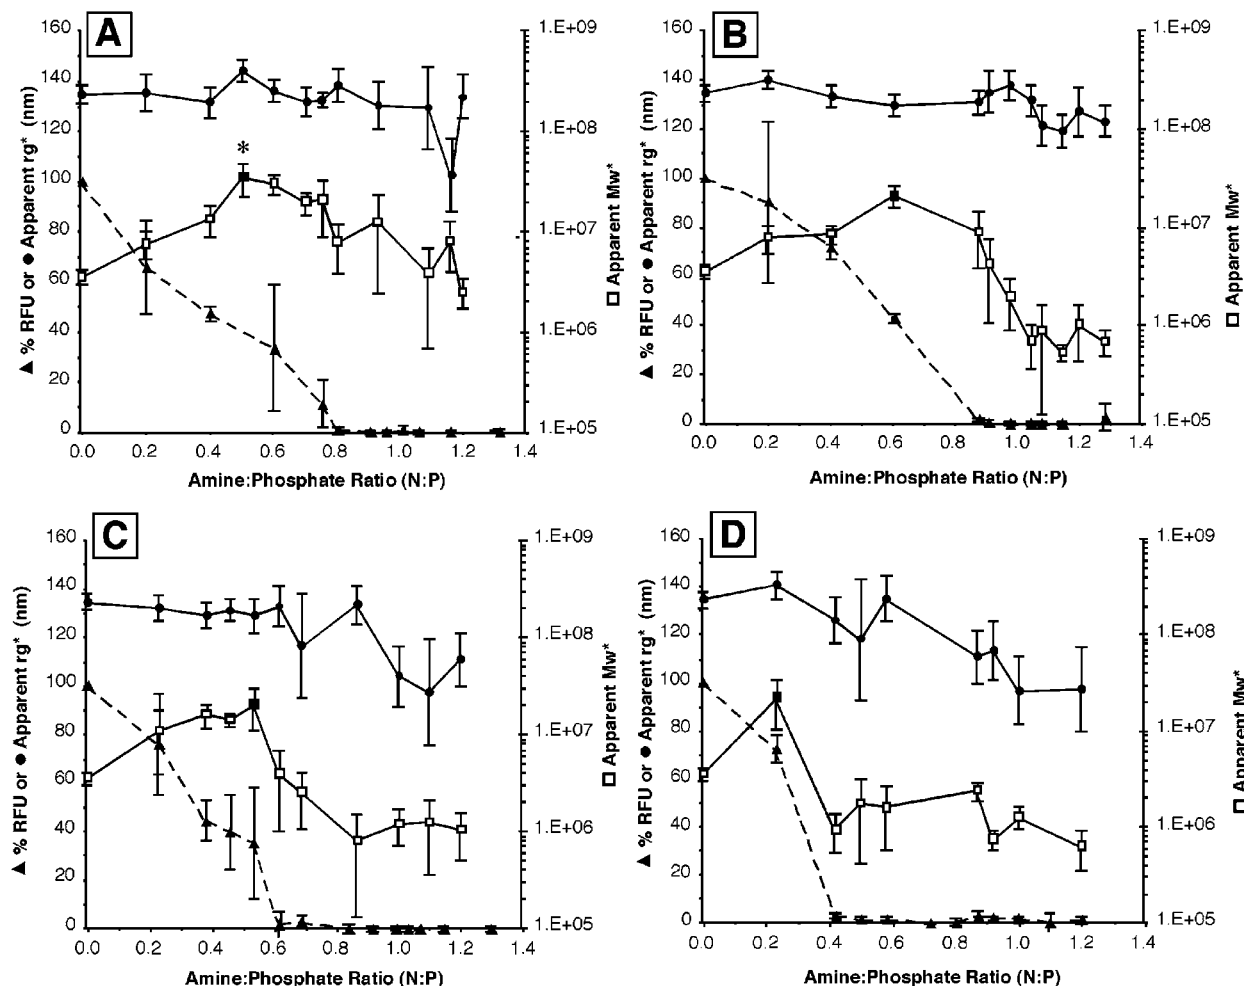

apparent  $M_w^*$  at N:P < N:P<sub>min</sub>, but showed similar overall trends with respect to the relative degree of condensation (Figure 4b–d). At charge ratios greater than N:P<sub>min</sub>, the  $M_w^*$  for each of the three terpolymers decreased more significantly than seen for pK42 and stabilized at approximately  $1 \times 10^6$  g/mol. Only complexes made with pK42–7k and pK42–11k displayed the expected decrease in  $r_g^*$  when DNA condensation was complete ( $p < 0.001$  at N:P = 1.2, ANOVA, Tukey HSD). The SEM images supported that there were many particles on the order of less than 100 nm; however, the large variance in the  $r_g^*$  is the result of heterogeneity in the particle size distribution.

**Degradation by DNase I.** Figure 5 shows the electrophoretic migration of free DNA and pK42–DNA complexes after exposure to DNase I and subsequent dissociation from polycations. Polymer staining with Coomassie Blue indicated that complex dissociation by NaOH was complete and maintained by the alkaline running buffer, since all staining was localized around the well, apart from the migrating DNA. At a pH of 12, the primary amines were largely deprotonated and, therefore, did not migrate toward the anode. Ethidium bromide staining of DNA revealed that simply making pK42–DNA complexes in the same manner as the triblock copolymer complexes dramatically decreased the extent of degradation by DNase I. Particles made with all pK–pLL–pEG triblock copolymers also showed improved DNA resistance to degradation over free DNA and freshly made pK42 particles (Figure 6). At 15 min, the percentage of intact DNA from particles made with the highest polylactide segment, pK42–11k, was significantly ( $p < 0.1$ , ANOVA, Tukey HSD) higher than that from similarly made (lyophilized) pK42–DNA particles.

## DISCUSSION

Ring-opening polymerization of L-lactide from poly(ethylene glycol) has been widely documented regarding the effect of monomer-to-initiator ratio as well as monomer-to-hydroxyl ratio (38–40). A survey of the literature enabled predictable control over pLL molecular weight in the terpolymer by adjusting the M/OH ratio. There was some difficulty in producing the lowest molecular weight pLL–pEG (5, 800), perhaps due to slight impurities in the system that helped consume the small amount of monomer. However, the polymerization rates were monitored as a function of reaction time (data not shown) and the desirable pLL molecular weight was obtainable simply by adjusting the stop time. Size exclusion chromatography for all copolymers revealed single peaks attributable to pLL–pEG–fmoc diblock copolymers that eluted earlier than pEG–fmoc alone, indicating that there was no unreacted pEG remaining. Polydispersities calculated by multiangle light scattering for all synthesized diblocks were below 1.1, and there was good agreement between molecular weights assessed by  $^1\text{H}$  NMR and static light scattering. Prior knowledge of the pEG molecular weight (3400) was useful in providing an internal standard for  $^1\text{H}$  NMR in calculating the degree of polymerization of other polymer segments as well as degree of substitution of functional end groups (Figure 1). In these experiments, the fmoc group limited reactivity to just the hydroxyl end of pEG during pLL polymerization. In the future, a cross-linker will be substituted for fmoc to enable conjugation of bioactive moieties to the end of the pEG chains.

The amount of pK present in each terpolymer was assessed by  $^1\text{H}$  NMR in DMSO- $d_6$  as well as indirectly

**Figure 4.** Static light scattering results of complexes made with (A) pK42, (B) pK42-5k, (C) pK42-7k, and (D) pK42-11k. The ethidium bromide fluorescence curves are overlaid as reference to correlate the degree of condensation to  $M_w^*$  and  $r_g$  trends. The peak  $M_w^*$  (indicated on each graph by the solid squares) for pK42 complexes (\*) were statistically greater than the peak  $M_w^*$  for all other samples ( $p < 0.001$ , ANOVA).

**Figure 5.** Alkaline agarose gel electrophoresis of free DNA, fresh pK42 complexes and lyophilized pK42 complexes after incubation with DNase I for varying time points. The top rows show coomassie blue staining of the dissociated polycation while the bottom rows reveal DNA stained by ethidium bromide.

by using a TNBS binding assay. A standard of pK42 was used to create the assay calibration curve since the binding efficiency was anticipated to be similar to that of the terpolymers. The amount of amines per milligram of terpolymer decreased with increasing pLL length since

**Figure 6.** Quantitative analysis of DNA degradation by DNase I. Complexes were made with pK42-5k (○), pK42-7k (□), pK42-11k (■), pK42 (▲) or pK42 without lyophilization (△) at a N:P = 1. At 15 min, degradation of fresh pK42 complexes (#) was significantly greater ( $p < 0.05$ ) than all other groups. Degradation of lyophilized pK42 complexes (\*) was significantly greater ( $p < 0.1$ ) than pK42-11k samples. ANOVA statistics and Tukey HSD post-hoc comparisons were used on triplicate samples.

the weight percent of the pLL-pEG diblock became more significant. Although pK and pLL-pEG were reacted at

1:1 molar ratios for all terpolymer synthesis, the degree of substitution increased with increasing pLL–pEG  $M_w$  possibly due to differences in purification efficiencies. The proton NMR results closely supported that from the TNBS assay (Table 2). SEC-MALLS data were not obtainable for the synthesized terpolymers due to solubility problems. Attempts at using several binary solvent mixtures resulted in very high and inconsistent  $dn/dc$  measurements due to preferential solvation of solvent components with the hydrophilic and hydrophobic polymer segments. To obtain accurate measurements, extensive dialysis and preequilibration would have been required, which could have reduced the molecular weight of the hydrolytically degradable copolymer (41, 42). The terpolymers were soluble in dimethyl sulfoxide, but aggregation and adsorption onto the column matrix occurred at the relatively high sample concentrations required for sufficient light scattering signal.

Figure 4 shows how the apparent  $M_w^*$  and apparent  $r_g^*$  changes with respect to the amine to phosphate charge ratio (N:P) can be used to characterize particle formation. For pK42, the  $M_w^*$  showed an initial dramatic increase at a N:P < 1 and decreased upon complete condensation. When there was excess DNA, each pK strand had the opportunity to interact with many DNA molecules, and the large increases in  $M_w^*$  most likely reflect that several DNA were linked together. Independent atomic force microscopy investigations have shown that partially condensed DNA on mica surfaces by spermidine, lipospermine, polyethyleneimine, and pK–pEG are multimolecular and possess centralized flowerlike conformations with highly overlapping crossover points (12, 43, 44). These observations would explain why  $r_g^*$  did not increase with corresponding  $M_w^*$  in our system. At high N:P ratios, condensation is complete and complex  $M_w^*$  decreases. For complexes made with pK42–7k and pK42–11k, a large decrease  $r_g^*$  was observed ( $p < 0.001$  between N:P = 0 and N:P = 1.2, ANOVA, Tukey HSD) despite large variances associated with those data due to the heterogeneous size population (Figure 2).

As the electrostatic repulsion is locally neutralized, other factors, including hydration, counterion, and hydrophobic forces, become more significant and are hypothesized to be the cause of complete condensation at less than electroneutral charge (45, 46). It is possible that the pLL segments of pK42–7k and pK42–11k were significant enough to aid condensation by hydrophobic interactions, as reflected in the lower N:P<sub>min</sub>. Our observations are supported by other theoretical and experimental investigations of the effect of surfactant hydrophobicity on its interaction with DNA (47, 48). In both studies, increasing the amount of hydrophobic moieties increased the surfactants' activity in associating with DNA. Corresponding analysis shows that at low N:P, the initial increase in particle  $M_w^*$  for pK42–7k and pK42–11k was not as dramatic as that for unmodified pK and was attributed to the presence of pLL and/or pEG. Since pEG is known to possess a large excluded volume, it is possible that it hindered the approach of other DNA molecules and reduced multi-molecular complex formation. In addition, if pLL participated in DNA condensation, it could have also constrained cationic counterion mobility and secondary DNA strand reorganization through hydrophobic interactions with neutralized pK and/or DNA (49, 50).

The complexes developed in this system deviated slightly from those predicted by traditional charge inversion and reentrance models (51, 52). The hydrophilic pEG

**Table 3.** Effect of Concentration Assumption on  $M_w$

	DNA+polymer ( $\times 10^{-6}$ g/mol)	DNA ( $\times 10^{-6}$ g/mol)
pK42	2.51 $\pm$ 0.80	5.13 $\pm$ 1.56
pK42–5k	1.03 $\pm$ 0.60	2.71 $\pm$ 1.36
pK42–7k	1.04 $\pm$ 0.54	3.47 $\pm$ 1.66
pK42–11k	0.64 $\pm$ 0.28	2.88 $\pm$ 1.17

segment aids in solubilizing complexes in aqueous media, thereby circumventing precipitation of charge neutralized particles. In addition, the relatively small variances in  $r_g^*$  at low N:P indicates that the polycation was distributed throughout the DNA instead of generating a mixed population of condensed and free DNA. The coexistence of condensed complexes and free DNA has been shown to be at least partially contingent on a large polycation charge density. Polyethyleneimine at low N:P ratios was shown to produce a mixed population of free and condensed DNA at a pH of 5; however, at pH 7 only partially condensed DNA was formed due to the reduced ionization of its amines (7). Another point of departure from theory was observed regarding  $M_w^*$  trends. It was expected that complex  $M_w^*$  should increase as the N:P ratio approached 1 since, electrostatic repulsion between partially neutralized DNA decreased. At N:P ratios greater than 1, excess polycation imparts a net positive charge that discourages intercomplex interactions and reduces complex  $M_w^*$ . While this trend on a similar system of pK and DNA was reported previously, our samples demonstrated a peak  $M_w^*$  at approximately  $1/2$  the N:P<sub>min</sub> instead of a N:P ratio near 1 (19).

For all complex systems, the  $M_w^*$  unexpectedly decreased below that of free DNA at high N:P ratios. This result is attributable to the fact the calculations of  $M_w^*$  and  $r_g^*$  are apparent rather than true values. At high N:P ratios, the condensing polycation is present in a large weight fraction but is small in size relative to DNA. Therefore, the assumption that sample concentration is a summation of both terpolymer and DNA overestimates sample concentrations at high N:P ratios. Equation 1 shows that  $R_\Theta$  is proportional to  $M_w^*$  and  $c$ , and if other parameters are held constant, then an overestimation in concentration would result in an artificially low  $M_w^*$  for a given  $R_\Theta$ . However, concentration did not affect calculations for  $r_g^*$  since they were determined from angle-dependent scattering and not overall light scattering signal. Table 3 illustrates this point by showing the  $M_w^*$  dependence using both concentration assumptions for each complex system at an N:P of 1.2. If it is assumed that DNA is the predominant scattering center due to its considerably larger size, then the concentration of condensing polymer is negligible with respect to its light scattering contribution (the effect on  $dn/dc$  is still considered significant), the recalculated  $M_w^*$  increases. For pK42, the difference in  $M_w^*$  is minimized, since pK42 contributes a small weight fraction. For pK42–11k, the adjustment for concentration is the largest due to the large weight fraction of pLL–pEG, which results in the largest percent increase in  $M_w^*$ . However, even after the concentration adjustment, the  $M_w^*$  of pK42 complexes remains statistically different from those made with the terpolymers ( $p < 0.001$ ). With such a system, it is difficult to definitively conclude which of the two assumptions to use for calculations. At high N:P charge ratios, the polymer contribution to the light scattering signal becomes significant and should be factored into the overall concentration in some capacity. The impact of system complexity, polydispersity, and particle inhomogeneity on other parameters, such as  $dn/dc$ , needs to be consid-

ered before specific physical interpretation can be extracted from these values (53, 54).

It has been shown that intracellular trafficking of plasmids condensed with polylysine involves endosomal compartmentalization and so plasmid degradation by nucleases is a concern (9). Condensation of DNA causes gross conformational changes that can hinder binding of nucleases, such as DNase I, whose activity is dependent on the insertion of its active loop into the minor groove. Figure 5 shows that freshly made pK42–DNA complexes slightly improve resistance to DNase I compared to naked DNA. However, lyophilized pK42–DNA complexes displayed even greater resistance to DNase I over those made and used immediately. DNase I has been shown to act as a catalyst that enables water to initiate a nucleophilic attack on the phosphodiester backbone (55). Lyophilization helped protect DNA in these complexes most likely by disrupting molecularly bound water that was not completely restored by resuspension. Since other differences in resistance to DNase I were not definitive by casual inspection of the electrophoresis gels, image analysis elucidated differences in the degree of plasmid degradation found in each lane. Figure 6 is a plot of the percentage of DNA remaining intact after various incubation times with DNase I. Complexes made with pK42–11k showed the greatest amount of intact DNA after 15 min of exposure. This observation could be the result of pLL interfering with DNase I binding either by further altering the backbone structure of condensed DNA or physically blocking binding sites. The ability of pLL to protect against nuclease degradation could extend the intracellular lifetime of plasmids and increase the likelihood of transcription. Ideally, a system can be developed where modulation over the pLL and pK molecular weights can be used to optimize DNA unpacking rates and, perhaps, temporal expression profiles. Future work will be performed in this direction using complexes functionalized with moieties for cell-specific targeting and endosomal escape.

## CONCLUSIONS

We have described the synthesis and characterization of poly(lysine-*g*-(lactide-*b*-ethylene glycol)) terpolymers that are capable of self-assembling with plasmid DNA. Static light scattering of complexed DNA was useful in characterizing differences in apparent  $M_w^*$  and  $r_g^*$  trends, which suggested that there were subtle changes in molecular association dynamics when pK was modified with pLL–pEG. In addition, terpolymers of pK–pLL–pEG demonstrated the ability to fully condense DNA at lower amine-to-phosphate ratios when compared to unmodified pK, while also improving upon pK's poor ability to protect condensed DNA from intracellular nucleases. These efforts to minimize the amount of pK necessary for complete plasmid condensation may improve transfection efficiency and reduce overall cytotoxicity.

# 4-(2-Aminooxyethoxy)-2-(ethylureido)quinoline–Oligonucleotide Conjugates: Synthesis, Binding Interactions, and Derivatization with Peptides

Tomoko Hamma<sup>†</sup> and Paul S. Miller\*

Department of Biochemistry and Molecular Biology, Bloomberg School of Public Health, Johns Hopkins University, 615 North Wolfe Street, Baltimore, Maryland 21205. Received November 13, 2002; Revised Manuscript Received January 9, 2003

Oligo-2'-*O*-methylribonucleotides conjugated with 4-(2-aminooxyethoxy)-2-(ethylureido)quinoline (AOQ) and 4-ethoxy-2-(ethylureido)quinoline (EOQ) were prepared by reaction of the AOQ or EOQ phosphoramidite with the protected oligonucleotide on a controlled pore glass support. Deprotection with ethylenediamine enabled successful isolation and purification of the highly reactive AOQ-conjugated oligomer. Polyacrylamide gel electrophoresis mobility shift experiments showed that the dissociation constants of complexes formed between an AOQ- or EOQ-conjugated 8-mer and complementary RNA or 2'-*O*-methyl-RNA targets (9- and 10-mers) were in the low nM concentration range at 37 °C, whereas no binding was observed for the corresponding nonconjugated oligomer, even at a concentration of 500 nM. Fluorescence studies suggested that this enhanced affinity is most likely due to the ability of the quinoline ring of the AOQ or EOQ group to stack on the last base pair formed between the oligomer and target, thus stabilizing the duplex. The binding affinity of a 2'-*O*-methyl RNA 15-mer, which contained an alternating methylphosphonate/phosphodiester backbone, for a 59-nucleotide stem-loop HIV TAR RNA target, increased 2.3 times as a consequence of conjugation with EOQ. The aminooxy group of AOQ-conjugated oligomers is a highly reactive nucleophile, which reacts readily with aldehydes and ketones to form stable oxime derivatives. This feature was used to couple an AOQ-oligomer with leupeptin, a tripeptide that contains a C-terminus aldehyde group. A simple method was developed to introduce a ketone functionality into peptides that contain a cysteine residue by reacting the peptide with bromoacetone. The resulting keto-peptide was then coupled to the AOQ-oligomer. This procedure was used to prepare oligonucleotide conjugates of a tetrapeptide, RGDC, and a derivative of HIV tat peptide having a C-terminus cysteine. The combination of the unique reactivity of the aminooxy group and enhanced binding affinity conferred by its quinoline ring suggests that AOQ may serve as a useful platform for the preparation of novel oligonucleotide conjugates.

## INTRODUCTION

Recent advances in chemical syntheses of modified oligonucleotides have enabled broad applications of antisense oligonucleotides as research tools in molecular biology; as diagnostic agents; and as potential therapeutics (see recent reviews in refs 1 and 2). The efficacy of antisense oligonucleotides relies on stable and specific hybridization with their RNA targets and on effective internalization by cells. A considerable amount of research has been devoted to synthesizing oligonucleotides that possess unique sugar, phosphate, or base moieties or with chemically reactive functional groups in an effort to enhance the binding affinities of the oligonucleotides for their targets. Furthermore, efforts have also been made to conjugate antisense oligonucleotides to small ligands, peptides, or proteins to facilitate their uptake by cells.

Chemically reactive functional groups such as psoralen (3, 4), dimethylanthraquinone (5), mitomycin (6), and 2-amino-6-vinylpurine (7) have been conjugated to oligonucleotides to achieve oligomer-target cross-linking.

However, these agents require photoactivation, reduction, or acidic conditions to trigger the cross-linking reaction. In contrast, groups such as aromatic 2-chloroethylamine (8, 9), cyclopropapyrroloindole (10), transplatin (11), and 5-methyl-N<sup>4</sup>, N<sup>4</sup>-ethanocytosine (12), when incorporated into oligonucleotides, can carry out alkylation when the oligonucleotide hybridizes to its target. Efficient covalent bond formation between an oligonucleotide and its target has been shown to correlate with the antisense efficacy in the cell (6, 11, 13).

The aminooxy group reacts readily with a variety of electrophiles. The high nucleophilicity of this group is attributed to the unshared pair of electrons on the oxygen atom adjacent to the amino nucleophilic center, inducing the so-called alpha effect (14). The high reactivity of the aminooxy group toward aldehydes and ketones (15–17) has been utilized for chemoselective conjugation of peptides (18, 19), proteins (20), carbohydrates (21–23), and oligonucleotides (15, 23–26), resulting in formation of a highly stable oxime linkage (15, 27). Alkoxyamines have also been shown to react with the 5–6 double bonds of cytosine and uracil to form covalent Michael adducts (28–31). It thus appeared possible that an aminooxy group, when appended to an oligonucleotide, might increase the binding affinity between the oligomer and its target as a result of covalent Michael adduct formation with a cytosine residue in the target.

To explore these possibilities, we have designed an antisense oligonucleotide bearing a 5'-4-(2-aminoxy-ethoxy)-2-(ethylureido)quinoline (AOQ) group. The interactions between this AOQ-derivatized oligonucleotide and complementary RNA and 2'-*O*-methyl-RNA targets were characterized by gel mobility shift assays and steady state fluorescence measurements. In addition, a novel, simple method was developed to conjugate the AOQ-derivatized oligonucleotide with small peptides. The increased binding of the AOQ-derivatized oligonucleotide to its target and its successful conjugation with biologically active peptides suggests that the AOQ group may be a useful modification for enhancing the efficacy of antisense oligonucleotides.

## EXPERIMENTAL PROCEDURES

**Materials.** 2-Amino-4-hydroxyquinoline hydrate (97%, Lancaster), 2-cyanoethyl diisopropyl chlorophosphoramidite (Chemgenes Corp.), bromoethane (98%, Acros Organics), and bromoacetone (1-bromo-2-propanone) (95%, Chem Service Inc.) were commercial products. Protected 2'-*O*-methylribonucleoside-3'-*O*-( $\beta$ -cyanoethyl-*N,N*-diisopropyl)phosphoramidites, ribonucleoside-3'-*O*-( $\beta$ -cyanoethyl-*N,N*-diisopropyl)-phosphoramidites, controlled pore glass supports, 4,5-dicyanoimidazole, 5-ethylthio-1*H*-tetrazole, and oligonucleotide synthesis reagents were purchased from Glen Research, Inc. Protected 2'-*O*-methylribonucleoside-3'-*O*-(*N,N*-diisopropyl)methylphosphoramidites were obtained from Chemgenes Corp. Ethyl acetate, dichloromethane, diisopropylethylamine, and triethylamine were stored over calcium hydride, whereas pyridine, chloroform, and *N,N*-dimethylformamide were stored over Linde-type 4 Å molecular sieves. Silica gel thin-layer chromatography (TLC) was carried out using Whatman aluminum-backed sheets that contained fluorescent indicator. Column chromatography was performed on Davisil-grade 634-type 60 Å silica gel, 100–200 mesh, obtained from Fisher Scientific. DEAE Sephadex A-25 columns were purchased from Sigma. Snake venom phosphodiesterase (SVP) from *Crotalus durissus* was purchased from Boehringer Mannheim, and calf intestinal alkaline phosphatase (CIP) and T4 polynucleotide kinase (PNK) were obtained from New England Biolabs. Synthetic leupeptin, H-Leu-Leu-Arg-H and synthetic tetrapeptide, H-Arg-Gly-Asp-Cys-OH, were obtained from Alexis Biochemicals and American Peptide Company, respectively. The derivative of HIV Tat peptide H-Gly-Arg-Lys-Lys-Arg-Gln-Arg-Arg-Arg-Pro-Gln-Cys-OH was synthesized and purified by the Protein/Peptide Sequencing Core Facility at Johns Hopkins University.

**General Methods.**  $^1\text{H}$  NMR spectra were acquired on a Bruker AMX 300 MHz spectrometer. Samples were prepared in dimethyl sulfoxide, and the chemical shifts were reported in ppm relative to the internal residual solvent peaks (DMSO: 2.5 ppm). MALDI-TOF mass spectrometry was carried out at the Johns Hopkins University Mass Spectrometry Facility and ESI mass spectrometry by the Scripps Research Institute. Reversed-phase (RP) HPLC was carried out on a Microsorb C-18 column ( $0.46 \times 15$  cm, C18, 10  $\mu\text{m}$ ) purchased from Varian Analytical using a flow rate of 1.0 mL/min. Strong anion exchange (SAX) HPLC was carried out on a Dynamax II column ( $0.46 \times 25$  cm) purchased from Rainin Instruments Co. using a flow rate of 0.6 mL/min. For the oligonucleotides, the columns were monitored at 260 and 290 nm for analytical runs and preparative runs, respectively. Peptides were analyzed and purified on the Microsorb C-18 column, monitored at 215 nm. Polyacryl-

amide gel electrophoresis was performed on  $20 \times 20 \times 0.75$  cm gels containing either 8% or 20% acrylamide in 1x TBE. Urea, 7 M, was added for denaturing gels. The gels were run in 1x TBE buffer, which contained 89 mM Tris, 89 mM boric acid, and 0.2 mM ethylenediamine-tetraacetate (EDTA) at pH 8.0.

**Oligonucleotides.** The sequences of the oligonucleotides are shown in Figure 1. They were synthesized on an Applied Biosystems Model 392 DNA/RNA synthesizer using commercially available phosphoramidites and phosphonamidites as described previously (32). The oligonucleotides were removed from the support and deprotected as described previously (32). Twenty  $A_{260}$  units of each crude oligomer, 1676, 1843, 1855, 1856, 1885, 1886, 1887, or 2016 were purified by SAX HPLC using a 30 min linear gradient of 0–0.4 M ammonium sulfate. RNA oligomer 1960 was purified on 20% polyacrylamide gels run under denaturing conditions (32). The oligomers were desalted using SEP PAK C-18 cartridges. The compositions of the oligomers were assessed by enzymatic digestion using SVP and CIP (33), and/or their molecular weights were determined by MALDI-TOF mass spectrometry. The extinction coefficients of the oligonucleotides were determined as described previously (33): 1676,  $1.3 \times 10^5$ ; 1843, AOQ-1843, EOQ-1843,  $6.23 \times 10^4$ ; 1855, 1856, 1885, 1886, 1887,  $7.67 \times 10^4$ ; 1960,  $1.0 \times 10^5$ ; and 2016,  $5.2 \times 10^4$ . HIV TAR RNA was prepared by in vitro transcription of a plasmid carrying a TAR RNA template (32). The 73 nucleotide run off transcript contained the 59 nucleotide TAR RNA sequence (underlined) 5'GAAUACUCAAGCUGGGUCUCUCUGGUUA-GAUUAGACUGAGCCUGGGAGCUCUCUGGCUAAC-UAGGGAACCCG.

**2-(2-Hydroxyethylureido)-4-hydroxyquinoline (2).** 2-Amino-4-hydroxyquinoline hydrate (**1**) (640 mg, 4 mmol, see Scheme 1) was coevaporated with anhydrous pyridine and dissolved in 40 mL of dry pyridine. To this stirred solution was added 10 equiv of 4-nitrophenylchloroformate (8.1 g, 40 mmol) dissolved in 20 mL dry chloroform (20 mL), and the reaction was allowed to stir for 60 min at room temperature. A thick orange suspension was obtained that was treated with 41 equiv of ethanolamine (10 mL, 164 mmol) and further stirred for 2 h at room temperature. The reaction was complete as determined by silica gel TLC [chloroform/methanol (4:1, v/v)], with conversion of the starting material ( $R_f = 0.25$ ) to a faster-moving product ( $R_f = 0.34$ ). The suspension was filtered through a 60 mL coarse sintered glass funnel, and the residue was washed briefly with 20% methanol in chloroform. The filtrate was concentrated under vacuum on a rotary evaporator to a syrup that was dissolved in a minimum amount of chloroform and applied to a column packed with a Davisil-grade 634-type 60 Å silica gel. The column was eluted using a gradient from 10% to 20% methanol in chloroform. Fractions containing the desired product were combined and concentrated to yield **2** as a brown syrup (1.2 g or 4 mmol, quantitative yield).  $^1\text{H}$  NMR ( $d_6$ -DMSO)  $\delta$  (ppm): 4.82 (s; 1H, ureido-NH), 4.64 (s; 1H, ureido-NH), 7.98–7.24 (m; 4H, quinoline H5–8), 7.00 (t; 1H, quinoline H3), 5.44 (s; 1H, quinoline –OH), 3.91–3.87 (t; 1H, –NHCH<sub>2</sub>CH<sub>2</sub>OH), 3.54–3–3.48 (t; 2H, –NHCH<sub>2</sub>CH<sub>2</sub>OH), 3.20–3.16 (t; 2H, –NHCH<sub>2</sub>CH<sub>2</sub>OH).

**2-(2-*O*-Monomethoxytritylureido)-4-hydroxyquinoline (3).** A solution of compound **2** (1.2 g, 4 mmol) in 40 mL of dry pyridine was treated with 5 equiv of monomethoxytrityl chloride (6.2 g, 20 mmol) for 4 h at room temperature. The clear orange solution was cooled in an ice bath, diluted with 10 mL of methanol and 2 mL of triethylamine, and then concentrated under vacuum

TAR RNA	Alternating Methylphosphonate Backbone

**Figure 1.** Sequences of antisense oligonucleotides and their targets. **X** is AOQ, EOQ, or no modification. The symbols mr and r indicate 2'-O-methylribonucleoside or ribonucleotide respectively; p is a phosphodiester linkage, and  $\underline{p}$  a methylphosphonate linkage.

on a rotary evaporator. The product, **3**, which was purified by silica gel column chromatography using a gradient of 0–10% methanol in chloroform, was obtained as a brown syrup (1.4 g or 2.69 mmol, 67%).  $R_f$ : 0.54 [chloroform/methanol (9:1, v/v)].

**2-(2-O-Monomethoxyltritylethylureido)-4-(2-phthalimidooxyethoxy)quinoline (4).** Compound **3** (1.4 g, 2.7 mmol) and 3 equiv of 2-phthalimidooxyethyl bromide (2.2 g, 8.1 mmol) were dissolved in dry *N,N*-dimethylformamide (10.8 mL), and the solution was treated with 3 equiv of dry powdered potassium carbonate (1.1 g, 8.1 mmol) overnight at room temperature. The potassium carbonate was removed by filtration, and the filtrate was concentrated under vacuum. The product, **4**, which was purified by silica gel column chromatography using a gradient of 0–5% methanol in chloroform, was obtained as a yellow syrup (1.4 g or 1.8 mmol, 67%).  $R_f$ : 0.28 [methanol:chloroform (1:19, v/v)].

**2-(2-Hydroxyethylureido)-4-(2-phthalimidooxyethoxy)quinoline (5).** Compound **4** (1.4 g, 1.8 mmol) was dissolved in 80% aqueous acetic acid (46 mL), and the solution was incubated at 37 °C for 45 min. The acetic acid was removed by coevaporation with 95% ethanol, and the product, **5**, was precipitated by addition of

absolute ethanol. The precipitate was collected on a fine porosity sintered glass funnel and dried under vacuum in a desiccator overnight to yield a light yellow powder (483 mg or 0.90 mmol, 50%).  $R_f$ : 0.1 [methanol:chloroform (1:4 v/v)]. The overall yield starting from **1** was 22%. The molecular weight of **5** was confirmed by ESI mass spectrometry ( $MH^+$ : calcd 437.4, found 437).  $^1H$  NMR ( $d_6$ -DMSO)  $\delta$  (ppm): 9.60 (s; 1H, ureido-NH), 9.53 (s; 1H, ureido-NH), 7.83 (s; 4H, phthalimide), 7.78–7.14 (m; 4H, quinoline H5–8), 6.77 (s; 1H, quinoline H3), 4.86–4.83 (t; 1H,  $-NHCH_2CH_2OH$ ), 4.67–4.45 (t; 4H,  $-OCH_2CH_2O-$ ), 3.58–3–3.30 (m; 4H,  $-NHCH_2CH_2OH$ ).

**2-[(2-Ureido)-4-(2-phthalimidooxyethoxy)quinoline]-ethyl-1-O- $\beta$ -cyanoethyl-*N,N*-diisopropylphosphoramidite (6).** Compound **5** (15 mg, 0.03 mmol) was dissolved in dry dichloromethane (600  $\mu$ L). Diisopropylethylamine (104.5  $\mu$ L, 0.60 mmol) and 2-cyanoethyl diisopropyl chlorophosphoramidite (41.7  $\mu$ L, 0.19 mmol) were added via syringe to the stirred solution, and the reaction was allowed to proceed at room temperature for 1 h. The product **6**, whose  $R_f$  was 0.21 on silica gel TLC [ethyl acetate:triethylamine, (95.5:0.5, v/v)], was purified by silica gel column chromatography using ethyl acetate/triethylamine (95.5:0.5, v/v). Fractions containing **6** were

**Scheme 1. Preparation of AOQ and EOQ Phosphoramidites<sup>a</sup>**

<sup>a</sup> Reagents: (i) 4-nitrophenyl chloroformate in chloroform and pyridine; (ii) ethanolamine; (iii) monomethoxytrityl chloride in pyridine; (iv) 2-phthalimidooxyethyl bromide, dimethylformamide, and potassium carbonate; (v) 80% acetic acid; (vi) 2-cyanoethyl-chlorodiisopropylphosphoramidite and diisopropylethylamine in dichloromethane. CE is 2-cyanoethyl.

combined and evaporated under vacuum to yield a clear light yellow syrup, which was dissolved in a minimum volume of dry dichloromethane (~300  $\mu$ L), and the solution was added dropwise with stirring to hexane at room temperature. The resulting precipitate was collected by centrifugation and dried under vacuum to yield a white solid (10.9 mg or 0.017 mmol, 57%). <sup>1</sup>H NMR (*d*<sub>6</sub>-DMSO)  $\delta$  (ppm): 9.70 (s; 1H, ureido-NH), 9.58 (s; 1H, ureido-NH), 7.83 (s; 4H, phthalimide), 7.79–7.15 (m, 4H; quinoline H5–8), 6.73 (s; 1H, quinoline H3), 4.68–4.46 (m, 4H, –OCH<sub>2</sub>CH<sub>2</sub>O–), 4.03–3.40 (m; –NHCH<sub>2</sub>–CH<sub>2</sub>O–), 2.91–2.73 (t; 4H, cyanoethyl), 1.23–1.12 (m; 24H, diisopropyl), 1.09–1.05 (m; 14H, diisopropyl). The MALDI-TOF mass spectrum was consistent for C<sub>25</sub>H<sub>24</sub>N<sub>5</sub>O<sub>8</sub>P (*m/z*: calc. 553.5, found 554.4), indicating that **6** had converted to its H-phosphonate derivative during analysis.

**2-(2-Hydroxyethylureido)-4-ethoxyquinoline (7).** Compound **3** (1.52 g, 2.9 mmol) and bromoethane (873  $\mu$ L, 12 mmol) were dissolved in 11.7 mL of dry dimethylformamide, and the solution was treated with dry, powdered potassium carbonate (1.6 g, 12 mmol) for 14 h at room temperature to give a new product whose *R<sub>f</sub>* was 0.75 [methanol: chloroform, (1:19 v/v)] on silica gel TLC. The potassium carbonate was removed by filtration and washed with several portions of dichloromethane. The filtrate was evaporated under vacuum, and the residue was treated with 58 mL of 80% aqueous acetic acid at 37 °C for 90 min. The acetic acid was removed by

coevaporation with 95% ethanol, and the resulting compound **7** was purified by silica gel column chromatography using 0–5% methanol in chloroform. Fractions containing **7** were combined and concentrated under vacuum to give an oil, *R<sub>f</sub>* = 0.18 [methanol: chloroform, (1:19 v/v)]. The oil was dissolved in a minimum volume of methanol, and heated water (50 °C) was added dropwise with stirring until the solution became turbid. This solution was heated until everything dissolved. The solution was then cooled slowly to 4 °C. The resulting solid was collected by filtration, washed several times with ice-cold water, and dried under vacuum. The product was obtained as a white powder (18 mg or 0.67 mmol, 17%), *R<sub>f</sub>* = 0.32 [ethyl acetate:triethylamine, (99.5:0.5, v/v)]. MALDI-TOF mass spectrometry (*m/z*: calcd 275.3, found 276.1).

**2-[(2-Ureido)-4-ethoxyquinoline]-ethyl-1-*O*- $\beta$ -cyanoethy-*N,N*-diisopropyl-phosphoramidite (8).** The synthesis of phosphoramidite **8** was identical to that of phosphoramidite **6** described above with the following modifications. After phosphitylation, the crude phosphoramidite was applied to a silica gel column using a mixture of petroleum ether and ethyl acetate (2:1 v/v), and the column was eluted with 0.5% triethylamine in ethyl acetate. The purified phosphoramidite was not precipitated in hexane. Rather, the oily product was transferred to an autosampler vial, evaporated under vacuum for 30 min, and the resulting oily residue was

used immediately for conjugation to the oligonucleotide as described below.

**Preparation of AOQ- and EOQ-Conjugated Oligonucleotides.** AOQ-1843, AOQ-2106, EOQ-1843, and EOQ-1676 were synthesized as follows. The oligo 2'-*O*-methylribonucleotides were synthesized as described above, and the 5'-DMT group was removed on the synthesizer. The oligonucleotide-CPG (10 mg) was mixed with AOQ phosphoramidite **6** in a 1.5 mL centrifuge tube or EOQ phosphoramidite **8** in a 4 mL autosampler vial. A 0.4 M solution of tetrazole in anhydrous acetonitrile was added, and the final concentration of the phosphoramidite was adjusted to 0.2 M by addition of anhydrous acetonitrile. The reaction mixture was incubated for 10 min at room temperature. The CPG was transferred to a synthesis cartridge and washed with 10 mL of acetonitrile, after which the oxidation and capping reactions were performed on the DNA synthesizer.

AOQ-1843 and AOQ-2106 were deprotected and purified as follows. The oligonucleotide-CPG, 10 mg, was treated with 30  $\mu$ L of a solution containing ethylenediamine, acetonitrile, 95% ethanol, and water (20:9:9:2 v/v) for 6 h at room temperature. The reaction mixture was cooled in an ice-water bath and neutralized by addition of 120  $\mu$ L of ice-cold 2 N hydrochloric acid. The deprotected oligomer was purified immediately by C-18 reversed phase HPLC using a 20 mL linear gradient of 0–50% acetonitrile in 50 mM sodium phosphate, pH 5.8. The oligomer was then desalted using a C-18 SEP PAK cartridge. The 50% aqueous acetonitrile solution containing the oligomer (9.9  $A_{260}$  units AOQ-1843; 0.34  $A_{260}$  units of AOQ-2106) was evaporated to dryness, and the dry residue was stored at  $-20^{\circ}\text{C}$ . The oligomers were analyzed by MALDI-TOF mass spectrometry: AOQ-1843 ( $m/z$ : calcd +  $\text{K}^+$  3001.8, found 3006.1); AOQ-2106 ( $m/z$ : calcd 1966.8, found 1967.1).

The EOQ-derivatized oligonucleotides were each deprotected and purified as follows. The oligonucleotide-CPG was treated with 400  $\mu$ L of concentrated ammonium hydroxide at  $65^{\circ}\text{C}$  for 5 h. After evaporation of solvents, the EOQ-oligonucleotide was purified by C-18 reversed-phase HPLC using a 20 mL linear gradient of 2–50% acetonitrile in 50 mM sodium phosphate, pH 7.8. Each purified EOQ-oligonucleotide was desalted on a C-18 SEP PAK cartridge and stored as a solution in 50% aqueous acetonitrile at  $4^{\circ}\text{C}$ . The oligonucleotides were analyzed by MALDI-TOF mass spectrometry: EOQ-1843 ( $m/z$ : calcd 2934.1, found 2935); EOQ-1676 ( $m/z$ : calcd +  $\text{K}^+$  5283.8, found 5279.0).

**Gel Mobility Shift Experiments.** Electrophoretic gel mobility shift assays were carried out as described previously (32). Oligonucleotide solutions with concentrations ranging from 0.5 nM to 100  $\mu$ M were prepared in binding buffer that contained 100 mM sodium chloride, 10 mM Tris, pH 7.5, and 0.5 mM EDTA in diethylpyrrolidone treated water. Solutions containing 0.2 nM of 5'-[ $^{32}\text{P}$ ]-end-labeled 1855, 1856, 1885, 1886, 1887, 1960, or TAR RNA (specific activity, 1000 Ci/mmol) were prepared in the same buffer. Equal volumes of oligomer and target solution (total volume, 10  $\mu$ L) were mixed in 0.5 mL centrifuge tubes, and 1  $\mu$ L of autoclaved 80% glycerol was added. Duplexes formed between 10-mer targets 1855, 1856, 1885, 1886, 1887, 1960, and 8-mer oligomers 1843, AOQ-1843, EOQ-1843, were incubated at  $37^{\circ}\text{C}$  for 1 h. Duplexes formed between TAR RNA and 15-mer oligomers 1676 or EOQ-1676 were incubated for 24 h at  $37^{\circ}\text{C}$ . The solutions were loaded onto a polyacrylamide gel using a 20  $\mu$ L syringe. Complexes formed with the short targets 1855, 1856, 1885, 1856, 1857, or

1960 were separated on a 20% nondenaturing acrylamide gel run at 500–600 V for 1.5 h at the same temperature at which the sample was incubated. In the case of the TAR RNA target, electrophoresis was carried out in a similar manner on an 8% nondenaturing polyacrylamide gel at 200–300 V for 2 h. The wet gels were visualized by phosphorimaging and quantitated using the phosphorimager software package. The apparent dissociation constants were determined as the half-maximal point on a plot of percent complex versus the log of oligomer concentration. Averages were obtained from at least three separate experiments.

**AOQ-1843–Leupeptin Conjugate.** Leupeptin (1.25  $\mu$ mol) was mixed with 5  $A_{260}$  units (0.8  $\mu$ mol) of AOQ-1843 in 54  $\mu$ L of 50% aqueous acetonitrile solution, and the solution was incubated for 60 min at room temperature. The AOQ-1843–leupeptin conjugate was purified by C-18 reversed-phase HPLC using a 20 mL linear gradient of 2–50% acetonitrile in 50 mM sodium phosphate, pH 5.8. The conjugate, which was obtained in quantitative yield, was desalted on a SEP PAK C-18 cartridge and analyzed by MALDI-TOF mass spectrometry ( $m/z$ : calcd 3373.4, found 3372.4).

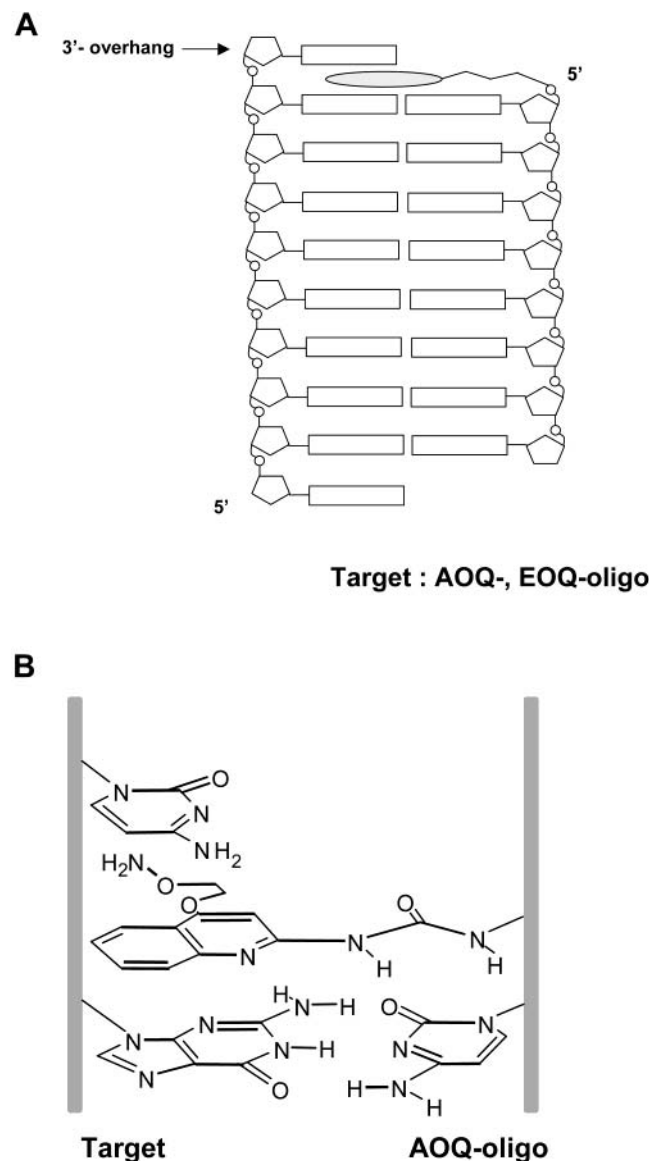

**AOQ-2106–RGDC or –Tat Conjugate.** A 0.2 M solution of bromoacetone in 50  $\mu$ L of 50% aqueous acetonitrile was added to either RGDC peptide (0.5 mg, 1.0  $\mu$ mol) or Tat peptide (0.5 mg, 0.3  $\mu$ mol) in a 1.5 mL centrifuge tube and the solution incubated for 1 h at room temperature. The reaction was shielded from light by covering the tube with aluminum foil during the incubation period. The resulting keto-peptide was purified by C-18 reversed phase HPLC using a 20 mL linear gradient of 2–50% acetonitrile in 0.1% trifluoroacetic acid. The fraction containing the keto-peptide was evaporated to dryness and redissolved in 50% aqueous acetonitrile. The keto-peptides were analyzed by MALDI-TOF mass spectrometry: keto-RDGC ( $m/z$ : calcd 506, found 506); keto-tat ( $m/z$ : calcd 1879, found 1880).

Keto-RDGC (19.5 nmol) was reacted with 0.1  $A_{260}$  unit (1.95 nmol) of AOQ-2106 in 53  $\mu$ L of 50% aqueous acetonitrile 1 h at room temperature. The resulting AOQ-2106–RDGC conjugate was purified by C-18 reversed-phase HPLC using a 20 mL linear gradient of 2–50% acetonitrile in 0.1% trifluoroacetic acid. Two peaks were observed that corresponded to the two oxime isomers. The conjugate was analyzed by MALDI-TOF mass spectrometry ( $m/z$ : calcd 2455, found 2457 for peaks 1 and 2, see Figure 6).

Keto-tat peptide (2.5 nmol) and 1.0  $A_{260}$  unit of AOQ-2106 (19.5 nmol) were incubated in 25  $\mu$ L of 50% aqueous acetonitrile for 1 h at room temperature. The resulting AOQ-2106–tat conjugate was separated from the unreacted AOQ-2106 by ion exchange chromatography. The reaction mixture was diluted with 75  $\mu$ L of 50% aqueous acetonitrile, and the solution was applied to a small (0.6  $\times$  1.2 cm) DEAE Sephadex A-25 column which had been preequilibrated with 50% aqueous acetonitrile. The column was washed with 50% aqueous acetonitrile, and the AOQ-2106–tat conjugate (1 nmol) was collected. The conjugate was analyzed by MALDI-TOF mass spectrometry: ( $m/z$ : calcd 3828, found 3829).

## RESULTS AND DISCUSSION

**AOQ- and EOQ-Conjugated Oligonucleotides.** The structures of the 4-(2-aminooxyethoxy)-2-(ethylureido)-quinoline (AOQ) and 4-ethoxy-2-(ethylureido)quinoline (EOQ) groups are shown in Figure 1. EOQ lacks an aminooxy group and thus is a nonreactive analogue of

**Figure 2.** Binding model. (A) The oval indicates either the AOQ or the EOQ group. (B) Possible stacking interaction between quinoline ring and neighboring bases. Left, target strand; right, antisense oligonucleotide strand.

AOQ. When bound to its target, the quinoline ring of an AOQ- or EOQ-conjugated oligonucleotide can potentially stack on the last base pair formed between the oligomer and the target as shown in Figure 2A. In this binding mode, the aminooxy group of the AOQ-oligomer could form a Michael adduct by reacting with the 5,6 double bond of a cytosine residue in the target as shown schematically in Figure 2B. Although such adduct formation would be expected to be transient, it could decrease the dissociation rate of the duplex, and consequently enhance the binding affinity of the AOQ-oligomer. In addition, the highly reactive aminooxy group can serve as a site for conjugation with other molecules that bear an aldehyde or ketone function.

To test these possibilities, AOQ or EOQ was conjugated via a phosphodiester linkage to the 5'-ends of oligo-2'-*O*-methylribonucleotides as shown in Figure 1. The sequences of these oligomers, with the exception of oligomer 2106, are complementary to the apical stem loop of HIV TAR RNA. Oligomer 1843 is complementary to nucleotides 31–38 of TAR RNA. Oligomer 1676, which contains alternating methylphosphonate/phosphodiester in-

ternucleotide linkages, is complementary to nucleotides 21–38 of TAR RNA.

AOQ- and EOQ-phosphoramidites were prepared as shown in Scheme 1. 2-Amino-4-hydroxyquinoline, **1**, was converted to its *p*-nitrophenylcarbamate derivative, **1a**, by reaction with *p*-nitrophenylchloroformate. Compound **1a** was not isolated but was converted to the hydroxyethylureido derivative, **2**, by treatment with ethanolamine. The primary hydroxyl group of **2** was selectively protected by reaction with monomethoxytrityl chloride to give **3**. The 4-hydroxy group of **3** was then alkylated with 2-phthalimidooxyethyl bromide in the presence of potassium carbonate to give the protected AOQ derivative **4**. Treatment of **4** with 80% acetic acid removed the monomethoxytrityl group to produce compound **5**. The corresponding EOQ derivative **7** was prepared by alkylation of **3** with bromoethane in the presence of potassium carbonate followed by removal of the monomethoxytrityl group. AOQ and EOQ derivatives **5** and **7** were each converted to their phosphoramidite derivatives, **6** and **8**, respectively, by reaction with 2-cyanoethyl chlorodiisopropylphosphoramidite. The phosphoramidites were purified by silica gel column chromatography. The AOQ phosphoramidite, **6**, was precipitated from hexane and was obtained as a white powder. In contrast the EOQ phosphoramidite, **8**, failed to precipitate and was obtained as an oil.

Both phosphoramidites were very reactive and under some conditions appeared to be susceptible to conversion to their H-phosphonate derivatives. For example, mass spectrometric analysis of AOQ phosphoramidite **6** gave a mass consistent with that of the H-phosphonate of AOQ (**6b**). This species most likely arose from intramolecular displacement of the phosphorus *N,N*-diisopropylamino group by the nitrogen of the ureido linkage to produce a five-member cyclic phosphoramidite (**6a**). The cyclic phosphoramidite would be expected to be very reactive and readily react with traces of water in the solvent to give the H-phosphonate derivative. Consistent with this explanation is the observation that acetonitrile solutions of the AOQ or EOQ phosphoramidite showed conversion to a slower migrating product when monitored by silica gel TLC. The formation of this new compound correlated with a decrease in coupling efficiency to the oligonucleotides, indicating the formation of an inactive species.

The AOQ- and EOQ-conjugated oligonucleotides were prepared by first synthesizing the oligomers on controlled pore glass supports and removing the 5'-terminal dimethoxytrityl group. The supports were then transferred to an eppendorf tube or a glass autosampler vial that contained the dry phosphoramidite. A solution of tetrazole in dry acetonitrile was then added via a syringe and the coupling reaction was allowed to proceed for 10 min. The support was then returned to the DNA synthesis column, and capping and oxidation were carried out on the DNA synthesizer.

We initially tried deprotecting the AOQ-conjugated oligonucleotide by standard treatment with concentrated ammonium hydroxide solution at 65 °C for 5 h. However, a multitude of peaks were observed when the reaction mixture was analyzed by reversed phase HPLC (data not shown). Many of these peaks were detected at both 260 and 320 nm, indicating the presence of the AOQ group. However, among the AOQ containing peaks, only one possessed a reactive aminooxy group, as assessed by its ability to react with acetone to form the dimethylloxime derivative. Thus, it appeared that most of the AOQ-containing oligomers represented species where the aminooxy group had reacted with some component in the

**Figure 3.** Reverse-phase HPLC profile of (A) unmodified oligomer 1843, (B) AOQ-1843, (C) EOQ-1843, (D) dimethylloxime derivative of AOQ-1843, (E) leupeptin conjugated AOQ-1843. A 20 mL linear gradient of 2–50% acetonitrile (1 mL/min) in 50 mM sodium phosphate buffer (pH 5.8) was used.

deprotection reaction solution. This observation is in agreement with that of Salo et al., who reported that attempts to purify aminoxy containing oligomers were unsuccessful when concentrated ammonium hydroxide was used for deprotection (16). To circumvent this problem, an alternate deprotection method was developed which involved treatment of the oligonucleotide with ethylenediamine (EDA) at room temperature (34). To preclude generation of side products resulting from transamination of C by EDA during deprotection,  $N^4$ -acetyl-C or  $N^4$ -isobutryl-C protected phosphoramidite and methylphosphonamidite, respectively, were used to synthesize the oligonucleotides (34, 35). In separate experiments, we confirmed that no transamination occurred when acetyl- or isobutryl-protected C was treated with ethylenediamine under these conditions.

The AOQ-oligo was cleaved from the support, and all the protecting groups, including the phthalimide group, were completely removed after treatment with ethylenediamine for 6 h at room temperature. For example, as shown in Figure 3B for AOQ-1843, essentially a single peak was observed when the reaction mixture was analyzed by C-18 reversed phase HPLC. This peak, which adsorbed at both 260 and 320 nm, had a longer retention time than that of nonconjugated oligomer, 1843, which did not absorb at 320 nm. As shown in Figure 3D, AOQ-1843 reacted readily with acetone to give the dimethylloxime derivative, whose retention time was greater than that of AOQ-1843. The deprotected AOQ-oligo was immediately purified by C-18 reversed-phase HPLC. Storage of the purified AOQ-oligo in aqueous acetonitrile over time resulted in the generation of additional compounds as observed by C-18 reversed phase HPLC (data not shown). These compounds most likely result from reaction of the aminoxy group with minute amounts of aldehydes and/or ketones present in the solution as previously observed by others (15, 17). To prevent these unwanted reactions, the solution containing the AOQ-oligo after desalting was immediately evaporated to dryness and stored at  $-20^{\circ}\text{C}$ . Under these conditions, the dry AOQ-oligo proved to be stable, and the aminoxy function remained active.

In contrast to the AOQ-oligomers, the EOQ-oligonucleotides were successfully deprotected by treatment

**Table 1.** Apparent Dissociation Constant of Duplexes Formed between AOQ- or EOQ-1843 and Various Targets

target	$K_d$ (nM) <sup>a</sup>		
	1843	EOQ-1843	AOQ-1843
2'-O-Me 1855	mrACUGGGAGCU >500 <sup>b</sup>	4.6 ± 2.5	9.2 ± 1.0
1856	mrACUGGGAGCC >500	5.8 ± 1.7	8.2 ± 2.4
1885	mrACUGGGAGCG >500	1.9 ± 0.4	5.5 ± 4.1
1886	mrACUGGGAGCA >500	1.6 ± 0.4	5.2 ± 0.9
1887	mrACUGGGAGC >500	15.3 ± 0.1	19.6 ± 3.5
RNA 1960	rACUGGGAGCC >500	5.7 ± 1.2	7.1 ± 1.6

<sup>a</sup> Apparent dissociation constants were determined at  $37^{\circ}\text{C}$  in a buffer containing 100 mM sodium chloride, 10 mM Tris pH 7.5, 0.5 mM EDTA. <sup>b</sup>The highest concentration used for the measurements.

with concentrated ammonium hydroxide at  $65^{\circ}\text{C}$ . As shown in Figure 3C, EOQ-1843 gave a single peak whose retention time on C-18 reversed phase HPLC was approximately 6 min longer than that of unconjugated 1843. As was the case for the AOQ-oligomers, the EOQ-oligonucleotides absorbed at both 260 and 320 nm. MALDI-TOF mass spectrometric analyses of both the AOQ- and EOQ oligomers gave molecular weights consistent with the structures of the derivatized oligomers.

**Interactions of AOQ- and EOQ-Conjugated Oligonucleotides with Complementary Oligonucleotide Targets.** The interactions of AOQ-1843 and EOQ-1843 with oligo-2'-O-methylribonucleotides 1855, 1856, 1885, 1886, and 1887 and with oligoribonucleotide 1960 were studied by gel electrophoretic mobility shift assays at  $37^{\circ}\text{C}$ . The sequences of the target oligonucleotides are shown Figure 1. AOQ- and EOQ-1843 are each complementary to nucleotides 2–9 of the target oligomers. Hybridization of AOQ- or EOQ-1843 to targets 1855, 1856, 1885, 1886, or 1960 gives a duplex with a 3'-overhanging end, whereas hybridization to 1887 produces a duplex that lacks a 3'-overhanging base. Most of the binding studies were carried out using the oligo-2'-O-methylribonucleotide targets because these oligomers are easier to synthesize and handle than are RNA targets. Duplexes formed between AOQ- or EOQ-1843 and either the 2'-O-methylribonucleotide or RNA target are predicted to be in the A-type conformation, and thus the binding affinities of the oligomers for either target were expected to be the same.

As shown in Table 1, conjugation of oligomer 1843 with either AOQ or EOQ dramatically increased its binding affinity to all the targets studied at  $37^{\circ}\text{C}$ . Thus, the dissociation constants,  $K_d$ , of AOQ- or EOQ-1843 to these targets are in the low nanomolar range, whereas no binding was observed between 1843 and any of the targets, even at a concentration of 500 nM, which was the highest concentration of oligomer tested. As expected, the  $K_d$  values of duplexes formed with 2'-O-methylribonucleotide target 1856 or RNA target 1960, which have identical sequences, are almost identical. This result confirms that the 2'-O-methylribonucleotide targets are good models for the RNA target in these binding studies.

Targets 1855, 1856, 1885, 1886, and 1960 each have a 3'-overhanging base adjacent to the oligomer binding site. Removal of this base to give target 1887 results in approximately 3–10 times increase in the  $K_d$  of the duplex. This suggests that to some extent binding involves the 3'-base residue. Saito et al. have demonstrated that 2-amino-1,8-naphthyridine can bind to guanine via formation of specific hydrogen bonds (36). The ureidoquinoline moiety of AOQ or EOQ is structurally similar to 2-amino-1,8-naphthyridine and thus could potentially form similar hydrogen bonds with the 3'-C

**Figure 4.** Potential hydrogen bond formation between the AQO or EOQ group and a cytosine in the target strand.

**Figure 5.** Emission spectra of EOQ-1843 with its complementary target. Emission spectra were measured in a buffer containing 100 mM sodium chloride, 10 mM Tris pH 7.5, and 0.5 mM ethylenediaminetetraacetate at room temperature. 1843 only (+), EOQ-1843 only (O), EOQ-1843:1843 duplex (●), and EOQ-1843:1855 duplex (□).

residue of targets 1856 or 1960, as illustrated in Figure 4. However, as shown in Table 1, the  $K_d$ s of the duplexes formed with 1855, 1856, 1885, or 1886, each of which has a different 3'-base residue, are very similar, and thus it is unlikely that such hydrogen bonding interactions are the source of enhanced binding exhibited by AOQ- or EOQ-1843.

Both AOQ- and EOQ-1843 showed increased binding affinities compared to that of 1843, suggesting that the common aromatic quinoline ring of AOQ and EOQ contributes significantly to the binding interaction. Steady-state fluorescence experiments at room temperature were used to further investigate the binding mode. Because there were no significant differences in the  $K_d$ s of AOQ- or EOQ-1843, EOQ-1843 was used in these studies. The quinoline ring of the EOQ group absorbs UV light at 310 and 322 nm and fluoresces at 351 nm when excited at 314 nm. This fluorescence was used to study the interaction of the quinoline fluorophore with neighboring bases in the duplexes. Strong quenching and a concomitant red shift of the emission maximum have been observed upon the intercalative binding of polycyclic aromatic hydrocarbon-derivatized oligonucleotides with complementary targets (37, 38, and references therein). On the other hand, moderate quenching and very little or no red shift of the emission maximum has been interpreted as pi-stacking of the fluorophore to the exterior of the last base pair of the duplex (38–40).

As shown in Figure 5, the emission maximum of EOQ-1843 was clearly observed at 351 nm when excited at 314 nm, whereas 1843 did not show such emission. Duplexes formed between EOQ-1843 and targets 1855, 1856, 1885,

1886, or 1887 all showed a moderate decrease in fluorescence intensity and no shift in the emission maximum. As expected, there was no change in fluorescence intensity when equal amounts of EOQ-1843 and 1843 were mixed because these two oligomers do not form a duplex. These results are consistent with stacking of the quinoline ring on the end of the duplex rather than full intercalation between the last two base pairs of the duplex. In this binding mode, further stabilization could occur if the quinoline ring interacts with a 3'-overhanging base as shown in Figure 2A. The observation that 1855 and 1856, which have a pyrimidine overhang, have slightly higher  $K_d$ s than 1885 and 1886, which have a purine overhang, is consistent with this model. Thus, the quinoline ring may stack more effectively with the purine overhang leading to a lower  $K_d$ . In essence, the AOQ and EOQ groups may serve as "caps" to prevent fraying of terminal bases on the duplexes (39, 41–43).

The  $K_d$ s of duplexes formed by EOQ-1843 are 1.2–3.2 times lower than those of duplexes formed by AOQ-1843. This result suggests that Michael adduct formation by AOQ-1843 either does not take place, or if it does, that such formation does not contribute to the overall stability of the duplex. Deuterium exchange experiments were carried out to directly investigate the possible formation of Michael adducts. Equal amounts of AOQ-1843 and RNA target 1960 were incubated at room temperature overnight in buffer prepared with deuterated water. RNA 1960, which contains two cytosines in proximity to the AOQ binding site, was then digested with a combination of snake venom phosphodiesterase and calf intestinal phosphatase, and the resulting cytidine was isolated by C-18 reversed phase HPLC. The molecular weight of the cytidine was then determined by EIS mass spectrometry. If a Michael adduct formed, deuterium from the buffer would be incorporated at the 5 position of cytidine, resulting in a 1 mass unit increase in the molecular weight. No mass increase was observed for the recovered cytidine, suggesting that the aminoxy group of AOQ-1843 does not participate to any significant extent in Michael adduct formation with the C residues of target RNA. A control experiment using 1-(2-aminoxyethyl) cytosine, which undergoes intramolecular Michael adduct formation (44), showed that adduct formation could be detected by both NMR and mass spectrometry (data not shown). The inability of AOQ-1843 to form a Michael adduct may be due to unfavorable positioning of the aminoxy group when AOQ-1843 is bound to its target.

AOQ- or EOQ-1843 shows at least a 2 orders of magnitude increased binding affinity for the short, linear RNA target, 1960, compared to the nonconjugated oligomer, 1843. To determine if an EOQ-conjugated oligomer could also bind to a longer, structured RNA target, we studied the interaction between EOQ-1676 and HIV TAR RNA. This RNA target, whose sequence and secondary structure are shown in Figure 1, consists of two stems, 20 base pairs and 4 base pairs in length, joined by a 3 base bulge and capped with a 6 base loop. We have shown previously that 1676, which contains a nuclease resistant alternating methylphosphonate/phosphodiester backbone, binds with high affinity to this target at 37 °C (32). The interactions of 1676 and EOQ-1676 with TAR RNA were analyzed by gel mobility shift experiments. As shown in Table 2, EOQ-conjugated 1676 forms a duplex with TAR RNA whose apparent  $K_d$  is approximately 2.3 times less than that of the duplex formed by nonconjugated 1676. These results demonstrate that conjugation

**Table 2. Apparent Dissociation Constants of TAR RNA Duplexes**

oligomer	$K_d$ (nM) <sup>a</sup>
1676	101 ± 19
EOQ-1676	43 ± 7.4

<sup>a</sup> Apparent dissociation constants were determined at 37 °C in a buffer containing 100 mM sodium chloride, 10 mM Tris pH 7.5, 0.5 mM EDTA.

with EOQ can also enhance the binding affinity of oligonucleotides for targets with extensive secondary structure.

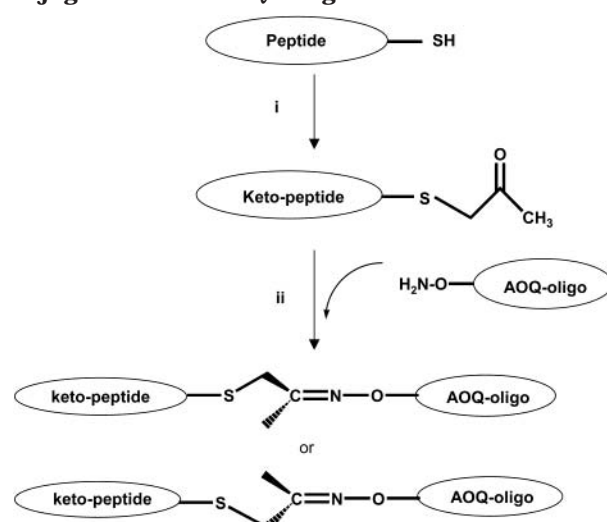

**Conjugation of AOQ-Derivatized Oligonucleotide with Peptides.** The aminooxy group reacts readily with aldehydes and ketones (15–17), and the resulting oxime linkage is very stable under physiological conditions (15, 27). This chemistry has been widely utilized for chemoselective ligation of a variety of compounds. In particular, Forget et al. have recently reported the successful preparation of peptide–oligonucleotide conjugates in which aldehyde containing peptides are conjugated with aminooxy-derivatized oligonucleotides or vice versa (15).

We have explored oxime formation to conjugate AOQ–oligonucleotides to small peptides. The AOQ group may be advantageous for this purpose because as shown above, AOQ-derivatized oligonucleotides have increased binding affinity for their RNA targets. Thus, the AOQ group could provide a duplex-stabilizing platform for chemoselective ligation of AOQ–oligonucleotides to a variety of compounds.

Initially, we conjugated commercially available, synthetic leupeptin to AOQ-1843. This tripeptide has a unique aldehyde group at its C-terminus that can react selectively with the aminooxy group of AOQ-1843 to form an oxime. As shown in the chromatogram in Figure 2E, the conjugation reaction was complete within 60 min at room temperature when carried out in 50% aqueous acetonitrile. The peptide–oligo conjugate was purified by C-18 reversed phase HPLC and its structure was confirmed by MALDI-TOF mass spectrometry analysis.

Conjugations between an oligonucleotide aminooxy group and a peptide aldehyde group are very efficient. Introduction of aldehyde groups into peptides can be accomplished by periodate oxidation of an N-terminus serine or threonine (27, 45), or by use of specific linker resins during solid-phase peptide synthesis (46, 47). An alternative approach would be to introduce into the peptide postsynthetically, a reactive functional group that could be conjugated with an aminooxy group of the oligonucleotide. To this end we developed a method to introduce a ketone functional group into a peptide by alkylating a cysteine residue in the peptide with bromoacetone, as illustrated in Scheme 2. The ketone functionality could be introduced anywhere in a peptide that already contains a cysteine residue or the peptide could be synthesized with a cysteine residue at its N terminus. The carbonyl group of the resulting keto-peptide then serves as a reactive site for conjugation with the aminooxy group of the oligonucleotide. This procedure is in some ways analogous to the recently reported procedure in which ketone modified DNA is conjugated with aminooxy-derivatized compounds (48).

We tested this procedure on a commercially available tetrapeptide, RGDC, and on a cysteine-modified 14 amino acid peptide derived from the transduction domain of HIV Tat protein. The RGD peptide motif has been used for cell targeting and gene delivery (49, 50), and the Tat peptide has been shown to promote the delivery of macromolecules into cells (51–53).

**Scheme 2. Synthesis of a Keto-Peptide and Conjugation to an AOQ–Oligo<sup>a</sup>**

<sup>a</sup> (i) Bromoacetone in 50% acetonitrile/water for 1 h at room temperature. (ii) 50% acetonitrile/water for 1 h at room temperature.

**Figure 6.** Reversed-phase (RP) HPLC profile of the reaction of keto-RGDC peptide and AOQ-2106 in 50% acetonitrile/water at room temperature. A 20 min linear gradient of 2–50% acetonitrile in 50 mM sodium phosphate (pH 5.8) was used. (A)  $T = 0$  h, (B)  $T = 1$  h.

The C-terminus cysteine residue of each peptide was first reacted with a 10–33-fold excess of bromoacetone to give the keto-peptide. The reaction was complete within 1 h as assayed by C-18 reversed phase HPLC. Three major peaks were observed in the chromatogram. The first peak was the unreacted bromoacetone, the second peak was the desired keto-peptide, and the third peak was the disulfide-linked peptide dimer. The keto-peptide was obtained in 50% yield for each peptide after purification by HPLC.

The keto-peptides were then reacted with the short oligo-2'-*O*-methylribonucleotide, AOQ-2106. As shown by the chromatograms in Figure 6, the conjugation reaction between keto-RGD and AOQ-2106 was complete within 1 h at room temperature. The peptide–oligonucleotide conjugate appeared as two peaks in the chromatogram. Subsequent characterization of each peak by MALDI-TOF mass spectrometry showed that they had identical molecular weights. Thus these two peaks are attributed to the two isomeric oximes shown in Scheme 2.

Keto-derivatized Tat peptide was reacted with AOQ-2016 in 50% acetonitrile/water at room temperature. Reactions were run using a 5-fold excess of keto-peptide to oligonucleotide or with a 8-fold excess of oligonucleotide to keto-peptide. Examination of the reaction mixtures by MALDI-TOF mass spectrometry showed the presence of a compound whose molecular weight was consistent with

the composition of the AOQ-2016-Tat conjugate. In addition to the conjugate, AOQ-2106 or keto-Tat peptide was also detected in the mass spectrum, depending on whether the reaction was run using an excess of oligonucleotide or an excess of keto-peptide.

Although we were able to detect the oligonucleotide–peptide conjugate by mass spectrometry, we were unable to detect the conjugate by C-18 reversed phase HPLC. A variety of solvent systems and columns were tested including those previously reported to be effective in eluting oligonucleotide–Tat conjugates (54, 55). This apparent irreversible absorption to the C-18 column appears to be a property of the conjugate because when unmodified 2106 and Tat peptide were mixed, both compounds could be detected by C-18 reversed phase HPLC.

We found that the Tat-2106 conjugate could be purified by DEAE Sephadex chromatography. The keto-Tat peptide has a net positive charge of +9, whereas AOQ-2106 has net negative charge of –4. Thus, the AOQ-2106–Tat conjugate would be expected to have a net positive charge of +5. We exploited this charge difference to purify the conjugate. Mass spectrometry showed that all of the keto-Tat could be converted to conjugate by carrying out the reaction in the presence of excess AOQ-2106. The excess AOQ-2106 was removed by simply passing the reaction mixture through a DEAE Sephadex column. The negatively charged AOQ-2106 was retained on the column, while the AOQ-2106–Tat conjugate, which is positively charged, passed through the column. The molecular weight of the purified oligo–Tat conjugate was confirmed by MALDI-TOF mass spectrometry analysis. Using this procedure, pure AOQ-2106–Tat conjugate was obtained at 39% yield.

## CONCLUSIONS

AOQ- and EOQ-conjugated oligo-2'-O-methylribonucleotides show enhanced binding affinities for complementary RNA targets. This most likely results from favorable stacking interactions between the quinoline ring and the terminal base pair of the duplex formed by the oligomer and the target. Although we could find no evidence that the aminoxy group of AOQ reacts with 5,6 double bond of cytosines in the target RNA, this functional group does provide a site for efficient conjugation of AOQ–oligonucleotides to peptides or other moieties that bear an aldehyde or ketone group. The combination of the unique reactivity of the aminoxy group and enhanced binding affinity conferred by its quinoline ring suggest that AOQ may serve as a useful platform for the preparation of novel oligonucleotide conjugates.

## ACKNOWLEDGMENT

The authors thank Dr. Eric Hildebrand for assistance with the fluorescence experiments, Dr. Anne Noronha for help obtaining the mass spectra, and Dr. David Noll for helpful comments and suggestions. This research was supported by a grant from the National Institutes of Health (GM57140).

# ***N*-Succinimidyl 3-[<sup>131</sup>I]Iodo-4-phosphonomethylbenzoate ([<sup>131</sup>I]SIPMB), a Negatively Charged Substituent-Bearing Acylation Agent for the Radioiodination of Peptides and mAbs**

Sriram Shankar, Ganesan Vaidyanathan,\* Donna Affleck, Phillip C. Welsh, and Michael R. Zalutsky

Received November 5, 2002; Revised Manuscript Received January 3, 2003

An important criterion in design of acylation agents for the radioiodination of internalizing monoclonal antibodies (mAbs) is to maximize the retention of radioiodine in the tumor following mAb intracellular processing. We have previously shown that labeling methods that generate positively charged catabolites have enhanced tumor retention. Herein we have extended this strategy to investigate the potential utility of labeling internalizing mAbs with an acylation agent that yielded labeled catabolites that would be negatively charged at lysosomal pH. The negatively charged acylation agent, *N*-succinimidyl 3-[<sup>131</sup>I]iodo-4-phosphonomethylbenzoate ([<sup>131</sup>I]SIPMB), was prepared from its tin precursor, *N*-succinimidyl 4-di-*tert*-butylphosphonomethyl-3-trimethylstannylbenzoate (*t*Bu-SPMTB), in 40% radiochemical yield. The free acid, 3-[<sup>131</sup>I]iodo-4-phosphonomethylbenzoic acid ([<sup>131</sup>I]IPMBA), was also prepared from the corresponding precursor, 4-di-*tert*-butylphosphonomethyl-3-trimethylstannylbenzoic acid (*t*Bu-PMTBA), in 80% radiochemical yield. The rapidly internalizing mAb L8A4 was conjugated to [<sup>131</sup>I]SIPMB in 25–40% yield with preservation of its immunoreactivity. Internalization and processing in the U87ΔEGFR glioma cell line was studied in a paired label format with L8A4 labeled with <sup>125</sup>I using the Iodogen method. Retention of initially bound radioactivity in these cells at 24 h from [<sup>131</sup>I]SIPMB-labeled mAb was approximately 6-fold higher than that for directly labeled mAb. Catabolite analysis demonstrated that this difference reflected an order of magnitude higher retention of low molecular weight species in these cells. The [<sup>131</sup>I]SIPMB-L8A4 conjugate was intact over the first 2 h; thereafter, lysine-[<sup>131</sup>I]SIPMB was the predominant catabolite. In contrast, L8A4 labeled using Iodogen rapidly gave rise to mono-[<sup>125</sup>I]iodotyrosine within 2 h, which then cleared rapidly from the cells. These results suggest that SIPMB could be a potent candidate for labeling internalizing mAbs and warrant further study.

## INTRODUCTION

Radiolabeled monoclonal antibodies (mAbs),<sup>1</sup> genetically derived mAb fragments, and peptides are attractive approaches for the targeted radiotherapy of tumors (Goel et al., 2001; Murray, 2000; Illidge and Brock, 2000; de Jong et al., 2002). Many of these potential radiotherapeutics are rapidly internalized in tumor cells after binding to their receptor or antigenic target (Zalutsky,

1997). Therefore, it is important to utilize labeling methods that result in a high degree of retention of the radionuclide in the tumor cell after intracellular processing of the labeled molecule. Conventional radioiodination methods yield molecules that are susceptible to the action of endogenous deiodinases; furthermore, the monoiodotyrosine arising from the lysosomal degradation of internalizing mAbs are rapidly eliminated from the tumor cells (Geisler et al., 1992; Press et al., 1996).

To overcome this problem, residualizing labels have been developed, so named because the catabolites generated from labeled internalizing proteins are trapped within the lysosomes. The first strategy investigated was the use of radioiodinated nonmetabolized disaccharide–tyramine conjugates (Ali et al., 1990; Thorpe et al., 1993; Stein et al., 1995). Although enhanced intracellular retention could be achieved, unacceptably low labeling yields and higher spleen and liver uptake due to aggregate formation during labeling were deterrents to their clinical application. Other approaches that are being pursued include the use of radioiodinated proteolytically inert D-amino acid prosthetic groups, either alone (Foulon et al., 2000; 2001) or conjugated to DTPA (Govindan et al., 1999).

Another approach is the use of labeled templates with basic functionalities in their structure with the rationale that radiolabeled catabolites bearing such moieties will be protonated at lysosomal pH of ~5 and hence will be trapped within the lysosomes (Chart 1). The usefulness

<sup>1</sup> Abbreviations: CMC, 1-cyclohexyl-3-(2-morpholinoethyl)-carbodiimide metho-*p*-toluenesulfonate; DTPA, diethylenetriamine pentaacetic acid; EGFRvIII, epidermal growth factor receptor variant III; GMIBA, 4-guanidinomethyl-3-iodobenzoic acid; INA, 5-iodo-3-nicotinic acid; IPMBA, 3-iodo-4-phosphonomethylbenzoic acid; IR, immunoreactive fraction; kDa, kilo-Dalton; mAb, monoclonal antibody; PMSF, phenylmethylsulfonyl fluoride; ScFv, single chain fragment; SGMIB, *N*-succinimidyl 4-guanidinomethyl-3-iodobenzoate; SIB, *N*-succinimidyl 3-iodobenzoate; SIPC, *N*-succinimidyl 5-iodopyridine-3-carboxylate; SIPMB, *N*-succinimidyl 3-iodo-4-phosphonomethylbenzoate; *t*Bu-IPMBA, 3-iodo-4-di-*tert*-butylphosphonomethylbenzoic acid; *t*Bu-PMTBA, 4-di-*tert*-butylphosphonomethyl-3-trimethylstannylbenzoic acid; *t*Bu-SIPMB, *N*-succinimidyl 3-iodo-4-di-*tert*-butylphosphonomethylbenzoate; *t*Bu-SPMTB, *N*-succinimidyl 4-di-*tert*-butylphosphonomethyl-3-trimethylstannylbenzoate; TCA, trichloroacetic acid; TFA, trifluoroacetic acid; TMSE, 2-(trimethylsilyl)ethyl.

**Chart 1. Commonly Used Acyl-Transfer Agents for Labeling Monoclonal Antibodies.**

of this approach has been corroborated by work done in our laboratory using the mAb L8A4, which reacts with the tumor specific epidermal growth factor receptor deletion mutant, EGFRvIII (Wikstrand et al., 1995, 1997). The intracellular retention in vitro of L8A4 labeled with *N*-succinimidyl 3- $^{131}\text{I}$ iodopyridine-5-carboxylate ( $^{131}\text{I}$ SIPC) increased by up to 65% compared to the same mAb radioiodinated via Iodogen or using *N*-succinimidyl 3- $^{131}\text{I}$ iodobenzoate ( $^{131}\text{I}$ SIB) (Reist et al., 1996; 1997). Even higher tumor retention (300–400% higher than directly labeled mAb) was achieved both in vitro and in vivo for L8A4 labeled with *N*-succinimidyl 4-guanidinomethyl-3- $^{131}\text{I}$ iodobenzoate ( $^{131}\text{I}$ SGMIB), an acylation agent containing a more basic guanidine moiety (Vaidyanathan et al., 2001; 2002).

Selection of catabolites that would be positively charged in order for residualization of radioactivity was based on the well-known trapping of cationic dyes such as chloroquine in lysosomes (Holtzman, 1989). If the mechanism of retention is inhibition of exocytosis of labeled catabolites by passive transport across lysosomal and/or cell membranes due to their charge, then labeling methods that generate negatively charged catabolites should work as well. To test this hypothesis, we sought a phosphonic acid group-containing derivative of SIB, the prototypical acylation agent developed in our laboratory for the radioiodination of mAbs (Zalutsky and Narula, 1987). Herein, we present the no-carrier-added synthesis of *N*-succinimidyl 3- $^{131}\text{I}$ iodo-4-(phosphonomethyl)benzoate ( $^{131}\text{I}$ SIPMB) from a tin precursor and its conjugation to the anti-EGFRvIII mAb L8A4. Internalization assays and radiolabeled catabolite analyses were performed to determine the potential utility of  $^{131}\text{I}$ SIPMB for labeling internalizing mAbs.

## MATERIALS AND METHODS

**General.** All chemicals were purchased from Aldrich unless otherwise noted. Sodium  $^{125}\text{I}$ iodide and sodium  $^{131}\text{I}$ iodide with specific activities of 1200 Ci/mmol and 2200 Ci/mmol, respectively, were obtained from Perkin-Elmer Life Sciences. Commercially available 3-iodotyrosine (Sigma) was used as an HPLC standard in the catabolite assays.

Melting points were determined on a Haake Buchler apparatus and were uncorrected. High-pressure liquid chromatography was performed using one of three systems: (1) a Beckman System Gold HPLC equipped with

a Model 126 programmable solvent module, a Model 166 NM variable wavelength detector, a Model 170 radioisotope detector, and Beckman System Gold remote interface module SS420X, using a 32 karat software (3.1 build 22) run on an IBM NetVista computer with Windows NT v 4.00.1381 workstation and Intel Pentium III processor with SSE; (2) a Waters Delta 600 semipreparative HPLC equipped with Millennium software, a Delta 600 dual injector option, a 600 Pump, a 600E controller, and a 2487 dual  $\lambda$  absorbance detector; or (3) a Perkin-Elmer Series 4 Liquid Chromatograph connected to a Perkin-Elmer LC-95 UV/visible spectrophotometer detector and a Perkin-Elmer LCI-100 Laboratory Computing Integrator. Methods were programmed using a Perkin-Elmer 6312 display terminal. For reversed-phase chromatography, a Waters  $\mu$  Bondapak C18 (10  $\mu\text{m}$ ,  $3.9 \times 300$  mm) column, a Waters XTerra RP<sub>18</sub> column (5  $\mu\text{m}$ ,  $4.6 \times 250$  mm), or a Bondclone 10 C18 column (10  $\mu\text{m}$ ,  $3.9 \times 300$  mm, Phenomenex, Torrance, CA) was used. Preparative reversed-phase HPLC was performed using a Waters XTerra RP<sub>18</sub> (7  $\mu\text{m}$ ,  $19 \times 150$  mm) column. Normal-phase HPLC was done using a  $4.6 \times 250$  mm Partisil (10  $\mu$ ) silica column (Alltech, Deerfield, IL). Size-exclusion HPLC was performed using a  $7.5 \times 600$  mm Tosohaas TSK gel G3000 SW (10  $\mu\text{m}$ ) gel filtration column (Montgomeryville, PA) eluted with PBS at 1 mL/min. Analytical TLC utilized aluminum-backed sheets (Silica gel 60 F<sub>254</sub>), and normal-phase column chromatography was performed using silica gel 60, both obtained from EM Science (Gibbstown, NJ). Column chromatographic fractions were collected either manually or using a Gilson model 203 micro fraction collector (Middleton, WI) or an ISCO Foxy 200 fraction collector (Lincoln, NE), and products were identified by TLC. In some cases, an ISCO UA-6 UV-Vis detector was placed between the column outlet and the fraction collector to identify fractions. Preparative thick layer chromatography was done using  $20 \times 20$  cm, 1000  $\mu$  plates (Whatman, Clifton, NJ). Before applying the sample, the plates were run in ethyl acetate to clean the plates of any adsorbed impurities and then air-dried for 15–20 min. Radio-TLC was initially analyzed using a System 200 Imaging Scanner (BioScan, Washington, D.C.) and then cut into strips and counted on an automated gamma counter (LKB 1282, Wallac, Finland). Proton and carbon NMR spectra were obtained on either a Varian Mercury 300 spectrometer or a Varian Mercury 400 spectrometer. Chemical shifts are reported in  $\delta$  units; solvent peaks were referenced appropriately. Mass spectra were obtained on a Hewlett-Packard GC/MS/DS Model HP-5988A instrument, or an Applied Biosystems DE Pro, or on a JEOL SX-102 high-resolution mass spectrometer.

**Cells, mAb, and Culture Conditions.** The U87 $\Delta$ EGFR cell line was established from U87 MG glioblastoma cells transfected with EGFRvIII cDNA (Nishikawa et al., 1994). Cells were grown in zinc option media (Life Technologies, Inc., Grand Island, NY). On the basis of quantitative flow cytometry and Scatchard analyses, this line expresses an average of  $4\text{--}13 \times 10^5$  EGFRvIII molecules per cell in cell culture (Wikstrand et al., 1997). The purification and characterization of mAb L8A4, a murine IgG<sub>1</sub>, have been reported (Wikstrand et al., 1995). It reacts specifically with and has high affinity for the 145-kDa deletion mutant EGFRvIII molecule present on many human malignancies including breast, lung, and ovarian carcinomas, as well as on malignant gliomas (Wikstrand et al., 1997).

**4-Bromomethyl-3-iodobenzoic Acid (2).** Photolytic benzyl bromination of 3-iodo-4-methylbenzoic acid (1,

1.31 g, 5 mmol) was performed by refluxing with *N*-bromosuccinimide (890 mg, 5.0 mmol) and catalytic azo-*N,N*-biscyclohexylcarbonitrile (122 mg, 0.5 mmol) in 50 mL of 1,2-dichloroethane for 5 h under argon in the presence of an incandescent lamp. The reaction mixture was diluted with 50 mL of CH<sub>2</sub>Cl<sub>2</sub>, washed with 100 mL of water, and 50 mL of brine, dried, and concentrated to give 2.17 g of the crude product mixture as a yellow oil. Column chromatographic purification using a stepwise gradient of 10 to 50% EtOAc/hexane containing 1% AcOH gave 1.06 g (62%) of **2** as a white solid: mp 199–202 °C. <sup>1</sup>H NMR (CD<sub>3</sub>OD, 400 MHz) δ 8.45 (d, *J* = 1.54 Hz), 7.98 (dd, 1H, *J* = 7.86, 1.54 Hz), 7.61 (d, 1H, *J* = 8.03 Hz), 4.68 (s, 2H). MS (DIPCI) *m/z* 341 (MH<sup>+</sup>), 261 (MH<sup>+</sup> – Br). HRMS (FAB<sup>–</sup>) Calcd for C<sub>8</sub>H<sub>5</sub><sup>79</sup>BrIO<sub>2</sub> (M – H)<sup>–</sup>: 338.8518, Found 338.8518.

**3-Iodo-4-di-*tert*-butylphosphonomethylbenzoic Acid (tBu-IPMBA, 3).** Di-*tert*-butyl phosphite (740 mg, 3.8 mmol) in 0.5 mL of anhydrous THF was reacted with 3.8 mL of potassium *tert*-butoxide (1.0 M in THF) at 0 °C for 1 h under argon. To this homogeneous solution was added a solution of **2** (260 mg, 0.75 mmol) in 5 mL of THF, and the reaction mixture was stirred under argon at reflux temperature for 1 h. Excess unreacted base was decomposed by reaction with ca. 2 mL of MeOH. All solvents were removed by rotary evaporation, and the residue was adsorbed on silica and directly chromatographed using a stepwise gradient of 40 to 75% EtOAc/hexane containing 1% AcOH to give 183 mg (57%) of the product as an off-white solid: mp 163–165 °C. <sup>1</sup>H NMR (CD<sub>3</sub>OD, 300 MHz) δ 8.46 (s, 1H), 7.52 (dd, 1H, *J* = 8.0, 2.9 Hz), 7.04 (dd, 1H, *J* = 8.1, 1.0 Hz), 3.41 (d, 2H, *J* = 22.4 Hz), 1.46 (s, 18H). <sup>13</sup>C NMR (CD<sub>3</sub>OD, 75 MHz) δ 168.0, 143.2, 141.9, 132.1, 131.7, 130.1, 101.8, 84.8, 43.8, 30.7. MS (FAB<sup>+</sup>) *m/z* 455.04 (MH<sup>+</sup>). HRMS (FAB<sup>+</sup>) Calcd for C<sub>16</sub>H<sub>25</sub>IO<sub>5</sub>P (MH<sup>+</sup>): 455.0484, Found 455.0497.

**4-Di-*tert*-butylphosphonomethyl-3-trimethylstannylbenzoic Acid (tBu-PMTBA, 4).** To a solution of **3** (80 mg, 0.16 mmol) in 2 mL of dioxane were added hexamethylditin (272 mg, 0.83 mmol) and bis(triphenylphosphine)palladium(II) chloride (12 mg, 0.016 mmol), and the heterogeneous mixture was stirred at reflux temperature under argon for 1 h. The insolubles were filtered over Celite, and unreacted tin reagent and other highly nonpolar components were eluted over a short column of silica gel using hexane. The polar components were eluted with neat EtOAc and concentrated and were subjected to preparative TLC purification with 35% EtOAc/hexane containing 1% AcOH to give 11 mg (13%) of **4** as a pale yellow oil: <sup>1</sup>H NMR (CDCl<sub>3</sub>, 300 MHz) δ 8.13 (s, 1H), 7.96 (d, 1H, *J* = 7.8 Hz), 7.58 (s, 1H, *J* = 6.5 Hz), 3.16 (d, 2H, *J* = 22.3 Hz), 1.38 (s, 18H), 0.38 (s, 9H, *J*<sub>Sn–H</sub> = 26.5 Hz). MS (FAB<sup>–</sup>) *m/z* 491.04 (M – H)<sup>–</sup>, 434.98 (M – C<sub>4</sub>H<sub>9</sub>). HRMS (FAB<sup>+</sup>) Calcd for C<sub>18</sub>H<sub>30</sub>O<sub>5</sub>P<sup>116</sup>Sn (M – CH<sub>3</sub>)<sup>+</sup>: 473.0848, Found 473.0861.

**N-Succinimidyl 3-Iodo-4-di-*tert*-butylphosphonomethylbenzoate (tBu-SIPMB, 5).** To a solution of **3** (70 mg, 0.165 mmol) in 1 mL of anhydrous THF were added *N*-hydroxysuccinimide (96 mg, 0.83 mmol) and 1-cyclohexyl-3-(2-morpholinoethyl)carbodiimide metho-*p*-toluenesulfonate (CMC; 354 mg, 0.83 mmol), and the heterogeneous mixture was stirred for 3 h at ambient temperature under a flow of argon. The product mixture was filtered through a sintered glass funnel, the residue was washed with EtOAc, and the filtrate was concentrated to give 189 mg of the crude product. Preparative TLC purification using 40% EtOAc/1% AcOH/hexane afforded 84 mg (93% yield) of **5** as an oil: <sup>1</sup>H NMR (CDCl<sub>3</sub>, 400 MHz) δ 8.6 (d, 1H, *J* = 1.4 Hz), 8.03 (dd,

1H, *J* = 8.2, 1.0 Hz), 7.62 (dd, 1H, *J* = 8.2, 2.7 Hz), 3.36 (d, 2H, *J* = 22.6 Hz), 2.91 (br s, 4H), 1.46 (s, 18H). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 100 MHz) δ 169.1, 160.3, 144.9, 141.2, 130.9, 129.7, 124.6, 101.2, 83.3, 30.4, 25.6, 20.7. MS (FAB) *m/z* 552.1 (M)<sup>+</sup>, 496.0 (M – isobutylene)<sup>+</sup>. HRMS (EI) Calcd for C<sub>20</sub>H<sub>28</sub>O<sub>7</sub>INP (M)<sup>+</sup>: 552.0648, Found 552.0649.

**N-Succinimidyl 4-Di-*tert*-butylphosphonomethyl-3-trimethylstannylbenzoate (tBu-SPMTB, 6).** To a solution of **5** (27 mg, 0.05 mmol) in 0.5 mL of anhydrous dioxane were added hexamethylditin (65 mg, 0.2 mmol) and catalytic Pd(TPP)<sub>2</sub>Cl<sub>2</sub> (8 mg, 0.01 mmol), and the heterogeneous reaction mixture was stirred at reflux temperature for 45 min. The reaction mixture turned black almost instantly upon commencing reflux. The Pd catalyst and inorganic salts were filtered over Celite. The tin reagent and other nonpolar byproducts were removed by elution over a short column of silica using hexane following which the stannylated product and other polar components were eluted with EtOAc. Preparative TLC purification of this product mixture using 100% EtOAc afforded 21 mg (70%) of **6** as a pale yellow oil: <sup>1</sup>H NMR (CDCl<sub>3</sub>, 300 MHz) δ 8.14 (s, 1H), 8.0 (dd, 1H, *J* = 8.24, 1.65 Hz), 7.65 (dd, 1H, *J* = 8.24, 2.40 Hz), 3.16 (d, 2H, *J* = 23.4 Hz), 2.91 (s, 4H), 1.40 (s, 18H), 0.39 (s, 9H, *J*<sub>Sn–H</sub> = 27.5 Hz). <sup>13</sup>C NMR (CDCl<sub>3</sub>, 75 MHz, selected peaks) δ 169.4, 148.1, 144.9, 138.2, 129.8, 82.7, 30.4, 30.3, 25.8. MS (FAB<sup>+</sup>) *m/z* 588.0 (M<sup>+</sup>), 532.0 (M – C<sub>4</sub>H<sub>8</sub>)<sup>+</sup>, 491 (M – succinimide). HRMS (FAB<sup>+</sup>) Calcd for C<sub>23</sub>H<sub>36</sub>NO<sub>7</sub>P<sup>116</sup>Sn (M<sup>+</sup>): 586.1172, Found 586.1170; Calcd for C<sub>23</sub>H<sub>36</sub>NO<sub>7</sub>P<sup>114</sup>-Sn: 584.1169, Found 584.1170.

**N-Succinimidyl 3-iodo-4-phosphonomethylbenzoate (SIPMB, 7).** A sample of **7** for a HPLC standard was obtained by deprotection of **5** (10 mg, 0.02 mmol) with 100 μL each TFA and CH<sub>2</sub>Cl<sub>2</sub> for 10 min. Excess TFA and other volatiles were removed under a stream of argon, and traces of the acid were removed by repeated coevaporation with CH<sub>2</sub>Cl<sub>2</sub> and hexane. <sup>1</sup>H NMR (CD<sub>3</sub>CN, 300 MHz) δ 8.54 (s, 1H), 8.05 (d, 1H, *J* = 7.83 Hz), 7.60 (m, 1H), 3.47 (d, 2H, *J* = 22.25 Hz), 2.83 (s, 4H). MS (FAB<sup>–</sup>) *m/z* 437.98 (M – H)<sup>–</sup>. HRMS (FAB<sup>–</sup>) Calcd for C<sub>12</sub>H<sub>10</sub>INO<sub>7</sub>P (M – H)<sup>–</sup>: 437.9240, Found 437.9245.

**3-Iodo-4-phosphonomethylbenzoic Acid (IPMBA, 8).** A sample of **8** for a HPLC standard was obtained as above by deprotection of **3** (8 mg, 0.02 mmol) for 15 min in 0.5 mL of TFA. Excess TFA was removed under a flow of argon and the residue coevaporated with CH<sub>2</sub>Cl<sub>2</sub> and hexane to give 6.5 mg (100%) of a white solid: mp 218–221 °C. <sup>1</sup>H NMR (CD<sub>3</sub>OD, 300 MHz) δ 8.45 (s, 1H), 7.94 (dd, 1H, *J* = 7.76, 1.44 Hz), 7.56 (dd, 1H, *J* = 7.96, 2.47 Hz), 3.43 (d, 2H, *J* = 22.4 Hz). MS (FAB<sup>–</sup>) *m/z* 340.81 (M – H)<sup>–</sup>. HRMS (FAB<sup>–</sup>) Calcd for C<sub>8</sub>H<sub>7</sub>IO<sub>5</sub>P (M – H)<sup>–</sup>: 340.9076, Found 340.9081. Analytical reversed-phase HPLC was performed to assay the purity of the sample using 0.1% TFA/water (A) and 0.1% TFA/CH<sub>3</sub>CN (B) using the following gradient: 95% A held for 10 min and ramped over 10 min to 95% B, held at 95% B for 5 min. *t*<sub>R</sub> = 19 min, with >95% purity.

**3-[<sup>131</sup>I]Iodo-4-di-*tert*-butylphosphonomethylbenzoic Acid (<sup>131</sup>I-3).** The radioiodination of tBu-PMTBA **4** was performed using a variation of conditions previously reported for other compounds (Vaidyanathan et al., 1998). Typically, to a vial containing 2–3 mCi of [<sup>131</sup>I]-iodide in 1–3 μL of NaOH was added ca. 0.4 mg of *N*-chlorosuccinimide in 10 μL of AcOH. The vial was vortexed and 0.2–0.3 mg of the tin precursor **4** in 10 μL of AcOH was added. The reaction mixture was vortexed again and maintained at room temperature for 30–45 min. The product (*t*<sub>R</sub> = 15 min) was isolated in ~80%

radiochemical yield from a normal-phase HPLC column eluted in isocratic mode with 50:50:0.1 EtOAc/hexane/AcOH.

**N-Succinimidyl 3- $^{131}\text{I}$ Iodo-4-di-*tert*-butylphosphonomethylbenzoate ( $^{131}\text{I}$ -5).** 1) Using the procedure outlined above,  $^t\text{Bu}$ -SPMTB **6** was radioiodinated to give  $^{131}\text{I}$ -5 in 40% radiochemical yield. The product ( $t_{\text{R}} = 33.0$  min) was isolated from a normal-phase HPLC column eluted at 1 mL/min with isocratic 50:50:0.1 EtOAc/hexane/AcOH. 2) Alternatively,  $^{131}\text{I}$ -3 synthesized as described earlier was reacted with 25  $\mu\text{L}$  each of 0.1 M disuccinimidyl carbonate (DSC) and pyridine in  $\text{CH}_3\text{CN}$  for 15 min at 75  $^\circ\text{C}$  (Vaidyanathan and Zalutsky, 1994). The reaction mixture was injected on a normal-phase HPLC column eluted with isocratic 50:50:0.1 EtOAc/hexane/AcOH to afford the product ( $t_{\text{R}} = 33.0$  min) in ~80% radiochemical yield.

**N-Succinimidyl 3- $^{131}\text{I}$ Iodo-4-phosphonomethylbenzoate ( $^{131}\text{I}$ -7).** Deprotection of the *tert*-butyl groups of  $^{131}\text{I}$ -5 was achieved readily by reaction with 100  $\mu\text{L}$  of TFA for 15 min at room temperature. All volatiles were removed by evaporation under a stream of argon. Persistent traces of TFA were removed by repeated coevaporation with EtOAc before coupling to mAb.

**3- $^{131}\text{I}$ Iodo-4-phosphonomethylbenzoic Acid ( $^{131}\text{I}$ -8).** Deprotection of [ $^{131}\text{I}$ ]-3 to [ $^{131}\text{I}$ ]-8 was performed as outlined above. Trace amounts of TFA were removed likewise by repeated coevaporation with EtOAc under a stream of argon.

**Glycine and Lysine Conjugate Synthesis.** These were prepared on a micromolar scale to be used principally as HPLC standards. The products were isolated by semipreparative reversed-phase HPLC and were characterized by mass spectrometry. The conditions for HPLC were as follows; a RP XTerra column was eluted with the following gradient consisting of 0.2% (v/v) HOAc in water (A) and 0.2% (v/v) HOAc in methanol (B) at 10 mL/min: Initial concentration of 5% B for 15 min was increased to 70% B over 10 min, maintained at 70% B for 5 min, and then increased to 100% B over 5 min.

**L-Lysine Conjugate of 4-Phosphonomethyl-3-iodobenzoic Acid.** To a solution of **5** (5.5 mg, 10.0  $\mu\text{mol}$ ) in 60  $\mu\text{L}$  of THF was added a solution of *N*- $\epsilon$ -Boc-L-lysine in 5  $\mu\text{L}$  of 0.1 M borate buffer, pH 8.5 (11.1 mg in 5  $\mu\text{L}$ , 45.0  $\mu\text{mol}$ ), and the mixture was stirred overnight at room temperature. THF was evaporated, and the residue was treated at room temperature for 15 min with 100  $\mu\text{L}$  of TFA. Excess TFA was evaporated under a stream of argon and residual traces of TFA were removed by coevaporation with methanol. The product ( $t_{\text{R}} = 28$  min) was isolated by semipreparative reversed-phase HPLC. MS (FAB $^-$ )  $m/z$  469.20 ( $\text{M} - \text{H}$ ) $^-$ .

**Glycine Conjugate of 4-Phosphonomethyl-3-iodobenzoic Acid.** To a solution of **5** (5.5 mg, 10.0  $\mu\text{mol}$ ) in 60  $\mu\text{L}$  of anhydrous THF was added a solution of glycine (3.5 mg, 50  $\mu\text{mol}$ ) in 5  $\mu\text{L}$  of 0.1 M borate pH 8.5, and the heterogeneous reaction mixture was stirred overnight at room temperature. The THF was evaporated, and the residue was treated at room temperature for 15 min with 100  $\mu\text{L}$  of TFA. Excess TFA was evaporated under a stream of argon, and residual traces of TFA were removed by coevaporation with methanol. The product ( $t_{\text{R}} = 32.5$  min) was isolated by semipreparative reversed-phase HPLC. MS (FAB $^-$ )  $m/z$  397.92 ( $\text{M} - \text{H}$ ) $^-$ . HRMS (FAB $^-$ ) Calcd for  $\text{C}_{10}\text{H}_{10}\text{INO}_6\text{P}$  ( $\text{M} - \text{H}$ ) $^-$ : 397.9291, Found 397.9295.

**Radiolabeling of the mAb L8A4.** 1. *Iodogen method.* To a  $1/2$ -dram vial coated with 10  $\mu\text{g}$  of Iodogen was added a solution of L8A4 in phosphate buffer, pH 7.14 (100  $\mu\text{L}$ ,

~2 mg/mL) and 1–2  $\mu\text{L}$  of  $^{125}\text{I}$  (0.5–1.0 mCi) in 0.1 N NaOH. The mixture was incubated at room temperature for 20 min, and the labeled mAb was isolated by gel filtration over a PD10 column (Amersham Biosciences, Piscataway, NJ) eluted with PBS.

2. *Using [ $^{131}\text{I}$ ]-SIPMB.*  $^{131}\text{I}$ -7 was coupled with ca. 150  $\mu\text{g}$  of mAb (1.5–2.9 mg/mL) in borate buffer (pH 8.5) for 30 min at room temperature. The radiolabeled mAb conjugate was isolated by filtration over a PD10 column eluted with PBS affording the acylated mAb in 25–40% yield.

**Octanol–Water Partition Coefficient.** The partition coefficient for  $^{131}\text{I}$ -8 was determined at two different pH values using PBS of pH 7.40 and 4.75. The buffer and *n*-octanol were each presaturated with the other prior to the experiment. About 250 000 CPM of [ $^{131}\text{I}$ ]-8 in 5–10  $\mu\text{L}$  of PBS were added in triplicate to a mixture of 1 mL each of *n*-octanol and buffer, and the contents were mixed thoroughly by vortexing for 1–2 min. The layers were separated by centrifugation. A 50  $\mu\text{L}$  aliquot of each layer in duplicate from each tube was withdrawn and counted for radioactivity, and the ratios of activities in *n*-octanol and buffer were calculated. The entire experiment was repeated twice.

#### Evaluation of Immunoreactivity of Labeled mAbs.

The assays were conducted using magnetic beads whose surfaces were coated with the extracellular domain of EGFRvIII or, as a negative control, BSA (Foulon et al., 2000). Specific binding was taken as the difference between the values obtained for the positive and the negative controls. The immunoreactive fraction of the mAb was determined according to the method of Lindmo (Lindmo et al., 1984).

**Internalization Assays.** Assays were performed in a paired-label format with U87 $\Delta$ EGFR cells at a density of  $5 \times 10^5$  cells per well as described (Vaidyanathan et al., 2001). Briefly, medium containing 1  $\mu\text{Ci}$  (0.5–1.0  $\mu\text{g}$  each, mAb excess) of the labeled mAbs was added, and the cells were incubated for 1 h at 4  $^\circ\text{C}$ . After washing, the cells were brought to 37  $^\circ\text{C}$ , and processed in triplicate at 0, 1, 2, 4, 8–10, 16, and 24 h as follows: The surface-bound radioactivity was removed by washing the cells with pH 2 Zinc Option medium, and the cells were solubilized in 0.5 mL of 0.5 N NaOH to determine internalized activity. Counts in the cell culture supernatants, acid washes (cell surface-bound), and the cell lysates (internalized) were expressed as the percentage of activity initially bound to the cells after the 1 h incubation at 4  $^\circ\text{C}$ .

**Paired-Label in Vitro Catabolism of L8A4 Labeled via SIPMB and Iodogen Methods.** To compare the in vitro catabolism of mAbs labeled using SIPMB (7) and Iodogen, an internalization assay was performed as above using about 1–3  $\mu\text{Ci}$  of each labeled mAb. After the surface-bound radioactivity was removed with acid washing, the cell pellets were lysed for 10 min at room temperature with 200  $\mu\text{L}$  of 0.5% NP40 in PBS containing the protease inhibitors aprotinin (0.02 mg/mL), leupeptin (0.05 mg/mL), PMSF (4 mM), and pepstatin (0.07 mg/mL). The cell debris was pelleted by centrifugation, and the cell lysates were isolated. High molecular weight components in cell lysates and initial cell culture supernatants, coinjected with gel filtration standards (BioRad) for comparison, were analyzed by size-exclusion HPLC. Fractions of 0.25 mL were collected and counted for  $^{125}\text{I}$  and  $^{131}\text{I}$  in an automated gamma counter, and the radioactivity was plotted versus time. To determine the low molecular weight catabolites, cell lysates, and cell culture supernatants at each time point were filtered at

4 °C for 240 min through Centricon-10 tubes (Amicon; 10 kDa cut off). The filtrates and the cartridges were counted for radioactivity prior to HPLC analyses of the filtrates to determine the fraction of low and high molecular weight components. The components of the filtrates were analyzed by reversed-phase chromatography. A C18 column (Bondclone) was eluted with a mobile phase gradient as described earlier in the Experimental Section. Fractions of 0.25 mL were collected and counted for radioactivity. Under these HPLC conditions, the retention times of the IPMBA, IPMBA-glycine, and IPMBA-lysine standards were 23.5, 32.5, and 28 min, respectively.

## RESULTS AND DISCUSSION

There is strong evidence that acylation agents for internalizing mAbs that generate positively charged catabolites increase the retention of radioiodine activity in tumor cells (Reist, 1996, 1997; Foulon, 2001; Vaidyanathan, 2001). The goal of these experiments was to develop an acylation agent bearing a negatively charged substituent to determine whether reagents of this type would offer similar advantages for labeling internalizing biomolecules. A practical motivation of the work is that use of negatively charged radioiodinated templates may be an approach for minimizing normal tissue accumulation, a problem noted particularly in the kidneys when the polycationic D-KRYRR peptide was used for mAb labeling (Foulon et al., 2000). Studies with both glycolated Fab fragments (Kobayashi et al., 2000) and copper complexes (Jones-Wilson et al., 1998; Sun et al., 2002) suggest that molecules bearing a negative charge are less avidly retained by the kidney and other normal tissues, presumably due to the negative charge on renal proximal tubules (Maack et al., 1992).

A benzyl phosphonic acid analogue was selected for this purpose for the following reasons. Phosphate esters and anhydrides are the most common functional groups present in nature's repertoire, and phosphonates have been extensively explored as phosphate surrogates in biology and medicine (Engel, 1977). Phosphonic acids are very polar compounds and, owing to their low first *pK<sub>a</sub>* of ca. 2–3 (Franz, 2001; Moe and Butler, 1983; Van Wazer, 1958), they are expected to exist in the anionic form even at a pH of 5. Thus, it can be expected that, after the degradation of the mAbs or oligopeptides, the catabolites bearing the radiolabeled phosphonic acid moiety will be negatively charged, which should impede their transport across lysosomal and cell membranes.

A methyl phosphonic acid derivative of 3-iodobenzoate was chosen as the target compound, which may be synthesized from 4-bromomethyl-3-iodobenzoic acid **2**. Commercially available 3-iodo-4-methylbenzoic acid **1** was brominated under free radical conditions. Initially, benzyl bromination utilizing the conventional conditions using *N*-bromosuccinimide (NBS) in CCl<sub>4</sub> and catalytic benzoyl peroxide was studied. However, the benzoic acid precursor remained mostly insoluble in the nonpolar solvent, even at reflux temperature, leading to largely heterogeneous reaction conditions that resulted in poor product yields even under prolonged refluxing conditions. This led us to attempt the bromination using NBS and the initiator azobiscyclohexylnitrile (Keck, 1987) in a higher boiling solvent, 1,2-dichloroethane (Sneath et al., 1976) (Scheme 1). The reaction mixture was homogeneous at reflux, but the reaction was still incomplete, and it afforded a mixture of the mono- and dibromo derivatives regardless of the stoichiometry of NBS employed.

**Scheme 2. Proposed Mechanism of the Origin of Methyl (3-Iodo-4-dimethylphosphonomethyl)benzoate from a Michaelis-Arbuzov Reaction**

However, when compared to the conventional procedure, these reaction conditions gave higher yields of the monobrominated product **2**. Column chromatographic isolation of **2** from the reaction mixture using a MeOH/EtOAc solvent system was cumbersome owing to "streaking" of the very polar benzoic acid derivatives on silica gel. A modified EtOAc/hex/AcOH system proved to be much more effective in separating the components of the reactions. The monobrominated derivative **2** was isolated in ca. 60% yield by gravity column chromatography of the reaction mixture using a stepwise gradient of 20–50% EtOAc/hexane containing 1% AcOH.

Benzyl phosphorylation of **2** was first attempted by Arbuzov reaction (Bhattacharya and Thyagarajan, 1981) with trimethyl phosphite. There were several drawbacks to this approach, foremost among which was the lack of mild conditions in removing the methyl protecting group to reveal the free phosphonic acid, penultimate to labeling the mAb, without affecting the sensitive *N*-succinimidyl carboxylate ester. Besides, the reaction of **2** with trimethyl phosphite afforded an ester, methyl (3-iodo-4-dimethylphosphonomethyl)benzoate, as the primary product in ca. 40–50% yield. This unexpected and unprecedented product may result from the nucleophilic displacement of a methyl group from the intermediate quaternary phosphonate of the Arbuzov reaction (Scheme 2) by the benzoic acid moiety. This approach was not successful, and the mechanism of the reaction was not explored further.

The synthesis of 2-trimethylsilylethyl (3-iodo-4-bromomethyl)benzoate (TMSE-**2**, structure not shown) has been reported earlier by our laboratory (Vaidyanathan et al., 2001). To preempt methyl esterification of the free carboxylic acid moiety, the Arbuzov reaction of TMSE-**2** was attempted. However, removal of the methyl groups of the dimethylphosphonate to give free phosphonic acid, prior to coupling to the mAb, involves stringent conditions (heating with TMSBr/CH<sub>3</sub>CN, Qian et al., 1996), and two additional steps of protection and deprotection

Scheme 3<sup>a</sup>

<sup>a</sup> i.  $(\text{Me}_3\text{Sn})_2$ ,  $\text{Pd}(\text{TPP})_2\text{Cl}_2$ , dioxane, reflux. ii. *N*-hydroxysuccinimide, CMC, THF.

of the carboxylic group were involved. Therefore, this route was replaced by the more direct route outlined in Scheme 1.

The *tert*-butyl group has been extensively used in peptide synthesis and total synthesis. It is renowned for its lability to acidic conditions and its ease of removal and has been used widely as a protecting group (Greene, 1991). The *tert*-butyl protecting group is removed easily under protic, e.g. TFA, and aprotic, e.g. TMSOTf, conditions alike (Greene, 1991). In fact, Burke et al. (1991) have utilized a *tert*-butyl protecting group in the synthesis of the aromatic  $\alpha$ -hydroxyphosphonate inhibitors of tyrosine kinases. The conditions for conversion of a benzyl di-*tert*-butylphosphonate to the free benzyl phosphonic acid (Burke et al., 1991) are known to be much milder compared to those for deprotection of the dimethylphosphonates (Qian, 1996). Therefore, we attempted to convert **2** to the di-*tert*-butylphosphonomethyl derivative **3** by its reaction with deprotonated di-*tert*-butyl phosphite (Baczko et al, 1996; Burke et al., 1991; Yao et al, 1999) (Scheme 1). A 5-fold excess of the phosphite reagent was deprotonated with  $\text{KO}^t\text{Bu}$  in THF at 0 °C and allowed to react with **2** in refluxing THF whereby the reaction proceeded cleanly to afford **3** in 57% yield.

Esterification of **3** to *N*-succinimidyl (3-iodo-4-di-*tert*-butylphosphonomethyl)benzoate **5** (*t*Bu-SIPMB) was achieved in high yield by reaction with *N*-hydroxysuccinimide and the water-soluble DCC-analogue, 1-cyclohexyl-3-(2-morpholinoethyl)carbodiimide metho-*p*-toluenesulfonate (CMC) (Scheme 3). The reaction was completed within 3 h, and the byproducts were simply filtered to afford, after chromatographic purification, **5** in 93% yield. Trimethylstannylation of **5** to **6** (*t*Bu-SPMTB) was accomplished by palladium-catalyzed coupling of the iodo precursor with hexamethylditin in refluxing dioxane (Scheme 3) (Wigerinck et al., 1993). It is imperative that anhydrous dioxane be utilized because residual moisture can lead to hydrolysis of the active ester under refluxing conditions. The stannylation reaction proceeded in 70% yield. Alternatively, stannylation of the free-acid **3** under the same conditions to give **4** followed by esterification to give **6** may also be performed (Scheme 3). The yield of the Pd-catalyzed stannylation reaction of **3** was very low ( $\approx 15\%$ ). Therefore, the former procedure was the approach of choice for the synthesis of **6**. However, the tin precursor **4** used to prepare  $^{131}\text{I}$ -**3** was synthesized using the latter method.

Radioiodination of **6** to  $^{131}\text{I}$ -**5** was accomplished employing *N*-chlorosuccinimide (NCS) in acetic acid as the oxidizing source as described (Vaidyanathan et al., 1998)

Scheme 4<sup>a</sup>

<sup>a</sup> i.  $^{131}\text{I}^-$ , NCS/AcOH; ii. Pyr, disuccinimidyl carbonate,  $\text{CH}_3\text{CN}$ ; iii. TFA.

and shown in Scheme 4. Alternatively, following an indirect route, **4** was radioiodinated to give  $^{131}\text{I}$ -**3** and converted to its active ester  $^{131}\text{I}$ -**5** by heating it with disuccinimidyl carbonate (DSC) and pyridine in  $\text{CH}_3\text{CN}$  (Vaidyanathan and Zalutsky, 1994) (Scheme 4). Although the two-step procedure resulted in a higher overall yield of  $^{131}\text{I}$ -**7** (ca. 80%), it was more labor and time intensive, involving two HPLC purification steps and evaporation of solvents, and therefore deemed less preferable to the one-step procedure. Furthermore, using the two-step procedure, the mAb coupling reaction often failed, with a maximum coupling yield of only 22% obtained. The immunoreactive fraction of the mAb conjugated with  $^{131}\text{I}$ -**7** synthesized in this fashion was low ( $\sim 20\%$ ) as well. We speculate that both problems might be attributable to the conjugation of an unidentified nonradioactive compound to the mAb that coeluted with  $^{131}\text{I}$ -**7**. As a consequence, the use of the one-step procedure for  $^{131}\text{I}$ -**5** is recommended.

Facile deprotection of  $^{131}\text{I}$ -**5** to give  $^{131}\text{I}$ -**7** was accomplished by treatment with anhydrous trifluoroacetic acid. Deprotection of  $^{131}\text{I}$ -**3** (*t*Bu- $^{131}\text{I}$ IPMBA) was carried out similarly to give  $^{131}\text{I}$ -**8** (Scheme 4). Excess trifluoroacetic acid usually was removed under a stream of argon. The effect of trace amounts of TFA on the pH of borate buffer used in the mAb coupling reaction was tested. Not surprisingly, even insignificant amounts of the strong acid caused considerable disruption of the pH of the buffer. To prevent damage to the mAb due to residual acid, traces of TFA were removed by repeated coevaporation with EtOAc. The pH of a borate buffer solution of  $^{131}\text{I}$ -**7**, coevaporated with EtOAc as described above, remained the same as that of the original buffer.

The  $^{131}\text{I}$ -**7** was coupled to mAb L8A4 with a yield of 25–40%, a value lower than reported for conjugation of mAbs with other acylation agents of this type (Vaidyanathan et al., 2001; Zalutsky and Narula, 1987). Coupling yields are affected by many factors including protein concentration (Vaidyanathan and Zalutsky, 1990), and the protein concentrations used in the current study were only in the range of 1.5–2.9 mg/mL. When  $^{131}\text{I}$ -**7** was conjugated with another mAb (murine 81C6) at  $\sim 16$  mg/mL concentration, a 75% coupling yield was obtained, which is consistent with previous results with other acylation agents at similar concentrations.

**Figure 1.** Paired-label in vitro internalization of L8A4 by U87ΔEGFR cells. L8A4 radioiodinated with [<sup>131</sup>I]SIPMB (A) and with <sup>125</sup>I using Iodogen (B). Percentage of radioactivity initially bound to cells that was surface-bound (●), internalized (■), and found in supernatant (◆) is shown.

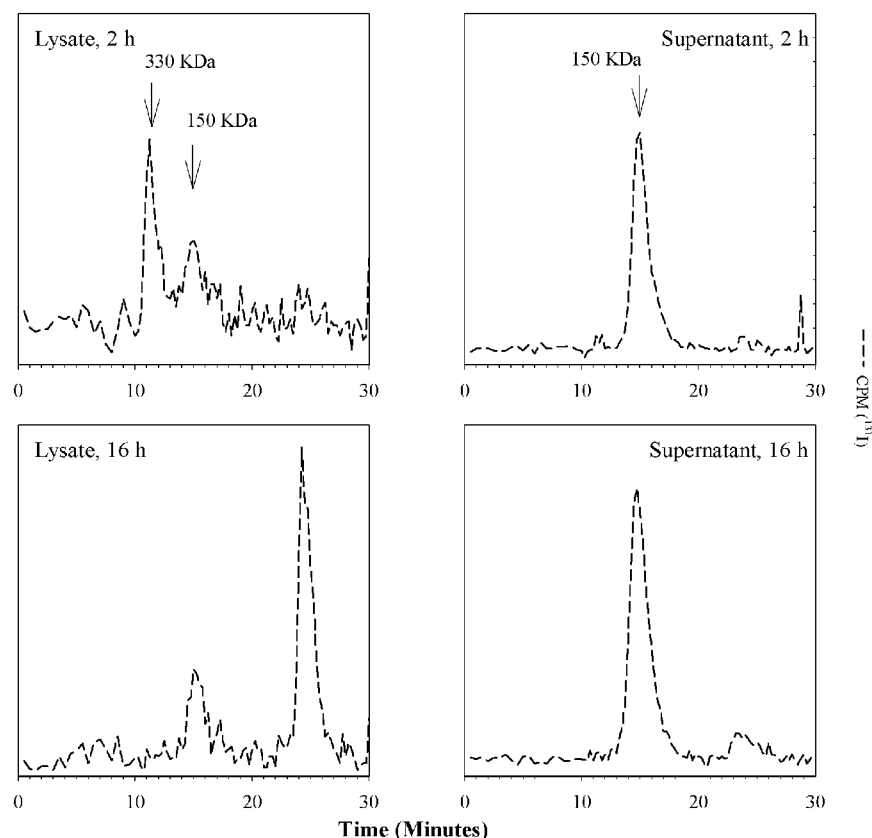

The % IR fraction was determined each time before internalization and metabolism studies to ensure the integrity of the radiolabeled mAb. The IR fraction of the mAb L8A4 labeled with [<sup>131</sup>I]SIPMB determined by the Lindmo method (Lindmo et al., 1984) was  $71 \pm 4.4\%$ . In comparison, the immunoreactive fraction for this batch of L8A4 labeled with <sup>125</sup>I using Iodogen was only  $50.7 \pm 9.5\%$ . TCA precipitation values of  $\geq 97.5\%$  for [<sup>131</sup>I]-SIPMB-labeled L8A4 were obtained for all preparations. Finally, no detectable high-molecular weight aggregates were seen by size-exclusion HPLC, with  $>95\%$  of injected radioactivity eluting with a retention time corresponding to the 150 kDa gel filtration standard, confirming mAb integrity postlabeling.

An internalization assay was performed in paired-label format on the EGFRvIII-expressing U87ΔEGFR cell line to determine whether labeling mAb L8A4 using [<sup>131</sup>I]-SIPMB increased the intracellular retention of radioiodine activity compared with a conventional radioiodination method (Iodogen). Typical results from one of three experiments are presented in Figure 1. Internalized

counts for the two labeling methods were similar from 0 h through 4 h; however, by the 10 h time point, there was an approximately 2-fold increase in intracellular counts for mAb labeled using [<sup>131</sup>I]SIPMB (SIPMB,  $22.9 \pm 3.4\%$ ; Iodogen,  $12.9 \pm 2.7\%$ ;  $P < 0.05$ , paired *t*-test). The enhancement in intracellular activity for mAb labeled using [<sup>131</sup>I]SIPMB compared with Iodogen increased with time, reaching a 6-fold advantage at 24 h (SIPMB,  $32.2 \pm 4.3\%$ ; Iodogen,  $5.4 \pm 0.8\%$ ;  $P < 0.05$ ). A corresponding increase in radioactivity in the supernatant was observed for mAb labeled using Iodogen. The degree of enhancement in intracellular counts for L8A4 labeled with negatively charged SIPMB compared with Iodogen is similar to that observed on this cell line when the positively charged SGMIB reagent was used for labeling this mAb (Vaidyanathan et al., 2001).

A catabolism study was undertaken next in order to determine whether the increased intracellular retention of radioiodine was related to the nature of the labeled species generated during the processing of mAbs labeled using [<sup>131</sup>I]SGMIB. Because of the well-known lysosomal

**Figure 2.** Radiochromatogram obtained from the size-exclusion HPLC of cell lysates and cell culture supernatants at 4 and 16 h from the paired-label in vitro metabolism study of L8A4 labeled with  $^{131}\text{I}$  using  $^{131}\text{I}$ SIPMB by U87EGFR cells.

proteolysis of internalizing mAbs, differences in the distribution of low molecular weight catabolites were initially investigated. Table 1 summarizes the percentage of the total low molecular weight catabolites (defined as labeled species that passed through a 10 kDa filter) that were found in the cell lysates following the binding of L8A4 labeled using the SIPMB and Iodogen methods. The fraction of low molecular weight catabolites that were cell-associated was considerably higher for SIPMB at all time points with a greater than 100-fold difference seen at 8 h. The results with the positively charged SGMIB acylation agent, performed under identical assay conditions (Vaidyanathan et al., 2001), also are shown in Table 1, and are qualitatively similar to those obtained with SIPMB.

The percentage of radioiodine activity present as low molecular weight species in tumor cell lysates and in the cell culture supernatant was calculated and the results are presented in Table 2; again, data for SGMIB are provided for comparison. With directly labeled mAb, less than 2% of the radioiodine activity in cell lysates was in the form of low molecular weight molecules, while for SIPMB, 28–32% of the activity was in the form of low

molecular weight species. Again, results for SGMIB were qualitatively similar to those observed in this study for mAb labeled using the SIPMB method. This suggests that, as with SGMIB-labeled mAb, the higher intracellular retention of activity observed with  $^{131}\text{I}$ SIPMB-labeled L8A4 is due to the increased presence of low molecular weight catabolites.

These data demonstrate that methods that involve coupling labeled templates bearing either a positive or a negative substituent to the mAb increase the retention of low molecular weight catabolites in tumor cells compared with directly labeled mAb. For radioiodination agents containing a benzoyl moiety, such as those used in this study, the chief low molecular weight catabolites are the free acid as well as its lysine and glycine conjugates (Garg et al., 1995). As an indication of its polarity, we determined the *n*-octanol:water partition coefficient for the free acid that would be generated from SIPMB-labeled mAbs, IPMBA, at physiological and lysosomal pH. The partition coefficient determined for IPMBA was  $0.02 \pm 0.01$  at pH 7.4 and  $0.03 \pm 0.00$  at pH 4.75. In comparison, those reported for GMIBA were  $0.02 \pm 0.00$  and  $0.06 \pm 0.00$  at pH 7.4 and 4.75, respectively

**Figure 3.** Radiochromatogram obtained from the reversed-phase HPLC of cell lysates and cell culture supernatants at 2 and 4 h from the paired-label in vitro metabolism study of L8A4 labeled with <sup>131</sup>I using [<sup>131</sup>I]SIPMB (short dashes) and with <sup>125</sup>I using Iodogen (solid line) by U87ΔEGFR cells.

(Vaidyanathan et al., 2001). Because of the high polarity of both acids at lysosomal pH, catabolites containing these groups should be retained in lysosomes, consistent with the results of internalization assays with L8A4 mAb labeled using SIPMB and SGMIB.

A catabolite analysis study was undertaken to determine the nature of the labeled species present in the cells and cell culture supernatants following exposure of mAb L8A4 to U87ΔEGFR cells in vitro. Size-exclusion HPLC of the [<sup>131</sup>I]SIPMB-L8A4 conjugate revealed that the majority of the radioiodine activity in the cell culture supernatant at all time points had a retention time corresponding to intact IgG (Figure 2). At 1 and 2 h, the predominant high molecular weight radioactive peak in the cell lysate coeluted with the 330 kDa molecular weight marker, which likely corresponds to a complex between the mAb and the 145 kDa EGFRvIII molecule. A peak corresponding to intact IgG also was seen. At 16 h, the mAb-EGFRvIII complex was absent and low molecular weight species predominated. These results were similar to those observed previously for the in vitro catabolism of L8A4 mAb labeled using the Iodogen, SGMIB, and SIPC methods (Reist et al., 1996; Vaidyanathan et al., 2001).

Reversed-phase HPLC was utilized to investigate the nature of the low molecular weight species generated after exposure of mAb L8A4 to U87ΔEGFR cells. To facilitate chromatogram interpretation, potential catabolites from the SIPMB template, namely IPMBA, lysine-IPMBA, and glycine-IPMBA conjugates, were prepared independently, isolated, and characterized by mass spectrometry. Analysis of the cell lysate indicated that the predominant low molecular weight catabolite of [<sup>131</sup>I]-SIPMB-L8A4 was the lysine-IPMBA conjugate (Figure 3); the free amine and carboxylate in the lysine adduct

being zwitterionic, the net charge of this catabolite retains a net negative charge. The peak corresponding to lysine-IPMBA was first seen at 4 h, and increased in quantity at the 8 and 16 h time points. Lysine conjugates can arise from the proteolytic cleavage of the acylated lysine from mAbs labeled using acylation agents (Arano et al., 1995; Duncan and Welch, 1993; Rogers et al., 1995). Consistent with the current results, the major catabolite of L8A4 labeled with [<sup>125</sup>I]SIPC was the lysine conjugate of [<sup>125</sup>I]iodonicotinic acid (Reist et al., 1996; Vaidyanathan et al., 2001).

Definitive levels of glycine-IPMBA were not observed following the degradation of [<sup>131</sup>I]SIPMB-L8A4. One of the pathways of aromatic carboxylic acid metabolism involves their conjugation with endogenous glycine, resulting in hippuric acid derivatives (Bridges et al., 1970; Hutt and Caldwell, 1990). If free benzoic acid derivatives are generated from the catabolism of mAbs labeled using benzoate templates, they can be subjected to similar metabolic process. For example, ex vivo and in vivo experiments have documented the formation of 3-[<sup>131</sup>I]iodobenzoyl-glycine from mAbs radioiodinated using [<sup>131</sup>I]SIB (Garg et al., 1995). Furthermore, when L8A4 was labeled with [<sup>131</sup>I]SGMIB, the glycine conjugate of the acid was the exclusive metabolite (Vaidyanathan et al., 2001). It appears that the metabolite that is preferentially formed, i.e., the lysine or the glycine conjugate, is dictated by the susceptibility of the amido group, formed between the mAb lysine ε-amino group and the acylation agent, toward proteolytic hydrolysis. Hence, it is reasonable to infer that the amide bond formed between SIPMB and the lysine ε-amino group is proteolytically inert, and therefore no free acid or glycine conjugate was generated under the in vitro assay conditions.

The major catabolite of L8A4 labeled using Iodogen that was observed previously was 3-[<sup>125</sup>I]iodotyrosine (Reist et al., 1996). The peak corresponding to iodotyrosine appeared in the reversed-phase HPLC radiochromatogram of the cell lysate at 1 and 2 h but was absent between the 4 and 16 h time points (Figure 2). This indicates that the iodotyrosine is formed and cleared rapidly from the cells after proteolysis of the protein. It is notable that no free iodide was seen in the lysate of L8A4 labeled by the Iodogen method at any time point. On the other hand, the predominant peak in the radiochromatogram of the cell culture supernatant for Iodogen-labeled L8A4 at all time points was free iodide. Significant levels of free iodide were not observed from L8A4 labeled using [<sup>131</sup>I]SIPMB in either the cell lysate or supernatant samples, except at a low level in the 1 h supernatant sample. This suggests that under these in vitro conditions, the IPMB template does not undergo appreciable levels of deiodination.

In conclusion, a method has been developed for the preparation of [<sup>131</sup>I]SIPMB, a radioiodination agent containing a negatively charged moiety. When labeled with this template, the anti-EGFRvIII mAb L8A4 retained immunoreactivity. Compared with mAb labeled using the Iodogen method, labeling L8A4 using SIPMB resulted in significantly enhanced retention of radioiodine activity in EGFRvIII-expressing tumor cells after mAb internalization. Our results suggest that this behavior likely reflects the generation of low molecular weight, polar catabolites that are retained intracellularly. Studies in animals bearing EGFRvIII-expressing xenografts are planned to further evaluate the potential utility of [<sup>131</sup>I]-SIPMB as a reagent for the radioiodination of internalizing mAbs.

#### ACKNOWLEDGMENT

This work was supported by Grants CA78417, CA42324, CA 91927, and NS20023 from the National Institutes of Health, and Grant 95ER62021 from the Department of Energy. We thank Dr. Darell Bigner, Department of Pathology, Duke University, for providing the L8A4 mAb and the U87ΔEGFR cell line.

Faculty of Pharmaceutical Sciences, Kumamoto University, 5-1 Oe-honmachi, Kumamoto 862-0973, Japan.  
Received September 24, 2002; Revised Manuscript Received January 11, 2003

The purpose of the present study is to optimize the structure of the polyamidoamine starburst dendrimer (dendrimer) conjugate with  $\alpha$ -cyclodextrin ( $\alpha$ -CDE conjugate) as a nonviral vector.  $\alpha$ -CDE conjugates of dendrimer (generation 3, G3) with various average degrees of substitution (DS) of  $\alpha$ -CyD of 1.1, 2.4, and 5.4 were prepared.  $\alpha$ -CDE conjugates formed the complexes with pDNA, resulting in a change of the particle sizes of pDNA complexes, but the distinction of physicochemical properties among their vector/pDNA complexes was only very slight. The membrane-disruptive ability of  $\alpha$ -CDE conjugates on liposomes encapsulating calcein and their cytotoxicity to NIH3T3 and HepG2 increased with an increase in the DS value of  $\alpha$ -CyD. In vitro gene transfer activity of  $\alpha$ -CDE conjugates in both NIH3T3 and HepG2 cells augmented as the charge ratio (vector/pDNA) increased, and the activity of  $\alpha$ -CDE conjugate (DS 2.4) was the highest at higher charge ratios among dendrimer (G3), the three  $\alpha$ -CDE conjugates, and TransFast. After intravenous administration of pDNA complexes in mice,  $\alpha$ -CDE conjugate (DS 2.4) delivered pDNA more efficiently in spleen, liver, and kidney, compared with dendrimer and other  $\alpha$ -CDE conjugates (DS 1.1 and 5.4). The potential use of  $\alpha$ -CDE conjugate (G3, DS 2.4) could be expected as a nonviral vector in vitro and in vivo, and these data may be useful for design of  $\alpha$ -CyD conjugates with other nonviral vectors.

## INTRODUCTION

Gene therapy may be one of the most important therapies for the next generation (1). The following four methods may be available for gene transfer, i.e., viral vector, nonviral vector, and physical methods as well as naked plasmid DNA (pDNA) method without vectors (2, 3). While nonviral vectors are currently not as effective as viral vectors, they do have certain advantages: they are easily prepared, are not limited by gene size, and can be vested through structural modification with the ability to carry pDNA to the target cells (4, 5). For these reasons, improvement in gene transfer activity of nonviral vectors is of utmost importance in the present study. Thereby the following four barriers should be targeted for improvement of transfection efficiency: an entrance to the cell, a release from the endosomes, an entrance to the nucleus, and a demining of the gene silencing (6, 7).

Cyclodextrins (CyDs) are cyclic ( $\alpha$ -1,4)-linked oligosaccharides of  $\alpha$ -D-glucopyranose containing a hydrophobic central cavity and hydrophilic outer surface (8, 9). The most common CyDs are  $\alpha$ -,  $\beta$ -, and  $\gamma$ -CyDs, which consist of six-, seven-, and eight-D-glucopyranose units, respectively. CyDs are known to form inclusion complexes with

a variety of guest molecules both in solution and in a solid state (10, 11). The solubilizing effect of CyDs on lipophilic compounds has many uses in the pharmaceutical field (12, 13), while CyDs at higher concentrations release membrane components such as phospholipids and cholesterol from plasma membranes of various cells including erythrocytes, leading to hemolysis and a change in membrane permeability of hydrophilic compounds (14–16). CyDs have recently been applied to gene transfer (17–19) and oligonucleotide delivery (20–23). Notably, Davis and his colleagues (24, 25) reported that of cationic  $\beta$ -CyD polymers, a water soluble  $\beta$ -CyD polymer with 6<sup>A</sup>,6<sup>D</sup>-dideoxy-6<sup>A</sup>,6<sup>D</sup>-di-(2-aminoethanethio)- $\beta$ -CyD and dimethylsuberimidate ( $\beta$ CDP6) resulted in much higher gene transfer activity than Superfect and poly-L-lysine in BHK-21 and CHO-K1 with less cytotoxicity. In addition, they recently reported that the ternary complex of  $\beta$ CDP6, galactosylated poly(ethylene glycol) conjugate with adamantane, and pDNA possesses higher transfection efficiency in hepatoma cells through receptor-mediated endocytosis (26).

We previously revealed that polyamidoamine (PAM-AM) dendrimer (dendrimer, generation 2, G2) conjugates with  $\alpha$ -,  $\beta$ -, and  $\gamma$ -CyD (CDE conjugates) improve gene transfer activity, and especially dendrimer conjugate (G2) with  $\alpha$ -CyD ( $\alpha$ -CDE conjugate (G2)) possesses the greatest gene transfer activity (27). Of the  $\alpha$ -CDE conjugates with a distinct generation (G2–G4) of dendrimer,  $\alpha$ -CDE conjugate (G3) elicits the greatest gene transfer activity (28). However, it remains unclear whether  $\alpha$ -CDE conjugates (G3) with several  $\alpha$ -CyD molecules possess more gene transfer activity in vitro as well as in vivo. In the present study, we prepared  $\alpha$ -CDE conjugates with several  $\alpha$ -CyD molecules (the average degree of substitution (DS), 1.1, 2.4, and 5.4) and investigated the physicochemical properties, membrane-disruptive ability, cyto-

<sup>1</sup> Abbreviations: CyDs, cyclodextrins; dendrimer, polyamidoamine starburst dendrimer; G, generation;  $\alpha$ -CyD,  $\alpha$ -cyclodextrin; CDE conjugate, dendrimer conjugate with cyclodextrin;  $\alpha$ -CDE conjugate, dendrimer conjugate with  $\alpha$ -cyclodextrin; pDNA, plasmid DNA; DS, the average degree of substitution; FCS, fetal calf serum; DMEM, Dulbecco's modified Eagle's medium; PBS, phosphate-buffered saline; HBSS, Hanks' balanced salt solution; TBE buffer, Tris/borate/EDTA buffer; eggPC, egg phosphatidylcholine; GFP, green fluorescent protein; RLU, relative light unit; FITC, fluorescein isothiocyanate.

toxicity, and in vitro and in vivo gene transfer activity of the  $\alpha$ -CDE conjugates, in comparison with dendrimer and TransFast.

## EXPERIMENTAL SECTION

**Materials.**  $\alpha$ -CyD was donated by Nihon Shokuhin Kako (Tokyo, Japan) and recrystallized from water. Dendrimers (ethylenediamine core, G3, the terminal amino groups = 32, molecular weight = 6909) were purchased from Aldrich Chemical (Tokyo, Japan). *p*-Toluenesulfonyl chloride was purchased from Nakalai Tesque (Kyoto, Japan). Fetal calf serum (FCS) and Dulbecco's modified Eagle's medium (DMEM) were purchased from Nichirei (Tokyo, Japan) and Nissui Pharmaceuticals (Tokyo, Japan), respectively. TransFast transfection reagent, plasmid pGL3 control vector encoding firefly luciferase and plasmid pRL-CMV-Luc vector encoding Renilla luciferase were obtained from Promega (Tokyo, Japan). pEGFP-N1 vector encoding green fluorescent protein (GFP) was purchased from Clontech (Tokyo, Japan). The purification of pDNA amplified in bacteria was carried out using QIAGEN EndoFree plasmid maxi kit (<0.1 EU/ $\mu$ g endotoxin). Other chemicals and solvents were of analytical reagent grade.

**Preparation of  $\alpha$ -CDE Conjugates.**  $\alpha$ -CyDs were attached to primary amino residues of dendrimer (G3) according to the method of Suh et al. (29). Monotosyl- $\alpha$ -CyD was prepared according to the method of Melton et al. (30). The methanol solution containing dendrimer ( $2.6 \times 10^{-5}$  mol) was added to a flask and evaporated under reduced pressure. Monotosyl- $\alpha$ -CyD (DS 1.1, 25 mg ( $2.6 \times 10^{-5}$  mol); DS 2.4, 100 mg ( $1.0 \times 10^{-4}$  mol); DS 5.4, 200 mg ( $2.0 \times 10^{-4}$  mol)); and dimethyl sulfoxide (DMSO, 1.0 mL) were added into the flask. Under nitrogen atmosphere, the mixture was stirred at 60 °C for 24 h.  $\alpha$ -CDE conjugates were purified by gel-filtration (TOSOH TSKGel HW-40S, Tokyo, Japan) and then precipitated with methanol to remove the free dendrimer.  $^1\text{H}$  NMR spectra of the  $\alpha$ -CDE conjugates were measured, and the molar ratio of dendrimer and  $\alpha$ -CyD was calculated from the peak areas of anomeric proton of  $\alpha$ -CyD and ethylene protons of the dendrimer.  $\alpha$ -CDE conjugate (DS 1.1): yield, 15%;  $^1\text{H}$  NMR (500 MHz,  $\text{D}_2\text{O}$ )  $\delta$  (from TMS) 4.95 (H1,  $\alpha$ -CyD), 3.90–3.65 (H3, H5, H6,  $\alpha$ -CyD), 3.59–3.46 (H2, H4,  $\alpha$ -CyD), 3.38–3.15 (dendrimer methylene), 3.05–2.91 (dendrimer methylene), 2.95–2.60 (dendrimer methylene), 2.60–2.42 (dendrimer methylene), 2.20–2.18 (dendrimer methylene).  $\alpha$ -CDE conjugate (DS 2.4): yield, 18%;  $^1\text{H}$  NMR (500 MHz,  $\text{D}_2\text{O}$ )  $\delta$  (from TMS) 4.94 (H1,  $\alpha$ -CyD), 3.86–3.74 (H3, H5, H6,  $\alpha$ -CyD), 3.53–3.47 (H2, H4,  $\alpha$ -CyD), 3.27–3.13 (dendrimer methylene), 3.05–2.81 (dendrimer methylene), 2.72–2.51 (dendrimer methylene), 2.36–2.31 (dendrimer methylene).  $\alpha$ -CDE conjugate (DS 5.4): yield, 23%;  $^1\text{H}$  NMR (500 MHz,  $\text{D}_2\text{O}$ )  $\delta$  (from TMS) 5.30–4.96 (H1,  $\alpha$ -CyD), 3.88–3.75 (H3, H5, H6,  $\alpha$ -CyD), 3.55–3.47 (H2, H4,  $\alpha$ -CyD), 3.40–3.12 (dendrimer methylene), 3.07–2.98 (dendrimer methylene), 2.74–2.54 (dendrimer methylene), 2.36–2.33 (dendrimer methylene). The chemical structure of  $\alpha$ -CDE conjugates is shown in Figure 1.

**Gel Electrophoresis.** Electrophoretic mobility of the complexes of pDNA/dendrimers or pDNA/ $\alpha$ -CDE conjugates was measured using a gel electrophoresis system. Various amounts of dendrimers or  $\alpha$ -CDE conjugates were mixed with 0.2  $\mu$ g of pDNA (pGL3 control vector) in Hanks's balanced salt solution (HBSS, pH 7.4). Gel electrophoresis was carried out at room temperature in TBE buffer (45 mM tris-borate, 1 mM EDTA, pH 8.0) in

**Figure 1.** Chemical Structure of  $\alpha$ -CDE conjugates (G3, DS 1.1, 2.4, and 5.4).

1% (w/v) agarose gel (include 0.1  $\mu$ g/mL ethidium bromide) using Mupid system (Cosmo Bio, Tokyo, Japan) at 100 V for 50 min. The pDNA bands were visualized using an UV illuminator.

**Measurements of Particle Size.** Dendrimer- or  $\alpha$ -CDE conjugate (G3)-containing solutions (0.1 mL in HBSS) at various charge ratios were added to pDNA (pGL3 control vector) solution (4  $\mu$ g/1.5 mL in HBSS) and incubated for 15 min. Immediately, particle sizes of the complexes of pDNA/dendrimer and pDNA/ $\alpha$ -CDE conjugates were determined by quasielastic (dynamic) light scattering using a Beckman Coulter N4 Plus machine (Fullerton, CA). The wavelength of the He-Ne laser used was 632.8 nm. The measurement was carried out at a fixed angle of 62.6°, and the measuring time was 102 s at 25 °C. The measurements were carried out at least in triplicates.

**Liposome Leakage Assay.** Liposomes were prepared from egg phosphatidylcholine (eggPC) by reverse phase evaporation (31) with an aqueous phase of 100 mM calcein which was dissolved by the addition of 3.75 equiv of sodium hydroxide and 50 mM NaCl, extruded through a 0.22  $\mu$ m cellulose acetate membrane and purified by centrifugation with an iso-osmotic buffer (200 mM NaCl, 25 mM HEPES, pH 7.3). The liposomal suspension (6.0  $\mu$ M eggPC) was prepared using 10 mM phosphate buffer (pH 12). Fifty microliters of  $\alpha$ -CDE conjugate solution adjusted at the appropriate concentration using 10 mM phosphate buffer (pH 12) was added to 5  $\mu$ L of the liposomal suspension, and then the resulting suspension was agitated with vial mixer for 30 min at room temperature. Nine hundred microliters of phosphate buffer (pH 12) was further added to the suspension. The intensity of fluorescence of the suspension was finally measured with a fluorophotometer (Hitachi F-4500, Tokyo, Japan) at 25 °C; excitation and emission wavelengths were 495 and 515 nm, respectively. The value for 100% leakage was further obtained by the addition of 1  $\mu$ L of Triton X-100 to the suspension.

**Cell Culture.** NIH3T3 cells, a mouse fibroblast cell line, and HepG2 cells, a human hepatocarcinoma cell line, were obtained from the Japan Health Sciences Foundation (Osaka, Japan) and American Type culture collection (Rockville, MD), respectively. NIH3T3 and HepG2 cells were grown in DMEM containing  $1 \times 10^5$  mU/mL of penicillin, and 0.1 mg/mL of streptomycin supplemented with 10% (v/v) FCS at 37 °C in a humidified 5%  $\text{CO}_2$  and 95% air atmosphere.

**Cytotoxicity.** The cell viability was assayed by using a Cell Counting Kit (WST-1 method) from Wako Pure Chemical Industries (Osaka, Japan) (32). In brief, NIH3T3 and HepG2 cells were seeded at  $2 \times 10^5$  cells onto 35-mm dishes (Iwaki, Tokyo, Japan) and incubated for 18 h in a humidified atmosphere containing 5% CO<sub>2</sub> and 95% air at 37 °C. Cells were washed twice with serum free medium and then incubated for 1 h with 800  $\mu$ L of serum-free medium containing pDNA or the complexes with various vectors. The culture medium (1.5 mL) supplemented with 10% (v/v) FCS was added to each well, and the cells were incubated for 24 h in a humidified atmosphere containing 5% CO<sub>2</sub> and 95% air at 37 °C. After washing twice with HBSS (pH 7.4) to remove pDNA and/or various vectors, 0.5 mL of fresh HBSS and 50  $\mu$ L of WST-1 reagent were added to the plates and incubated for 4 h at 37 °C. The absorbance of aliquot (100  $\mu$ L) of the solution was measured at 405 nm, with a reference of the absorbance at 630 nm, with a microplate reader (Bio-Rad Model 550, Tokyo, Japan).

**In Vitro Gene Transfer.** In vitro transfection of the complexes of pDNA/dendrimers, pDNA/ $\alpha$ -CDE conjugates, or pDNA/TransFast was performed utilizing the expression of pDNA encoding firefly luciferase gene (pGL3 control vector) and pDNA encoding GFP (pEGFP-N1 vector) in NIH3T3 and HepG2 cells. The pDNA (2.0  $\mu$ g) was mixed with dendrimer or  $\alpha$ -CDE conjugates at various charge ratios. The pDNA complexes with dendrimers or  $\alpha$ -CDE conjugates were then allowed to stand for 15 min at room temperature. The cells ( $2 \times 10^5$  per 35 mm culture dish) were seeded 18 h before transfection and then washed twice with serum-free medium. Eight hundred microliters of serum-free medium containing pDNA or the complexes with various vectors was added to each dish and then incubated at 37 °C for 1 h. The culture medium (1.5 mL) supplemented with 10% (v/v) FCS was added to each dish. Control transfection was performed with TransFast in the same manner described above. The charge ratio of pDNA/TransFast was 1/1, at which an optimal gene transfer activity was obtained under the present experimental conditions. After transfection for 25 h, the gene expression was measured as follows: when pGL3 control vector was used, firefly luciferase content in the cell lysate was quantified using the Promega luciferase assay reagent (Tokyo, Japan) and a luminometer (Lumat LB9506, EG&G Berthold Japan, Tokyo, Japan). Absolute light emission generated from the luciferase enzyme reaction was determined. It was confirmed that  $\alpha$ -CyD and  $\alpha$ -CDE conjugates have no influence on the luciferase assay under the experimental conditions. Total protein content of the supernatant was determined by BCA protein assay kit (Pierce, Rockford, IL). One million relative light units correspond approximately to 1.6 ng of firefly luciferase. When pEGFP-N1 vector was used, NIH3T3 and HepG2 cells after transfection for 25 h were washed three times with PBS and then immediately scraped with 1 mL of PBS. The cells were collected and filtered through nylon mesh. Data were collected for  $2 \times 10^5$  cells on a FACS-Calibur flow cytometer using CellQuest software (Becton-Dickinson, Mountain View, CA).

**In Vivo Gene Transfer.** Four-weeks-old BALB/c female mice were intravenously injected in the tail vein with 500  $\mu$ L of a suspension containing the complex of pDNA/dendrimer (pRL-CMV-Luc) and that of pDNA/ $\alpha$ -CDE conjugates in 5% (w/v) mannitol at the amount of 50  $\mu$ g of pDNA in 1 min under anesthesia with ether. Twelve and 24 h after administration, the mice were sacrificed, and lung, heart, liver, spleen, and kidney were

isolated. The organs were washed twice with ice-cold saline and were added to 1 mL of the Promega cell lysis buffer (Tokyo, Japan) containing the Roche protease inhibitor, Complete (Tokyo, Japan). The organs were homogenized with a Polytron tissue grinder. After three cycles of freezing and thawing, the homogenate was centrifuged for 10 min at 10 000g (4 °C), and 20  $\mu$ L of the supernatant was added to 100  $\mu$ L of the Promega Renilla luciferase assay buffer (Tokyo, Japan). Luminescence was immediately measured for 10 s (Lumat LB9506, EG&G Berthold Japan, Tokyo, Japan). Total protein content of the supernatant was determined by BIO-RAD DC protein assay kit (Tokyo, Japan). One million relative light units correspond approximately to 0.4 ng of Renilla luciferase.

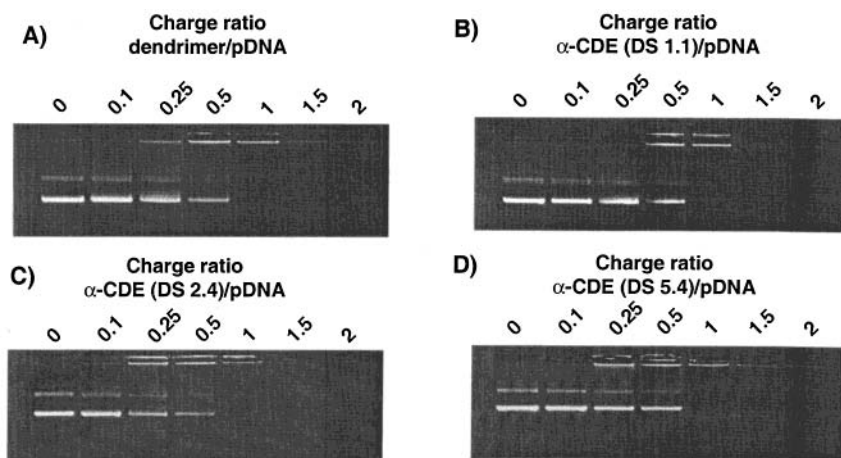

**Data Analysis.** Data are given as the mean  $\pm$  SEM. Statistical significance of mean coefficients for the studies was performed by analysis of variance followed by Scheffe's test. *p*-Values for significance were set at 0.05.

## RESULTS

**Physicochemical Properties of pDNA Complexes with  $\alpha$ -CDE Conjugates.** We first studied the complexations between pDNA/dendrimer (G3) or pDNA/ $\alpha$ -CDE conjugate (DS 1.1, 2.4 and 5.4) using agarose electrophoresis. As shown in Figure 2A, the intensity of the band derived from pDNA decreased as the charge ratio of pDNA/dendrimer increased, and at the charge ratio of 1/1 the band disappeared. Similar patterns were observed in the pDNA/ $\alpha$ -CDE conjugates (DS 1.1, 2.4, and 5.4) systems (Figure 2B–D). CyDs alone did not change the electrophoretic band pattern of pDNA (data not shown). These results suggest that  $\alpha$ -CDE conjugates form the complexes with pDNA in a manner similar to dendrimer.

Next, the particle sizes of the complexes of pDNA/dendrimers and pDNA/ $\alpha$ -CDE conjugates were measured by quasielastic (dynamic) light scattering. As shown in Figure 3, the particle sizes of the complexes of pDNA/dendrimer or pDNA/ $\alpha$ -CDE conjugates were smallest at a charge ratio of 1/1, which was consistent with the ratio that the band disappeared (Figure 3). These results suggest that  $\alpha$ -CDE conjugates (DS 1.1, 2.4, and 5.4) form the most compact complexes (approximately 200 nm) at a charge ratio of 1/1, and at higher charge ratios the particle sizes of these complexes of pDNA/vectors were almost comparable (approximately 550 nm). Thus, it is evident that physicochemical properties of the pDNA complexes with  $\alpha$ -CDE conjugates differ only very slightly for that with dendrimer.

**Liposome Leakage Assay.** CyDs are known to induce hemolysis and to enhance the permeation of water-soluble drugs through biological membranes of epithelial cells via the release of membrane components such as phospholipids and cholesterol as described above (13, 14). In addition, we proposed the possibility that the enhancing mechanism by which  $\alpha$ -CDE conjugates augment the release of pDNA from endosomes to cytoplasm after cellular uptakes (25, 26). To confirm the membrane-disruptive ability of  $\alpha$ -CDE conjugates, we examined the effects of  $\alpha$ -CDE conjugates on the release of calcein from eggPC liposomes. As shown in Figure 4, dendrimer (G3) and  $\alpha$ -CDE conjugates (DS 1.1) did not release calcein from liposomes, whereas  $\alpha$ -CDE conjugates (DS 2.4 and 5.4) released it, indicating that  $\alpha$ -CDE conjugates possess membrane-disruptive ability. These results suggest that  $\alpha$ -CDE conjugates might increase the release of pDNA or the pDNA complex from endosomes following cellular uptake.

**Figure 2.** Agarose gel electrophoretic analysis of the complexes of pDNA/dendrimer (G3) and pDNA/ $\alpha$ -CDE conjugates (DS 1.1, 2.4, or 5.4) using TBE buffer (pH 8.0). The solutions containing the complexes of pDNA/dendrimer or pDNA/ $\alpha$ -CDE were incubated for 15 min at room temperature after slight agitation. The electrophoresis was performed at 100 V for about 50 min. A, dendrimer (G3); B,  $\alpha$ -CDE conjugate (DS 1.1); C,  $\alpha$ -CDE conjugate (DS 2.4); D,  $\alpha$ -CDE conjugate (DS 5.4).

**Figure 3.** Particle sizes of the complexes with pDNA/dendrimer (G3) or pDNA/ $\alpha$ -CDE conjugate (DS 1.1, 2.4, or 5.4). Dendrimer- or  $\alpha$ -CDE conjugate (DS 1.1, 2.4, or 5.4)-containing solutions at various charge ratios were added to pDNA solution and then incubated for 15 min. Particle sizes of the pDNA complexes with dendrimer and  $\alpha$ -CDE conjugates were determined by quasielastic (dynamic) light scattering: open circle, dendrimer (G3); closed circle,  $\alpha$ -CDE conjugate (DS 1.1); open square,  $\alpha$ -CDE conjugate (DS 2.4); closed square,  $\alpha$ -CDE conjugate (DS 5.4).

**Cytotoxicity.** Figure 5 shows cytotoxicity of dendrimer and  $\alpha$ -CDE conjugates in NIH3T3 and HepG2 cells. In both cells, cytotoxicity of dendrimer and  $\alpha$ -CDE conjugates was negligible up to a charge ratio of 100/1 (vector/pDNA), and slight cytotoxicity of  $\alpha$ -CDE conjugate (DS 5.4) was observed at a charge ratio of 200/1 (vector/pDNA). Above the charge ratio, the cytotoxic activity increased in the order of  $\alpha$ -CDE conjugate (DS 1.1) < (DS 2.4) < (DS 5.4) in NIH3T3 cells (Figure 5A). Likewise,  $\alpha$ -CDE conjugate (DS 5.4) provoked cytotoxicity to HepG2 cells in a concentration-dependent manner, but other  $\alpha$ -CDE conjugates showed only slight cytotoxicity (Figure 5B), suggesting that HepG2 cells are more resistant to the cytotoxic effect of  $\alpha$ -CDE conjugates than NIH3T3 cells. These results indicate that cytotoxicity of  $\alpha$ -CDE conjugates depends on the DS value of  $\alpha$ -CyD.

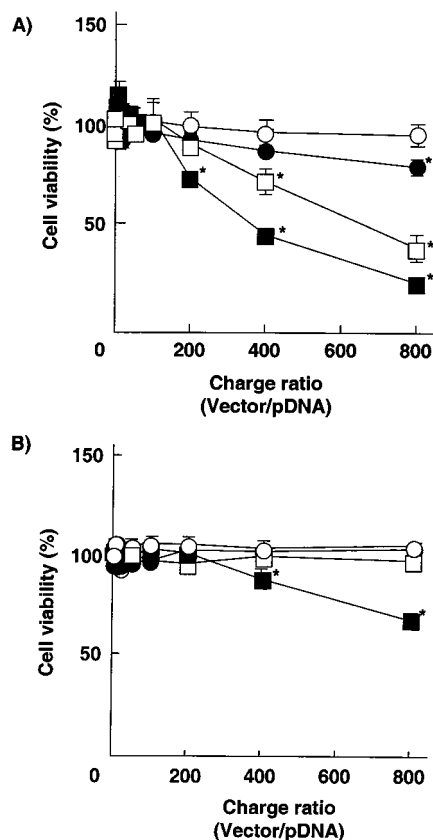

**In Vitro Transfection.** The in vitro gene transfer activity of dendrimer (G3) and  $\alpha$ -CDE conjugates (G3, DS 1.1, 2.4, and 5.4) was examined and compared with that of TransFast, which was employed as a positive control. Figures 6A and 6B show gene transfer activity of dendrimer and  $\alpha$ -CDE conjugates in NIH3T3 and HepG2 cells, respectively. When pDNA alone in the

**Figure 4.** Membrane-disruptive activity of dendrimer and  $\alpha$ -CDE conjugates (DS 1.1, 2.4, or 5.4) to liposomes. The solutions containing dendrimer and  $\alpha$ -CDE conjugates at various concentrations were added to the suspension containing egg phosphatidylcholine liposomes encapsulated calcein and mixed for 30 min at room temperature. The intensity of fluorescence of liposomal suspension was measured with fluorophotometer: open diamond,  $\alpha$ -CyD; open circle, dendrimer (G3); closed circle,  $\alpha$ -CDE conjugate (DS 1.1); open square,  $\alpha$ -CDE conjugate (DS 2.4); closed square,  $\alpha$ -CDE conjugate (DS 5.4). Each point represents the mean  $\pm$  SEM of four experiments.

absence and presence of  $\alpha$ -CyD was transfected to cells, no luciferase activity was observed (data not shown). Gene transfer activity of dendrimer and  $\alpha$ -CDE conjugates (DS 1.1 and 2.4) increased as the charge ratio (vector/pDNA) increased up to the charge ratio of 400/1 in NIH3T3 cells, and the activity of  $\alpha$ -CDE conjugate (DS 5.4) was greatest up to a charge ratio of 50/1. Of the three  $\alpha$ -CDE conjugates,  $\alpha$ -CDE conjugate (DS 2.4) provided the highest gene transfer activity at the charge ratios of 200/1 and 400/1. The enhancing effect of  $\alpha$ -CDE conjugate (DS 2.4) on gene transfer activity was approximately 3 times higher than that of TransFast in NIH3T3 cells (Figure 6A). The effects of the charge ratio on the activity in HepG2 cells were similar to those in NIH3T3 cells, the greatest gene transfer activity of  $\alpha$ -CDE conjugate (DS 2.4) was elicited at the charge ratio of 400/1. These results indicate that  $\alpha$ -CDE conjugate (DS 2.4) possesses superior gene transfer activity to dendrimer and  $\alpha$ -CDE conjugate (DS 1.1 and 5.4) at the higher charge ratios.

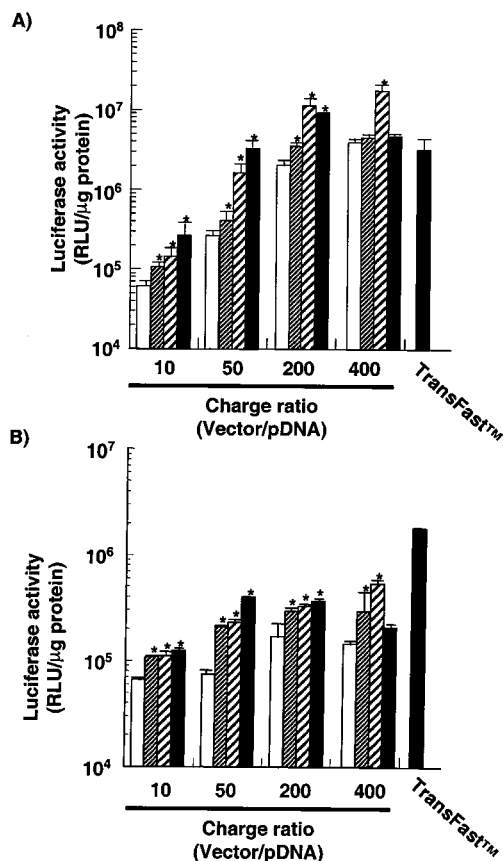

Next, we studied transfection efficiency of dendrimer or  $\alpha$ -CDE conjugates (DS 1.1, 2.4 and 5.4) using GFP by flow cytometer. Here pDNA complexes with dendrimer

**Figure 5.** Cytotoxicity of the complexes of pDNA/dendrimer or pDNA/ $\alpha$ -CDE conjugate (DS 1.1, 2.4, and 5.4) at various charge ratios in NIH3T3 cells (A) and HepG2 cells (B). The cell viability was assayed by WST-1 method as described in the Experimental Section. Open circle, dendrimer (G3); closed circle,  $\alpha$ -CDE conjugate (DS 1.1); open square,  $\alpha$ -CDE conjugate (DS 2.4); closed square,  $\alpha$ -CDE conjugate (DS 5.4). Each point represents the mean  $\pm$  SEM of four experiments. \* $p < 0.05$ , compared with dendrimer (G3).

or  $\alpha$ -CDE conjugates formed at charge ratios of 50/1 and 200/1 (vector/pDNA) were used. As shown in Figure 7A, the curve shifted to right-hand as the DS value of  $\alpha$ -CDE conjugates increased at a charge ratio of 50/1 in NIH3T3 cells. At a charge ratio of 200/1 the curves corresponding to  $\alpha$ -CDE conjugates (DS 2.4 and 5.4) overlapped and were shifted to the right of those of the dendrimer and  $\alpha$ -CDE conjugate (DS 1.1) in NIH3T3 cells (Figure 7B). In addition, a similar pattern was observed in HepG2 cells (Figures 7C and 7D). These results clearly indicate that  $\alpha$ -CDE conjugates (DS 2.4 and 5.4) provide superior gene transfer activity to dendrimer and  $\alpha$ -CDE conjugate (DS 1.1), and  $\alpha$ -CDE conjugate (DS 2.4) possesses almost comparable gene transfer efficiency of  $\alpha$ -CDE conjugate (DS 5.4) at a charge ratio of 200/1. On the other hand, when the complex of pDNA/TransFast was transfected at a charge ratio of 1/1, the corresponding curve showed a different pattern from that of pDNA/ $\alpha$ -CDE conjugates (Figure 7). These results suggest that of the three  $\alpha$ -CDE conjugates,  $\alpha$ -CDE conjugate (DS 2.4) possesses superior gene transfer activity at higher charge ratios of more than 200/1 to dendrimer,  $\alpha$ -CDE conjugates (DS 1.1 and 5.4), and TransFast, although gene transfer efficiency of  $\alpha$ -CDE conjugate (DS 2.4) was comparable to  $\alpha$ -CDE conjugate (DS 5.4). In addition, the gene transfer mode of  $\alpha$ -CDE conjugate (DS 2.4) may be somewhat different from that of TransFast.

**In Vivo Transfection.** Figure 8 shows gene transfer activity 12 and 24 h after intravenous administration of

**Figure 6.** Gene transfer activity of the complexes of pDNA/dendrimer (G3) or pDNA/ $\alpha$ -CDE conjugates (DS 1.1, 2.4, and 5.4) at various charge ratios in NIH3T3 cells (A) and HepG2 cells (B). The luciferase activity in cell lysates was determined 25 h after incubation with pDNA alone or various complexes. The charge ratio of pDNA and TransFast is 1/1. Open column, dendrimer (G3); dark hatched column,  $\alpha$ -CDE conjugate (DS 1.1); light hatched column,  $\alpha$ -CDE conjugate (DS 2.4); closed column,  $\alpha$ -CDE conjugate (DS 5.4). One million relative light units correspond approximately to 1.6 ng of firefly luciferase. Each value represents the mean  $\pm$  SEM of four experiments. \* $p < 0.05$ , compared with dendrimer (G3).

the suspension containing the complexes of pDNA/dendrimer and pDNA/ $\alpha$ -CDE conjugates to tail vein of mice. Here we used pRL-CMV-Luc as plasmid DNA due to preferable gene expression in vivo. In the present study, we chose a charge ratio of pDNA/ $\alpha$ -CDE conjugate of 10/1 (vector/pDNA) because intravenous administration of the suspension containing pDNA complex with  $\alpha$ -CDE conjugate (DS 5.4), not  $\alpha$ -CDE conjugates (DS 1.1 and 2.4), at a charge ratio of 20/1 was fatal to mice (data not shown). Luciferase activity was much higher in the spleen than in other tissues, followed by the liver at 12 h after administration. The activity was higher in liver rather than spleen at 24 h, although the gene expression markedly lowered to less than one-hundredth (Figure 8). When the magnitude of gene transfer activity between nonviral vectors used here was compared,  $\alpha$ -CDE conjugate (DS 2.4) provided gene transfer activity higher than dendrimer and other  $\alpha$ -CDE conjugates in spleen at 12 h and in liver and kidney at 24 h following administration, respectively. In addition,  $\alpha$ -CDE conjugate (DS 5.4) significantly increased gene transfer activity compare to both dendrimer and other  $\alpha$ -CDE conjugates in liver at 12 h, but not in other tissues. These results indicate that  $\alpha$ -CDE conjugate (DS 2.4) possesses the preferable gene transfer activity in vivo.

**Figure 7.** Transfection efficiency of the complexes of pDNA/dendrimer (G3) or pDNA/ $\alpha$ -CDE conjugates (DS 1.1, 2.4, and 5.4) at various charge ratios in NIH3T3 cells (A, B) and HepG2 cells (C, D). pEGFP-N1 vector encoding GFP was used. The charge ratios of the complexes of dendrimer/pDNA,  $\alpha$ -CDE conjugates/pDNA were 50/1 (A, C) and 200/1 (B, D) and the charge ratio of and TransFast™ expression in the cells was measured with a flow cytometer.

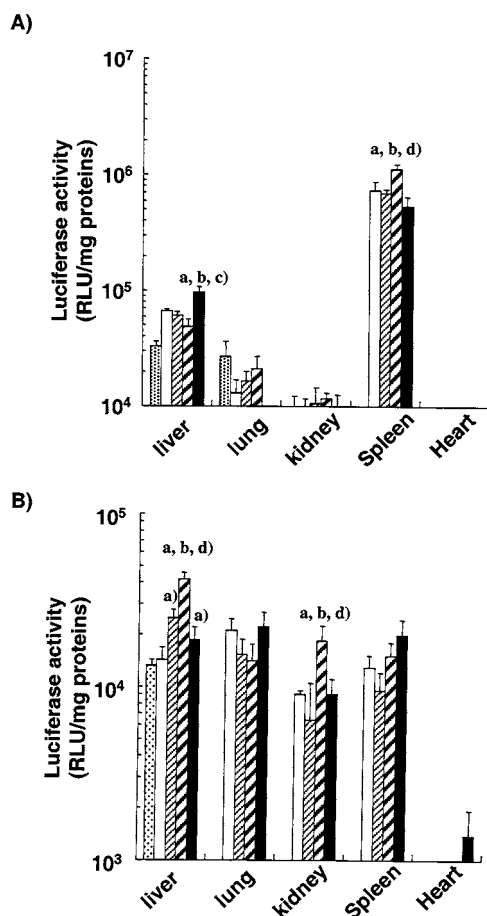

## DISCUSSION

In the present study, we clarified that gene transfer activity of  $\alpha$ -CDE conjugates is markedly affected by the DS values of  $\alpha$ -CyD in the conjugate, and of the three conjugates,  $\alpha$ -CDE conjugate (DS 2.4) possesses high gene transfer activity in vitro and in vivo with less cytotoxicity.

The physicochemical properties of polyplexes such as the particle size and net charge markedly affect gene transfer efficiency (6). From the molecular structure's point of view, the primary amino groups of  $\alpha$ -CDE conjugates apparently decrease with an increase in the DS value of  $\alpha$ -CyD; therefore, the interaction between  $\alpha$ -CDE conjugates and pDNA was expected to decrease. Contrary to our expectation,  $\alpha$ -CDE conjugates (DS 1.1, 2.4, and 5.4) formed the polyplexes in a similar way (Figures 2 and 3). This similarity of the complexation can be due to more than 28 residual free primary amino groups because dendrimer (G3) possesses terminal 32 amino groups in a molecule and the calculated values of the numbers of charge centers in dendrimer (G3) and  $\alpha$ -CDE conjugates (DS 1.1, 2.4, and 5.4) at physiological pH were 32, 30.9, 28.6, and 26.6, respectively (33). Thus, it is apparent that physicochemical properties are almost identical among the pDNA complexes with three  $\alpha$ -CDE conjugates. Regarding the particle size, it may be unreasonable that  $\alpha$ -CDE conjugates (DS 1.1, 2.4, and 5.4) form the most compact complexes (approximately 200 nm) at a charge ratio of 1/1 because neutral particles tend to aggregate. However, the lack of aggregation was observed up to 15 min after mixing pDNA and  $\alpha$ -CDE conjugates, at which the particle sizes were determined. This restricted aggregation may be preferable to prepare the injection containing pDNA/ $\alpha$ -CDE conjugates. Unfortunately, we could not show the morphological data of the polyplexes with dendrimer and  $\alpha$ -CDE conjugates here, but their morphology might be independent of the charge

ratio at the higher charge ratios because of the almost identical particle size of their polyplexes (Figure 3).

Polyplex-mediated transfection should overcome at least one of the major barriers for transfection, that is, the escape of pDNA from endosomes (34). We previously proposed the possibility that  $\alpha$ -CDE conjugate (DS 1.1) may enhance the release of pDNA or the pDNA complexes with  $\alpha$ -CDE conjugates from the endosomal compartment after the cellular uptake into NIH3T3 cells (27, 28). In the present study, we indeed revealed that  $\alpha$ -CDE conjugates are efficiently capable of releasing calcein from liposomes, depending on the DS value of  $\alpha$ -CDE conjugates, suggesting that  $\alpha$ -CDE conjugates (DS 2.4 and 5.4) potentially possess endosomal membrane-disruptive ability through the interaction between  $\alpha$ -CyD moiety and the membrane components after endocytosis into the cells. This inference may be supported by the findings that the disruption of liposomal membranes was not observed by adding dendrimer (G3) (Figure 4). However, it should be noted that the concentrations of  $\alpha$ -CDE conjugates acquired for liposomal disruption were higher than those under the in vitro transfection condition (approximately 20  $\mu$ M at a charge ratio of 200/1); thereby, it is possible that an endosomal disruption by  $\alpha$ -CDE conjugates hardly takes place after transfection. At the same time, we demonstrated that  $\alpha$ -CyD induces hemolysis through the extraction of membrane components from the erythrocyte membranes (14), and  $\alpha$ -CDE conjugates include fluorescent guest molecule, 2-(*p*-toluidinyl)naphthalene-6-sulfonate potassium salt (28), supporting the possible membrane-disruptive activity of  $\alpha$ -CDE conjugates. In addition, we observed more fluorescence in cytoplasm after transfection of fluorescein isothiocyanate (FITC)-labeled pDNA with  $\alpha$ -CDE conjugate (DS 2.4) compared to that with dendrimer in NIH3T3 cells (data not shown). Therefore, these results imply that  $\alpha$ -CDE conjugates might increase the release

**Figure 8.** In vivo gene transfer activity of the complexes of DNA/dendrimer or  $\alpha$ -CDE (DS 1.1, 2.4, 5.4). pRL-CMV-Luc encoding Renilla luciferase was used as pDNA. The solution containing pDNA and the suspensions containing the complexes of pDNA/dendrimer or with pDNA/ $\alpha$ -CDE conjugate were injected to tail vein of BALB/c mice. Twelve (A) and 24 h (B) after administration, the mice were sacrificed, and then lung, heart, liver, spleen, and kidney were isolated. The organs were washed and homogenized. After centrifugation of the homogenate, the supernatant was taken and added to Promega Renilla luciferase assay buffer. The luciferase activity in the solution was measured using a luminometer. Dotted column, pDNA alone; open column, dendrimer (G3); dark hatched column,  $\alpha$ -CDE conjugate (DS 1.1); light hatched column,  $\alpha$ -CDE conjugate (DS 2.4); closed column,  $\alpha$ -CDE conjugate (DS 5.4). One million relative light units correspond approximately to 0.4 ng of Renilla luciferase. Each value represents the mean  $\pm$  SEM of 4–9 mice. Four, six, six, nine, and six mice at 12 h were used in pDNA alone, pDNA/dendrimer, pDNA/ $\alpha$ -CDE conjugate (DS 1.1), pDNA/ $\alpha$ -CDE conjugate (DS 2.4), and pDNA/ $\alpha$ -CDE conjugate (DS 5.4) groups, and nine mice at 24 h were used in all of the groups. (a)  $p < 0.05$  compared with dendrimer (G3), (b)  $p < 0.05$  compared with  $\alpha$ -CDE conjugate (DS 1.1), (c)  $p < 0.05$  compared with  $\alpha$ -CDE conjugate (DS 2.4), (d)  $p < 0.05$  compared with  $\alpha$ -CDE conjugate (DS 5.4).

of pDNA or the pDNA complex from endosomes following cellular uptake, although it remains unclear to what extent the membrane disruptive ability of  $\alpha$ -CDE conjugates contributes to the enhancing effect on gene transfer activity. Further experiments should be performed to clarify the enhancing effect of  $\alpha$ -CDE conjugate on an endosomal escape of pDNA using FITC-labeled BSA with nuclear localization signal peptide. In addition,  $\alpha$ -CDE conjugate (DS 1.1), whose endosomal membrane-disruptive ability in the cells we proposed (27), did not release calcein from liposomes (Figure 4). This inconsistency may be due to the difference of the experimental conditions between cellular and liposomal systems.

From a safety point of view,  $\alpha$ -CDE conjugate (DS 5.4) may be inferior to  $\alpha$ -CDE conjugate (DS 2.4) because  $\alpha$ -CDE conjugate (DS 5.4) showed more cytotoxicity in vitro (Figure 5) and in vivo as mentioned above. In addition, the concentrations of dedrimer and  $\alpha$ -CDE conjugate (DS 1.1, 2.4, and 5.4) at a charge ratio of 100/1 were 24.38, 25.25, 26.36, and 29.33  $\mu$ M, respectively, under the present experimental condition regarding cytotoxicity. The cytotoxic effect of  $\alpha$ -CDE conjugate (DS 5.4) may allow transfection efficiency to attenuate at the higher charge ratios (Figure 5). So far, CyDs have been reported to fail to enter into the cells because of their hydrophilicity and high molecular weight (14). On the other hand, our preliminary results demonstrated that  $\alpha$ -CDE conjugates enter into the cells in terms of the adsorptive endocytotic machinery as other cationic non-viral vectors (35, 36). Therefore, the cytotoxic effect of  $\alpha$ -CDE conjugates might be exerted by an intracellular event such as an endosomal disruption. The results that the physical mixture of  $\alpha$ -CyD and pDNA complex with dendrimer (G3) showed neither cytotoxic nor an enhancing effect on gene transfer activity (27, 28) may also support the cellular uptake of  $\alpha$ -CDE conjugates. There are still some critical issues, however, as to the intracellular trafficking of pDNA complexes with  $\alpha$ -CDE conjugates after cellular uptake, i.e., (1) whether the pDNA complexes can enter into nucleus; (2) where the pDNA complexes with  $\alpha$ -CDE conjugates dissociate into each component; (3) how  $\alpha$ -CDE conjugates are released from the cells. Elaborate studies are further required to address these issues.

The introduction of  $\alpha$ -CyD to dendrimer (G3) is likely to increase not only the net luciferase activity but also the number of cells expressing GFP (Figure 7), indicating that  $\alpha$ -CDE conjugates improved both net gene transfer activity and transfection efficiency to each cell. In addition, the gene transfer activity of  $\alpha$ -CDE conjugate (G3, DS 2.4) was 3 or 4 times higher than that of TransFast at the charge ratios of 200/1 and 400/1 in NIH3T3 cells. The improving effect of  $\alpha$ -CDE conjugates on gene transfer activity may also be due to the distinct mechanism for the endosomal escape of pDNA or its complex:  $\alpha$ -CDE conjugates, and TransFast may allow pDNA to escape from the endosomes through the lipid extraction from the endosomal membranes and the membrane fusion with L-dioleoyl phosphatidyl-ethanolamine, a constituent of TransFast, respectively. However, the prominent gene transfer activity of  $\alpha$ -CDE conjugates compared with TransFast was not observed in HepG2 cells. The reason for this difference in the gene transfer activity between the cells remains unknown, but the different sensitivity between NIH3T3 and HepG2 cells to the cytotoxic effects of  $\alpha$ -CDE conjugates and TransFast may be involved.

The free  $\alpha$ -CDE conjugate may play a critical role for gene transfer activity. In the agarose gel electrophoretic study, the bands disappeared at a charge ratio of 1/1, suggesting that  $\alpha$ -CDE conjugates sufficiently form the complexes with pDNA at the charge ratio, where the calculated molar ratio of the pDNA complexes with  $\alpha$ -CDE conjugates (DS 1.1, 2.4, and 5.4) were 351, 363, and 404 ( $\alpha$ -CDE conjugate/pDNA), respectively. Thus, the free extent of  $\alpha$ -CDE conjugates must be raised, when the charge ratio increases in the range of 1/1–400/1, because the molar ratios were so high that  $\alpha$ -CDE conjugates may be unable to bind to pDNA. Therefore, the enhancement of gene transfer activity may be due to the additional free  $\alpha$ -CDE conjugates at the higher

charge ratios, although the precise extent of free fraction was unknown.

$\alpha$ -CDE conjugates, especially  $\alpha$ -CDE conjugate (G3, DS 2.4), may be used as in vivo gene transfer agents. As mentioned in the Experimental Section, 500  $\mu$ L of test solutions or suspensions were injected to the tail vein in a minute in the present study, suggesting that in vivo gene transfer activity could not be attributed to a hydrodynamics-based gene transfer because of low volume and injection rate (37). The gene expression was observed in several tissues after intravenous administration of the pDNA complexes with  $\alpha$ -CDE conjugates (DS 1.1, 2.4, and 5.4) (Figure 8). It should be noted that the luciferase activity in spleen at 12 h after administration of pDNA complex with  $\alpha$ -CDE conjugate (DS 2.4) was over  $1 \times 10^6$  RLU/mg proteins and the values in liver, lung, and kidney at 24 h were even over  $1.5 \times 10^4$  RLU/mg proteins. In addition, the high gene transfer activity of  $\alpha$ -CDE conjugates, especially  $\alpha$ -CDE conjugate (DS 2.4) may result from a change in an intracellular trafficking of pDNA in various organs, at least in part, after intravenous administration in mice. In vivo luciferase activities 24 h after intravenous administration of the complex of pDNA/ $\alpha$ -CDE conjugate (DS 2.4) at a charge ratio of 20/1 were  $13759 \pm 1062$ ,  $10220 \pm 935$ ,  $23831 \pm 7820$ ,  $9566 \pm 768$ , and  $10019 \pm 1962$  RLU/mg proteins in liver, lung, kidney, spleen, and heart, respectively. Thus, in vivo gene transfer activity of  $\alpha$ -CDE conjugates at the charge ratio of 20/1 was lower than that at 10/1, inconsistent with the in vitro results. This inconsistency could be attributed to a distinct sensitivity to cytotoxicity of nonviral vector between in vitro and in vivo, because intravenous administration of  $\alpha$ -CDE conjugate (DS 5.4) was fatal at the charge ratio of 20/1 in mice, but not in vitro. Taken together, these results suggest that  $\alpha$ -CDE conjugate (DS 2.4) possesses a promising in vivo gene transfer activity.

The in vivo luciferase activity elicited by  $\alpha$ -CDE conjugates in spleen was significantly lower below one-hundredth at 24 h compared with at 12 h after administration. This may not be, however, due to the cytotoxic effect of  $\alpha$ -CDE conjugates because the pDNA complex with dendrimer provided a similar pattern of gene transfer activity in spleen to that of  $\alpha$ -CDE conjugates (Figure 8). It is possible that the rapid impairment of gene expression could not be attributed to the epigenetic effects such as methylation of pDNA and histone deacetylation because the administration of DNA methyltransferase inhibitor, 5-azacytidine, and a histone deacetylase inhibitor, trichostatin A, did not increase the gene expression (data not shown), despite the fact that these inhibitors have been reported to enhance and prolong the expression of transgenes (38–41). It may be possible that a degradation of pDNA and/or unknown mechanisms play a critical role in this impairment. Further investigation regarding the extension as well as the modulation of in vivo gene expression elicited by  $\alpha$ -CDE conjugates is necessary.

In conclusion,  $\alpha$ -CDE conjugate (G3, DS 2.4) was shown to be the best  $\alpha$ -CDE conjugate among the  $\alpha$ -CDE conjugates prepared in a series of the studies, because it provided good gene transfer activity in vitro and in vivo with low cytotoxicity. Consequently, the potential use of  $\alpha$ -CDE conjugate (G3, DS 2.4) could be expected as a nonviral vector to deliver gene in vitro and in vivo and these data may be useful for design of  $\alpha$ -CyD conjugates with other nonviral vectors.

## ACKNOWLEDGMENT

We thank Dr. Makoto Uemura for assistance with the light scattering experiments using a Beckman Coulter N4 Plus machine at the Kumamoto Industrial Research Institute. This work was partially supported by a Grant-in-Aid from Tokyo Biochemical Research Foundation, a Grant-in-Aid from the Research Foundation for Pharmaceutical Sciences, a Grant-in-Aid for Encouragement of Young Scientists from the Ministry of Education, Science and Culture of Japan (12771464) and a Grant-in-Aid for Scientific Research (C) from Japan Society for the Promotion of Science (14572158).
