Abstract—A series of novel C2-*exo* unsaturated pyrrolo[2,1-*c*][1,4]benzodiazepines (PBDs) has been synthesised via a versatile *pro*-C2 ketone precursor. C2-*exo*-unsaturation enhances both DNA-binding reactivity and in vitro cytotoxic potency. © 2000 Elsevier Science Ltd. All rights reserved.

The pyrrolo[2,1-c][1,4]benzodiazepine (PBD) antitumour antibiotics have generated interest as potential anticancer and gene-targeting agents.¹ All biologically active PBDs (e.g. DC-81 1 and tomaymycin 2) have an electrophilic imine or carbinolamine moiety at the N10-C11 position and (S)-stereochemistry at C11a which enables a snug fit in the minor groove of DNA followed by covalent bonding to guanine at N2. Bonding occurs in a sequence specific fashion with a preference for PuGPu motifs. Typical examples of PBD natural products such as DC-81 and tomaymycin possess the same aromatic substitution pattern, although tomaymycin possesses C2exo unsaturation. As tomaymycin is significantly more potent than DC-81,2-4 a series of analogues of tomaymycin has been synthesised to confirm the significance of C2 unsaturation.

Access to C2-exo unsaturated compounds was obtained via the versatile pro-C2 ketones, **15a,b** (Scheme 1). These provided the opportunity to prepare a series of diverse C-ring-unsaturated PBDs such as the four novel exo unsaturated structures reported here, as well as a series of C2-endo unsaturated relatives.⁵

The ketone intermediates 15a,b were prepared from commercially available L-trans-4-hydroxyproline (5), which was N-protected as the benzyl carbamate 6 and then converted to the methyl ester 7 in quantitative yield. Reduction to the diol 8 using LiBH₄, and subsequent selective TBDMS protection furnished the silyl ether 9 in 70% yield. Cleavage of the N-Cbz group by catalytic hydrogenation afforded amine 10, which was coupled to the 4-methoxy⁷ (11a) or 4-benzyloxy⁶ (11b) benzoyl chloride derivatives of 11 to yield amides 12a,b in high yield. Reduction of the nitro groups with Raney nickel followed by Alloc protection of the resulting anilines 13a,b gave the allyl carbamates 14a,b in high yield. Swern oxidation of the C2-hydroxyl groups afforded the crucial C-ring ketones 15a,b in excellent yield.

The *exo*-methylene compounds **16a,b** were prepared by Wittig olefination of **15a,b** at 0 °C, whereas reflux conditions were required for introduction of the E/Z ethylidene moiety in **16c,d** (Scheme 2). Treatment of the silyl ethers **16a–d** with TBAF in THF generated the primary alcohols **17a–d** in good yields. B-ring cyclisation was achieved by subjecting alcohols **17a–c** to Swern conditions⁸ to give the N10-Alloc-protected carbinolamines **18a–c** in moderate yield. Oxidation with Dess–Martin periodinane effected cyclisation of **17d** to the PBD precursor **18d** in 83% yield. Finally, the Alloc protecting groups were removed upon treatment with catalytic

Figure 1.

Pd(0) in the presence of pyrrolidine as an allyl scavenger to give the target PBDs $19-22^{12}$ in quantitative yield. The C2-ethylidine compounds 21 and 22 were obtained as mixtures of E- and Z-isomers (e.g., 9:1 Z:E ratio for 21) which were not separated. This behaviour contrasts with the natural product tomaymycin and its C δ -O-methyl-ated derivative, which exist exclusively in the E-form. ¹⁰

The new PBD compounds were assessed for cytotoxic potency in three human ovarian carcinoma cell lines and

two derived cisplatin-resistant counterparts (Table 1) using a published procedure.11 Their DNA-binding reactivities were examined from the time course and extent of effects on double-stranded calf thymus DNA using a thermal denaturation (T_m) assay designed to probe drug-induced helical stabilisation.^{3,4} Compared to the C2-unsubstituted C8-methyl DC-81 (3), the C2methylene (19) and C2-ethylidene (21; examined as a mixture of geometric isomers) compounds significantly enhanced the stabilisation of DNA ($\Delta T_{\rm m}$ values: $\times 6.0$, $\times 4.5$ and $\times 4.1$ for **19**, and $\times 3.5$, $\times 3.4$ and $\times 3.3$ for **21** at 0, 4 and 18 h, respectively). Although cytotoxicity did not change significantly in the A2780 and CH1 lines, potency was increased by approximately 4- and 19-fold for 19 and 21 in the SKOV-3 line. Similarly, compared to 4 (C8-benzyl-DC-81), 20 and 22 (as a mixture of isomers) significantly enhanced the stabilisation of DNA ($\Delta T_{\rm m}$ values: $\times 5.0$, $\times 3.0$ and $\times 3.3$ for **20**, and $\times 4.6$, $\times 4.1$ and ×5.8 for 22 at 0, 4 and 18 h, respectively). However, cytotoxic potency increased in both the A2780 (i.e., $\times 5.8$

for **20**; $\times 3.4$ for **22**) and SKOV-3 lines ($\times 5.0$ for **22**). Furthermore, **22** was 7.2-fold more cytotoxic in the cisplatin-resistant A2780^{cisR} line than **4**. It should be noted that tomaymycin, which differs in structure from **21** only in having a C8-OH rather than a C8-OCH₃ substituent, raises $T_{\rm m}$ significantly over the three time points and is 270-fold more cytotoxic in CH1. This establishes the importance of a free hydroxyl group at the C8-position in maximising both DNA stabilisation and cytotoxicity.

In conclusion, we have developed a versatile synthetic route to C2-exo unsaturated PBD analogues which is illustrated by the syntheses of 19–22. The versatile ketone intermediates 15a,b can be efficiently synthesised on a large scale (i.e., >20 g), and should be applicable to the synthesis of a wide range of C2-exo and C2-endo⁵ derivatives. Cytotoxicity and thermal denaturation data for 19–22 confirm that C2-unsaturation enhances both cytotoxic potency and DNA-binding affinity.
