Received 24 September 2002; revised 28 October 2002; accepted 29 October 2002

**Abstract**—A series of novel  $\beta$ -amino acids has been synthesized and tested for their in vitro antifungal activity against *Candida albicans*. A steep SAR was observed.  $\beta$ -Amino acid **21** (BAY 10-8888/PLD-118) revealed the most favourable activity–tolerability profile and was selected for clinical studies as a novel antifungal for the oral treatment of yeast infections.

## Introduction

Major increases in the incidence of systemic fungal infections caused by the yeast *Candida albicans* have been observed during the last two decades, particularly in immunocompromised patients.<sup>1</sup> A critical need exists for new antifungal agents to treat these life-threatening infections.<sup>2</sup>

The 2-aminocyclohexenecarboxylic acid **1**, originally designed as pyridoxal phosphate suicide inhibitor, turned out to also have activity against *C. albicans*<sup>3</sup> (Scheme 1). However, in toxicological studies **1** showed a less favourable profile. Along with the reported antifungal activity of the natural  $\beta$ -amino acid cispentacin **2**<sup>4</sup> this prompted us to initiate a derivatization program to identify cyclic  $\beta$ -amino acids with superior oral efficacy and tolerability.

Scheme 1. Antifungal  $\beta$ -amino acids.

Here we report the synthesis of a variety of representative cyclic  $\beta$ -amino acids (**3–51**, Table 1) and their in vitro antifungal activity against *C. albicans*.

## Chemistry

Several strategies were employed to synthesize the cyclic  $\beta$ -amino acids listed in Table 1.<sup>5,6</sup>

The synthesis of example **6** was accomplished as described in Scheme 2 starting from dihydropyran **52**, which was derived from unnatural L-glucose.<sup>7</sup>

Example **21** was prepared in a straightforward manner as depicted in Scheme 3.<sup>8</sup> In the key step a highly enantioselective, quinine-mediated alcoholysis of the *meso*-anhydride **60** provided cinnamyl ester **61** (84% yield) with ee  $\geq 97\%$ . Subsequent Curtius rearrangement and Pd-catalyzed removal of the cinnamyl protecting groups afforded **21** with ee  $\geq 99.5\%$ . This process was successfully used to produce 5 kg of  $\beta$ -amino acid **21**. The absolute configuration of **21** was assigned by X-ray crystallography. Cispentacin **2** as well as examples **7** and **25** were prepared in an analogous fashion.<sup>8</sup>

The *trans*-diastereomer **26** was obtained via isomerization of the protected  $\beta$ -amino acid ester obtained from the Curtius rearrangement of **61** using DBU in refluxing

procedure described in Scheme 5, exemplified by the synthesis of compound **34** starting from **62**.<sup>9</sup>

Further analogues were prepared via Hofmann degradation with hypochlorite as exemplified in Scheme 6 for the synthesis of analogues **35** and **36**.

The trifluoromethyl substituted derivative **42** was prepared from cispentacin **2** by treatment with SF<sub>4</sub>/HF at 110 °C.<sup>10</sup> Compounds **43** and **44** were obtained starting from diethyl 2-oxocyclopentanephosphonate<sup>11</sup> and 2-oxocyclopentanesulfonic acid,<sup>12</sup> respectively, via hydrogenation of the corresponding oximes in the presence of PtO<sub>2</sub> (cat.)/Ac<sub>2</sub>O.

Other examples were synthesized as described or in analogy to known methods,<sup>5, 13–15</sup> for example, via cycloaddition of chlorosulfonyl isocyanate to the corresponding alkenes.<sup>5</sup>

## Results and Discussion

All compounds were evaluated for their inhibitory activity against *C. albicans* (Table 1).<sup>16</sup>

2-Aminocyclohexenecarboxylic acid **1** and cispentacin **2** showed potent antifungal activity in this assay (IC<sub>50</sub> 0.03 and 0.13 mg/L, respectively).

<sup>a</sup>Racemic.<sup>b</sup>m.d., mixture of diastereomers.<sup>c</sup>Configuration not known.

A very limited study on the structure–activity-relationship (SAR) of cispentacin **2** as previously described<sup>13</sup> indicated strict structural requirements for antifungal activity. The same trend could be observed in this more extensive study. Whereas dehydro-cispentacin **3** showed only slightly lower potency (IC<sub>50</sub> 0.5 mg/L), transposition or hydrogenation of the double bond in **1** resulted in a significant loss of activity (examples **4**, **5**). Likewise, insertion of heteroatoms (examples **6–10**), reduction of ring size (**11**) or methyl substitution (**13–17**) had a negative impact on antifungal activity. A variety of open-chain analogues, as exemplified by compound **12**, were inactive.

We also investigated the SAR at position 4 of the cyclopentane ring in more detail. Among these derivatives (**18–24**), only the introduction of an *exo*-methylene group resulted in strong antifungal activity. Compound **21** (IC<sub>50</sub> 0.13 mg/L) was equipotent to cispentacin **2** and selected for further derivatizations.

The (1*R*, 2*S*)-configuration of **21** turned out to be essential, since stereoisomers **25** and **26** demonstrated only weak antifungal activity. Again, a very steep SAR was observed, resulting in significant loss of potency, when the double bond of **21** was shifted to other positions (**27–29**, **34**), small substituents were introduced (**30–33**) or the ring size was altered (**35–38**). Modifications of the carboxyl (**39–47**) and the amino substituent (**48–51**) indicated that both groups are crucial for potent in vitro activity against *C. albicans*. Methyl ester **45** and dipeptides such as **48**, however, showed strong in vivo antifungal activity probably due to proteolytic cleavage in plasma to release **21**.

β-Amino acid **21** (BAY 10-8888) exhibits its antifungal activity by a unique dual mode of action.<sup>17</sup> First, it is accumulated about 200-fold in yeast cells by active transport via permeases specific for branched-chain amino acids. Inside the cell **21** inhibits specifically isoleucyl-tRNA synthetase, resulting in inhibition of protein synthesis and cell growth. In contrast, active transport and inhibition of protein synthesis of cispentacin **2** appears to be mediated by the corresponding enzymes specific for proline.<sup>17</sup> Acting as mimetics of small amino acids may explain the observed narrow SAR of antifungal β-amino acids.

Among all so far prepared β-amino acids **21** exhibited the most favourable activity-tolerability profile and was selected for further development. It showed high efficacy in rat and mouse systemic candidiasis models including azole-resistant strains<sup>18</sup> and a favourable pharmacokinetic (almost 100% oral bioavailability in rats, dogs, rabbits; 7 h half-life in man) and safety profile.

In conclusion, an extensive chemical optimization on β-amino acids revealed very steep SAR for antifungal activity and led to the identification of the novel β-amino acid **21**. An efficient asymmetric synthesis could be developed for this compound. BAY 10-8888 **21** is currently being investigated in phase II clinical studies

as PLD-118 by Pliva, Croatia for the oral treatment of yeast infections.
