ABSTRACT

A new class of potent NK₁ receptor antagonists with a tetrahydroindolizinone core has been identified. This series of compounds demonstrated improved functional activities as compared to previously identified 5,5-fused pyrrolidine lead structures. SAR at the 7-position of the tetrahydroindolizinone core is discussed in detail. A number of compounds displayed high NK₁ receptor occupancy at both 1 h and 24 h in a gerbil foot tapping model. Compound **40** has high NK₁ binding affinity, good selectivity for other NK receptors and promising in vivo properties. It also has clean P₄₅₀ inhibition and hPXR induction profiles.

The neurokinin-1 receptor (NK₁) is present in high concentrations in central and peripheral nerve systems.¹ Through the studies of the physiological effect of the ligand substance P, the NK₁ receptor has been selected as a therapeutic target for treatment of chemotherapy-induced nausea and vomiting (CINV), post-operative nausea and vomiting (PONV),^{2,3} urinary incontinence⁴ and other disorders. Aprepitant (EmendTM)⁵ is currently the only NK₁ antagonist on market, and it is approved for the treatment of CINV and PONV. In our NK₁ antagonist backup program, we focused our efforts on the discovery of efficacious compounds that are orally bioavailable and brain-penetrating with minimum potential for drug–drug interactions.

Previously, we have disclosed a novel class of NK₁ antagonists based on the 5,5-fused pyrrolidine core (**1**) (Fig. 1).^{6,7a} These compounds displayed sub-nanomolar NK₁ affinity,⁸ moderate functional activity,⁹ and had good efficacy in the gerbil foot tapping model.¹⁰ We have designed and synthesized a new class of NK₁ antagonist with a 6,5-fused tetrahydroindolizinone core (**1a**) in order to expand the scope of this class of compounds, to improve functional activity and to minimize potential P₄₅₀ inhibition and hPXR induction issues. Herein, the initial SAR results at the 7-position of this fused system are presented.

The tetrahydroindolizinone derivatives^{7b} were synthesized as illustrated in Scheme 1. The intermediate **2**^{7a} was oxidized to its

aldehyde, which was further oxidized to carboxylic acid **3** with NaClO₂. One carbon homologation of acid **3** with diazomethane and AgOBz provided ester **5**. Ester **5** was partially reduced to aldehyde **6** by DIBAL-H. Addition of the anion of *t*-BuOAc to aldehyde **6** afforded aldol product **7**, which upon deprotection by HCl and intramolecular EDC coupling provided hexahydroindolizinone **8** (Scheme 1). Oxidation of alcohol **8** to ketone **9** was achieved with PCC-alumina in 63% yield. The enolate of ketone **9** reacted with 2-[*N,N*-bis(trifluoromethanesulfonyl)amino]-5-chloropyridine to provide vinyl triflate **10**. Compounds **11–29** and **37** were prepared from intermediate **10** by the Suzuki coupling reaction. Compounds **38** and **40** were prepared from triflate **10** by Stille coupling reactions. Compounds **39** and **41** were prepared from olefinic compounds **38** and **40**, respectively by selective hydrogenation (25 psi H₂, 10%

Pd–C in MeOH). Alkene **33** was prepared from **8** through formation of its mesylate followed by elimination of MsOH under basic condition.

Lactone compounds **34** and **35** were prepared according to Scheme 2. Palladium catalyzed coupling reaction of **10** with diol **10a** provided lactol **10b**, which was oxidized with Ag_2CO_3 to afford lactones **34** and **35**.¹¹

Oxadiazoles **30–32** were prepared by palladium catalyzed reaction of **10** with CO to generate an acyl-palladium intermediate,

which reacts with amidoximes to afford **30–32** (Scheme 2).¹² Direct displacement of OTf of **10** with 4-OH piperidine provided **36**.

Biological results for compounds with β -aromatic substituents are shown in Table 1. With a few exceptions (**12–14**, **20**, **27** and **32**), most of the analogs in Table 1 displayed potent sub-nanomolar NK_1 binding affinities. In presence of 50% human serum, their NK_1 binding activities varied widely. Polar compounds had smaller serum shifts (**16** vs **17**, **20** vs **21** and **22** vs **23**). A significant improvement in IP-1 functional activity was observed for these 6,5-fused

compounds with β -substituents compared with unsubstituted compound **33**. In general, the IP-1 functional activity of these 6,5-fused compounds was also significantly better than that of the 5,5-fused pyrrolidine compounds previously disclosed (IP-1: 28–90%).^{7a} A majority of these compounds had IP-1 activities below 20% substance P response remaining (SPRR) at 100 nM antagonist concentration. Among compounds with a six-membered ring substituents at the 7-position, compared to compound **11**, a substituent at the 4-position of the phenyl group had a positive impact on the IP-1 activity (**11** vs **12–16**). Compounds with a pyridyl substituent also had improved IP-1 activities compared to compound **11**. Except compounds **26** and **27**, compounds with a five-membered ring substituent were less potent than compounds with a six-membered ring substituents in the IP-1 assay. The NK₁ binding affinity and the functional activity did not always directly correlate

(for example, compound **12** had weaker NK₁ binding activity and excellent IP-1 activity). There was also no correlation between the polarity of a compound and its IP-1 functional activity (**25** vs **26** and **27**).

Some of the compounds with potent NK₁ binding and functional activity were also tested in the gerbil foot tapping assay¹⁰, which measured how effective the compound blocked the NK₁ receptor at 24 h in the gerbil brain (Table 1). Data from this assay also provided an indication of the duration of parent or active metabolites, and an indication of brain penetration. Compounds **16** and **17** demonstrated complete inhibition of gerbil foot tapping at 24 h at an iv dose of 3 mg/kg.

The SAR learned from Table 1 was applied in the design of compounds with non-aromatic β substituents at the 7-position and data are presented in Table 2. These compounds all have a polar

group at the far side of the attachment to reduce serum shifts. All of them exhibited sub-nanomolar binding potency on the NK₁ receptor. They had lower shifts in affinity in the presence of human serum as compared to the compounds with β -aromatic substituents, probably due to higher polarity. Importantly, all of them had excellent functional activities. In the gerbil foot tapping assay, all tested compounds displayed potent efficacy at 1 h or 24 h. Compound **40** was prepared initially as an intermediate for compound **41**. The *t*-Bu group of compound **41** was used to block possible metabolism of the piperidine group. It was surprising to find that compound **40** is more potent than **41** in the gerbil foot tapping assay despite the fact that compound **41** is about fourfold (ninefold with human serum) more potent than compound **40** in the binding assay.

Given its single dose potency in the gerbil foot tapping assay, compound **40** was titrated to have an ID₅₀ = 0.05 mg/kg at 1 h and an ID₅₀ = 0.49 mg/kg at 24 h (Table 3). These data indicate that compound **40** was one of the most potent compounds in this assay.

Table 3
In vivo activity of compound **40** in Gerbil^a

Time (h)	ID ₅₀	ID ₅₀ (at 1 mpk, iv)	
		Plasma	Brain
1	0.05	0.57	6.9
24	0.49	—	—

^a Plasma drug levels determined by LC–MS following protein precipitation.

Table 4
Pharmacokinetic profile of **40**

	<i>t</i> _{1/2} (h)	Vd (L/kg)	Clp (mL/mg/kg)	nAUC (po) (μ M h kg/mg)	F (%)
Rat	2.8	7.2	33	0.05	5.3
Dog	8.8	11	17	0.69	44

Table 5
P₄₅₀ inhibition and hPXR induction data for compound **40**

	Cyp 2C9	Cyp 2D6	Cyp 3A4	PXR
IC ₅₀ (μ M)	36.5	35.7	>50	>30

At 1 h, the IC₅₀ values in plasma and brain are 0.57 and 6.9 nM, respectively indicating that low plasma and brain concentrations drive efficacy in gerbil and a high b/p ratio.

Compound **40** was evaluated for PK properties in rat and dog (Table 4). In rat, it showed high clearance (33 mL/min/kg), very low oral AUC (0.05), desirable plasma half-life (2.8 h) and poor oral bioavailability. However, in dog, the PK profile improved with moderate clearance (11 mL/min/kg), better oral AUC (0.69), good half-life, and improved oral bioavailability.

Compound **40** had a low affinity for cytochrome P₄₅₀ enzymes and a reduced potential for induction as measured by a hPXR induction assay (Table 5), which indicated that compound **40** may have reduced liability for drug–drug interactions.

In summary, a new class of NK₁ receptor antagonists based on a tetrahydroindolizinone core with substitutions at the 7-position has been identified. These 6,5-fused pyrrolidine NK₁ antagonists generally had sub-nanomolar NK₁ binding affinities and excellent functional IP-1 activities. Many of these analogs have potent in vivo efficacy in the gerbil model at 24 h. Compound **40** had excellent efficacy in the gerbil foot tapping model at both 1 h and 24 h. It also had a clean profile in human P₄₅₀ inhibition and PXR induction assays, thus reducing the potential for drug–drug interactions.

Acknowledgments

The authors wish to thank the Synthetic Services Group for scale-up of synthetic intermediate **2**.
