### ABSTRACT

A novel series of adenosine  $A_{2A}$  receptor antagonists was identified by high-throughput screening of an encoded combinatorial compound collection. The initial hits were optimized for  $A_{2A}$  binding affinity,  $A_1$  selectivity, and in vitro microsomal stability generating orally available 2-aminoimidazo[4,5-b]pyridine-based  $A_{2A}$  antagonist leads.

© 2010 Published by Elsevier Ltd.

Adenosine mediates various biological functions through its interaction with a family of G-protein-coupled receptors. To date, four subtypes of adenosine receptors (A<sub>1</sub>, A<sub>2A</sub>, A<sub>2B</sub>, and A<sub>3</sub>) have been identified and each exhibits a unique expression pattern and physiological role. Adenosine receptor subtype A<sub>2A</sub>, located in the striatum of the brain, contributes to the regulation of motor activity by modulating dopamine D<sub>2</sub> receptor activation.<sup>2</sup> Hence, inhibition of the interaction of adenosine with the A<sub>2A</sub> receptor may provide a potential treatment for Parkinson's disease.3 Notably, A2A antagonists such as xanthine KW-6002,4 pyrazolotriazolopyrimidine SCH420814,<sup>5</sup> and triazolopyrimidine V2006/BIIB-014<sup>6</sup> have advanced to human clinical trials for motor-related disorders. In addition, chemotypes such as thiazolopyrimidines, benzofurans, benzofurans, and 6-furanyl-4-carboxamidylpyrimidines<sup>9</sup> have been recently disclosed as A<sub>2A</sub> antagonists. In our efforts, high-throughput screening of an extensive encoded combinatorial compound collection  $^{10}$  ( $\sim$ 4.5 million compounds screened) also identified multiple active chemotypes. We have recently reported the discovery of substituted aminothiazoles11 and trisubstituted purinones12 as A2A receptor antagonists identified through this screening campaign. Herein, the optimization of a third chemotype, based on a 2-aminoimidazopyridine scaffold, identified via this high-throughput screen is discussed.

The initial hit, benzimidazole 1a, was an active  $A_{2A}$  antagonist (46 nM) but lacked microsomal stability (11% remaining after 0.5 h treatment with human liver microsomes). Intriguingly, the hit lacked a furan moiety, a common feature of non-xanthine a antagonists. Hence, a hit to lead effort was initiated with the goal of converting this active in vitro hit into an orally available, brain penetrant lead molecule. In addition, selectivity against the a receptor subtype was considered desirable in light of the potential for cardiovascular or renal effects associated with antagonism of the a subtype.

Benzimidazoles **1a–1h** were synthesized via the solid-phase route outlined in Scheme 1. Acid-cleavable linker 4-(4'-formyl-3'-methoxy)phenoxy butyric acid<sup>16</sup> was coupled to amino-TentaGel generating resin **6**. Reductive amination with 3-methoxybenzylamine followed by HATU-mediated coupling of 4-fluoro-3-nitrobenzoic acid produced intermediate **8**. Subsequent fluorine displacement, nitro reduction, and cyclization with cyanogen bromide yielded resin-bound aminobenzimidazole **11**, a key intermediate which enabled access to various R<sup>3</sup> substitutions on the 2-amino group of the benzimidazole core.

The unsubstituted aminobenzimidazole 1b (generated via direct cleavage of resin-bound intermediate 11) exhibited a dramatic drop in binding affinity with the  $A_{2A}$  receptor (Table 1). Additionally, analogs containing smaller alkyl secondary amides or tertiary amides in this  $R^3$  position were inactive (data not shown). Hence, a focus was placed on optimizing the substitution of the benzoyl amide.

Compds	$R^3$	Human $A_{2A}$ binding $K_i$ $(nM)^{16}$
1a	3-Cyanobenzoyl	46
1b	Н	6770
1c	3-Fluorobenzoyl	210
1d	3-Chlorobenzoyl	439
1e	3-Trifluoromethylbenzoyl	>10,000
1f	3-Methoxybenzoyl	2380
1g	2-Chlorobenzoyl	4710
1h	4-Cyanobenzoyl	1670

As is demonstrated in Table 1, alternative electron-withdrawing substituents such as 3-fluoro (**1c**) and 3-chloro (**1d**) suffered five or 10-fold reductions in binding affinity, respectively, when compared to the 3-cyano parent (**1a**). The more lipophilic electron-withdrawing 3-trifluoromethyl group (**1e**) was inactive in the assay. Substitution with an electron-donating methoxy group on the 3-position of the benzamide also produced a weakly active analog (**1f**). Relocation of the electron-withdrawing group to either the 2-position (**1g**) or 4-position (**1h**) on the ring also led to a drop in affinity.

Similarity between the 2-aminobenzamidazole core of these compounds and the 2-aminobenzothiazole core of previously disclosed  $A_{2A}$  antagonists<sup>18</sup> was noted. However, various benzoyl substitution patterns were allowed on the previously disclosed 2-aminobenzothiazole scaffold.<sup>18</sup> In contrast, as indicated in Table 1, the 3-cyano substitution on this 2-aminobenzamidazole (**1a**)

Reagents and conditions: (a) R<sup>1</sup>RNH, DIEA, DCM; rt; (b) R<sup>2</sup>NH<sub>2</sub>, THF, rt; (c) Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>, NaHCO<sub>3</sub>, 1,4-dioxane/H<sub>2</sub>O, rt; (d) 3-cyanobenzoyl isothiocyanate<sup>18</sup>, DCM, EDC, Et<sub>3</sub>N, rt.

uniquely provided high binding affinity. This 3-cyanobenzoyl group was held constant through further optimization efforts.

A limited set of examples indicated increased microsomal stability when the benzimidazole core was replaced with an imidazo[4,5-b]pyridine core (Table 2; compare **2a** to **2b** and **2c** to **2d**). Since this change did not negatively affect binding affinity and the potential for added microsomal stability was desirable, the imidazopyridine series was the main focus moving forward.

A solution-phase synthetic route (Scheme 2) was employed for the generation of imidazopyridine analogs aimed at understanding the SAR of the R<sup>1</sup> and R<sup>2</sup> moieties. The appropriate *ortho*-nitro, halogen-substituted benzoic ester was reacted with an amine to generate intermediate **12**. Nitro reduction to diamine **13**, cyclization with cyanogen bromide to **14**, and coupling with 3-cyanobenzoic acid produced ester **15**. Hydrolysis yielded acid **16** which was converted to the analogs **2–4** via carbodiimide-mediated amide formation. Alternatively, as outlined in Scheme 3, acid chloride **17** could be reacted with two sequential amines to generate intermediate **18**. Nitro reduction and cyclization with 3-cyanobenzoyl isothiocyanate<sup>19</sup> yielded the desired analogs **2–4**.

As suggested by the human  $A_{2A}$  binding affinity of compounds in Table 2, elimination of the original  $R^1$  3-methoxybenzyl moiety was tolerated allowing a reduction of the molecular weight. While simplification to the primary amide was not allowed (Table 3; **3a**), analog **2d** suggested that tertiary amides might be preferred, thereby removing one undesired hydrogen bond donor from this potential CNS molecule. As demonstrated in Table 3, other tertiary

amides were indeed tolerated. While the highly simplified dimethylamide analog **3b** had less affinity than **1a**, slightly larger alkyl amides were more tightly bound (**3c** and **3d**).

An in vitro cAMP functional assay was employed to further characterize the activity of these analogs in rat cells (Table 3).<sup>20</sup> Sterically crowded R<sup>1</sup> alkylamides (as in analogs **3e–3g**) imparted enhanced activity in this cAMP functional assay. In addition, these sterically crowded R<sup>1</sup> analogs demonstrated improved selectivity against the A<sub>1</sub> receptor subtype.

The compounds discussed thus far have harbored a fixed 3-methoxypropyl moiety at the N3-position of the imidazole ring. Changes to this  $R^2$  position were explored while maintaining a simple N-piperidinylamide in the  $R^1$  position (Table 4; **4a-4j**).

**Scheme 4.** Synthesis of analogs **5a–5d**. Reagents and conditions: (a) 3-methoxy-propylamine, DIEA, THF, rt, 83%; (b) CO, EtOH, Et<sub>3</sub>N, PdCl<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>, 70 °C, 37%; (c) procedures outlined in Scheme 3.

Truncation of the longer 3-methoxypropyl chain (2d) to a simplified methyl group (4a) resulted in a 15-fold drop in binding affinity for the A<sub>2A</sub> receptor. Replacement of the oxygen in the methoxypropyl group with a methylene (4b) caused an even sharper drop in affinity. However, the hydroxypropyl analog 4c exhibited only a minor loss of affinity for the receptor. Hence, it was hypothesized that the oxygen of this chain served as a hydrogen bond acceptor with the A<sub>2A</sub> receptor. Replacement with a different functional group capable of accepting a hydrogen bond, for instance an acetamide (4e), was tolerated lending support to the hypothesis. The aromatic analogs in this series (4f-4i) also support the requirement for a hydrogen bond acceptor. Para-fluorobenzyl analog 4h is a comparatively weak binder of the A2A receptor in relation to the pyridinylmethyl analogs 4i and 4j. The location of the hydrogen bond accepting moiety is important since the 3-pyridylmethyl analog 4i is sixfold less tightly bound then the 4-pyridylmethyl analog **4j**. Additionally, the 3-methoxyphenyl analog **4f** is fourfold more tightly bound than the 4-methoxybenzyl analog 4g. Surprisingly, the 3-methoxybenzyl analog (not shown) was inactive in the assay.

A series of relatively conservative modifications to the 3-methoxypropyl R<sup>3</sup> group was tested while maintaining a *N*-morpholino amide in the R<sup>1</sup> position (**4k**-**4n**). When compared to the 3-methoxypropyl analog **4k**, relocation of the oxygen closer to

the imidazopyridine core (**4I**) was detrimental to the binding affinity. Extension of the methoxy group to an ethoxy (**4m**) or isopropoxy group (**4n**) was also not tolerated.

Clearly, the 3-methoxypropyl chain (2d) was providing an optimal electronic and steric display to the  $A_{2A}$  receptor. In addition, none of the changes outlined in Table 4 enhanced selectivity against the  $A_1$  receptor subtype.

Since the R<sup>1</sup> amide proved to be the most tolerant toward change, the possibility of relocating this functional group from the 6-position to the 5-position of the imidazopyridine was explored. The synthesis of these analogs (**5a-5d**) is outlined in Scheme 4. Treatment of 2,6-dichloro-3-nitropyridine (**19**) with 3-methoxypropylamine led to intermediate **20**. Palladium-catalyzed carbonylation<sup>21</sup> generated ester **21** which was converted to the desired analogs via the steps outlined in Scheme 3.

In general the SAR for the 5-substituted amides was similar to the 6-position amide analogs (Table 5). Again, small alkyl tertiary amides were preferred at  $R^1$  with the N-methyl-N-isopropylamide derivative  ${\bf 5d}$  exhibiting high activity in both the  $A_{2A}$  binding and functional assays. The 5-carboxamido-substituted analogs were generally less stable to microsomes than their 6-substituted counterparts. However, analog  ${\bf 5c}$  was particularly notable since it maintained moderate stability in the liver microsome assay.

Selected compounds which exhibited activity in the cAMP functional assay,  $A_1$  selectivity, and in vitro microsomal stability were tested for brain levels in rat after oral dosing.<sup>22</sup> A comparison of two example analogs is provided in Table 6. Analog **5c** exhibited the best overall profile of desired in vitro activity, good plasma exposure, and modest brain levels after oral dosing in the rat.

In summary, a novel class of  $A_{2A}$  antagonists has been discovered via a high-throughput screen. These analogs represent the third chemotype of  $A_{2A}$  antagonists identified from an encoded combinatorial compound collection. Initial optimization of this series led to the synthesis of 2-aminoimidazopyridine **5c**, an orally available  $A_{2A}$  antagonist ( $K_i = 12 \text{ nM}$ ) which exhibits 80-fold selectivity against the  $A_1$  receptor and activity in an in vitro cAMP accumulation assay.

- A rat functional assay was chosen to support in vivo rat model studies. Rat pheochromocytoma (PC-12) cells (ATCC, CRL-1721) were maintained in 1x Ham's F12 medium (Invitrogen) supplemented with 10% horse serum (Invitrogen), 2% FBS (Invitrogen), and 1× Penn/Strep (Invitrogen) in rat tail collagen (BD Biosciences)-treated tissue culture flasks. cAMP was quantified using the Perkin Elmer LANCE™ cAMP 384 kit. On the day of the assay, 5000 PC-12 cells were pre-incubated with compound for 15 min and then stimulated with 50 nM CGS-21680 for 15 min in a final volume of 18  $\mu$ L. Assay was conducted in  $1 \times$  HBSS (Invitrogen), 5 mM HEPES (Invitrogen), 0.05% BSA, (Sigma), 50 μM rolipram (Sigma), pH 7.4 buffer at 37 °C/5% CO<sub>2</sub>. Final DMSO concentration was 0.5%. Following stimulation, the cells were lysed with cAMP detection solution provided with the assay kit. Signal was allowed to develop for 1 hour and detected using the EnVision™ Multiplate Reader or the Victor™ Multilabel counter (Perkin Elmer). Assays were performed in duplicate and compounds were tested a minimum of two times. The data were fit to a one-site competition binding model for IC50 determination using the program GraphPad Prism (GraphPad Software, Inc., San Diego, CA) and  $K_i$  values were calculated using the Cheng-Prusoff equation.

- 22. Procedure for the rat brain level determination: male Sprague–Dawley rats were used for all studies. Rats were acclimated to the vivarium for 5–7 days before each study. On the day before the study, the rats were fasted overnight (18–20 h) but allowed free access to water. The next day, each rat was weighed and dosed (based on the individual animal's body weight) via oral intubation with test compounds suspended in 0.5%MC. One, 2 or 4 h after compound administration rats (two/group) were euthanized by CO<sub>2</sub> asphyxiation. Blood was collected by cardiac puncture and plasma prepared. Brain tissue was collected following organ perfusion to remove any excess blood. The brain tissue was homogenized on ice in cold PBS. The plasma and homogenized brain tissue were stored frozen until the time of analysis using LC/MS/MS. Standards curves, quality control and appropriate blank samples were included and all samples were analyzed. Results were expressed as the brain/plasma ratio (ng/g) at the specified time.
