The E1 Reaction of Menthyl and Neomenthyl Tosylates in Aprotic Solvents

Masatomo Nojima, Masakatsu Yoshimura, and Niichiro Tokura Department of Applied Chemistry, Faculty of Engineering, Osaka University, Suita (Received May 11, 1971)

The El reaction has been studied, especially in protic solvents, in relation to the S_Nl reaction.¹⁾ In contrast to the insistence of Ingold²⁾ that the intermediates of the S_Nl and El reactions were the same, and that there was no solvent effect upon the ratio of the afforded olefin and the replaced product, Winstein³⁾ established that an elimination from the intimate ion pair occurred in the solvent with a low ionizing power:

We examined the El reactions of menthyl and neo-

menthyl tosylates in dimethylsulfoxide (DMSO), dimethylformamide (DMF), acetonitrile, methylene chloride, and 1,2-dichloroethane respectively in hopes of clarifying the effects of the aprotic solvents upon the rates and to obtain insight into the mechanism of this reaction.

The first-roder rate constants are tabulated in Table 1, along with the derived values of the thermodynamic quantities, the enthalpy and entropy of activation, ΔH^+ and ΔS^+ . Although no linearity between the rates and the dielectric constants of the solvents was observed, the rate increased as the dielectric constants of the solvent increased. These results may be explained as follows: the use of solvents with high dielectric constants is advantageous for the ionization and dissociation of the substrate.⁴⁾

The rate ratios between neomenthyl and menthyl tosylates in various solvents are summarized in Table 2. It has been suggested that the hydrogen participation in the ionization step of neomenthyl tosylate contributes to the large acetolysis rate ratio between neomenthy

a) Calculated from data at other temperatures.

Table 2. The rate ratios between neomenthyl and menthyl tosylate in the various solvents

Solvent	Rate ratio (II/I)	
DMF	150	
Methylene chloride	22	
EtOH	99	
AcOH	59	

and menthyl tosylates.⁵⁾ The rate ratio in the reaction in DMF was 150, while in methylene chloride it was 22. These results suggest that the hydrogen paticipation does not play an important role, at least in the

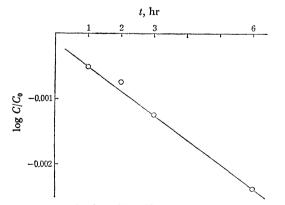

Fig. 1. Isomerization of I to II. C_0 : initial concentration of I. C: concentration of I at time t.

reaction in methylene chloride.

An isomeric change in the configuration of the substrate was found in the reaction in DMF. The El reaction of menthyl tosylate in DMF at 75°C, followed by the reduction of the reaction mixture by lithium amide, led to the isolation of neomenthol, olefins, and menthol. From the relationship of $\log C/C_0$ to the reaction time (Fig. 1), the rate of the isomerization of menthyl tosylate to neomenthyl tosylate was estimated to be $2.38\times10^{-7}\,\mathrm{sec^{-1}}$, which is one order of magnitude smaller than the rate of the olefin formation ($2.10\times10^{-6}\,\mathrm{sec^{-1}}$). The neomenthyl derivative was not detected in the reaction mixtures obtained by reactions in any other solvents except DMF.

Experimental

Materials. DMSO and DMF were purified by drying them over calcium hydride, and they were distilled under diminished pressure. Acetonitrile was purified by the method of Coetzee et al.⁶) Methylene chloride and 1,2-dichloroethane was dried over calcium chloride and distilled. Menthyl tosylate was obtained by following the method of Winstein;⁴) mp 92.2—93.3°C (lit, 93.5—94.0⁴). Neomenthyl tosylate was prepared from neomenthol with tosyl chloride; mp 62.5—63.9°C⁷) (lit, 63.0—63.5°C).

Kinetic Procedure. The rates were measured by using glass tubes which could be closed by means of a polyethylene cap. The thermostats were of a conventional design and maintained the temperature within±0.05°C. The reaction mixtures were prepared from the known weight of a solute and from the solvent volumetrically. The reactions were followed by withdrawing ampoules from the thermostat at suitable intervals and by titrating them with a sodium acetatemethanol solution, using bromophenol blue as the indicator.

The Reaction in DMF. The reaction of menthyl tosylate (300 mg) was performed in the presence of two equivalent moles of lutidine in 20 ml of the solvent at 75°C. The reaction mixture was poured into ice water, extracted by petroleum ether, and dried over anhydrous sodium sulfate. After the evaporation of the solvent, the reaction mixture was reduced with five equivalent moles of lithium amide in ammonia at 70°C for 4 hr. The reaction mixture was hydrolysed by aq. hydrochloric acid, extracted by ether, and dried over anhydrous sodium sulfate. After the evaporation of the solvent, the products were analyzed by means of a Hitachi K-53 vpc apparatus, equipped with a flame-ionization detector on a PEG 6000 column operated at 180°C.

The Reduction of Menthyl Tosylate. 19 Into a lithium amide-ammonia solution prepared by dissolving 0.8 g (0.05 mol) of lithium in 100 ml of ammonia, we added 1.6 g (0.005 mol) of menthyl tosylate dissolved in 10 ml of ether. After four hours methanol was added and the mixture was extracted with ether. Then the reaction mixture was treated and analyzed as has been described above; only menthol was present.
