

Reactions between Nucleophiles and Sulfonium Ions Containing Electron-withdrawing Substituents

Haruo MATSUYAMA, Hiroshi MINATO, and Michio KOBAYASHI

Department of Chemistry, Faculty of Science, Tokyo Metropolitan University, Fukazawa, Setagaya, Tokyo 158

(Received May 27, 1975)

Sulfonium ions containing electron-withdrawing substituents are formed by the reactions between sulfonium ylides and suitable electrophiles. Reactivities of these sulfonium ions ($\text{MeRS}^+-\text{CX}(\text{CO}_2\text{Me})_2$) with nucleophiles (Y^-) are investigated. The products found are those of 1) C-attack ($\text{MeSR} + \text{YCX}(\text{CO}_2\text{Me})_2$), 2) Me-attack ($\text{MeY} + \text{RSCX}(\text{CO}_2\text{Me})_2$) and 3) R-attack ($\text{RY} + \text{MeSCX}(\text{CO}_2\text{Me})_2$). When R is (+)-2-octyl and Y^- is bromide ion, the RY found is (–)-2-octyl bromide with 59% optical purity. The mechanism of these reactions are discussed.

It has been shown that the reactions between trialkylsulfonium ions and nucleophiles yielding sulfides and alkylated nucleophiles have features different from ordinary $\text{S}_{\text{N}}1$, $\text{S}_{\text{N}}2$ or competitive $\text{S}_{\text{N}}1$ – $\text{S}_{\text{N}}2$ reactions on carbon atoms.

In ordinary $\text{S}_{\text{N}}2$ reactions on carbon atoms (for instance, the leaving groups are halides), the relative reactivities of benzyl and methyl compounds are not much different from unity,¹⁾ whereas benzylation predominates in the reaction of dimethyl-1-phenylethylsulfonium ion with nucleophiles.²⁾ When di-*t*-butylmethylsulfonium ion reacts with methyl sulfide, exclusive *t*-butylation takes place with no methylation accompanied.³⁾ Thus when

sulfides are leaving groups, the behavior of the substitution are occasionally quite different from that with halides or ammonium ions as leaving groups. No comprehensive explanations have been proposed yet.

In an attempt to understand the reactions between sulfonium ions and nucleophiles, the reactivities of the sulfonium ions containing electron-withdrawing substituents have been investigated, and the results are described in this paper.

Results and Discussion

Sulfonium ions containing electron-withdrawing substituents were prepared by the reaction between sulfonium ylides and suitable electrophiles.

When sulfonium bis(methoxycarbonyl)methylide (**1**) was mixed in chloroform with Br–Br, Cl–Cl, PhS–Cl, PhS–Br, MeS–Br or H–Br, they reacted instantaneously at room temperature. Usually it was not possible to

a) Determined from its methyl singlet absorption. b) The CO₂Me (δ 3.77—3.86, broad singlet) absorptions of (RS)XCQ₂, (MeS)XCQ₂ and XYCQ₂ usually could not be resolved. The amount of (MeS)XCQ₂ was determined from its MeS singlet, and that of XYCQ₂ was estimated by assuming the equimolar formation of MeSR and XYCQ₂. Then the amount of (RS)XCQ₂ could be calculated. c) Q=CO₂Me. d) The amounts of PhCH₂Y (or MeSCH₂Y) were determined from its singlet near 4.50 ppm. The amounts of other RY's were estimated from the assumption of equimolar formation of RY and (MeS)XCQ₂ (determined from its MeS singlet).

isolate the sulfonium salts. It was possible to isolate a white solid sulfonium salt from the reaction between **1a** (R=Me) and HBr; they decomposed when they were dissolved in chloroform and allowed to stand at room temperature for 5 hrs. The products of the reaction of **1a** (R=Me) and **1b** (R=Ph) with several electrophiles are listed in Table 1.

When R in **1** is an alkyl group, competitive S_N2 attacks on the methyl and alkyl groups are expected. Ylide **1** with various alkyl groups was allowed to react with X—Y, and the products are shown in Table 2.

The results shown in Tables 1 and 2 can be summarized as follows. The ylides and electrophiles react and form sulfonium ions and anions Y[⊖], which further react in three different ways (namely, Me-attack, R-attack and C-attack).

The course of the reaction depends upon the structure of the sulfonium ion (R and X) and the nucleophile Y[⊖].

1) When R is Me, methyl attack of Y[⊖] predominates

except one case, in which X is MeS.

When X is MeS, Me₂S group easily leaves from Me₂S[⊕]—C(SMe)(CO₂Me)₂; it is known that R—S groups can stabilize the adjacent carbonium ion by resonance effect as shown below.⁴⁾

X	Br	Cl	H	PhS	PhS
Y	Br	Cl	Br	Cl	Br

When X is PhS, such resonance effect is not great enough to help the elimination of Me₂S.

2) When R is Ph, and X is MeS or PhS, the elimination of PhSMe and the apparent C-attack of Y[⊖] predominate.

Apparently PhSMe is a better leaving group than Me₂S,⁵⁾ and even when X is PhS (a poorer resonance-stabilizing group), the elimination of PhSMe takes place readily.

3) When X is Br or Cl, the main reaction is methyl attack of Y[⊖] and RSM₂ elimination is not observed.

It is reasonable that the carbon atom containing three electron-withdrawing groups (two CO₂Me's and one halogen) does not allow the RSM₂ elimination resulting in the formation of a carbonium ion.

4) When R=Ph and X=H, both the RSM₂ elimination and the methyl attack of Y[⊖] take place.

It is interesting to note that when one of the substitu-

ents is benzyl or methylthiomethyl group, the reaction is exclusive benzylation or methylthiomethylation of the nucleophile with no accompanying methylation. The ratio between the yields of methylated and alkylated products are calculated and summarized in Table 3. They are quite different from what are expected for ordinary S_N2 reactions on carbon. For instance, the relative reactivities of alkyl bromides with bromide anion in acetone at 25 °C are Me 1.0, Et 0.013, *i*-Pr 0.0086, and PhCH₂ 1.0.⁶⁾ The remarkable feature in the results shown in Table 3 is that the reactivity of methyl group is comparable to that of ethyl group, smaller than that of isopropyl group, and far smaller than that of benzyl group.

The relative reactivities of phenylmethylalkylsulfonium perchlorates with iodide anion in acetone at 50 °C are Me 1.0, Et 0.20, *n*-Pr 0.16, and *i*-Pr 0.05, and apparently these reactions involve S_N2 attack on the sulfonium alkyl groups.⁷⁾

Table 3 shows that benzyl and methylthiomethyl are far more reactive than methyl group. These results suggest that these reactions may involve an S_N1-like process. In the reactions of **1** with hydrogen bromide, however, the reactivity of isopropyl group is smaller than that of methyl group. Thus, *sec*-alkyl groups are more reactive than methyl group only when the α atom in X is a hetero atom such as Br, Cl or S.

Reversible bond-formation between sulfonium sulfur atom and an anion is a possible process, since evidence for the formation of a tetravalent sulfur intermediate from a sulfonium ion and chloride ion has been presented,⁹⁾ and many examples of tetravalent sulfur intermediates were described in a recent review.⁹⁾ In an attempt to elucidate the mechanism of these reactions, a sulfonium ylide with optically active (+)-2-C₈H₁₇

Scheme.

a) Relative reactivities are the ratio RY/MeY, calculated from Table 2.

Reactions of Ylides **1a or **1b** with Chlorine.** (a) The reaction between a CHCl_3 (10 g) solution of **1a** (1.0 g, 5.14 mmol) and a CCl_4 solution of Cl_2 (0.42 g, 6.0 mmol) was exothermic and instantaneous, and gave MeCl (δ 3.0, s) and $\text{Cl}(\text{MeS})\text{C}(\text{CO}_2\text{Me})_2$ (liquid, 0.92 g, 4.34 mmol, 84%; IR (neat), 1740

cm^{-1} (ν_{CO}); NMR (CDCl_3), δ 3.88 (6H, s, CO_2Me) and 2.25 (3H, s, MeS). Found: C, 32.75; H, 3.82%. Calcd for $\text{C}_6\text{H}_5\text{O}_4\text{ClS}$: C, 32.82; H, 4.13%.

(b) In a similar manner, a mixture of a CHCl_3 (19 g) solution of **1b** (2.61 g, 10.3 mmol) and a CCl_4 solution of Cl_2 (0.78 g, 11.0 mmol) gave MeCl (δ 2.97, s) and $\text{Cl}(\text{PhS})\text{C}(\text{CO}_2\text{Me})_2$ (liquid, 2.49 g, 9.09 mmol, 88%; IR (neat), 1740 cm^{-1} (ν_{CO}); NMR (CCl_4), δ 7.30—7.60 (5H, m, PhS) and 3.68 (6H, s, CO_2Me). Found: C, 48.17; H, 3.92%. Calcd for $\text{C}_{11}\text{H}_{11}\text{O}_4\text{ClS}$: C, 48.10; H, 4.04%. Methyl phenyl sulfide (PhSMe , δ 2.49, s) was not found.

Reactions of Ylides 1a or 1b with Benzenesulfonyl Chloride.

(a) When PhSCl (1.60 g, 11.1 mmol) was added to a chloroform (15 g) solution of **1a** (1.98 g, 10.3 mmol), they reacted instantaneously, and the solution turned from red to colorless. The amounts of the products were determined by NMR spectroscopy with nitromethane as an internal standard. From the low-boiling fraction trapped in liquid nitrogen, methyl chloride was identified by NMR (δ 2.97, s). The high-boiling fraction solidified at room temperature, and recrystallization from benzene yielded white crystals of $\text{MeS}(\text{PhS})\text{C}(\text{CO}_2\text{Me})_2$, 2.51 g (8.77 mmol, 85%); mp $71\text{--}72^\circ\text{C}$; IR (KBr), 1730 cm^{-1} (ν_{CO}); NMR (CCl_4), δ 7.30 (5H, s, PhS), 3.64 (6H, s, CO_2Me) and 2.15 (3H, s, MeS). Found: C, 50.52; H, 4.93%. Calcd for $\text{C}_{12}\text{H}_{14}\text{O}_4\text{S}_2$: C, 50.33; H, 4.93%.

(b) In a similar manner, a mixture of a CHCl_3 (9 g) solution of **1b** (1.75 g, 6.87 mmol) and PhSCl (1.01 g, 7.0 mmol) gave PhSMe (from hexane eluates; 0.71 g, 5.75 mmol, 84%), $\text{Cl}(\text{PhS})\text{C}(\text{CO}_2\text{Me})_2$ (oil from benzene eluates; 1.66 g, 6.05 mmol, 88%).

Reactions of Ylides 1a or 1b with Benzenesulfonyl Bromide.

(a) A mixture of a CHCl_3 (14 g) solution of **1a** (1.95 g, 10.0 mmol) and a CCl_4 (6 g) solution of PhSSPh (1.1 g, 5.0 mmol) and bromine (0.8 g, 5.0 mmol) reacted instantaneously, and gave MeBr (δ 2.64, s) and $\text{MeS}(\text{PhS})\text{C}(\text{CO}_2\text{Me})_2$ (1.83 g, 6.4 mmol, 64%; mp $71\text{--}72^\circ\text{C}$).

(b) A mixture of a CHCl_3 (10 g) solution of **1b** (2.54 g, 10.0 mmol) and a CCl_4 (10 g) solution of PhSSPh (1.1 g, 5.0 mmol) and bromine (0.8 g, 5.0 mmol) gave PhSMe (δ 2.49, from hexane eluates; 0.81 g, 6.50 mmol, 65%) and $\text{Br}(\text{PhS})\text{C}(\text{CO}_2\text{Me})_2$ (oil from benzene eluates; 3.09 g, 7.70 mmol, 97%).

Reactions of Ylides 1a or 1b with Methanesulfonyl Bromide.

(a) In a similar manner, a mixture of a CHCl_3 (10 g) solution of **1a** (1.92 g, 10 mmol) and a CCl_4 (9 g) solution of MeSSMe (0.42 g, 5.0 mmol) and bromine (0.8 g, 5.0 mmol) reacted instantaneously, and gave Me_2S (δ 2.10, s, 75%), MeBr (δ 2.64, s, 25%; produced from the reaction of free bromine) and $\text{Br}(\text{MeS})\text{C}(\text{CO}_2\text{Me})_2$ (oil from benzene eluates; 2.24 g, 8.40 mmol, 84%).

(b) A mixture of a CHCl_3 (10 g) solution of **1b** (1.90 g, 10 mmol) and a CCl_4 (8 g) solution of MeSSMe (0.42 g, 0.5 mmol) and bromine (0.8 g, 5.0 mmol) gave PhSMe (δ 2.49, s; from hexane eluates; 1.0 g, 8.0 mmol, 80%), MeBr (δ 2.64, s, 20%; produced from the reaction of free bromine) and $\text{Br}(\text{MeS})\text{C}(\text{CO}_2\text{Me})_2$ (oil from benzene eluates; 2.21 g, 8.30 mmol, 83%).

Reactions of Ylides 1a or 1b with Hydrogene Bromide.

(a) When hydrogen bromide gas was bubbled through a CHCl_3 solution of **1a**, its NMR spectrum showed the formation of a sulfonium salt (Me_2S^+ , δ 3.42, s). Evaporation of the solvent yielded white solids (NMR (CHCl_3), δ 4.01 (6H, s, CO_2Me) and 3.42 (6H, s, Me_2S^+). When they were dissolved in CHCl_3 and allowed to stand for 5 hr at room temperature, the NMR spectrum showed the quantitative formation of MeBr (δ 2.63, s) and $\text{MeSCH}(\text{CO}_2\text{Me})_2$ (δ 2.25, s).

(b) When a CCl_4 solution of hydrogen bromide was added to

a CHCl_3 solution of **1b**, they reacted instantaneously, and it was not possible to isolate the sulfonium salt. The amounts of MeBr (δ 2.62, s, 34%) and PhSMe (δ 2.46, s, 66%) were determined by use of nitromethane as an internal standard.

Reactions of Ylides 1c—h with Halogens, PhSCl or HBr.

The CDCl_3 solutions of Ylides **1c—h** (0.7—1.0 mmol) and X—Y (0.8—1.1 mmol) containing nitromethane (internal standard, 50 μl , 0.79 mmol) were let to react in NMR tubes at 25°C , and the amounts of the reaction products were determined from their singlet methyl absorption by NMR spectroscopy (see Table 2); Me—Br (δ 2.62—2.64), Me—Cl (2.90—2.98), MeSEt (2.05—2.12), $\text{MeSBu-}n$ (2.07), $\text{MeSPr-}i$ (2.10), $\text{MeSC}_8\text{H}_{17}\text{-}sec$ (1.99), MeSCH_2Ph (1.92), $\text{MeSCH}_2\text{-SMe}$ (2.10), $\text{Br}(\text{MeS})\text{C}(\text{CO}_2\text{Me})_2$ (2.23), $\text{Cl}(\text{MeS})\text{C}(\text{CO}_2\text{Me})_2$ (2.23), $\text{MeS}(\text{PhS})\text{C}(\text{CO}_2\text{Me})_2$ (2.19—2.20) and $\text{MeSCH}(\text{CO}_2\text{Me})_2$ (2.25).

Synthesis of (+)-2-Octylmethylsulfonium Bis(methoxycarbonyl)-methylide (1f').

(−)-2-Octyl bromide was prepared from the reaction between (+)-2-octanol (purchased from Fluka, $[\alpha]_D^{25} + 11^\circ$) (15 g) and PBr_3 (34.8 g) below $+5^\circ\text{C}$; yield, 13.8 g (62.6%); bp $55^\circ\text{C}/3\text{ mmHg}$ (lit.¹⁸) $61^\circ\text{C}/3\text{ mmHg}$; $[\alpha]_D^{25} - 36.62^\circ$ (c 8.36, 95% ethanol) (lit.¹⁵) $[\alpha]_D^{25} - 34.25^\circ$.

(+)-2-Octyl methyl sulfide was prepared from the reaction between (−)-2-octyl bromide (11.1 g) and sodium methylmercaptide (20% aq solution, 42 g) in ethanol; yield, 75.0%; bp $84\text{--}85.5^\circ\text{C}/10\text{ mmHg}$; $[\alpha]_D^{25} + 8.78^\circ$ (c 11.8, CHCl_3).

Ylide **1f'** was not obtained by copper-catalyzed decomposition of methyl diazomalonate in the sulfide.¹² Therefore, it was prepared by transylidation.¹³ A chloroform (11.5 g) solution of **1b** (3.04 g), (+)-2-octyl methyl sulfide (6.0 g) and dimethoxy disulfide (1.3 g; a catalyst) was kept at 40°C . After 4 days, its NMR spectrum showed the complete disappearance of **1b**. Sulfides and the catalyst were distilled off under reduced pressure at $55^\circ\text{C}/3\text{ mmHg}$, and the NMR spectrum of the residual oil showed that it is ylide **1f'**; yield, 2.5 g (72%); IR (neat), 1620 and 1670 cm^{-1} (ν_{CO}); NMR (CDCl_3), δ 3.74 (6H, s, CO_2Me), 2.88 (3H, s, MeS^+) and 0.88—1.44 (16H, m, 2-octyl group); $[\alpha]_D^{25} - 28.64^\circ$ (c 10.5, CHCl_3).

Reactions of Ylide 1f' with Bromine. A CCl_4 (13.8 g) solution of Br_2 (1.38 g, 8.62 mmol) was added drop by drop to a CHCl_3 (21 g) solution of **1f'** (2.5 g, 8.62 mmol). The completion of the reaction was ascertained by the IR spectrum (ν_{CO} , 1730 cm^{-1}). The NMR spectrum showed the formation of 2-octyl bromide (79.3%) and methyl bromide (20.7%). After the reaction mixture was concentrated under reduced pressure, the residue was subjected to column chromatography (Florisil), and the *n*-hexane eluates yielded 2-octyl bromide. Its purity was checked by gas chromatography. $[\alpha]_D^{25} - 21.48^\circ$ (c 5.96, 95% ethanol).

Reactions of Sulfonium Ion 2a with Nucleophiles.

(a) A nitromethane solution of **2a** (1.0 mmol) and tetraphenylarsonium chloride (2.0 mmol) was heated at 50°C for 5 min. After evaporation, the NMR spectrum of the residue (soluble in CCl_4) showed the presence of $\text{MeS}(\text{PhS})\text{C}(\text{CO}_2\text{Me})_2$ (δ 2.20, s, MeS; 90%).

(b) A $\text{DMSO-}d_6$ solution of **2a** (1.0 mmol) and methyl sulfide (1.5 mmol) was placed in an NMR tube at 25°C . After 4 days, the amounts of trimethylsulfonium salt (δ 2.89, s, Me_3S^+ ; 81%) and $\text{MeS}(\text{PhS})\text{C}(\text{CO}_2\text{Me})_2$ (δ 2.17, s, MeS; 84%) were determined by NMR spectroscopy.

(c) A $\text{DMSO-}d_6$ solution of **2a** (1.0 mmol) and pyridine (2.0 mmol) was placed in an NMR tube at 25°C . After 2 hr, the amounts of **1a** (δ 2.88, s, Me_3S^+ ; 79%) and $\text{MeS}(\text{PhS})\text{C}(\text{CO}_2\text{Me})_2$ (δ 2.17, s, MeS; 20%) were determined by NMR spectroscopy.

Reaction of Ylide **1e with Methanesulfonyl Chloride.** In an NMR tube a CDCl_3 solution of **1e** (1.0 mmol) and a CCl_4 solution of MeSCl were mixed. Rapid reaction took place, yielding $\text{MeSPr-}i$ and $\text{Cl(MeS)C(CO}_2\text{Me)}_2$ quantitatively. The NMR spectrum showed the absence of isopropyl chloride.
