# Reaction Mechanism of the Photooxidation of the Toluene-NO<sub>2</sub>-O<sub>2</sub>-N<sub>2</sub> System in the Gas Phase

Hajime Акімото,\* Mikio Hoshino, Gen Inoue, Michio Окида, and Nobuaki Washida

The National Institute for Environmental Studies, P.O. Yatabe, Ibaraki 300-21 (Received February 15, 1978)

Photooxidation of the toluene (34 ppm)– $NO_2(8-207 ppm)$ – $N_2$  and/or  $O_2(1 atm)$  system has been studied in a 67 dm³ reaction chamber. The reaction was initiated by  $O(^3P)$  atoms formed in the photolysis of  $NO_2$ . The main products were benzaldehyde, cresols, benzyl nitrate, m-nitrotoluene, 6-nitro-p-cresol, and 2-nitro-p-cresol. Their relative yields were studied as functions of reactant concentrations. The formation mechanisms of the products were proposed on the basis of the reactions of  $O(^3P)$  and OH radicals with toluene in the presence of  $NO_2$  and  $O_2$ .

Studies have been made on the photochemical oxidation of alkylbenzenes in the presence of nitrogen oxides  $(NO_x)$  and air in relation to photochemical air pollution. However, they deal mostly with ozone formation and the so-called "photochemical reactivity." A few reports have been given on the reaction products and mechanisms of the gas phase photooxidation of alkylbenzenes— $NO_x$ —air system.

Kopczynski³) studied the photooxidation of alkylbenzenes–NO<sub>2</sub>–air systems using a long-path infrared spectrometer and identified aldehydes, CO, CO<sub>2</sub>, formic acid, and peroxyacetyl nitrate as reaction products. Nojima et al.⁴a) studied the photooxidation of the benzene–NO<sub>2</sub>–air system and identified nitrobenzene, nitrophenols, and dinitrophenols. They also reported⁴b) the formation of glyoxal, methylglyoxal, and biacetyl which would have been produced by the cleaving of benzene rings in the photooxidation of benzene, toluene, and xylene. Ando et al.⁵b) studied the formation yield of nitrobenzenes in the benzene–NO<sub>2</sub>–O<sub>2</sub>–N<sub>2</sub> system as functions of O<sub>2</sub> and NO<sub>2</sub> concentrations.

Photooxidation of alkylbenzenes in the atmosphere is thought to be initiated by OH or O atoms. The photooxidation of alkylbenzene–HNO<sub>2</sub>-air systems, in which OH radicals initiated the oxidation of benzene, toluene, and ethylbenzene, was studied and the reaction mechanisms were discussed in our previous study.<sup>6</sup> In this work,<sup>7</sup> photooxidation of the reaction systems of toluene (34 ppm), NO<sub>2</sub>(8—207 ppm) in N<sub>2</sub> and/or O<sub>2</sub> at 1 atm was studied for the case in which O atoms from NO<sub>2</sub> initiate the oxidation, giving most of the oxidized products. The final reaction products and their relative yields as functions of reactant concentrations are reported and a discussion of the reaction mechanisms is presented.

## **Experimental**

Figure 1 shows a schematic diagram of the apparatus. The reaction chamber is a Pyrex cylinder, 225 mm i.d., 1660 mm in length,  $67 \text{ dm}^3$  in volume: evacuated to less than  $1 \times 10^{-6}$  Torr. Metal parts containing gas inlets and outlets are attached to both ends of the Pyrex cylinder with Viton O-rings, the inside walls of the metal parts being lined with Teflon in order to avoid any catalytic reactions on the metal surfaces. Each end of the reaction chamber is sealed with a Pyrex window 20 mm thick, through which a photolyzing light beam can be transmitted into the gas sample.

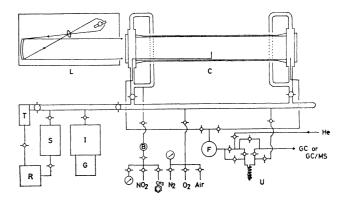

Fig. 1. Schematic diagram of the experimental apparatus. C: Reaction chamber; L: xenon arc lamp house; I: sputter ion pump; G: titanium getter pump; S: sorption pump; T: foreline trap; R: rotary pump; B: gas burette; F: sampling flask; U: low temperature spiral trap.

The light source was a 500 W xenon short arc lamp. A parallel light beam of ca. 200 mm $\phi$  was obtained by using an elliptical mirror, lens, and an off-axis parabolic mirror. The effective light intensity as measured by the primary photo-decomposition rate of NO<sub>2</sub> was 0.08 min<sup>-1</sup>. The wavelengths of the irradiated light were greater than 320 nm. An oil free pumping system consisting of a sputter ion pump, titanium getter pump, cryo-sorption pump, and a rotary pump with a liquid nitrogen cooled foreline trap was used.

Toluene and NO<sub>2</sub> were first put into a 105-ml glass flask and then expanded into the reaction chamber. Air, O2, or N2 was then introduced through four gas inlets shown in Fig. 1. The pressure was measured with Capsulon gauges (Edward High Vacuum Co.), 50 and 760 Torr full scale which were calibrated by a mercury manometer. In order to confirm that the sample gases were mixed homogeneously, four sampling ports were attached to the chamber (only two of them are shown in Fig. 1), at the center, at one-fourth of the chamber length distance from one end, and at both ends. One hour after the gases had been introduced the concentration of the toluene taken from the four different ports was found to be the same, and irradiation was thus started. Sampling was repeatedly carried out through the center port at suitable time intervals. "Pure Air" (dew point lower than -70 °C),  $O_2$  (>99.9%, graded as "Pure gas B") and  $N_2$  (>99.995%, graded as "Pure gas B") were supplied from Nippon Sanso Co. NO<sub>2</sub> was obtained by mixing NO (research grade, Matheson) with excess O2. Toluene (research grade, Wako Pure Chemical Ind.) was used without further pruification except

degassing. It contains ca. 0.01% xylenes, as impurity, which is negligible in the present study.

The reaction mixture was first introduced into a 700ml constant volume glass flask and then concentrated in a GC sampling tube. The sampling tube, a Pyrex spiral of 2 mm i.d., about 4 m in extended length, was cooled to -60 °C. After the concentration, the sampling tube was heated with hot water and the sample was fed directly into a gas chromatograph. This procedure was found to minimize the yields of the products of thermal reactions of NO2 with toluene and cresols in the smapling tube. Sampling for the GC analysis was made periodically every 45-60 min. GC analysis was carried out using a 3-m column of 5% SE-30 on Shimalite W. The GC oven temperature was raised from 80 to 200 °C at a rate of 4 °C/min. The concentration of NO<sub>2</sub> was monitored for several runs by the method of single beam photometry at a wavelength of 450 nm using the irradiation light as a light source. Identification of product was carried out by comparing the reference mass pattern and GC retention time using a GC-MS (JEOL, JMS-100) and a GC. In order to obtain the reference mass patterns and GC retention times, standard samples of benzaldehyde, o-, m-, p-cresols, benzyl nitrate, o-, m-, p-nitrotoluenes, onitrophenol, and 2- nitro-p-cresol were used. All chemicals except for benzyl nitrate were commercial products (Wako Pure Chemical Co.). Benzyl nitrate was prepared by fractional distillation of the reaction mixture of benzyl chloride and AgNO3 in a dried acetonitrile solution. Identification of 6-nitro-o-cresol was performed by comparing the GC retention time with the reference sample obtained by the thermal reaction between o-cresol and NO<sub>2</sub>. The mass pattern of 6-nitro-o-cresol was found to be nearly identical with that of 2-nitro-p-cresol.

For several experimental runs on the photooxidation of the HNO<sub>2</sub>-NO<sub>x</sub>-toluene-air system, known amounts of toluene and NO<sub>2</sub> were first introduced into the reaction chamber and then HNO<sub>2</sub>-air mixture was introduced under a total pressure of 1 atm. The HNO<sub>2</sub>-air mixture was produced by using 10 ml of 0.05 M NaNO<sub>2</sub> and 10 ml of 5% H<sub>2</sub>SO<sub>4</sub>.6) The concentrations of HNO<sub>2</sub> and nitrogen oxides in the HNO<sub>2</sub>-air mixture were determined<sup>6</sup>) by the method of Cox<sup>8</sup>) using a commercial chemiluminescence NO<sub>x</sub> analyzer (Monitor Labs, Model 8440). The HNO<sub>2</sub>-air mixture produced by the above method was found to contain ca. 12 ppm of HNO<sub>2</sub> and 2 ppm each of NO<sub>2</sub> and NO.

# Results

The reaction products observed in the photooxidation of the toluene (34 ppm)-NO<sub>2</sub>(8-207 ppm)-air(1 atm) system were benzaldehyde, cresols, benzyl nitrate, *m*-nitrotoluene, 6-nitro-o-cresol, and 2-nitro-p-cresol. Smaller amounts of o-nitrophenol and o- and p-nitrotoluene were also detected. The relative yield of ocresol was about 80% of the total amout of cresols, the sum of m- and p-cresol being about 20% of the total. By means of the gas chromatograph column used in this work, m- and p-cresols could not be seperated. Figure 2 shows the relative product yields as functions of irradiation time for a typical run of toluene (34 ppm), NO<sub>2</sub> (7.7 ppm) and 1 atm air. In the present study product analysis was carried out at a low reactant conversion (<1%). Under these conditions amounts of all the products increased linearly with irradiation time and ratios of products could be calculated from

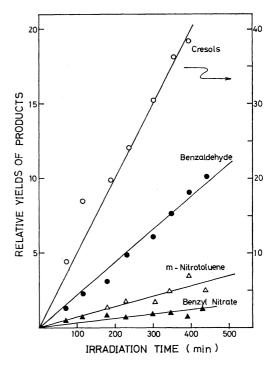

Fig. 2. Relative yields of the products vs. irradiation time in the photooxidation of NO<sub>2</sub> (7.7 ppm)-toluene (34 ppm)-air (1 atm) system. ○ Gresols; ● benzaldehyde; △ m-nitrotoluene and ▲ benzyl nitrate.

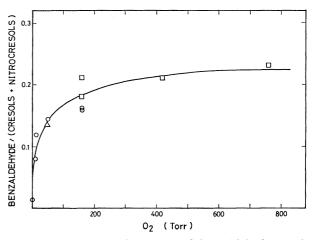

Fig. 3. The formation ratio of benzaldehyde to the sum of cresols and nitrocresols vs. partial pressure of O₂ in the photooxidation of NO₂-toluene (34 ppm)-O₂-N₂ (1 atm) system. Initial concentration of NO₂ are △ 6.4, ○ 24, and □ 30 ppm.

the slope ratio of the linear plots.

In order to clarify the formation mechanism of the products, experiments were carried out by varying the initial concentrations of  $O_2$  and  $NO_2$ . Figure 3 shows the ratio of benzaldehyde to cresol as a function of  $O_2$  partial pressure for several initial concentrations of  $NO_2$ . In these experiments, total pressure was kept at 760 Torr using  $N_2$  as a buffer gas. It should be noted that in the absence of  $O_2$  ( $NO_2$ -toluene- $N_2$  system) no benzaldehyde was formed, cresol being the major condensable product with trace amounts of

nitrocresols. The yields of nitrocresols were found to be much smaller than those in the  $NO_2$ -toluene-air system for the same initial concentration of  $NO_2$ . As shown in Fig. 3, the ratio of benzaldehyde to cresols increases with increase in the concentration of  $O_2$ , reaching a saturated value at an  $O_2$  partial pressure higher than a few hundred Torr.

The ratio of nitrocresols (the sum of 6-nitro-o-cresol and 2-nitro-p-cresol) to cresols increases linearly with the concentration of NO<sub>2</sub> (Fig. 4), NO<sub>2</sub> being measured by UV absorption at 450 nm. Figure 5 shows the ratio of benzaldehyde to the sum of cresols and nitrocresols as a function of the photo-equilibrium concentration of NO<sub>2</sub>. In the reaction system of air at 1 atm, the concentration of NO<sub>2</sub> reached the photoequilibrium level within 20 min after irradiation was started, remaining nearly constant during the course of irradiation time. The photo-equilibrium concentration of NO<sub>2</sub> was about 50% of the initial concentration of NO<sub>2</sub>.

As shown in Fig. 5 the yield ratio of benzaldehyde to the sum of cresols and nitrocresols is independent of the concentration of NO<sub>2</sub>. Thus, the yield of other products could be normalized by the sum of cresols and nitrocresols. Typical data for the product yields are given in Table 1.

The ratio of benzyl nitrate to benzaldehyde increased

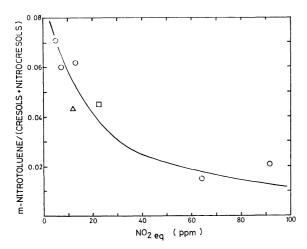

Fig. 7. The formation ratio of m-nitrotoluene to the sum of cresols and nitrocresols vs. equilibrium concentration of NO<sub>2</sub> for the NO<sub>2</sub>-toluene (34 ppm)-O<sub>2</sub>/N<sub>2</sub> system. Partial pressure of O<sub>2</sub> are  $\bigcirc$  160,  $\triangle$  418, and  $\square$  760 Torr.

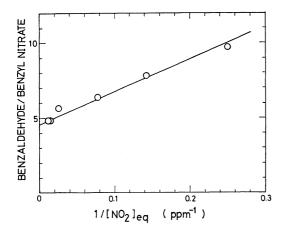

Fig. 8. The formation ratio of benzaldehyde to benzyl nitrate vs. the reciprocal of the equilibrium concentration of NO<sub>2</sub> for the NO<sub>2</sub>-toluene (34 ppm)-air (1 atm) system.

of NO<sub>2</sub>. It is remarkable that the relative yield of m-nitrotoluene, one of the nitrated products decreases with increase in NO<sub>2</sub> concentration. In order to compare the yield of m-nitrotoluene in the NO<sub>2</sub>-toluene-air system with that in the HNO<sub>2</sub>-NO<sub>x</sub>-toluene-air system at a comparable initial concentrations of NO<sub>2</sub>, two runs for the HNO<sub>2</sub> (12 ppm)-NO<sub>2</sub> (15 ppm and 25 ppm)-toluene(34 ppm)-air(1 atm) system were carried out. The result is shown in Fig. 9, where four data points for HNO<sub>2</sub> runs of lower NO<sub>2</sub> concentrations (less than 2 ppm) are taken from the work of Hoshino et al.<sup>6</sup>)

#### **Discussion**

Formation Mechanisms of Cresol and Nitrocresol. Since in the present study the wavelength of the irradiated light is greater than 320 nm and toluene absorbs no light in this spectral region, the photooxidation is initiated by O(<sup>3</sup>P) atoms formed in the photolysis of NO<sub>2</sub>:

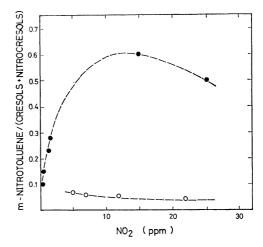

Fig. 9. The formation ratio of *m*-nitrotoluene to the sum of cresols and nitrocresols *vs.* initial concentration of NO<sub>2</sub> for the HNO<sub>2</sub>-NO<sub>2</sub>-toluene (34 ppm)-air (1 atm) system (●) and the NO<sub>2</sub>-toluene (34 ppm)-air (1 atm) system (○).

$$NO_2 + h\nu(320-400 \text{ nm}) \longrightarrow NO + O(^3P).$$
 (1)

The reaction of O(3P) atoms with toluene has been studied9-11) in some detail by mercury photosensitization of the N2O-toluene system. The main volatile products were cresols and CO. Small amounts of phenol, methane, and ethane, and predominant polymer formation were observed. There are differences in the relative yields of cresol isomers in these studies. The ratios of o-cresol to total cresols were reported to be 64% (Jones and Cvetanović<sup>9)</sup>), 78% (Grovenstein and Mosher<sup>10)</sup>), and 94% (Gaffney et al.11). Formation of p-cresol was noted only by Jones and Cvetanović.9) In the present reaction system of NO<sub>2</sub>-toluene-O<sub>2</sub>-N<sub>2</sub>, the cresols are the major condensable products in the absence of  $O_2$ , and also main products in the presence of O2 (see Table 1). In both cases, more than 80% of total cresols was o-cresol. This is closer to the results of Gaffney et al. 11) From these data, the formation of ocresols in the present reaction system is considered to be mainly due to the reaction of the O(3P) atom with toluene. This reaction would proceed via oxygen atom addition to the benzene ring followed by the intramolecular hydrogen atom transfer reaction.<sup>9)</sup>

$$\bigcirc_{\text{CH}^3}^{\text{H}} \qquad \qquad \bigcirc_{\text{CH}^3}^{\text{OH}} \qquad \qquad (3)$$

The existence of the long-lived biradical formed in Reaction 2 has been suggested in the work of Mani and Sauer.<sup>12)</sup> However, it should be noted that the reaction of OH radicals with toluene also gives o-cresol.<sup>6)</sup>

The ratio of nitrocresols to cresols increases linearly with the photo-equilibrium concentration of NO<sub>2</sub>, while the ratio of the sum of cresols and nitrocresols to benzaldehyde remains constant (Figs. 4 and 5). The results suggest that nitrocresols should be formed in the competitive reaction of NO2 with the same precursor as that giving cresols. The following reaction mechanism is proposed:

$$\stackrel{\text{CH}_3}{\bigoplus} \stackrel{\text{O}}{\cdot} + \text{NO}_2 \longrightarrow \stackrel{\text{CH}_3}{\bigoplus} \stackrel{\text{O}}{\oplus} \stackrel{\text{C}}{\longrightarrow} (4)$$

where  $NO_x$  denotes NO or  $NO_2$ . The result showing that the formation of nitrocresol is suppressed in the absence of O<sub>2</sub> can be explained by the absence of Reaction 5. According to Reactions 2-6, 6-nitro-ocresol should be the major product among nitrocresol isomers if we assume that NO2 combines with the biradical almost entirely at the carbon atom adjacent to the one to which the oxygen atom is attached (Reaction 4).

Formation Mechanisms of Benzaldehyde and Benzyl Nitrate. Benzaldehyde and benzyl nitrate were formed only in the presence of O<sub>2</sub>. Formation of these products strongly suggests the presence of the benzyloxyl radical as their precursor in the reaction system. Competitive reactions

yield the relation

$$\frac{[\text{B.A.}]}{[\text{B.N.}]} = \frac{k_7}{k_{8a}} \frac{[\text{O}_2]}{[\text{NO}_2]_{\text{eq}}} + \frac{1}{k_{8a}} \left( k_{8b} + k_9 \frac{[\text{NO}]_{\text{eq}}}{[\text{NO}_2]_{\text{eq}}} \right) \quad (10)$$

where B.A. and B.N. stand for benzaldehyde and benzyl

nitrate, respectively, and [NO]<sub>eq</sub> and [NO<sub>2</sub>]<sub>eq</sub> are the concentrations of NO and NO2 under photoequilibrium. Under the conditions of 1 atm air,  $[NO]_{eq}/[NO_2]_{eq}$  was nearly constant (≈1.0) irrespective of the initial NO<sub>2</sub> concentration. Thus, the plot of [B.A.]/[B.N.] vs. [O<sub>2</sub>]/[NO<sub>2</sub>]<sub>eq</sub> should give a straight line according to Eq. 10. The points (circular) in Fig. 6 are plotted again in Fig. 8 on the scale of [B.A.]/[B.N.] vs. 1/  $[NO_2]_{eq}$ . From the slope of Fig. 8, the value of  $k_7/k_{8a}$  was deduced to be  $1.4 \times 10^{-4}$ . For similar reactions of methoxyl radicals

$$CH_3O + O_2 \longrightarrow CH_2O + HO_2$$
 (11)

the value of  $k_{11}/k_{12}=5.6\times10^{-5}$  was given by Wiebe et al. (13) Glasson (14) reported the value of  $k_{11}/k_{12a}$  $(7.4\pm0.7)\times10^{-5}$ . Our value for the benzyloxyl radical is nearly of the same order of magnitude, but slightly higher than the above values for the methoxyl radical.

Benzyloxyl radicals are thought to be formed via reactions

Analogous reactions for alkyl radicals have been proposed by Heicklen et al.15) According to the above reaction scheme, no benzaldehyde and benzyl nitrate would be formed in the absence of O<sub>2</sub>. Their yields would increase with the increase of the concentration of  $O_2$  to the extent where all benzyl radicals are trapped by O<sub>2</sub>. Our experimental result (Fig. 3) confirmed that this is the case for benzaldehyde. Our results that no benzaldehyde and benzyl nitrate could be detected in the O2 free system also suggests the above reaction mechanism. Recently, Sloane<sup>16)</sup> observed the product with an m/e of 106 in the reaction of O(3P) and toluene under molecular beam conditions and proposed a reaction

$$\begin{array}{c}
\text{CHO} \\
\downarrow \\
\downarrow \\
+ \text{ O(^3P)} \longrightarrow \begin{array}{c}
\downarrow \\
\downarrow \\
\downarrow \\
\end{array} + \text{ H}_2.$$
(15)

If this reaction had occurred in the present reaction system, benzaldehyde would have been formed even in the O<sub>2</sub> free system. Thus, Reaction 15 is not important under our experimental conditions.

Formation Mechanism of m-Nitrotoluene. The yield of m-nitrotoluene decreases with increase of  $NO_2$ . This unexpected behavior of m-nitrotoluene can be explained if we assume that it is formed by the reaction which is initiated by OH radicals rather than by O(3P) atoms. In our study of the photooxidation of toluene in the HNO<sub>2</sub>-NO<sub>x</sub>-toluene-air system, where the OH radical reaction predominates, the relative yield of m-nitrotoluene to cresols is much higher than that in the present system. The yield of m-nitrotoluene in the  $\mathrm{HNO}_2$ - $\mathrm{NO}_x$ -toluene-air system is compared with that in the  $\mathrm{NO}_2$ -toluene-air system in Fig. 9. In the  $\mathrm{HNO}_2$  system, the relative yield of m-nitrotoluene to cresols+nitrocresols increases when the concentration of  $\mathrm{NO}_2$  increases in the region less than 10 ppm of  $\mathrm{NO}_2$ . An opposite tendency is observed in the  $\mathrm{NO}_2$  system. The formation mechanism of m-nitrotoluene and cresols in the  $\mathrm{HNO}_2$ - $\mathrm{NO}_x$ -toluene-air system, was proposed<sup>6</sup>) to be as follows.

$$\begin{array}{c}
\stackrel{\text{CH}}{\underset{\text{H}}{\bigcirc}}_{3}^{\text{OH}} \\
\stackrel{\text{H}}{\underset{\text{H}}{\bigcirc}}_{2}
\end{array}$$

$$+ \text{H}_{2}\text{O} \cdot (19)$$

The increase in the ratio of m-nitrotoluene to cresols with increase in the concentration of  $NO_2$  can be explained by the competition between Reactions 17 and 18. On the other hand, in the present reaction system of  $NO_2$ -toluene-air, most of the cresols are formed in the reaction of  $O(^3P)$  with toluene, m-nitrotoluene being assumed to be formed in Reactions 16, 18, and 19. In this case, the competition between Reaction 16 and the following Reactions 20 and 21 would result in a decrease in the relative yield of m-nitrotoluene at higher  $NO_2$  concentrations because of the quenching of OH radicals by  $NO_2$  and NO.

$$OH + NO_2 \xrightarrow{M} HNO_3$$
 (20)

$$OH + NO \xrightarrow{M} HNO_{2}$$
 (21)

Although second order rate constants at 760 Torr for Reactions 20 and 21 are comparable, <sup>17,18)</sup> Reaction 20 would be more effective sink of OH radicals since the photolysis of HNO<sub>2</sub> regenerates them.

Formation of Benzyl Radicals. According to the proposed reaction mechanism, side chain oxidation products, benzaldehyde and benzyl nitrate are formed via benzyloxyl radicals, which should be formed from benzyl radicals via Reactions 13 and 14. Benzyl radicals could be formed in the present reaction by the reaction of toluene with either O(3P) or OH radicals, i.e.,

$$CH_3$$
  $CH_2$ .  $+ OH \longrightarrow + H_2O$ . (23)

OH radicals are produced mainly by the reaction

$$HO_2 + NO \longrightarrow OH + NO_2$$
 (24)

where HO<sub>2</sub> radicals are formed in Reactions 5, 7, and 17. Reaction 22 and the photolysis of HNO<sub>2</sub> formed in Reactions 6, 8b, and 21 would also contribute to the production of OH radicals.

OH radicals abstract hydrogen atoms from the methyl group of toluene (Reaction 23) and also add to benzene ring (Reaction 16) at room temperature. From the pressure dependence of the rate constant of the reaction of OH radicals with toluene, Davis et al. 19) deduced that over half of the total reaction proceeds via addition reaction. Perry et al. 20) estimated the room temperature rate constant of the hydrogen abstraction reaction by extrapolation of the data above 380 K, where the reaction is assumed to proceed solely via abstraction, and obtained the fraction of the abstraction reaction of  $16\pm0.07\%$  at room temperature. In our product analysis study of OH radicals with toluene, 6) the fraction of abstraction reaction was estimated to be 25-35%.

The reaction of toluene with  $O(^3P)$  has been thought to proceed only via ring addition since no dibenzyl formation takes place in the mercury photosensitization of the  $N_2O$  and toluene system. However, the  $NO_2$  dependency on the formation of m-nitrotoluene (Fig. 9) shows that the contribution of OH radicals in the  $NO_2$  system is not remarkable. Thus, the formation of benzaldehyde in the present study would be explained by Reaction 22. About  $20\,\%$  of the reaction of  $O(^3P)$  with toluene should proceed via hydrogen abstraction from the methyl group of toluene.

The discrepancy might be caused by either of the following: (1) the contribution of OH radicals cannot be neglected in the present NO<sub>2</sub> system; the NO<sub>2</sub> dependency on the formation of m-nitrotoluene is a result of other unknown reactions or, (2) although benzyl radicals are formed in the mercury photosensitization of the N<sub>2</sub>O and toluene system, they are quenched by the excess of oxygen atoms, turning polymers.

The authors wish to thank Dr. Matsui, the Hokuriku University, for his suggestion to synthesize benzyl nitrate.
