(Received October 21, 1980)

Triphenylselenonium halides were readily prepared in good yields by the one-step reaction of seleninyl chloride with phenylmagnesium halides, followed by treatment with hydrogen halides. The yields of triphenylselenonium halides are markedly affected by the molar ratio of seleninyl chloride to the phenylmagnesium halides. In order to interpret the above results, some probable intermediates, such as diphenyl selenoxide, dibromodiphenylselenium, and diphenyl selenide, were investigated by allowing them to react with the phenylmagnesium halides. A pathway which consists of competitive and successive reactions is discussed.

Trimethylselenonium hydroxide ($(\text{CH}_3)_3\text{Se}^+\text{OH}^-$) is a very useful methylation reagent for carboxylic, thiol, and aromatic hydroxyl groups.¹⁾ Hampton²⁾ has reported on the use of diphenyliodonium chloride ($\text{Ph}_2\text{I}^+\text{Cl}^-$) for terminal phenylation. Triarylselenonium halides ($\text{Ar}_3\text{Se}^+\text{X}^-$), which may be expected as arylation reagents, could be prepared by a convenient one-step synthesis.³⁾ Strecker and Willing⁴⁾ have obtained only diphenyl selenide (Ph_2Se) and diphenyl (Ph_2) by the reaction of seleninyl chloride (SeOCl_2) with phenylmagnesium bromide (PhMgBr); they have not described the formation of selenonium salt. However, the addition of about three moles of arylmagnesium halides to one mole of SeOCl_2 afforded the corresponding triarylselenonium salts, together with Ph_2Se and Ph_2 .³⁾ This method is useful for the preparation of selenonium salts, since the usual methods require several steps.^{5,6)}

In order to clarify the formation path of triphenylselenonium halides ($\text{Ph}_3\text{Se}^+\text{X}^-$), the reaction of phenylmagnesium halides (PhMgX) with such probable intermediates as diphenyl selenoxide (Ph_2SeO), dibromodiphenylselenium (Ph_2SeBr_2), and diphenyl selenide (Ph_2Se) were investigated.

Results and Discussion

Reaction of PhMgX with SeOCl_2 . After the addition of 3.5-fold mole of various PhMgX 's to SeOCl_2 in THF or ether, the solution was maintained at the reflux temperature for 2 h.⁷⁾ The hydrolysis of the reaction mixtures with aqueous hydrobromic acid (HBr ca. 1 mol dm^{-3}) gave $\text{Ph}_3\text{Se}^+\text{X}^-$, Ph_2Se , and Ph_2 , as is shown in Table 1. It is of interest that $\text{Ph}_3\text{Se}^+\text{Br}^-$ appeared in the reaction of SeOCl_2 with the PhMgCl was afforded by the treatment of the resulting reaction mixtures with HBr . In the case of PhMgI , $\text{Ph}_3\text{Se}^+\text{I}^-$ was produced, even though the mixtures were similarly treated with HBr .⁸⁾

The reaction with PhMgCl , followed by treatment with HBr , gave $\text{Ph}_3\text{Se}^+\text{Br}^-$ in a 56% yield, but the yield of selenonium salt in the same reaction in the presence of MgBr_2 fell to 39%, which is comparable to the yield of the reaction with PhMgBr ,⁹⁾ as is shown in Table 1. These findings indicate the occurrence of halogen exchange in the reaction system during the period of reaction and the treatment with HBr . It is considered that the lower yield of selenonium salt

in the reaction with PhMgBr results from the formation of more reactive, but less selective, SeOBr_2 by halogen exchange between SeOCl_2 and the resulting MgBr_2 during the reaction. The considerable lowering in the yield in the case of PhMgI is thought to be due to the decomposition of the unstable SeOI_2 .¹⁰⁾

These results indicate that the seleninyl halides (SeOX_2) generated by halogen exchange react with three moles of PhMgX to give triphenylselenonium halogenomagnesium oxide ($\text{Ph}_3\text{Se}^+\text{OMgX}^-$), which then affords $\text{Ph}_3\text{Se}^+\text{X}^-$ upon subsequent hydrolysis with HBr .

The product distributions of $\text{Ph}_3\text{Se}^+\text{Br}^-$, Ph_2Se , and Ph_2 varied with the ratio of PhMgX to SeOCl_2 . Figure 1 shows a typical curve for the yield of each product obtained by the addition of PhMgBr to SeOCl_2 in ether. The production of Ph_2SeBr_2 was at its maximum at the molar ratio of 1.5; thereafter, it decreased rapidly to zero at the ratio of 2.5, in contrast to the increase in Ph_2Se and Ph_2 . The amount of selenonium salt increased gradually with the increase in PhMgBr until the molar ratio of 3.5. At more than 3.5, a rapid decrease in the selenonium salt led to the formation of Ph_2Se and Ph_2 . Thus, the present reaction is considered to be a complicated successive reaction.

Reaction of PhMgBr with Ph_2SeBr_2 . A solution of PhMgBr in ether was added to equimolar amounts of Ph_2SeBr_2 , and then the mixture was worked-up as above. The selenonium salt which was expected as the primary product was not obtained at all, but

TABLE 1. ADDITION OF PhMgX TO A SOLUTION OF SeOCl_2 ^{a)}
(Followed by HBr work-up)

X PhMgX	MgX ₂	Yield ^{b)} /mmol		
		$\text{Ph}_3\text{Se}^+\text{Br}^-$	Ph_2Se	Ph_2 ^{c)}
Cl	—	16.9 (56.2)	11.7 (39.0)	4.2 (14.3)
Br	—	11.2 (37.3)	14.9 (49.5)	7.9 (26.3)
I ^{d)}	—	0.8 (2.5) ^{e)}	10.6 (35.2)	9.9 (33.1)
Cl	MgCl_2	16.4 (54.5)	12.1 (40.2)	5.4 (18.1)
Cl	MgBr_2	11.7 (39.0)	15.1 (50.5)	9.6 (32.0)

a) PhMgX (105 mmol) was added to a solution of SeOCl_2 (30 mmol) in THF (100 ml). b) Yields given in parentheses indicate the mol% based on SeOCl_2 . c) Formation from Ph_4Se was assumed. d) Ether was used as the solvent. e) $\text{Ph}_3\text{Se}^+\text{I}^-$.

Fig. 1. Dependence of the yield of each product on the molar ratio of PhMgBr to SeOCl₂.

equimolar amounts of Ph₂Se and Ph₂ were.¹¹⁾ This fact shows that Ph₂SeBr₂ reacts with PhMgBr to give, probably, an unstable tetraphenylselenium (Ph₄Se), which then immediately decomposed to Ph₂Se and Ph₂. It was found that Ph₂SeBr₂ is not connected with the production of selenonium salt.

On the other hand, no product was furnished by the reaction of Ph₂Se with PhMgBr.

Reaction of PhMgBr with Ph₂SeO. Ph₂SeO could not be isolated in the reaction of SeOCl₂ with PhMgBr, but it appeared to be one of the most probable intermediates. Wildi¹²⁾ has reported the production of triphenylsulfonium bromide (Ph₃S⁺Br⁻) by the reaction of diphenyl sulfoxide (Ph₂SO) with PhMgBr.

The reaction of Ph₂SeO with PhMgBr, followed by hydrolysis with HBr, gave Ph₃Se⁺Br⁻, Ph₂Se, and Ph₂ in yields of 25, 63, and 10% respectively. It seems that selenonium salt was produced through triphenylselenonium bromomagnesium oxide (Ph₃Se⁺OMgBr⁻) according to the following equation.

Some of the Ph₃Se⁺OMgBr⁻ reacts further with PhMgBr to afford Ph₂Se and Ph₂ via Ph₄Se:

However, the significant formation of Ph₂Se can not be interpreted by considering only the above reaction. It may be supposed that Ph₂Se is produced by the elimination of oxygen from Ph₂SeO, which is liable to be reduced, but the detailed process has not been ascertained.¹³⁾

Consequently, the reaction proceeds first through halogen exchange between SeOCl₂ and PhMgX, as well as, the MgX₂ which is generated during the period of reaction, and the resulting SeOX₂ reacts with PhMgBr to give Ph₂SeO and Ph₂SeBr₂. Selenonium salts are chiefly derived from Ph₂SeO, and Ph₂Se and Ph₂, from Ph₂SeBr₂. From these results, it seems reasonable that the maximum yield of selenonium salts is at the molar ratio of PhMgX to SeOCl₂ of 3.5, and that the reaction proceeds through competitive and successive paths which are complicated by

halogen exchange.

Experimental

The melting points, determined on a Yanagimoto micro-melting-point apparatus (MP-J3), are uncorrected. The IR spectra were obtained with a Shimadzu IR-27G spectrophotometer. The mass spectra were measured with a JEOL JMS-01SG apparatus. The general procedure for the reaction of PhMgX with SeOCl₂ was the same as in a previous paper.³⁾ The yields of Ph₃Se⁺X⁻ and Ph₂Se, based on the SeOCl₂ used, and of Ph₂ were estimated and considered to result from the decomposition of Ph₄Se to Ph₂Se and Ph₂.

Reaction of PhMgCl with SeOCl₂ in the Presence of MgBr₂. Anhydrous MgBr₂ (5.5 g, 30 mmol) was added to a solution of SeOCl₂ (5.0 g, 30 mmol) in THF (100 ml). The mixture gradually became brownish and was then allowed to react with PhMgCl (105 mmol) in THF under reflux for 2 h. After the THF had been evaporated *in vacuo*, the mixture was hydrolyzed with HBr (*ca.* 1 mol dm⁻³) and extracted with benzene; the remaining aqueous solution was further extracted with chloroform. The benzene extract was dried over sodium sulfate, and the benzene was evaporated *in vacuo*. The residue was distilled under reduced pressure to give Ph₂ (1.5 g; 32%) and Ph₂Se (3.6 g; 50.5%).

Ph₂: mp 69–70 °C; IR 3055, 3025, 1473, 1423, 902, 725, 690 cm⁻¹. These values were identical with those of an authentic sample.

Ph₂Se: bp 106 °C/2 mmHg; IR 3060, 1575, 1475, 1440, 1000, 735 cm⁻¹; MS *m/e* 234 (M⁺), 154 (M⁺–Se). Found: C, 61.77; H, 4.42%. Calcd for C₁₂H₁₀Se; C, 61.81; H, 4.32%.

The chloroform extract afforded Ph₃Se⁺Br⁻ (4.6 g; 37%) upon recrystallization from chloroform–acetone(1:5): mp 236 °C decomposed; IR 3050, 1580, 1430, 990, 765, 745, 734 cm⁻¹; MS *m/e* 234 (M⁺–PhBr), 157 (M⁺–Ph₂). Found: C, 55.32; H, 3.79%. Calcd for C₁₆H₁₅SeBr: C, 55.42; H, 3.88%.

Reaction of PhMgBr with Ph₂SeBr₂. SeOCl₂ (5.0 g; 30 mmol) was added to PhMgBr (45 mmol) in ether (100 ml), and the mixture was stirred under reflux for 1 h. After the removal of the ether, the reaction mixtures were treated with HBr (*ca.* 1 mol dm⁻³), and then crude Ph₂SeBr₂ was precipitated. The crystals were collected and recrystallized from ether to afford Ph₂SeBr₂ (2.4 g; 21.6%): mp 147.5 °C decomposed; IR 1600, 1460, 1150, 990, 738, 681 cm⁻¹. Found: C, 36.62; H, 2.61%. Calcd for C₁₂H₁₀Br₂Se: C, 36.67; H, 2.57%.

Ph₂SeBr₂ (12.3 g; 31 mmol) was added to a solution of PhMgBr (31 mmol) in ether (50 ml) at 34 °C, and the mixture was hydrolyzed with HBr (*ca.* 1 mol dm⁻³) and extracted with benzene and then with chloroform. Ph₂Se (3.5 g; 47.9%), Ph₂ (1.9 g; 42.4%), and unreacted Ph₂SeBr₂ (4.9 g; 40%) were obtained from the benzene extracts. From the chloroform extract, though, no product was obtained.

Reaction of PhMgBr with Ph₂SeO. Ph₂SeO was prepared by the method of Rheinboldt.¹⁴⁾ PhMgBr (60 mmol) was added, drop by drop, over a period of 1 h at 34 °C to an equimolar amount of Ph₂SeO (60 mmol) in ether (50 ml). After the addition, the ether was removed and the residue was hydrolyzed with HBr (*ca.* 1 mol dm⁻³), and then extracted with benzene and subsequently with chloroform, as has been described above. From the extracts, Ph₂Se (6.2 g; 63.5%), Ph₃Se⁺Br⁻ (5.9 g; 25.2%), and Ph₂ (0.86 g; 10.0%) were afforded.
