Synopsis. Pd/TiO₂ catalyst reduced by flowing hydrogen at 500 °C, appearing with a strong SMSI effect, was found to be an active and selective catalyst for hydrogenation of CO₂ to methanol while the catalyst showed poor activity and selectivity if it was reduced below 400 °C.

Considerable attention is now focused on CO₂ hydrogenation to CH₃OH for environmental consideration. Most of efforts were made on CuO–ZnO catalyst series until now.^{1–7)} Although supported Pd catalysts have been found to be effective for methanol synthesis from CO hydrogenation, hydrogenation of CO₂ on supported Pd catalyst under atmospheric pressure produce only methane.^{8,9)} Ramaroson et al. conducted this reaction under very severe condition (120 bar, 350 °C) using supported Pd catalyst but CH₃OH selectivity was low than 40% if produced CO was considered.^{10,11)} Solymosi et al. studied the supported Pd catalyst on Al₂O₃, SiO₂, TiO₂, and MgO but all of the methanol selectivity was lower than 30%.^{12,13)} We recently discovered that a Pd/CeO₂ catalyst reduced with hydrogen at high temperature exhibited high activity and long lifetime for methanol synthesis from CO₂ and H₂.¹⁴⁾ We report in this paper that a new Pd/TiO₂ catalyst which is prepared by being reduced with H₂ at 500 °C, where strong metal-support interaction (SMSI) appears, shows excellent activity and stability for CO₂ hydrogenation to CH₃OH.

Experimental

Commercially available TiO₂ powder (Aerosil) was moulded to 20–40 mesh, then it was impregnated with PdCl₂ from its hot acidic aqueous solution (Kojima Chemicals, 98.5%). Palladium loading was 4% by weight. After degasification and evaporation, the catalyst precursor was dried in air at 120 °C for 12 h and reduced by flowing hydrogen at 400 °C for 4 h to form Pd metal, and then passivated by argon containing 1% O₂. Before reaction the catalyst was reduced with flowing hydrogen in reactor in situ at the temperature varying between 550 and 200 °C for 1 h. Reactor was a fixed bed flow type one and was operated under pressurized conditions. Methanol analysis was conducted with a gas chromatograph (Shimadzu GC-9A) with a flame ionization detector (FID) equipped with a Porapak R column. Catalyst weight was 0.5 g.

X-Ray diffraction (XRD) measurements were conducted with a Rigaku RINT 2400 instrument. Measurements of CO chemisorption were carried out at room temperature by using a conventional gass-made vacuum system. The amount of CO required for a monolayer coverage of Pd metal surface

(q_m) was estimated by extrapolating the flat part of an adsorption isotherm to the zero of the equilibrium pressure for adsorption. Assuming that each surface Pd atom can adsorb one CO molecule, the dispersion of Pd was calculated from the q_m value.

Results and Discussion

In Table 1, reaction performances of Pd/TiO₂ reduced by hydrogen at different temperature are compared. Reduction time for each catalyst was 1 h. When the reduction temperature was between 200 and 400 °C, no obvious change happened to its activity and selectivity. The selectivities of methane and CO were rather high. However, when it was reduced at 500 °C for 1 h, although the rate of CO₂ conversion was nearly the same, selectivity of methanol increased tremendously to 84.9%, which was accompanied by the marked decrease in the formations of CO and CH₄.

In Fig. 1 are compared the durability of the 400 °C-reduced catalyst and the 500 °C-reduced catalyst. Not only CO₂ conversion but also methanol selectivity of the 500 °C-reduced catalyst was very stable. But for the 400 °C-reduced catalyst, along with its gradually decreased CO₂ conversion, its CH₃OH formation capacity decreased very quickly as its CH₃OH selectivity was 2.1% after 8 h from reaction start.

In Fig. 2 are exhibited XRD patterns of fresh or used Pd/TiO₂ catalysts reduced at 400 or 500 °C, respectively. Pd metal and TiO₂ were recognized for all catalysts. New Ti₂O₃ phase was discerned in 500 °C-reduced Pd/TiO₂. No change happened to the XRD pattern of used 500 °C-reduced catalyst compared to its fresh state. But for the 400 °C-reduced catalyst, PdO appeared on the used catalyst besides Pd metal while only Pd existed on its fresh catalyst. No change occurred on the TiO₂ support of fresh or used 400 °C-reduced catalyst.

The most probable explanation for the deactivation of the catalyst reduced at lower than 400 °C should be the oxidation of Pd metal, resulting from water formed through CH₄ or CO formation, or CO₂, because the PdO was confirmed on the deactivated catalyst.

Also it should be noted that the particle size of Pd determined by Scherrer method from XRD peaks was the same for both catalysts. Considering the Pd particle size determined from CO chemisorption (Table 2), it is able to conclude that partially-reduced support of 500 °C-reduced catalyst, Ti₂O₃, migrated back onto

Table 1. Hydrogen Reduction Temperature Effect on Pd/TiO₂ Catalyst

Reduced temp °C	CO ₂ conversion %	MeOH selectivity %	CH ₄ selectivity %	CO selectivity %
200	4.4	1.0	50.7	48.3
400	4.9	4.2	44.6	51.2
500	4.7	84.9	7.4	7.7
550	4.5	81.2	10.3	8.5

All data was recorded when MeOH selectivity was highest. Total pressure: 30 bar; temperature: 230 °C; catalyst weight: 0.5 g; $W/F=10$ g-cat h mol⁻¹.

Table 2. CO Chemisorption and XRD Results of Pd/TiO₂

	400 °C-reduced Pd/TiO ₂	500 °C-reduced Pd/TiO ₂
CO uptake ^{a)} (μmol g ⁻¹)	1.15	0.17
Dispersion (%)	0.31	0.045
Pd size from CO adsorption (Å)	3005	20690
Pd size by XRD (Å)	2840	2840

a) CO uptake here contains no physically-adsorbed CO.

Pd surface and covered most exposed Pd surface, which is an indicative property of SMSI effect.¹⁵⁾ As a result, CO uptake of 500 °C-reduced catalyst was so small that calculated Pd particle size from CO chemisorption was too big.

SMSI model is still a subject of controversy. One kind of opinion is that metal particles are hexagonal in outline, of uniform thickness and very thin, indicating a pill-box morphology, accompanied by partially-reduced oxide formation of the reducible support.^{16,17)}

The other kind of theory is the migration and dispersion of partially-reduced oxide support on metal.^{18,19)} The SMSI effect behaved here should belong to the latter category. SMSI is generally regarded as a reason for catalyst deactivation due to its remarkable suppression for reactants adsorption.²⁰⁾ Interestingly, SMSI showed positive effect here to increase astonishingly methanol formation from CO₂+H₂.

As a different evidence supporting SMSI phenomenon in 500 °C-reduced Pd/TiO₂, repeated reduction-oxi-

dation was performed to investigate the chemisorption behavior of this catalyst, which is also regarded as an indicative property of SMSI.¹⁵⁾ As demonstrated in Table 3, the fresh sample reduced at 400 °C shows a normal H/Pd ratio. It should be mentioned that reduction of the catalyst by H₂ at 400 °C for 4 h to make itself clear of Cl in the catalyst preparation would lead to sintering of Pd which resulted in the low H/Pd ratio. Reduction at 500 °C suppressed the sorption of hydrogen, leading to the very low H/Pd ratio which is inconsistent with the XRD result. Reducing the sample at 400 °C following the 500 °C reduction did not restore hydrogen sorption. However the oxidation of the 500 °C-reduced sample at 400 °C for 1 h followed by the reduction at 400 °C completely restored the hydrogen sorption capacity. A second reduction at 500 °C

Table 3. Reversibility of SMSI Effect by Oxidation for Pd/TiO₂

Treatment ^{a)}	H/M
LTR ^{b)}	0.67%
HTR ^{c)}	0.057%
LTR	0.057%
O ₂ , 400 °C, 1 h	
LTR	0.62%
HTR	0.055%

a) Sequential experiments on one sample. b) H₂ reduction, 400 °C, 1 h; evacuation, 400 °C, 1 h. c) H₂ reduction, 500 °C, 1 h; evacuation, 500 °C, 1 h.

suppressed hydrogen sorption once more demonstrating the reversibility of the effect by oxidation. The H/Pd ratios in Table 3 are slightly higher than the CO/Pd ratios in Table 2. This should be attributed to hydrogen dissolution in Pd metal. These facts show clearly the occurrence of SMSI phenomenon.

In our experiments with a Pd/TiO₂ catalyst, no hydrocarbons other than methane were detected. So the carbon chain growth could be neglected. We think that CO₂ was adsorbed disassociately on reduced palladium-titania surface, to form adsorbed CO and surface oxygen atom on Ti₂O₃. The formed surface oxygen could react with hydrogen to form water and active site Ti³⁺ was kept stable to produce CO and oxygen atom. If the surface oxygen atom reoxidized Ti₂O₃ to restore original TiO₂ state, catalyst activity based on Ti₂O₃ will drop irreversibly, as happened at Pd/TiO₂ reduced at temperature ranging from 200 to 400 °C. It is speculated from CO chemisorption data that CO formed from CO₂ on Ti₂O₃ migrated to Pd site and was successively hydrogenated to methanol there. In a word, Ti₂O₃ originated from SMSI reduced CO₂ to CO and Pd metal hydrogenated the CO to methanol.
